LOCALIZATION OF DIRECTED POLYMERS IN CONTINUOUS SPACE

YURI BAKHTIN, DONGHYUN SEO

Abstract. The first main goal of this article is to give a new metrization of the Mukherjee–Varadhan topology, recently introduced as a translation-invariant compactification of the space of probability measures on Euclidean spaces. This new metrization allows us to achieve our second goal which is to extend the recent program of Bates and Chatterjee on localization for the endpoint distribution of discrete directed polymers to polymers based on general random walks in Euclidean spaces. Following their strategy, we study the asymptotic behavior of the endpoint distribution update map and study the set of its distributional fixed points satisfying a variational principle. We show that the distribution concentrated on the zero measure is a unique element in this set if and only if the system is in the high temperature regime. This enables us to prove that the the asymptotic clusterization (a natural continuous analogue of the asymptotic pure atomicity property) holds in the low temperature regime and that the endpoint distribution is geometrically localized with positive density if and only if the system is in the low temperature regime.

1. Introduction

The directed polymer model was introduced in the physics literature [HH85], [HHF85], [Kar85], [KN85], [KZ87] and mathematically formulated by Imbrie and Spencer [IS88]. Since then, many models of directed polymers in random environment were studied in the literature over last several decades, see, e.g. books [Szn98], [Gia07], [dH09], [Com17] and multiple references therein. The common feature of these models is that they are based on Gibbs distributions on paths with the reference measure usually describing a process with independent increments (random walks, if the time is discrete) and the energy of the interaction between the path and the environment is given by a space-time random potential (with some decorrelation properties) accumulated along the path.

One of the intriguing phenomena that these models exhibit is the transition of dynamics of directed polymers between high/low temperature regimes. In the high temperature regime, directed polymers have diffusive behavior which is similar to that of the classical random walks and the endpoint distributions of polymer paths of length $n$ are typically spread over domains of size of the order of $n^{1/2}$ (see [Bol89], [SZ96], [AZ96]). On the other hand, in the low temperature regime, they are super-diffusive, i.e. the typical transverse displacement of polymer paths is of the order of $n^\xi$ with $\xi > 1/2$. In particular, it has been conjectured that $\xi = 2/3$ for $d = 1$, based on two following observations: (i) when $\beta = +\infty$, the directed polymer models coincide with the last passage percolation (LPP) models; (ii) Integrable LPP models have shown the spatial fluctuation of order $n^{2/3}$ and the fluctuation of passage times of order $n^{1/3}$ placing LPP in the KPZ universality class [Cor12]. This has been proved in some integrable models, see [Sep12], [BCF14]. Besides the super-diffusive behavior, it is known that polymer measures are mostly concentrated within a
relatively small region in the low temperature regime, see [CV06], [Var07], [Lac10], [BK10]. Such localization phenomenon of directed polymers is closely related to the intermittency of the solution of stochastic heat equation, see [CM94], [BC95], [Kho14]. It is believed that the size of the small region is $O(1)$ but this has been proved only for integrable models, see [CN16]. It is also conjectured that a similar picture holds for generalized directed polymers, see [BK18].

While many integrable models for (1+1)-dimensional directed polymers have been extensively studied (see [MO07], [ACQ11], [MFQR13], [AKQ14]), the results on higher dimensions are rather restricted. In [BC16] and its improved version [Bat18], a novel machinery was suggested to study localization of directed polymers that are discrete in space and time. This approach is based on another recent achievement, a compactification of the space of probability measures on $\mathbb{R}^d$ with respect to the weak convergence [MV16] (we will refer to this compactification as the MV topology in this paper). In [BC16], the authors introduce a simple metrization of the MV topology induced on the space of measures concentrated on $\mathbb{Z}^d$ and they were able to obtain localization results for discrete directed polymers by using the metric.

The first goal of this paper is to develop a new metrization of the MV topology that will be useful for space-continuous polymer models. Our new metrization is inspired by the one used in the discrete setting in [BC16] and is based on coupling in optimal transport. Its relation to the metric given in [MV16] resembles the equivalence between the definitions of the Kantorovich–Wasserstein distance via optimal coupling (2.9) and via Lipschitz test functions (2.10) known as the Kantorovich duality.

The second goal of this paper is to introduce a broad family of time-discrete and space-continuous polymer models where polymers are understood as discrete sequences of points in $\mathbb{R}^d$, and to generalize the entire program of [BC16] to these models with the help of our new metrization of the MV topology.

As this paper was being prepared we learned that similar results were obtained in [BM18] for a specific model where the reference measure is Brownian and the random potential is the space-time white noise mollified with respect to the space variable. We stress that the only assumption we need on the reference measure for polymers is that it defines a random walk, with no restriction on the distribution of i.i.d. steps in contrast to a concrete model of [BM18].

Due to the absence of assumptions on the random walk steps, we can say that our results generalize those of [BC16] and [Bat18] (except that a moment assumption on the potential is slightly weaker in [Bat18]) since one can embed any i.i.d. random potential indexed by $\mathbb{Z}^d$ into a stationary potential on $\mathbb{R}^d$ with a small dependence range.

In addition, we give a new result that go beyond the asymptotic pure atomicity results of [BC16] and [BM18]. Under the assumption that the reference measure is absolutely continuous with respect to the Lebesgue measure, a clusterization property holds for the random density of the polymer endpoint distribution in low temperature regime. An important feature of our work is that our results are based on the new metrization of the MV topology which is of independent interest.
The article is organized as follows: In the remaining part of Section 1, we introduce our general model of directed polymers, review the results in discrete setting, and state our results for localization/delocalization of directed polymers. In Section 2, we review the MV topology and introduce a new metric which is equivalent to the original MV metric and useful for our analysis of polymer measures. In Sections 3, 4, and 5, we develop a program parallel to [BC16], proving the continuity of the update map that maps the law of the endpoint distribution to the one of the next step endpoint distribution and proving that the empirical measure of the endpoint distribution of directed polymers converges to the set of free energy minimizers which is a subset of the set of fixed points of the update map. We will also see how the set of free energy minimizers can characterize the high/low temperature regimes. In Section 6, we introduce an asymptotic clusterization property that is an analogue of the asymptotic pure atomicity studied in [Var07], [BC16] for discrete directed polymers, and prove that it holds for the endpoint distribution in the low temperature regime. In Section 7, we show that the endpoint distribution of directed polymer is asymptotically geometrically localized with positive density.

Acknowledgements. We are grateful to Erik Bates, Chiranjeeb Mukherjee, and Raghu Varadhan for stimulating discussions. YB thanks NSF for partial support via grant DMS-1811444.

1.1. The model of directed polymers in stationary environment. We begin with a Markov chain \((\omega_n)_{n\in\mathbb{N}}, \{P^x\}_{x\in\mathbb{R}^d}\) on \(\mathbb{R}^d\), defined on a measurable space \((\Omega_p, \mathcal{F})\), where

- \(\Omega_p = (\mathbb{R}^d)^\mathbb{N} = \{\omega = (\omega_n)_{n\geq 0} : \omega_n \in \mathbb{R}^d\}\),
- \(\mathcal{F}\) is the cylindrical \(\sigma\)-algebra on \(\Omega_p\),
- For each \(x \in \mathbb{R}^d\), \(P^x\) is the unique probability measure such that \((\omega_{n+1} - \omega_n)_{n\geq 0}\) are i.i.d.

\[P^x(\omega_0 = x) = 1, \quad P^x(\omega_{n+1} - \omega_n = dy) = \mathcal{Z}(dy)\]

for any nondegenerate Borel probability measure \(\mathcal{Z}\) on \(\mathbb{R}^d\).

We denote expectation with respect to \(P^x\) by \(E^x\). We also write \(P\) and \(E\) for \(P^0\) and \(E^0\). For \(n \in \mathbb{N}\), let denote \(P^n\) the law of \((\omega_1, \cdots, \omega_n)\) under \(P^x\).

The random environment that we will consider is a real-valued, non-constant random field \((X(u))_{u\in\mathbb{N}\times\mathbb{R}^d}\), defined on a probability space \((\Omega_x, \mathcal{G}, \mathbb{P})\) such that

- \((X(n, \cdot))_{n\in\mathbb{N}}\) are independent and identically distributed,
- \((X(1, x))_{x\in\mathbb{R}^d}\) is stationary and \(L\)-dependent for some finite number \(L\), i.e., for any subset \(A, B \subset \mathbb{R}^d\) with \(d_0(A, B) > L\) (\(d_0\) = the Euclidean distance), \((X(1, x))_{x\in A}\) and \((X(1, x))_{x\in B}\) are independent of each other.
- \(X(1, \cdot)\) has continuous trajectories, i.e., the mapping \(x \mapsto X(1, x)\) is \(\mathbb{P}\)-a.s. continuous.

The continuity condition can actually be weakened, see Remark 3.5. We will write \(\mathbb{E}\) for expectation with respect to \(\mathbb{P}\). \(X(1, x)\) will be sometimes shortened to \(X(x)\) for convenience. We denote by \(\beta \geq 0\) the inverse temperature parameter and will assume

\[\lambda(\kappa) := \log \mathbb{E}\left[\exp(\kappa X(0))\right] < \infty \quad \text{for} \; \kappa \in [-2\beta, 2\beta].\]
For given $n \in \mathbb{N}, x \in \mathbb{R}^d$, we define the point-to-point quenched polymer measure, starting from $x$, at time $n$ as

$$\mathcal{M}_n^x(d\omega) = \frac{1}{Z_n} \exp \left( \beta \sum_{k=1}^{n} X(k, \omega_k) \right) P^x(d\omega),$$

where

$$Z_{n,x} = E^x \left[ \exp \left( \beta \sum_{k=1}^{n} X(k, \omega_k) \right) \right]$$

is called the point-to-line partition function. Let $\mathcal{M}_n, Z_n$ denote the polymer measure and the partition function corresponding to $P$, of length $n$. Notice that $(\mathcal{M}_n)_{n \geq 0}, (Z_n)_{n \geq 0}$ are random processes adapted to the filtration $(\mathcal{G}_n)_{n \geq 0}$ given by

$$\mathcal{G}_n = \sigma(X(k,x) : 1 \leq k \leq n, x \in \mathbb{R}^d).$$

### 1.2. An outline of previous results in discrete setting.

Directed polymer models have been largely studied on the lattice $\mathbb{Z}^d$. In this section, we recall the well-known results in the discrete setting, which will be extended to the continuous model in this paper. To stress the similarity with our model, we will use the same notation here as for our continuous setting. That is, in this section, we let $\mathcal{M}_n$ be the quenched polymer measure on paths of length $n$ defined on $(\mathbb{Z}^d)^\mathbb{N}$ by

$$\mathcal{M}_n(d\omega) = \frac{1}{Z_n} \exp \left( \beta \sum_{k=1}^{n} X(k, \omega_k) \right) P(d\omega),$$

where

- $P$ is the distribution of the $d$-dimensional simple random walk starting at 0,
- the random environment $(X(k,x))_{k \in \mathbb{N}, x \in \mathbb{Z}^d}$ is given by a collection of non-constant, i.i.d. random variables defined on some probability space $(\Omega, \mathcal{G}, \mathcal{P})$ and
- $Z_n = E \left[ \exp \left( \beta \sum_{k=1}^{n} X(k, \omega_k) \right) \right]$ is the partition function.

Most of the mathematical results on directed polymers were obtained mainly by analyzing the asymptotic behavior of the partition function $Z_n$. One of the interesting quantities, called the quenched free energy, is given by

$$F_n = \frac{1}{n} \log Z_n.$$

It turned out that the phase transition in directed polymer model is characterized by the discrepancy between the quenched free energy and the annealed free energy, which is

$$\frac{1}{n} \log \mathbb{E}[Z_n] = \lambda(\beta).$$

Applying a superadditivity argument developed in [CH02], we see that the limit

$$\lim_{n \to \infty} \mathbb{E}F_n = \sup_{n \geq 1} \mathbb{E}F_n := p(\beta)$$

is well-defined. The following exponential concentration inequality enables us to make (1.1) stronger:
**Theorem A** (Theorem 1.4 in [LW09], for $Q = 1$). Let $\beta > 0$ be fixed such $\mathbb{E} e^{\beta |X(1,0)|} < \infty$ Then, there is a constant $c > 0$, depending only on $\beta$ and the law of $X$, such that

$$
P \left( \frac{1}{n} \log W_n(\beta) - \mathbb{E} \log W_n(\beta) \right) > x \right) \leq \begin{cases} 2e^{-ncx^2} & \text{if } 0 \leq x \leq 1, \\ 2e^{-ncx} & \text{if } x > 1. \end{cases}$$

In particular,

$$
\lim_{n \to \infty} F_n(\beta) = p(\beta) \quad \text{a.s. and } L_p \text{ for all } p \in [1, \infty) \quad (1.2)
$$

We remark that Theorem A was proved for discrete setting but the proof can be easily adapted to our space-continuous setting. Therefore, we will use (1.2) later without further proof.

The *Lyapunov exponent* of the system is defined as

$$
\Lambda(\beta) := \lambda(\beta) - p(\beta) \geq 0, \quad (1.3)
$$

where the inequality follows from Jensen’s inequality. Before describing the phase transition of directed polymers, we give a statement for the existence of critical temperature.

**Theorem B** (Theorem 3.2 in [CY06], Proposition 2.4 in [Bat18]). $\Lambda(\beta)$ is non-decreasing in $\beta$. In particular, there is a critical inverse temperature $\beta_c = \beta_c(d) \in [0, \infty]$ such that

$$
0 \leq \beta \leq \beta_c \Rightarrow \Lambda(\beta) = 0, \\
\beta > \beta_c \Rightarrow \Lambda(\beta) > 0.
$$

Theorem B was first proved in [CY06] when the reference measure is the simple random walk and $\lambda(\kappa)$ exists for all $\kappa \in \mathbb{R}$. [Bat18] enhanced this by extending to reference measures given by arbitrary random walks on $\mathbb{Z}^d$ and weakening the moment condition of random environment. Extending this result to general random walks on $\mathbb{R}^d$ is straightforward.

We now collect three statements which describe how the Lyapunov exponent identifies the phase transition of directed polymers. We denote by

$$
\rho_i(\cdot) = M(\omega_i \in \cdot)
$$

the endpoint distribution of directed polymer of length $i$.

**Theorem C** (Corollary 2.2 and Theorem 2.3 (a) in [CSY03]).

$$
\Lambda(\beta) > 0 \iff \exists c > 0 \text{ s.t. } \liminf_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \max_{x \in \mathbb{Z}^d} \rho_i(\{x\}) \geq c \quad \mathbb{P}\text{-a.s.}
$$

Theorem C tells that the endpoint distribution can localize partial mass in the low temperature regime. Vargas proposed in [Var07] the notion of “asymptotic pure atomicity”, which describes the localization of the entire mass of the endpoint distribution. For any $i \geq 0, \epsilon > 0$, let

$$
\mathcal{B}_i^\epsilon = \{x : \rho_i(\{x\}) > \epsilon\}.
$$
Then, \((\rho_i)_{i \geq 0}\) is said \textit{asymptotically purely atomic} if for any sequence \((\epsilon_i)_{i \geq 0}\) tending to 0, we have
\[
\lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \rho_i(B_{\epsilon_i}^r) = 1 \quad \text{P-a.s.}
\]

Convergence in probability was used in [Var07] and the author proved that if \(\lambda(\beta) = \infty\), then \((\rho_i)_{i \geq 0}\) is asymptotically purely atomic. Bates and Chatterjee replaced it with almost sure convergence and proved the following:

\textbf{Theorem D} (Theorem 6.3 in [BC16], Theorem 5.3 in [Bat18]).

\[
\Lambda(\beta) > 0 \iff (\rho_i)_{i \geq 0} \text{ is asymptotically purely atomic.}
\]

Theorem E illustrates how the favorable sites, which localize mass in the endpoint distribution of directed polymers, cluster together. For \(\delta > 0, K > 0\), let \(\mathcal{G}_{\delta, K}\) be the collection of probability measures on \(\mathbb{Z}^d\) that assign mass greater than \(1 - \delta\) to some subset of \(\mathbb{Z}^d\) having diameter at most \(K\). (We use the \(l_1\) distance here.) We say that a sequence \((\alpha_i)_{i \geq 0}\) of probability measures in \(\mathbb{R}^d\) is \textit{geometrically localized with positive density} if for every \(\delta > 0\), there exist \(K > 0, \theta > 0\) such that
\[
\liminf_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} 1_{\{\alpha_i \in \mathcal{G}_{\delta, K}\}} \geq \theta \quad \text{P-a.s.}
\]

\textbf{Theorem E} (Theorem 7.3 (a), (c) in [BC16], Theorem 5.4 in [Bat18]).

\[
\Lambda(\beta) > 0 \iff (\rho_i)_{i \geq 0} \text{ is geometrically localized with positive density.}
\]

1.3. Main results of this paper. The first main result of this paper is the development of a new metrization of the translation-invariant compactification of the space of probability measures. The structure of the metric and relevant background are provided in Section 2. As an application of the theory developed in Section 2, we prove analogues of Theorems D and E for our model of directed polymers in the continuous space. Before stating our results, we denote the \textit{quenched endpoint distribution} for the polymer of length \(n\) by
\[
\rho_n(dx) = \mathcal{M}_n(\omega_n \in dx).
\]

The following asymptotic clusterization result (an analogue of Theorem D on asymptotic pure atomicity) is proved in Section 6, see Theorems 6.6 and 6.7:

\textbf{Theorem 1.1.} For \(r > 0, \epsilon > 0\), and a probability measure \(\alpha\) on \(\mathbb{R}^d\), let us define
\[
\mathcal{A}_\alpha^\epsilon(r) := \{x \in \mathbb{R}^d : \alpha(B_r(x)) > \epsilon V_d r^d\}, \quad \mathcal{A}_\alpha^\epsilon = \left\{x \in \mathbb{R}^d : \liminf_{r \downarrow 0} \frac{\alpha(B_r(x))}{V_d r^d} > \epsilon\right\},
\]

where \(V_d\) is the volume of the unit ball in \(\mathbb{R}^d\).

(a) If \(\beta > \beta_c\), then for every \(r > 0\) and every sequence \((\epsilon_i)_{i \geq 0}\) tending to 0,
\[
\lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \rho_i(A_{\alpha_i}^\epsilon(r)) = 1 \quad \text{P-a.s.,} \quad (1.4)
\]
and
\[
\lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \rho_i(A_{\rho_i}^i) = 1 \quad \text{P-a.s.} \tag{1.5}
\]
(b) If \( \beta \leq \beta_c \), then for every \( r > 0 \), there is a sequence \((\epsilon_i)_{i \geq 0}\) tending to 0, such that
\[
\lim_{n \to \infty} \sum_{i=0}^{n-1} \rho_i(A_{\rho_i}^i(r)) = 0 \quad \text{P-a.s.} \tag{1.6}
\]

The following localization result (an analogue of Theorem E) is proved in Section 7, see Theorem 7.3:

**Theorem 1.2.** For \( \delta > 0 \), \( K > 0 \), let us define a set
\[
G_{\delta,K} = \{ \alpha \in \mathcal{M}_1 : \max_{x \in \mathbb{R}^d} \alpha(B_K(x)) > 1 - \delta \},
\]
where \( \mathcal{M}_1 \) is the collection of probability measures on \( \mathbb{R}^d \).

(a) If \( \beta > \beta_c \), then for all \( \delta > 0 \), there exist \( K < \infty \) and \( \theta > 0 \) such that
\[
\liminf_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} 1_{\{ \rho_i \in G_{\delta,K} \}} \geq \theta \quad \text{P-a.s.},
\]
(b) If \( \beta \leq \beta_c \), then for all \( \delta \in (0,1) \) and \( K > 0 \),
\[
\lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} 1_{\{ \rho_i \in G_{\delta,K} \}} = 0 \quad \text{P-a.s.}
\]

2. **Compactification of a space of probability measures**

In [BC16], the authors pointed out that the usual topologies of weak/vague convergence of probability measures are inadequate to capture the localization phenomenon of directed polymers. To tackle the issue, they used an analogue of the compact metric space \((\tilde{X}, D)\) constructed in the work of Mukherjee and Varadhan [MV16]. While the Mukherjee–Varadhan (MV) topology was originally defined through test functions, Bates and Chatterjee introduced a different form of metric on the space of sub-probability distributions on \( \mathbb{N} \times \mathbb{Z}^d \) in [BC16] and showed that their metric space is equivalent to the discrete version of the MV topology. In this section, we construct a metrization of the original MV topology that is similar to the metric introduced in [BC16].

2.1. **Mukherjee–Varadhan topology.** For any \( a \geq 0 \), we denote by \( \mathcal{M}_a = \mathcal{M}_a(\mathbb{R}^d) (\mathcal{M}_{\leq a}) \) the space of measures on \( \mathbb{R}^d \) with mass \( a \) (less than or equal to \( a \)) and by \( \tilde{\mathcal{M}}_a = \mathcal{M}_a/\sim \) the quotient space of \( \mathcal{M}_a \) under spatial shifts on \( \mathbb{R}^d \). For any \( \alpha \in \mathcal{M}_a \), its orbit is defined by
\[
\tilde{\alpha} = \{ \alpha * \delta_x : x \in \mathbb{R}^d \} \in \tilde{\mathcal{M}}_a,
\]
where \( \alpha_1 * \alpha_2 \) denotes the convolution of \( \alpha_1 \) and \( \alpha_2 \) in \( \mathcal{M}_{\leq a} \), i.e., for any measurable set \( A \) in \( \mathbb{R}^d \),
\[
\alpha_1 * \alpha_2(A) = \int_{(\mathbb{R}^d)^2} 1_A(x+y)\alpha_1(dx)\alpha_2(dy).
\]
In particular, if \( \alpha_2(dx) = f(x)dx \), then \( \alpha_1 \ast \alpha_2(dx) = \int f(x-y)\alpha_1(dy)dx \).

Let us recall the notions of the weak topology and the vague topology on \( \mathcal{M}_a \) and \( \mathcal{M}_{\leq a} \) which will be used in this paper. We say that a sequence \((\mu_n)_{n \in \mathbb{N}}\) in \( \mathcal{M}_a \)(or \( \mathcal{M}_{\leq a} \)) converges to \( \mu \) in the weak topology and write \( \mu_n \Rightarrow \mu \) if

\[
\lim_{n \to \infty} \int_{\mathbb{R}^d} f(x)\mu_n(dx) = \int_{\mathbb{R}^d} f(x)\mu(dx),
\]

for all bounded continuous functions \( f \) on \( \mathbb{R}^d \). We say a sequence \((\mu_n)_{n \in \mathbb{N}}\) in \( \mathcal{M}_{\leq a} \) converges to \( \mu \) in the vague topology and write \( \mu_n \rightharpoonup \mu \) if (2.1) holds for all continuous functions with compact support. Note that the weak convergence preserves the total mass of measures, while the vague convergence may fail to do so. Another distinction between two topologies is that \( \mathcal{M}_{\leq a} \) is compact in the vague topology, but not in the weak topology. Throughout this paper, we denote the zero measure on \( \mathbb{R}^d \) or \( \mathbb{N} \times \mathbb{R}^d \) by \( 0 \).

Let us define

\[
\tilde{\mathcal{X}} = \left\{ \mu = \{\tilde{\alpha}_i\}_{i \in I} : I \subset \mathbb{N}, \alpha_i \in \mathcal{M}_{\leq 1}\setminus\{0\}, \sum_{i \in I} \alpha_i(\mathbb{R}^d) \leq 1 \right\}
\]

to be the space of all empty, finite or countable collections of orbits of sub-probability measures on \( \mathbb{R}^d \). For convenience, we slightly depart from the original definition in [MV16] and do not allow \( \alpha_i \) to be a zero measure. We remark that \( \{\tilde{\alpha}_i\}_{i \in I} \) should be understood as an unordered list. In particular, an orbit \( \tilde{\alpha} \) could be repeated more than once in \( \mu = \{\tilde{\alpha}_i\}_{i \in I} \). Let us introduce an interpretation of \( \tilde{\mathcal{X}} \) as a quotient space of \( \mathcal{X} = \mathcal{M}_{\leq 1}(\mathbb{N} \times \mathbb{R}^d) \). We denote the \( \mathbb{N} \)-support of \( \mu \in \mathcal{X} \) by

\[
S_\mu = \left\{ i \in \mathbb{N} : \|\alpha_i\| > 0 \right\}.
\]

**Definition 2.1.** Let \( \mu = \{\alpha_i\}_{i \in \mathbb{N}}, \nu = \{\gamma_i\}_{i \in \mathbb{N}} \in \mathcal{X} \). We write \( \mu \sim \nu \) if \( |S_\mu| = |S_\nu| \) and there is a bijection \( \sigma : S_\mu \to S_\nu \) such that \( \tilde{\alpha}_i = \tilde{\gamma}_{\sigma(i)} \) for all \( i \in S_\mu \).

The space \( \tilde{\mathcal{X}} \) is the quotient of space \( \mathcal{X} \) under the equivalence relation defined as Definition 2.1. In order to define the metric and convergence in \( \tilde{\mathcal{X}} \), we need to specify test functions. For an integer \( k \geq 2 \), let \( \mathcal{F}_k \) be the space of continuous functions \( f : (\mathbb{R}^d)^k \to \mathbb{R} \) which are translation invariant and vanishing at infinity, i.e.

\[
f(x_1 + y, \cdots, x_k + y) = f(x_1, \cdots, x_k) \quad \forall x_1, \cdots, x_k, y \in \mathbb{R}^d, \quad (2.3)
\]

\[
\lim_{\max_{i \neq j}|x_i - x_j| \to \infty} f(x_1, \cdots, x_k) = 0.
\]

Note that \( \mathcal{F}_k \), equipped with the uniform norm, is separable. Therefore, if we denote by \( \mathcal{F} = \bigcup_{k \geq 2} \mathcal{F}_k \), we can choose a countable dense subset \( \{f_r(x_1, \cdots, x_k_r)\}_{r \in \mathbb{N}} \) of \( \mathcal{F} \). We also check that for any \( f \in \mathcal{F}_k \) and \( \mu = \{\tilde{\alpha}_i\} \in \tilde{\mathcal{X}} \), the functional

\[
\Lambda(f, \mu) := \sum_{i \in I} \int f(x_1, \cdots, x_k) \prod_{j=1}^k \alpha_i(dx_j)
\]

is well-defined due to (2.3).
For any $\mu, \nu \in \tilde{X}$, we now define
\[
D(\mu, \nu) = \sum_{r=1}^{\infty} \frac{1}{2^r (1 + \|f_r\|)} |\Lambda(f_r, \mu) - \Lambda(f_r, \nu)|.
\]

Here $\|f\|$ denotes the uniform norm. We state a theorem proved in [MV16].

**Theorem 2.2** (Theorem 3.1 and Theorem 3.2 in [MV16]). The metric space $(\tilde{X}, D)$ is a compactification of $M_1$.

### 2.2. Reinterpretation of the MV topology.

Due to the analogy with [BC16], the compact metric space $(\tilde{X}, D)$ is expected to be suitable for studying localization for directed polymers on $\mathbb{N} \times \mathbb{R}^d$. However, one might have difficulties in extracting some information on two elements $\mu = \{\bar{\alpha}_i\}, \nu = \{\bar{\gamma}_j\} \in \tilde{X}$ close to each other. More precisely, one would expect that if $D(\mu, \nu)$ is very small, one can match large parts of measures $\alpha_i$ and $\gamma_j$ by applying appropriate translations to subsets of $\mathbb{R}^d$. The metric $D$ does not provide such information explicitly. Similarly to having two definitions of the Wasserstein distance in terms of Lipschitz test functions and in terms of couplings, it would be natural and helpful to introduce an equivalent metric on $\tilde{X}$ that is based on coupling. Adopting the ideas from [BC16], we construct such an equivalent metric which allows us to obtain explicit estimates needed to show continuity of some functionals defined on $\tilde{X}$.

Before constructing the metric rigorously, we need to introduce some notations. We define a distance between two elements $u = (i, x)$ and $v = (j, y)$ of $\mathbb{N} \times \mathbb{R}^d$ by
\[
|u - v| = \mathbbm{1}_{\{i=j\}} \cdot |x - y| + \mathbbm{1}_{\{i \neq j\}} \cdot \infty.
\]

In some contexts, it will be convenient to denote this distance by $d_0(u, v)$ and we will also use the same notation $d_0$ for the Euclidean norm in $\mathbb{R}^d$. This definition is natural in the sense that we would like to record two concentrated regions getting away from each other on different copies of $\mathbb{R}^d$. For $r > 0$, we denote by $B_r(u)$ the open ball centered at $u$ with radius $r$ in $\mathbb{N} \times \mathbb{R}^d$ and similarly by $B_r(x)$ in $\mathbb{R}^d$. Notice that $B_r(u) = \{i\} \times B_r(x)$ by (2.5).

The right-hand side in (2.4) can be expressed in terms of functions defined on $\mathbb{N} \times \mathbb{R}^d$ instead of $\mathbb{R}^d$. More precisely, for an integer $k \geq 2$, let $\mathcal{G}_k$ be the space of continuous functions $g : (\mathbb{N} \times \mathbb{R}^d)^k \to \mathbb{R}$ that are translation-invariant and vanishing at infinity, i.e.
\[
g(u_1 + v, \ldots, u_k + v) = g(u_1, \ldots, u_k) \quad \forall u_1, \ldots, u_k, u_1 + v, \ldots, u_k + v \in \mathbb{N} \times \mathbb{R}^d,
\]

\[
\lim_{\max_{i \neq j} |u_i - u_j| \to \infty} g(u_1, \ldots, u_k) = 0.
\]

(2.6)

For any $g \in \mathcal{G}_k$, $g \neq 0$ only if all $u_1, u_2, \ldots, u_k$ belong to the same copy of $\mathbb{R}^d$ due to (2.6). Therefore, there is a unique $f \in \mathcal{F}_k$ such that
\[
g(u_1, \ldots, u_k) = \begin{cases} f(x_1, \ldots, x_k) & \text{if } u_j = (i, x_j) \text{ for some } i \in \mathbb{N}, \\ 0 & \text{otherwise.} \end{cases}
\]
In other words, there is a natural bijection

$$M_k : \mathcal{F}_k \to \mathcal{G}_k.$$  \hfill (2.7)

Then, considering \( \mu \) as an element of \( X \), we have

$$\Lambda(f, \mu) = \int (M_k f)(\vec{u}) \mu^{\otimes k}(d\vec{u}).$$

Another remark is that any continuous function \( f : (\mathbb{R}^d)^{k-1} \to \mathbb{R} \) vanishing at infinity can be identified an element of \( \mathcal{F}_k \) by mapping it to \( \tilde{f}(x_1, x_2, \cdots, x_k) = f(x_2 - x_1, \cdots, x_k - x_1). \) \hfill (2.8)

For any \( \alpha \in \mathcal{M}_{\leq 1} \) (or \( X \)) and non-negative function \( f \) which is integrable with respect to \( \alpha \), we write \( \bar{\alpha} = f \alpha \) if \( \bar{\alpha} \) is defined as \( \bar{\alpha}(A) = \int_A f \alpha(dx) \) for each measurable set \( A \). Moreover, we say \( \bar{\alpha} \) is a sub-measure of \( \alpha \) (denoted by \( \bar{\alpha} \leq \alpha \)) if \( 0 \leq f \leq 1 \). For any signed measure \( \mu \) on \( \mathbb{R}^d \) or \( \mathbb{N} \times \mathbb{R}^d \), denote by \( \| \mu \| \) the total variation of \( \mu \).

2.3. The Wasserstein distance. In this section, we recall the basics on the Wasserstein distance. Similar notions were first introduced to solve the Monge–Kantorovich transportation problem and it turned out that such distances can be used extensively in the variety of fields (see, e.g., [Vil09]).

To any metric \( d_1 \) on \( \mathbb{R}^d \) generating the Euclidean topology, we can associate a transport distance on measures as follows. For \( \alpha, \gamma \in \mathcal{M}_a (a > 0) \), let \( \Pi(\alpha, \gamma) \) be the collection of Borel probability measures on \( (\mathbb{R}^d)^2 \) such that the marginal distribution of the first argument is \( \alpha/a \) and of the second argument is \( \gamma/a \). Then, the Wasserstein distance between \( \alpha \) and \( \gamma \) is defined by

$$W(\alpha, \gamma) = a \inf_{\pi \in \Pi(\alpha, \gamma)} \int_{\mathbb{R}^2} d_1(x, y) \pi(dx, dy).$$ \hfill (2.9)

It is known that the infimum on \( \Pi \) is achieved. In this paper, we choose to work with a bounded metric

$$d_1(x, y) = |x - y| \wedge 1,$$

so that \( W \) metrizes the topology of weak convergence of \( \mathcal{M}_a \).

For \( \bar{\alpha}, \bar{\gamma} \in \bar{\mathcal{M}}_a \), we define

$$\tilde{W}(\bar{\alpha}, \bar{\gamma}) = \inf_{x \in \mathbb{R}^d} W(\alpha, \gamma \circ \delta_x).$$

Since the choice of representatives does not affect the value of \( \tilde{W} \), it is well-defined. One can check that \( \tilde{W} \) is a metric on \( \bar{\mathcal{M}}_a \) and metrizes the weak topology of \( \bar{\mathcal{M}}_a \). The latter is defined in the following sense:

$$\bar{\alpha}_n \Rightarrow \bar{\alpha} \text{ in } \bar{\mathcal{M}}_a \iff \exists (x_n)_{n \in \mathbb{N}} \text{ in } \mathbb{R}^d \text{ such that } \alpha_n \ast \delta_{x_n} \Rightarrow \alpha \text{ in } \mathcal{M}_a.$$

A result of [PR14] allows us to apply the Wasserstein distance to \( \alpha, \gamma \in \mathcal{M}_{\leq a} \) with different masses. More precisely, the generalized Wasserstein distance \( \hat{W} \) can be defined by

$$\hat{W}(\alpha, \gamma) = \inf_{\hat{\alpha} \leq a, \hat{\gamma} \leq \gamma \over \| \hat{\alpha} \| = \| \hat{\gamma} \|} \left( W(\bar{\alpha}, \bar{\gamma}) + \| \alpha - \bar{\alpha} \| + \| \gamma - \bar{\gamma} \| \right)$$
and it is proved in [PR14] that the infimum on the right hand side is achieved.

The result known as the Kantorovich duality states that for any \( \alpha, \gamma \in \mathcal{M}_{\leq 1} \) with the same mass,

\[
W(\alpha, \gamma) = \sup_{f} \left( \int_{\mathbb{R}^d} f(x)\alpha(dx) - \int_{\mathbb{R}^d} f(y)\gamma(dy) \right),
\]

where the supremum is taken over all 1-Lipschitz continuous functions \( f : (\mathbb{R}^d, d_1) \to (\mathbb{R}^d, d_0) \), i.e.,

\[
|f(x) - f(y)| \leq |x - y|, \quad x, y \in \mathbb{R}^d, \quad \sup f - \inf f \leq 1.
\]

It follows from (2.10) that for any measures \( \mu = \mu_1 + \mu_2 \) and \( \nu = \nu_1 + \nu_2 \) and representatives \( \nu_1, \nu_2 \) chosen from \( \mathcal{X} \), we have

\[
W(\mu, \nu) \leq W(\mu_1, \nu_1) + W(\mu_2, \nu_2).
\]

2.4. Construction of a metric in \( \tilde{\mathcal{X}} \). We are now ready to define a metric in \( \tilde{\mathcal{X}} \). From now on, for any \( \mu = \{\tilde{\alpha}_i\}_{i \in I} \in \tilde{\mathcal{X}} \), we will abuse the notation \( \mu \) and use it for both the element of \( \tilde{\mathcal{X}} \) and representatives chosen from \( \mathcal{X} \). When \( \mu \) is used in integration, we mean that an explicit representative, such as \( (\alpha_i)_{i \in \mathbb{N}} \), is chosen where \( \alpha_i = 0 \) for all \( i > |I| \).

Let \( \mu = \{\tilde{\alpha}_i\}, \nu = \{\tilde{\gamma}_{i}\} \in \tilde{\mathcal{X}} \) be given. We first introduce a family of functionals estimating the mass of the heaviest region for a measure in \( \mathcal{X} \). For \( r \geq 0 \), we define a function \( I_r \) on \( \mathcal{X} \) by

\[
I_r(\mu) = \sup_{\alpha \in \mathcal{M}_{\leq 1}, \gamma \in \mathcal{M}_{\leq 1}} \int_{\mathbb{R}^d} f_r(x - y)\alpha(dy) = \sup_{u \in \mathcal{M}_{\leq 1} \times \mathbb{R}^d} \int_{\mathcal{M}_{\leq 1} \times \mathbb{R}^d} g_r(u - v)\mu(dv),
\]

where

\[
f_r(x) = \begin{cases} 1, & |x| \leq r \\ 0, & |x| > r + 1, \\ r + 1 - |x|, & |x| \in (r, r + 1], \end{cases}
\]

and \( \tilde{g}_r = M_2 \tilde{f}_r \) (See (2.7) and (2.8)). Note that \( f_r \) is 1-Lipschitz continuous with respect to \( d_1 \). We collect some useful properties of \( I_r \):

- \( I_r(\mu) \) is comparable with the mass of the heaviest ball of radius \( r \) under \( \mu \), i.e.,

\[
\sup_{u \in \mathcal{M}_{\leq 1} \times \mathbb{R}^d} \mu(B_r(u)) \leq I_r(\mu) \leq \sup_{u \in \mathcal{M}_{\leq 1} \times \mathbb{R}^d} \mu(B_{r+1}(u)). \tag{2.13}
\]

- \( I_r \) is sub-additive, i.e., \( I_r(\mu + \nu) \leq I_r(\mu) + I_r(\nu) \).

- \( I_r \) is monotone, i.e., if \( \mu \leq \nu \), then \( I_r(\mu) \leq I_r(\nu) \).

- Since \( \mathcal{M}_{\leq 1} \) is naturally embedded in \( \mathcal{X} \), we can define \( I_r(\alpha) \) for \( \alpha \in \mathcal{M}_{\leq 1} \) in the same way.

For any \( \alpha, \gamma \in \mathcal{M}_{\leq 1} \) with the same mass, (2.10) implies

\[
|I_r(\alpha) - I_r(\gamma)| \leq \sup_{x \in \mathbb{R}^d} \left| \int_{\mathbb{R}^d} f_r(x, y)d\alpha(y) - \int_{\mathbb{R}^d} f_r(x, y)d\gamma(y) \right| \leq W(\alpha, \gamma). \tag{2.14}
\]

One can check that the choice of the representative of an element in \( \tilde{\mathcal{X}} \) does not change the value of \( I_r(\mu) \) so \( I_r \) is also well-defined on \( \tilde{\mathcal{X}} \).
Definition 2.3. For any $\mu = \{\alpha_i\}, \nu = \{\gamma_i\} \in \tilde{X}$, let $P_{\mu,\nu}$ be the collection of sets $\{(\mu_k,\nu_k)\}_{k=1}^n$ of pairs of (sub)measures such that

1. For each $k$, there are $i, j \in \mathbb{N}$ such that $\mu_k \leq \alpha_i$ and $\nu_k \leq \gamma_j$.
2. For each $k$, $\|\mu_k\| = \|\nu_k\| > 0$.
3. Collections $\{\operatorname{supp}(\mu_k)\}_{k=1}^n$ and $\{\operatorname{supp}(\nu_k)\}_{k=1}^n$ are each composed of mutually disjoint sets.

Then, an element in $P_{\mu,\nu}$ is called "$(\mu,\nu)$-matching". We have the empty matching $\emptyset$ included in any $P_{\mu,\nu}$.

For $\phi = \{(\mu_k,\nu_k)\}_{k=1}^n \in P_{\mu,\nu}$, we define

$$\deg(\phi) := \inf \left\{ d_0(\operatorname{supp}(\mu_{k_1}),\operatorname{supp}(\mu_{k_2})), d_0(\operatorname{supp}(\nu_{k_2}),\operatorname{supp}(\nu_{k_2})) : 1 \leq k_1 < k_2 \leq n \right\}$$

and set $\deg(\emptyset) = \infty$.

Definition 2.4. $(r, \phi, \vec{x})$ is called a $(\mu,\nu)$-triple if $r \geq 0$, $\phi = \{(\mu_k,\nu_k)\}_{k=1}^n \in P_{\mu,\nu}$, $\deg(\phi) > 2r$, and $\vec{x} = (x_1, \cdots, x_n) \in (\mathbb{R}^d)^n$.

For any $(\mu,\nu)$-triple $(r, \phi, \vec{x})$, we define

$$d_{r,\phi,\vec{x}}(\mu,\nu) = \sum_{k=1}^n W(\mu_k,\nu_k \ast \delta_{x_k}) + I_r(\mu - \sum_{k=1}^n \mu_k) + I_r(\nu - \sum_{k=1}^n \nu_k) + 2^{-r}.$$ 

While $\mu_k, \nu_k$ are treated as elements in $\mathcal{M}_{\leq 1}$ in the first term on the right-hand side, they are viewed as elements of $\mathcal{X}$ in the $I_r$ terms. For the empty matching, $d_{r,\emptyset,\vec{x}}(\mu,\nu) = I_r(\mu) + I_r(\nu) + 2^{-r}$ does not depend on $\vec{x}$. We can now define

$$d(\mu,\nu) = \inf_{r,\phi,\vec{x}} d_{r,\phi,\vec{x}}(\mu,\nu),$$

where the infimum is taken over all $(\mu,\nu)$-triples. One can check that the choice of representatives of $\mu$ and $\nu$ does not affect the value of $d(\mu,\nu)$ so it is well-defined. One can readily check that

$$d(\mu,\nu) \leq 2, \quad \mu,\nu \in \tilde{X}, \quad (2.15)$$

by choosing the empty matching and letting $r \to \infty$ in a $(\mu,\nu)$-triple.

Let $\phi^{-1} := \{(\nu_k,\mu_k)\}_{k=1}^n \in P_{\nu,\mu}$. Then, we see that $\deg(\phi) = \deg(\phi^{-1})$ and hence

$$d_{r,\phi,\vec{x}}(\mu,\nu) = d_{r,\phi^{-1},-\vec{x}}(\nu,\mu),$$

which implies that $d$ is symmetric. With two propositions below, we prove that $d$ is a metric.

Proposition 2.5. $d(\mu,\nu) = 0$ if and only if $\mu = \nu$.

Proof. Since the “if” part is obvious, it suffices to prove the “only if” part. Let $d(\mu,\nu) = 0$. We may assume $\|\alpha_i\| \geq \|\alpha_{i+1}\|$ and $\|\gamma_i\| \geq \|\gamma_{i+1}\|$ for all $i$. For each $m \in \mathbb{N}$, there is a $(\mu,\nu)$-triple $(r_m, \phi_m = \{(\mu_{m,k},\nu_{m,k})\}_{k=1}^n, \vec{x}_m = (x_{m,1}, \cdots, x_{m,n_m}))$ such that

$$a_m := d_{r_m,\phi_m,\vec{x}_m}(\mu,\nu) < \frac{1}{m}.$$ 

Note that $r_m \to \infty$. 

Suppose $\alpha_1 = 0$ (i.e. $\mu = 0$). If $\|\gamma_1\| > \delta > 0$, since the empty matching is the only option, we have

$$a_m > I_{r_m}(\nu) \geq I_{r_m}(\gamma_1) > \delta$$

for all sufficiently large $m$, which is a contradiction. Hence, $\|\gamma_1\| = 0$ and $\mu = \nu = 0$.

Now suppose $\|\alpha_1\| > 0$. By the same argument as above, we have $\|\gamma_1\| > 0$. We may assume

$$\|\alpha_1\| \geq \|\gamma_1\|, \tag{2.16}$$

and let $p \in \mathbb{N}$ be an integer such that $\|\gamma_1\| = \cdots = \|\gamma_p\| > \|\gamma_{p+1}\|$.

Since $a_m$ converges to 0, there is at least one integer $l = l(m)$ such that $\mu_{m,l} \leq \alpha_1$ for all sufficiently large $m$. In fact, if this does not hold, then

$$a_m > I_{r_m}(\mu - \sum_k \mu_{m,k}) \geq I_{r_m}(\alpha_1) \to \|\alpha_1\| > 0,$$

a contradiction. By rearranging the order of pairs in $\phi_m$, we may assume that $\mu_{m,1} \leq \alpha_1$ and it has the biggest mass among $(\mu_{m,k} : \mu_{m,k} \leq \alpha_1)_k$.

For any $\varepsilon \in (0, \|\alpha_1\|/4)$, let us choose $R = R(\varepsilon)$ such that $\alpha_1(B_R(0)^c) < \varepsilon$. Then, for all $m$ satisfying $r_m > R$, there is at most one sub-measure $\mu_{m,j(m)} \leq \alpha_1$ whose support has an overlap with $B_R(0)$ since $\deg(\phi_m) > 2r_m > 2R$. If $\mu_{m,j(m)}(B_R(0)) \leq \alpha_1(B_R(0)) - \varepsilon$ for infinitely many $m$, then, for these $m$ we have

$$a_m \geq I_{r_m}(\mu - \sum_k \mu_{m,k}) \geq I_{r_m}(\mathbb{1}_{B_R(0)}\alpha_1 - \mathbb{1}_{B_R(0)}\mu_{m,j(m)}) \geq \varepsilon,$$

which implies that $a_m$ does not converge to 0. Therefore,

$$\|\mu_{m,j(m)}\| > \alpha_1(B_R(0)) - \varepsilon > \|\alpha_1\| - 2\varepsilon \tag{2.17}$$

for all sufficiently large $m$, and for such $m$, $j(m) = 1$ by the definition of $\mu_{m,1}$.

We claim that there is $q \in \mathbb{N}$ such that $\nu_{m,1} \leq \gamma_q$ for infinitely many $m$. To see this, let $q_m$ be an integer such that $\nu_{m,1} \leq \gamma_{q_m}$. If there is no such an integer $q$ as claimed above, we have $q_m \to \infty$ as $m \to \infty$. It follows that $\|\gamma_{q_m}\| \to 0$. On the other hand, for all sufficiently large $m$, $\|\gamma_{q_m}\| \geq \nu_{m,1} = \|\mu_{m,1}\| > \|\alpha_1\| - 2\varepsilon$ by (2.17), which is a contradiction. Hence, the claim is proved and, moreover, we obtain

$$\|\gamma_q\| > \|\alpha_1\| - 2\varepsilon.$$

Here, $q = q(\varepsilon)$ may depend on $\varepsilon$. However, since $\|\gamma_{q(\varepsilon)}\| > \|\alpha_1\| - 2\varepsilon \geq \|\alpha_1\|/2$ for all $\varepsilon \in (0, \|\alpha_1\|/4)$ and, given $\nu$, there are at most $\left\lfloor \frac{2}{\|\alpha_1\|} \right\rfloor$ (Here, $\lfloor \cdot \rfloor$ denotes the integer part) indices $i$ such that $\|\gamma_i\| \geq \|\alpha_1\|/2$, there is $q \in \mathbb{N}$, independent of $\varepsilon$, such that $q = q(\frac{1}{\varepsilon})$ for infinitely many $n$. For such $q$, we have $\|\gamma_q\| \geq \|\alpha_1\|$. Combining this with (2.16) we obtain $\|\alpha_1\| = \|\gamma_q\|$, so $q \leq p$. By interchanging $\gamma_1$ and $\gamma_q$, we may assume $q = 1$.

Let small $\varepsilon > 0$ be given. We choose $R$ as above and $R' = R'(\varepsilon)$ such that $\gamma_1(B(0,R')^c) < \varepsilon$. We can obtain $\|\nu_{m,1}\| > \|\gamma_1\| - 2\varepsilon$ for all sufficiently large $m$ by applying the same argument used used.
for $\alpha_1$. Then, for all sufficiently large $m$,

$$\tilde{W}(\alpha_1, \gamma_1) \leq W(\mu_{m,1}, \nu_{m,1} \ast \delta_{x_{m,1}}) + W(\alpha_1 - \mu_{m,1}, (\gamma_1 - \nu_{m,1}) \ast \delta_{x_{m,1}}) \leq a_m + 2\epsilon.$$  

We used (2.11) in the first inequality. Letting $m \to \infty$ first and then $\epsilon \downarrow 0$, we have $\tilde{W}(\alpha_1, \gamma_1) = 0$, i.e. $\tilde{\alpha}_1 = \tilde{\gamma}_1$. Peeling off $\alpha_1$ and $\gamma_1$ from $\mu$ and $\nu$ and repeating the same process to obtain $\tilde{\alpha}_i = \tilde{\gamma}_i$ for all $i$, we complete the proof. \hfill $\square$

**Proposition 2.6.** $d(\mu, \nu) \leq d(\mu, \eta) + d(\eta, \nu)$.

**Proof.** Let $\epsilon > 0$ be given. We can choose triples

$$\left(r_1, \phi_1 = \{(\mu_k, \eta_k^{(1)})\}_{k=1}^{n_1}, \tilde{x}^{(1)} = (x_k^{(1)})_{k=1}^{n_1}\right), \left(r_2, \phi_2 = \{(\eta_k^{(2)}, \nu_k)\}_{k=1}^{n_2}, \tilde{x}^{(2)} = (x_k^{(2)})_{k=1}^{n_2}\right)$$

such that

$$d_{r_1,\phi_1,\tilde{x}^{(1)}}(\mu, \eta) < d(\mu, \eta) + \epsilon, \quad d_{r_2,\phi_2,\tilde{x}^{(2)}}(\eta, \nu) < d(\eta, \nu) + \epsilon.$$  

We say that $\eta_k^{(1)}$ and $\eta_k^{(2)}$ overlap, if the measure $\tilde{\eta}_{k,d} = \min(f, g)\eta$ has non-zero mass, where $f, g$ are the Radon-Nikodym derivatives of $\eta_k^{(1)}$, $\eta_k^{(2)}$ with respect to $\eta$. We collect such overlap measures between $\{\eta_k^{(1)}\}$ and $\{\eta_k^{(2)}\}$ and relabel them as $\{\tilde{\eta}_k\}_{k=1}^{n_1}$.

For each $1 \leq k \leq n$, there is exactly one $j_1 = j_1(k)$ such that $\tilde{\eta}_k = f_{j_1} \eta_{j_1}^{(1)}$ for some measurable $f_{j_1}$ with $0 \leq f_{j_1} \leq 1$. The function $j_1$ maps $\{1, 2, \cdots, n\}$ to $\{1, 2, \cdots, n_1\}$. We can construct a similar function $j_2 : \{1, 2, \cdots, n\} \to \{1, 2, \cdots, n_2\}$ satisfying $\tilde{\eta}_k = g_{j_2} \eta_{j_2(k)}^{(2)}$ for some measurable $g_{j_2}$ with $0 \leq g_{j_2} \leq 1$.

Let us fix any $k \in \{1, 2, \cdots, n\}$ and denote by $\pi_{j_1(k)}$ the optimal coupling between $\mu_{j_1}$ and $\eta_{j_1}^{(1)} \ast \delta_{\tilde{x}_{j_1}^{(1)}}$:

$$W(\mu_{j_1}, \eta_{j_1}^{(1)} \ast \delta_{\tilde{x}_{j_1}^{(1)}}) = \|\mu_{j_1}\| \int d_1(x, y) \pi_{j_1}(dx, dy).$$  

Then, there is a sub-measure $\tilde{\mu}_k \leq \mu_{j_1(k)}$ such that $\tilde{\mu}_k$ is coupled to $\tilde{\eta}_k \ast \delta_{\tilde{x}_{j_1}^{(1)}}$ by $\pi_{j_1}$. More precisely, we can define $\tilde{\pi}_k(dx, dy) := f_{j_1(y)} \pi_{j_1(\tilde{x}_{j_1}^{(1)})}$, notice that $\tilde{\eta}_k \ast \delta_{\tilde{x}_{j_1}^{(1)}}(\cdot) = \|\mu_{j_1}\| \int \tilde{\pi}(dx, \cdot)$, and define $\tilde{\mu}_k(dy) = \|\mu_{j_1}\| \int \tilde{\pi}(\cdot, dy)$. The identity

$$W(\mu_{j_1}, \eta_{j_1}^{(1)} \ast \delta_{\tilde{x}_{j_1}^{(1)}}) = W(\mu_{j_1} - \tilde{\mu}_k, (\eta_{j_1}^{(1)} - \tilde{\eta}_k) \ast \delta_{\tilde{x}_{j_1}^{(1)}}) + W(\tilde{\mu}_k, \tilde{\eta}_k \ast \delta_{\tilde{x}_{j_1}^{(1)}}) \tag{2.18}$$

is a specific case of the following lemma:

**Lemma 2.7.** Let $M$ and $N$ be two measures with equal total masses and let $\pi$ be the optimal coupling between them. That is,

$$M(\cdot) = \|M\| \int \pi(\cdot, dy), \quad N(\cdot) = \|M\| \int \pi(dx, \cdot), \quad W(M, N) = \|M\| \int d_1(x, y) \pi(dx, dy).$$

Let $\tilde{N} = f \tilde{N}$ for some measurable $f$ satisfying $0 \leq f(y) \leq 1$ for all $y$. We define then $\tilde{\pi}(dx, dy) = f(y) \pi(dx, dy)$, notice that $\tilde{N}(\cdot) = \|M\| \int \tilde{\pi}(dx, \cdot)$, and define $\tilde{M}(\cdot) = \|M\| \int \tilde{\pi}(\cdot, dy)$. Then, we have

$$W(M, N) = W(M - \tilde{M}, N - \tilde{N}) + W(\tilde{M}, \tilde{N}).$$
proof of lemma. Choosing couplings

$$\frac{\|M\|}{\|M - \bar{M}\|}((1 - f(y))\pi(dx, dy), \frac{\|M\|}{\|M\|}f(y)\pi(dx, dy)$$

for $$(M - \bar{M}, N - \bar{N})$$ and $$(\bar{M}, \bar{N})$$, respectively, gives

$$W(M, N) \geq W(M - \bar{M}, N - \bar{N}) + W(\bar{M}, \bar{N}).$$

The reverse inequality follows from (2.11).

For any $$1 \leq k \leq n_1$$, applying (2.18) inductively to $$l \in j^{-1}(k)$$, we obtain

$$W(\mu_k, \eta_k^{(1)} \ast \delta_{x_k^{(1)}}) = W(\bar{\mu}_k - \sum_{l \in j^{-1}(k)} \bar{\mu}_l, (\eta_k^{(1)} - \sum_{l \in j^{-1}(k)} \bar{\eta}_l) \ast \delta_{x_k^{(1)}}) + \sum_{l \in j^{-1}(k)} W(\bar{\mu}_l, \bar{\eta}_l \ast \delta_{x_k^{(1)}}). \quad (2.19)$$

Repeating the same process for $$\nu$$ in place of $$\mu$$, we can define $$\bar{\nu}_k$$. Now define $$\phi = \{[\bar{\mu}_k, \bar{\nu}_k]\}_{k=1}^n$$, $$r = \min(r_1, r_2)$$ and $$\bar{x} = (x_{j_1}^{(1)} + x_{j_2}^{(2)}) \in \mathbb{R}^n$$. One can see that $$\deg(\phi) \geq \min(\deg(\phi_1), \deg(\phi_2)) \geq \min(2r_1, 2r_2) = 2r$$, so $$(r, \phi, \bar{x})$$ is a $$(\mu, \nu)$$-triple.

From the subadditivity property of $$I_r$$ and the inequality

$$d(\mu, \nu) \leq d_{r, \phi, \bar{x}}(\mu, \nu) = \sum_{k=1}^n W(\bar{\mu}_k, \bar{\nu}_k \ast \delta_{x_k}) + I_r(\mu - \sum_{k=1}^n \bar{\mu}_k) + I_r(\nu - \sum_{k=1}^n \bar{\nu}_k) + 2^{-r}$$

$$\leq \sum_{k=1}^n W(\bar{\mu}_k, \bar{\nu}_k \ast \delta_{x_k}) + I_r(\mu - \sum_{k=1}^{n_1} \mu_k) + I_r(\sum_{k=1}^{n_1} \mu_k - \sum_{k=1}^n \bar{\mu}_k)$$

$$+ \sum_{k=1}^{n_1} W(\bar{\nu}_k, \bar{\nu}_k \ast \delta_{x_k}) + I_r(\nu - \sum_{k=1}^{n_2} \nu_k) + I_r(\sum_{k=1}^{n_2} \nu_k - \sum_{k=1}^n \bar{\nu}_k) + 2^{-r}. \quad (2.20)$$

We claim that

$$\sum_{k=1}^{n_1} \eta_k^{(1)} - \sum_{k=1}^{n_2} \bar{\eta}_k = \eta - \sum_{k=1}^{n_1} \eta_k^{(1)} \leq \eta - \sum_{k=1}^{n_2} \eta_k^{(2)}. \quad (2.21)$$

To see this, let $$f_k, g_k$$ be the Radon-Nikodym derivatives of $$\eta_k^{(1)}, \eta_k^{(2)}$$ with respect to $$\eta$$. Since $$\{\text{supp}(\eta_k^{(1)})\}, \{\text{supp}(\eta_k^{(2)})\}$$ are disjoint, respectively, we have $$\sum f_k \leq 1$$ and $$\sum g_k \leq 1$$ pointwise. Therefore,

$$\sum_{k=1}^{n_1} \eta_k^{(1)} + \sum_{k=1}^{n_2} \eta_k^{(2)} - \sum_{k=1}^{n_1} \bar{\eta}_k = \left(\sum_{k=1}^{n_1} f_k \vee \sum_{k=1}^{n_2} g_k\right)\eta \leq \eta,$$

which proves the claim. Note that (2.21) can be rewritten as $$\sum \eta_k^{(2)} - \sum \bar{\eta}_k \leq \eta - \sum \eta_k^{(1)}.$$
We next observe that
\[
I_r \left( \sum_{k=1}^{n_1} \mu_k - \sum_{k=1}^{n} \tilde{\mu}_k \right) = I_r \left( \sum_{k=1}^{n_1} \left( \mu_k - \sum_{l \in j^{-1}_1(k)} \tilde{\mu}_l \right) \right)
\]  
\[= \sup_{u \in \mathbb{N} \times \mathbb{R}^d} \sum_{k=1}^{n_1} \int g_r(u, v) \left( \mu_k - \sum_{l \in j^{-1}_1(k)} \tilde{\mu}_l \right) (dv) = \sup_{k} I_r \left( \mu_k - \sum_{l \in j^{-1}_1(k)} \tilde{\mu}_l \right). \tag{2.22}
\]

In the last identity, we used the fact that since \( \deg(\phi_1) > 2r_1 \geq 2r \), the support of \( g_r(u, \cdot) \) cannot intersect with \( \text{supp}(\mu_k) \) and \( \text{supp}(\mu_m) \) at the same time for any \( k \neq m \). Similarly, we have
\[
I_r \left( \sum_{k=1}^{n_1} \eta_k^{(1)} - \sum_{k=1}^{n} \tilde{\eta}_k \right) = \sup_{k} I_r \left( \eta_k^{(1)} - \sum_{l \in j^{-1}_1(k)} \tilde{\eta}_l \right). \tag{2.23}
\]

We now see that
\[
I_r \left( \sum_{k=1}^{n_1} \mu_k - \sum_{k=1}^{n} \tilde{\mu}_k \right) \leq I_r \left( \sum_{k=1}^{n_1} \mu_k - \sum_{k=1}^{n} \tilde{\mu}_k \right) - I_r \left( \sum_{k=1}^{n_1} \eta_k^{(1)} - \sum_{k=1}^{n} \tilde{\eta}_k \right) + I_r \left( \eta - \sum_{k=1}^{n_2} \eta_k^{(2)} \right)
\]
\[= \sup_k I_r \left( \mu_k - \sum_{l \in j^{-1}_1(k)} \tilde{\mu}_l \right) - I_r \left( \eta_k^{(1)} - \sum_{l \in j^{-1}_1(k)} \tilde{\eta}_l \right) + I_r \left( \eta - \sum_{k=1}^{n_2} \eta_k^{(2)} \right)
\]
\[\leq \sup_k \left[ I_r \left( \mu_k - \sum_{l \in j^{-1}_1(k)} \tilde{\mu}_l \right) - I_r \left( \eta_k^{(1)} - \sum_{l \in j^{-1}_1(k)} \tilde{\eta}_l \right) \right] + I_r \left( \eta - \sum_{k=1}^{n_2} \eta_k^{(2)} \right)
\]
\[\leq \sup_k W \left( \mu_k - \sum_{l \in j^{-1}_1(k)} \tilde{\mu}_l, \left( \eta_k^{(1)} - \sum_{l \in j^{-1}_1(k)} \tilde{\eta}_l \right) \right) + I_r \left( \eta - \sum_{k=1}^{n_2} \eta_k^{(2)} \right)
\]
\[= \sup_k \left[ \sum_{k=1}^{n_1} W \left( \mu_k, \eta_k \right) - \sum_{k=1}^{n_1} W \left( \tilde{\mu}_k, \tilde{\eta}_k \right) \right] + I_r \left( \eta - \sum_{k=1}^{n_2} \eta_k^{(2)} \right)
\]
\[\leq \sum_{k=1}^{n_1} W \left( \eta_k, \nu_k \right) + I_r \left( \sum_{k=1}^{n_2} \nu_k + \sum_{k=1}^{n_1} \tilde{\nu}_k \right) \leq \sum_{k=1}^{n_1} W \left( \eta_k, \nu_k \right) + I_r \left( \eta - \sum_{k=1}^{n_1} \eta_k^{(1)} \right).
\tag{2.24}
\]

where, along with monotonicity of \( I_r \), we used (2.21) in the first line, (2.22) and (2.23) in the second line, shift-invariance of \( I_r \) and (2.14) in line 4, (2.19) in line 5, and in the last line we replaced the maximal term by the sum of all terms. For the same reason, we obtain
\[
\sum_{k=1}^{n_2} W \left( \tilde{\eta}_k, \tilde{\nu}_k \right) + I_r \left( \sum_{k=1}^{n_2} \nu_k - \sum_{k=1}^{n_2} \tilde{\nu}_k \right) \leq \sum_{k=1}^{n_2} W \left( \eta_k, \nu_k \right) + I_r \left( \eta - \sum_{k=1}^{n_2} \eta_k^{(2)} \right).
\tag{2.25}
\]

Collecting (2.20), (2.24) and (2.25), we have
\[
d(\mu, \nu) \leq \sum W \left( \mu_k, \eta_k^{(1)} \right) + I_r \left( \mu - \sum \mu_k \right) + I_r \left( \eta - \sum \eta_k^{(1)} \right)
\]
\[+ \sum W \left( \eta_k^{(2)}, \nu_k \right) + I_r \left( \nu - \sum \nu_k \right) + I_r \left( \eta - \sum \eta_k^{(2)} \right) + 2^{-r}
\]
\[\leq d_{r_1, \phi_1, x^{(1)}}(\mu, \eta) + d_{r_2, \phi_2, x^{(2)}}(\eta, \nu) < d(\mu, \eta) + d(\eta, \nu) + 2\epsilon.
\]

Letting \( \epsilon \downarrow 0 \) completes the proof.
Having proved that \( d \) is a metric on \( \mathcal{X} \), we can now study properties of the metric space \( (\mathcal{X}, d) \).

### 2.5. Compactness and equivalence to the MV topology.

In this section, we prove that \( (\mathcal{X}, d) \) is compact and \( d \) is equivalent to the MV metric. We recall that \( \mathcal{M}_1 \) is naturally embedded in \( \mathcal{X} \) since we can identify any \( \tilde{\alpha} \in \mathcal{M}_1 \) with the element \( \{\tilde{\alpha}_i\} \) in \( \mathcal{X} \) having representative

\[
\alpha_i = \begin{cases} 
\alpha & \text{if } i = 1, \\
0 & \text{otherwise}.
\end{cases}
\]

**Theorem 2.8.** The space \( (\mathcal{X}, d) \) is a compactification of \( \mathcal{M}_1 \), i.e.,

(a) the collection of orbits \( \mathcal{M}_1 \) is dense in \( (\mathcal{X}, d) \);

(b) for any sequence \( (\mu_n)_{n \in \mathbb{N}} \) in \( \mathcal{M}_1 \), there is a subsequence convergent in \( (\mathcal{X}, d) \).

**Proof.** This proof is similar to that of Theorem 3.2 in [MV16].

(a) Let \( \mu = \{\tilde{\alpha}_i\} \in \mathcal{X} \) and \( 0 < \epsilon < 1 \) be given. There are \( n = n(\epsilon) \), \( R = R(\epsilon) \) such that

\[
\sum_{j > n} \|\alpha_j\| < \epsilon, \quad \sum_{j=1}^n \alpha_j(B_R(0)^c) < \epsilon.
\]

We may assume \( 2^{-R} < \epsilon \). For any \( M > 0 \), we denote by \( \mathcal{Z}_M \) the product measure on \( \mathbb{R}^d \) with centered Gaussian marginals of variance \( M \). We can choose \( M = M(\epsilon) \) such that \( I_R(\mathcal{Z}_M) < \epsilon \) and \( \bar{x} = (x_1, \ldots, x_n) \in (\mathbb{R}^d)^n \) with \( \max_{i \neq j} |x_i - x_j| > 2R \). Let

\[
\mu_\epsilon = \mu_{n,M} := \sum_{j=1}^n \alpha_j \cdot \delta_{\bar{x}_j} \cdot \left(1 - \sum_{j=1}^n \|\alpha_j\|\right) \mathcal{Z}_M \in \mathcal{M}_1.
\]

Considering a \((\mu_\epsilon, \mu)\)-triple

\[
\left(R, \phi = \left\{\left(1_{B_R(x_j)}(\alpha_j \ast \delta_{\bar{x}_j}), 1_{B_R(0)} \alpha_j\right)\right\}_{j=1}^n, \bar{x}\right)
\]

gives

\[
d(\mu_\epsilon, \mu) \leq d_{R,\phi,\bar{x}}(\mu_\epsilon, \mu)
\]
\[
= \sum_{j=1}^n \frac{W\left(1_{B_R(x_j)}(\alpha_j \ast \delta_{\bar{x}_j}), 1_{B_R(0)} \alpha_j \ast \delta_{\bar{x}_j}\right)}{R}
\]
\[
+ I_R\left(\mu_\epsilon - \sum_{j=1}^n 1_{B_R(x_j)}(\alpha_j \ast \delta_{\bar{x}_j})\right) + I_R\left(\mu - \sum_{j=1}^n 1_{B_R(0)} \alpha_j\right) + 2^{-R}
\]
\[
\leq 2\left(\sum_{j=1}^n \alpha_j(B_R(0)^c) + \sum_{j>n} \|\alpha_j\|\right) + I_R\left((1 - \sum_{j=1}^n \|\alpha_j\|) \mathcal{Z}_M\right) + 2^{-R}
\]
\[
< 2 \cdot 2\epsilon + \epsilon + \epsilon = 6\epsilon,
\]

which implies that \( (\mu_\epsilon)_{\epsilon > 0} \) converges to \( \mu \).

(b) We now show that for any \( (\mu_n)_{n \in \mathbb{N}} \) in \( \mathcal{M}_1 \), there is a subsequence that converges to \( \nu \in \mathcal{X} \). Since \( I_r \) is bounded by 1, by passing to a subsequence, we may assume that for every \( r > 0 \), there
is \( q_0(r) \geq 0 \) such that
\[
\lim_{n \to \infty} I_r(\mu_n) = q_0(r).
\]

Let \( \mu_{n,0} = \mu_n \). For each \( m \in \mathbb{N} \), we can choose inductively a subsequence \( (\mu_{n,m})_{n \geq 1} \) of \((\mu_{n,m-1})_{n \geq 1}\) such that the limit
\[
\lim_{n \to \infty} I_m(\mu_{n,m}) = q_0(m)
\]
exists. Since \( I_m(\mu_{n,m}) \leq I_{m+1}(\mu_{n,m}) \), \( q_0(m) \) is non-decreasing in \( m \). Therefore, \( q_0 := \lim_{m \to \infty} q_0(m) \) is well-defined and one has
\[
\lim_{n \to \infty} I_m(\mu_{n,n}) = q_0(m), \quad \lim_{r \to \infty} \lim_{n \to \infty} I_r(\mu_{n,n}) = q_0.
\]

For simplicity of notation, we write \( \mu_n \) for \( \mu_{n,n} \) from now on.

If \( q_0 = 0 \) (i.e. \( q_0(r) = 0 \) for all \( r > 0 \)), then for any \( r > 0 \), by choosing the empty matching \( \emptyset \), we have
\[
\limsup_{n \to \infty} d(\mu_n, \emptyset) \leq \limsup_{n \to \infty} d_{r,0,0}(\mu_n, \emptyset) = \limsup_{n \to \infty} I_r(\mu_n) + I_r(\emptyset) + 2^{-r} = 2^{-r}.
\]

Letting \( r \to \infty \), we obtain that \( \tilde{\mu}_n \) converges to \( \emptyset \) in \((X, d)\).

If \( q_0 > 0 \), by choosing a suitable sequence \((a_{n,1})_{n \in \mathbb{N}} \) in \( \mathbb{R}^d \), we have for some \( r > 1 \),
\[
\mu_n * \delta_{a_{n,1}}(B_r(0)) = I_{r-1}(\mu_n) \geq \frac{q_0}{2}
\]
for all sufficiently large \( n \). Due to the compactness of \( M_1 \) in the vague topology, by taking a subsequence if needed, we may assume
\[
\lambda_n := \mu_n * \delta_{a_{n,1}} \rightharpoonup \alpha_1.
\]

Note that \( \|\alpha_1\| \geq q_0/2 \). By Lemma 2.2 in [MV16], there is a decomposition \( \mu_n = \alpha_n,1 + \beta_{n,1} \) such that
\[
\alpha_n,1 * \delta_{a_{n,1}} \Rightarrow \alpha_1, \quad \beta_{n,1} * \delta_{a_{n,1}} \rightharpoonup 0.
\]

In particular, it is proved in Theorem 3.2 of [MV16] that if \( q_0 = 1 \), then \( \beta_{n,1} \) can be taken to be \( \emptyset \), so we have \( \tilde{\mu}_n \to \tilde{\alpha}_1 \) in \((X, d)\).

If \( 0 < q_0 < 1 \), we can repeat this iteratively. More precisely, for each \( k \in \mathbb{N} \), we can define \( q_k = \lim_{r \to \infty} \lim_{n \to \infty} I_r(\beta_{n,k}) \) in the same way as \( q_0 \). Then, there is a a sequence \((a_{n,k+1})_{n \in \mathbb{N}} \) in \( \mathbb{R}^d \) such that
\[
\beta_{n,k} = \alpha_{n,k+1} + \beta_{n,k+1}
\]
and
\[
\|\alpha_{k+1}\| \geq \frac{q_k}{2}, \quad \alpha_{n,k+1} * \delta_{a_{n,k+1}} \Rightarrow \alpha_1, \quad \beta_{n,k+1} * \delta_{a_{n,k+1}} \rightharpoonup 0.
\]

If there is \( k \in \mathbb{N} \) such that \( q_k = 0 \), then we have the following decomposition for \( \mu_n \):
\[
\mu_n = \sum_{j=1}^{k} \alpha_{n,j} + \beta_{n,k}.
\]
where

\[ \lim_{r \to \infty} \lim_{n \to \infty} I_r(\beta_{n,k}) = 0, \]

\[ \alpha_{n,j} \ast \delta_{a_{n,j}} \Rightarrow \alpha_j, \quad \beta_{n,j} \ast \delta_{a_{n,j}} \to 0, \quad 1 \leq j \leq k, \]  

\[ \lim_{n \to \infty} |a_{n,i} - a_{n,j}| = \infty, \quad i \neq j. \]  

(2.26)

(2.27)

To see (2.27), let us assume that it is not true. By taking a subsequence, we may assume the limit

\[ b := \lim_{n \to \infty} (a_{n,i} - a_{n,j}) \] 

exists for some \( i > j \). We observe that

\[ \beta_{n,i} \ast \delta_{a_{n,i}} \geq \alpha_{n,j} \ast \delta_{a_{n,j}} = (\alpha_{n,j} \ast \delta_{a_{n,j}}) \ast \delta_{a_{n,i} = a_{n,j}}. \]

(2.28)

Since \( \beta_{n,i} \ast \delta_{a_{n,i}} \to 0, \)

\[ \lim_{n \to \infty} \beta_{n,i} \ast \delta_{a_{n,i}}(K) = 0 \]  

(2.29)

for any compact set \( K \) in \( \mathbb{R}^d \). On the other hand, it follows from \( \alpha_{n,j} \ast \delta_{a_{n,j}} \Rightarrow \alpha_j \) and \( \|\alpha_j\| \geq q_j - 1/2 \) that there is a compact set \( K_j \) such that \( \alpha_{n,j} \ast \delta_{a_{n,j}}(K_j) \geq q_j - 1/3 \) for all sufficiently large \( n \). Let

\[ K'_j = \{ x \in \mathbb{R}^d : x - b \in B_1(y) \text{ for some } y \in K_j \}. \]

Then, one can readily check that \( \alpha_{n,j} \ast \delta_{a_{n,i}}(K'_j) \geq q_j - 1/3 \) for all sufficiently large \( n \). Combining this with (2.29) gives contradiction to (2.28).

We claim that \( \mu_n \to \mu = \{ \bar{\alpha}_1, \ldots, \bar{\alpha}_k \} \) in \( (\bar{X}, d) \). The argument is the same as in the proof of (2.30) below, and we omit it here.

If \( q_k > 0 \) for every \( k \in \mathbb{N} \), then there are \( (\alpha_{n,j}), (\beta_{n,j}) \) in \( \mathcal{M}_{\leq 1} \) and \( (a_{n,j}) \) in \( \mathbb{R}^d \) such that for all \( n, k \in \mathbb{N}, (2.26), (2.27) \) hold and

\[ \mu_n = \sum_{j=1}^{k} \alpha_{n,j} + \beta_{n,k}. \]

Since \( \|\alpha_j\| \geq q_j - 1/2 \) and \( \sum_{j \in \mathbb{N}} \|\alpha_j\| \leq 1 \), we have \( q_j \to 0 \). We claim that

\[ \bar{\mu}_n \to \mu := \{ \bar{\alpha}_j \}_{j \in \mathbb{N}} \text{ in } (\bar{X}, d). \]  

(2.30)

Let \( \epsilon > 0 \) be given. We first choose \( k = k(\epsilon) \in \mathbb{N} \) such that \( q_k < \epsilon \). There is \( r = r(\epsilon) \) such that

\[ \sum_{j=1}^{k} \alpha_j(B_r(0) \cap) < \epsilon, \quad \sum_{j=1}^{k} \alpha_{n,j}(B_r(0) \cap) < \epsilon \]

for all sufficiently large \( n \geq N_1 \). We may assume \( 2^{-r} < \epsilon \). We can also find \( N_2 \) such that

\[ \inf_{i \neq j} |a_{n,i} - a_{n,j}| > 2r \text{ for all } n \geq N_2. \]

Recalling the definition of \( f_r \) in (2.12), we choose a \( (\mu, \mu_n) \)-matching \( \phi = \{ (f_r \alpha_j, f_r(\cdot + a_{n,j}) \alpha_{n,j}) \}_{j=1}^{k} \) and \( \bar{x}_n = (a_{n,1}, \ldots, a_{n,k}) \). For all \( n \geq \max(N_1, N_2), \)

\[ d(\mu, \mu_n) \leq d_{r, \phi, \bar{x}_n}(\mu, \mu_n) = \sum_{j=1}^{k} W \left( f_r \alpha_j, f_r(\alpha_{n,j} \ast \delta_{a_{n,j}}) \right) \]

...
\begin{align}
+ I_r \left( \mu - \sum_{j=1}^{k} f_r \alpha_j \right) + I_r \left( \sum_{j=1}^{k} \left( 1 - f_r (\cdot + a_{n,j}) \right) \alpha_{n,j} + \beta_{n,k} \right) + 2^{-r}. \tag{2.31}
\end{align}

By (2.26), we have for each $1 \leq j \leq k$,
\begin{align}
\lim_{n \to \infty} W \left( f_r \alpha_j, f_r (\alpha_{n,j} \ast \delta_{a_{n,j}}) \right) = 0. \tag{2.32}
\end{align}

It follows from the subadditivity of $I_r$ that
\begin{align}
I_r \left( \mu - \sum_{j=1}^{k} f_r \alpha_j \right) &\leq \sum_{j=1}^{k} I_r \left( (1 - f_r) \alpha_j \right) + I_r \left( \{ \alpha_{j+k} \}_{j \in \mathbb{N}} \right) \\
&\leq \sum_{j=1}^{k} \alpha_{n,j} (B_r(0)^{r}) + q_k < 2\epsilon. \tag{2.33}
\end{align}

Similarly, we can also obtain
\begin{align}
I_r \left( \sum_{j=1}^{k} (1 - f_r (\cdot + a_{n,j})) \alpha_{n,j} + \beta_{n,k} \right) &\leq \sum_{j=1}^{k} I_r \left( (1 - f_r (\cdot + a_{n,j})) \alpha_{n,j} \right) + I_r (\beta_{n,k}) < 2\epsilon. \tag{2.34}
\end{align}

Plugging (2.32), (2.33) and (2.34) into (2.31), one has $\limsup_{n \to \infty} d(\mu, \mu_n) < 5\epsilon$, completing the proof. \hfill \Box

In our proof of the equivalence between the MV topology and the topology defined by our metric $d$, we will use the following theorem:

**Theorem 2.9** (Theorem 26.6 in [Mum00]). Let $X,Y$ be two topological spaces and let $f : X \to Y$ be a bijective continuous function. If $X$ is compact and $Y$ is Hausdorff, then $f$ is homeomorphism.

**Proposition 2.10.** $(\tilde{X}, d)$ is equivalent to $(\tilde{X}, D)$.

**Proof.** We fix $k \geq 2$. Since $(\tilde{X}, d)$ is compact by Proposition 2.8 and $(\tilde{X}, D)$ is Hausdorff being a metric space, it suffices, due to Theorem 2.9, to show the continuity of the identity map $e : (\tilde{X}, d) \to (\tilde{X}, D)$.

By the Portmanteau Theorem, $\Lambda(f, \mu^{(n)}) \to \Lambda(f, \mu)$ for all $f \in \mathcal{F}_k$ is equivalent to $\Lambda(f, \mu^{(n)}) \to \Lambda(f, \mu)$ for all bounded, Lipschitz continuous $f \in \mathcal{F}_k$. Therefore, it suffices to show that for given $\epsilon > 0$ and bounded Lipschitz continuous $f \in \mathcal{F}_k$, there is $\delta = \delta(\epsilon, f) > 0$ such that
\begin{align}
d(\mu, \nu) < \delta \quad \Rightarrow \quad |\Lambda(f, \mu) - \Lambda(f, \nu)| < \epsilon.
\end{align}

We may assume $0 \leq f \leq 1$ and $f$ is 1-Lipschitz continuous. Let us choose $M = M(\epsilon, f) > 0$ such that $f(x_1, \cdots, x_k) < \epsilon/4$ whenever $\max_{i \neq j} |x_i - x_j| \geq M$ and let
\begin{align}
\delta = \min \left( \frac{\epsilon}{4k}, 2^{-M} \right).
\end{align}

Let us assume that $d(\mu, \nu) < \delta$. Then there is a $(\mu, \nu)$-triple
\begin{align}
(r, \phi = \{(\mu_j, \nu_j)\}_{j=1}^{n}, \tilde{y} = (y_1, \cdots, y_n)) \tag{2.35}
\end{align}
such that $d_{r,\phi,\delta}(\mu, \nu) < \delta$. Let

$$\mu^s = \{\alpha_j^s\} = \mu - \sum_{j=1}^{n} \mu_j, \quad \nu^s = \{\gamma_j^s\} = \nu - \sum_{j=1}^{n} \nu_j.$$

Notice that since $r > M$, we have $\sup_{u \in \mathbb{N} \times \mathbb{R}^d} \mu^s(B_M(u)) \leq I_r(\mu^s) < \delta$.

Let $\alpha_j^c = \alpha_j - \alpha_j^s = \sum_{l: \mu_l \leq \alpha_j} \mu_l$ for each $j$. We divide each term of $\Lambda(f, \mu)$ into a core part and a sparse part:

$$\int f(x_1, \ldots, x_k) \prod_{i=1}^{k} \alpha_j(x_i) = \int f(x_1, \ldots, x_k) \prod_{i=1}^{k} (\alpha_j^c + \alpha_j^s)(x_i)
\leq \int f(x_1, \ldots, x_k) \prod_{i=1}^{k} \alpha_j^c(x_i) + \sum_{\tilde{t} \in \{c, s\}^{k} \setminus \{c\}^k} \int f(x_1, \ldots, x_k) \prod_{i=1}^{k} \alpha_j^t(x_i). \quad (2.36)$$

Let $A = \{x \in \mathbb{R}^d : \max_{i \neq j} |x_i - x_j| \geq M\}$ and $|t|$ be the number of occurrences of $s$ in $\tilde{t}$. For any $\tilde{t} \in \{c, s\}^{k} \setminus \{c\}^k$, there is a number $l$ such that $t_l = s$, so

$$\int f(x_1, \ldots, x_k) \prod_{i=1}^{k} \alpha_j^t(x_i) = \int f(x) \prod_{i=1}^{k} \alpha_j^t(x_i) + \int f(x) \prod_{i=1}^{k} \alpha_j^t(x_i)
\leq \frac{c}{4} \|\alpha_j^c\|^{k-|t|}\|\alpha_j^s\|^{|t|} + \int_{|x_i - x_{i-1}| < M} \prod_{i=1}^{k} \alpha_j^t(x_i)
\leq \frac{c}{4} \|\alpha_j^c\|^{k-|t|}\|\alpha_j^s\|^{|t|} + \sup_{x \in \mathbb{R}^d} \alpha_j^t(B_M(x))\|\alpha_j^c\|^{k-|t|}\|\alpha_j^s\|^{|t|-1}
\leq \frac{c}{4} \|\alpha_j^c\|^{k-|t|}\|\alpha_j^s\|^{|t|} + \delta\|\alpha_j^c\|^{k-|t|}\|\alpha_j^s\|^{|t|-1}. \quad (2.37)$$

From the binomial theorem, we have

$$\sum_{\tilde{t} \in \{c, s\}^{k} \setminus \{c\}^k} \|\alpha_j^c\|^{k-|t|}\|\alpha_j^s\|^{|t|} \leq \sum_{\tilde{t} \in \{c, s\}^k} \|\alpha_j^c\|^{k-|t|}\|\alpha_j^s\|^{|t|} \leq \|\alpha_j\|^k \leq \|\alpha_j\| \quad (2.38)$$

and, by the mean value theorem,

$$\sum_{\tilde{t} \in \{c, s\}^{k} \setminus \{c\}^k} \|\alpha_j^c\|^{k-|t|}\|\alpha_j^s\|^{|t|-1} = \left(\frac{\|\alpha_j^c\| + \|\alpha_j^s\|}{\|\alpha_j^c\|}\right)^k - \|\alpha_j^c\|^k = kp^{k-1} \leq k\|\alpha_j\| \quad (2.39)$$

for some $p \in [\|\alpha_j^c\|, \|\alpha_j\|]$. Combining (2.38) and (2.39) with (2.37) gives

$$\sum_{\tilde{t} \in \{c, s\}^{k} \setminus \{c\}^k} \int f(x_1, \ldots, x_k) \prod_{i=1}^{k} \alpha_j^t(x_i) \leq \left(\frac{c}{4} + k\delta\right)\|\alpha_j\|. \quad (2.40)$$

For the core part,

$$\int f(x_1, \ldots, x_k) \prod_{i=1}^{k} \alpha_j^c(dx_i) = \int f(x_1, \ldots, x_k) \prod_{i=1}^{k} \left(\sum_{l: \mu_l \leq \alpha_j} \mu_l\right)(dx_i)$$
\[
\leq \sum_{l; \mu_l \leq \alpha_j} \int f(x_1, \ldots, x_k) \prod_{i=1}^k \mu_i(dx_i) + \frac{\epsilon}{4} \|\alpha_j\|^k, \tag{2.41}
\]
where we used in the inequality the fact that \(\deg(\phi) \geq 2r > M\), so \(|f| < \epsilon/4\) on the support of the off-diagonal products of \(\mu_l\)'s. Substituting (2.40) and (2.41) into (2.36) and summing over all \(j\), we obtain
\[
\Lambda(f, \mu) \leq \sum_{j=1}^n \Lambda(f, \mu_j) + \frac{\epsilon}{2} + k\delta. \tag{2.42}
\]
On the other hand, it follows from the non-negativity of \(f\) that
\[
\Lambda(f, \mu) \geq \Lambda(f, \sum_{j=1}^n \mu_j) \geq \sum_{j=1}^n \Lambda(f, \mu_j). \tag{2.43}
\]
Estimates similar to (2.42) and (2.43) also hold true for \(\Lambda(f, \nu)\).

We now give an upper bound for \(W(\alpha^{\otimes k}, \gamma^{\otimes k})\) in terms of \(W(\alpha, \gamma)\). Let \(\pi\) be the optimal coupling of \((\alpha, \gamma)\). Then, \(\pi^{\otimes k}\) is a coupling of \((\alpha^{\otimes k}, \gamma^{\otimes k})\) and
\[
W(\alpha^{\otimes k}, \gamma^{\otimes k}) \leq \int (|\vec{x} - \vec{y}| \wedge 1) \pi^{\otimes k}(d\vec{x}, d\vec{y}) \leq \int \sum_{j=1}^k (|x_j - y_j| \wedge 1) \pi^{\otimes k}(d\vec{x}, d\vec{y})
= \sum_{j=1}^k \int (|x_j - y_j| \wedge 1) \pi(dx_j, dy_j) = kW(\alpha, \gamma). \tag{2.44}
\]
Combining (2.42), (2.43) and (2.44), we conclude that
\[
|\Lambda(f, \mu) - \Lambda(f, \nu)| < \sum_{j=1}^n |\Lambda(f, \mu_j) - \Lambda(f, \nu_j)| + \frac{\epsilon}{2} + k\delta
\leq \sum_{j=1}^n W(\mu_j^{\otimes k}, (\nu_j * \delta_{y_j})^{\otimes k}) + \frac{\epsilon}{2} + k\delta
\leq k \sum_{j=1}^n W(\mu_j, \nu_j * \delta_{y_j}) + \frac{\epsilon}{4} + k\delta \leq 2k\delta + \frac{\epsilon}{2} \leq \epsilon,
\]
where the inequality in the second line follows from the translational invariance of \(\Lambda\) and (2.10) (we recall that \(\vec{y} = (y_1, \ldots, y_n)\) was introduced in (2.35) as an element of the \((\mu, \nu)\)-triple).

\[\square\]

3. The update map

In this section, following [BC16], we define an “update map” \(T : \mathcal{P}(\tilde{X}) \to \mathcal{P}(\tilde{X})\) which maps the law of the polymer endpoint distribution of length \(n\) to that of length \(n + 1\), and prove that \(T\) is continuous. As in Section 1.3, the endpoint distribution for the polymer of length \(n\) is denoted by
\[
\rho_n(dx) = \mathcal{M}_n(\omega_n \in dx).
\]
Notice that \(\rho_n\) is a random measure on the probability space \((\Omega_e, \mathcal{G}, P)\) of random environment.
3.1. The conditional update map. In this section, we define a “conditional” update map $T : \tilde{X} \to \mathcal{M}_1(\tilde{X})$ that maps $\rho_n$ to the law of $\rho_{n+1}$ given $\mathcal{G}_n$. We observe that

$$\rho_{n+1}(dx) = \frac{1}{Z_{n+1}} E \left[ \exp \left( \beta \sum_{i=1}^{n+1} X(i, \omega_i) \right) 1_{\{\omega_{n+1} \in dx\}} \right]$$

$$= \frac{1}{Z_{n+1}} \int_{(\mathbb{R}^d)^n} \exp \left( \beta \sum_{i=1}^{n+1} X(i, y_i) + \beta X(n + 1, x) \right) P_{n+1}(dy_1, \cdots, dy_n, dx)$$

$$= \frac{1}{Z_{n+1}} \int_{(\mathbb{R}^d)^n} \exp \left( \beta \sum_{i=1}^{n+1} X(i, y_i) + \beta X(n + 1, x) \right) P_n(dy_1, \cdots, dy_n) \mathcal{Z}(d(x - y_n))$$

$$= \frac{Z_n}{Z_{n+1}} \int_{\mathbb{R}^d} e^{\beta X(n+1,x)} \rho_n(dy_n) \mathcal{Z}(d(x - y_n))$$

$$= \frac{Z_n}{Z_{n+1}} e^{\beta X(n+1,x)} \rho_n \ast \mathcal{Z}(dx).$$

Integrating over $x$ on the both sides gives

$$\frac{Z_{n+1}}{Z_n} = \int_{\mathbb{R}^d} e^{\beta X(n+1,x)} \rho_n \ast \mathcal{Z}(dx).$$

Since $X(n + 1, \cdot)$ is independent of $\mathcal{G}_n$, the law of $\rho_{n+1}$ given $\mathcal{G}_n$ is equal to the law of

$$\rho(dx) := \frac{e^{\beta Y(x)} \rho_n \ast \mathcal{Z}(dx)}{\int_{\mathbb{R}^d} e^{\beta Y(z)} \rho_n \ast \mathcal{Z}(dz)}, \quad (3.1)$$

where $Y(\cdot) \overset{d}{=} X(\cdot)$ and $Y$ is independent of $\mathcal{G}_n$.

In general, for $\mu = \{\alpha_i\} \in \mathcal{X}$, we can consider a $\mathcal{X}$-valued random variable $\hat{\mu} = \{\hat{\alpha}_i\}$ given by

$$\hat{\alpha}_i(dx) := \frac{e^{\beta Y(x)} \alpha_i \ast \mathcal{Z}(dx)}{\sum_{j=1}^{\infty} \int_{\mathbb{R}^d} e^{\beta Y(j,z)} \alpha_j \ast \mathcal{Z}(dz) + (1 - \|\mu\|)e^{\lambda(\beta)}}, \quad (3.2)$$

where $(Y(u))_{u \in \mathbb{N} \times \mathbb{R}^d} \overset{d}{=} (X(u))_{u \in \mathbb{N} \times \mathbb{R}^d}$.

Notice that $(3.2)$ is a generalization of $(3.1)$ because $\|\rho_n\| = 1$ for all $n \in \mathbb{N}$. The additional term in the denominator allows us to define $\hat{\mu}$ when $\mu \equiv 0$ and we will see later that this term makes the (conditional) update map continuous.

For any $\mu = \{\alpha_i\} \in \mathcal{X}$ and $\gamma \in \mathcal{M}_{\leq 1}$, we will write

$$\mu \ast \gamma := \{\alpha_i \ast \gamma\}. \quad (3.3)$$

One can check that the convolution is also well-defined for $\mu \in \tilde{X}$. The measure $\hat{\mu}$ can be now expressed in terms of $(3.3)$ and integration on $\mathbb{N} \times \mathbb{R}^d$ as follows:

$$\hat{\mu}(du) := \frac{e^{\beta Y(u)} \mu \ast \mathcal{Z}(du)}{\int_{\mathbb{N} \times \mathbb{R}^d} e^{\beta Y(w)} \mu \ast \mathcal{Z}(dw) + (1 - \|\mu\|)e^{\lambda(\beta)}}, \quad (3.4)$$
We now would like to have (3.4) to be well-defined on \( \tilde{\mathcal{X}} \). For a fixed environment though, \( \hat{\mu} \) does depend on the choice of the representative of \( \mu \). However, the next proposition claims that the law of \( \hat{\mu} \) is independent of the choice of representative.

**Proposition 3.1.** For \( \mu_1, \mu_2 \in \mathcal{X} \) with \( \mu_1 \sim \mu_2 \), define \( \hat{\mu}_1, \hat{\mu}_2 \) as in (3.4). Then, \( \hat{\mu}_1 \overset{d}{=} \hat{\mu}_2 \) as \( \tilde{\mathcal{X}} \)-valued random variables.

**Proof.** It suffices to find a coupling of \((Y_1, Y_2)\) such that

- \( Y_1, Y_2 \) are random fields with the same law as \( X \),
- \( Y_i \) are used to define \( \hat{\mu}_i \) in (3.4),
- \( \hat{\mu}_1 = \hat{\mu}_2 \) in \( \tilde{\mathcal{X}} \).

Let \( \mu_1 = \{\alpha_1\}, \mu_2 = \{\gamma_1\} \). From Definition 2.1, there are a sequence \( \{x_i\} \) in \( \mathbb{R}^d \) and a bijection \( \sigma : S_{\mu_2} \rightarrow S_{\mu_1} \) such that \( \gamma_i = \alpha_{\sigma(i)} * \delta_{x_i} \) for all \( i \in S_{\mu_2} \). Let \( Y_1, W \) be independent random fields with the same law as \( X \) and set

\[
Y_2(i, x) = \begin{cases} 
Y_1(\sigma(i), x - x_i) & \text{if } i \in S_{\mu_2}, \\
W(i, x) & \text{otherwise}.
\end{cases}
\]

Then, we have for any \( i \in S_{\mu_2} \),

\[
\hat{\gamma}_i(dx) = \frac{e^{\beta Y_2(i, x)} \gamma_i * \mathcal{Z}(dx)}{\sum_{j=1}^{\infty} \int_{\mathbb{R}^d} e^{\beta Y_2(j, z)} \gamma_j * \mathcal{Z}(dz) + (1 - ||\mu_2||) e^{\lambda(\beta)}}
= \frac{e^{\beta Y_1(\sigma(i), x - x_i)} \alpha_{\sigma(i)} * \delta_{x_i} * \mathcal{Z}(dx)}{\sum_{j \in S_{\mu_2}} \int_{\mathbb{R}^d} e^{\beta Y_1(\sigma(j), z - x_i)} \alpha_{\sigma(j)} * \delta_{x_i} * \mathcal{Z}(dz) + (1 - ||\mu_1||) e^{\lambda(\beta)}}
= \frac{e^{\beta Y_1(\sigma(i), x)} \alpha_{\sigma(i)} * \mathcal{Z}(dx)}{\sum_{j=1}^{\infty} \int_{\mathbb{R}^d} e^{\beta Y_1(j, z)} \alpha_j * \mathcal{Z}(dz) + (1 - ||\mu_1||) e^{\lambda(\beta)}}
= \hat{\alpha}_{\sigma(i)} * \delta_{x_i}(dx),
\]

which implies that \( \hat{\alpha}_{\sigma(i)} \) and \( \hat{\gamma}_i \) belong to the same orbit. \( \square \)

Let us denote the space of probability measures on \( \tilde{\mathcal{X}} \) by \( \mathcal{P}(\tilde{\mathcal{X}}) \). Proposition 3.1 allows us to define the update map \( T : \tilde{\mathcal{X}} \rightarrow \mathcal{P}(\tilde{\mathcal{X}}) \) by

\[
T : \mu \mapsto \text{law of } \hat{\mu}.
\]

Since \( \tilde{\mathcal{M}}_1 \) is naturally embedded in \( \tilde{\mathcal{X}} \), we can identify the endpoint distribution \( \rho_n \) with a random element of \( \tilde{\mathcal{X}} \). As we discussed before, we have

\[
T \mu(d\nu) = \mathbb{P}(\rho_{n+1} \in d\nu \mid \rho_n = \mu),
\]

or equivalently,

\[
T \rho_n(d\nu) \overset{a.s.}{=} \mathbb{P}(\rho_{n+1} \in d\nu \mid \rho_n) \overset{a.s.}{=} \mathbb{P}(\rho_{n+1} \in d\nu \mid G_n). \tag{3.5}
\]
Therefore, $T \mu(d\nu) := \Gamma(\mu, d\nu)$ can be understood as a transition kernel for the Markov chain $(\rho_n)_{n \geq 0}$ on $\tilde{X}$.

### 3.2. Construction of $d$ revisited

Before proceeding to prove the continuity of the conditional update map, we explore an alternative construction of $d$. For any $\mu, \nu \in \tilde{X}$, we call $\varphi := \{(\mu_k, \nu_k)\}_{k=1}^n$ a $(\mu, \nu)$-g-matching (standing for generalized matching) if it is a $(\mu, \nu)$-matching for which the second condition of the matching is relaxed (see Definition 2.3). That is, paired sub-measures don’t need to have the same mass in a g-matching (see Definition 2.4). We can define $\text{deg}(\varphi)$ and a g-triple $(r, \varphi, \vec{x})$ in the same way as for matchings. We denote the set of all $(\mu, \nu)$-g-matchings by $G_{\mu, \nu}$.

Given a g-triple $(r, \varphi, \vec{x})$, we define

$$d_{r, \varphi}(\mu, \nu) := \sum_{k=1}^n W(\mu_k, \nu_k * \delta_{x_k}) + I_r(\mu - \sum_{k=1}^n \mu_k) + I_r(\nu - \sum_{k=1}^n \nu_k) + 2^{-r}.$$ 

We claim that

$$d_g(\mu, \nu) := \inf_{r, \varphi} d_{r, \varphi}(\mu, \nu) = \inf_{r, \varphi} d_{r, \varphi}(\mu, \nu) = d(\mu, \nu).$$

The inequality $d(\mu, \nu) \geq d_g(\mu, \nu)$ is obvious because every matching is a g-matching. To see the reverse inequality, let us take any $\epsilon > 0$ and choose a g-triple $(r, \varphi) = \{(\mu_k, \nu_k)\}_{k=1}^n, \vec{x})$ such that $d_{r, \varphi}(\mu, \nu) < d_g(\mu, \nu) + \epsilon$. For each pair $(\mu_k, \nu_k)$ there exist sub-measures $\tilde{\mu}_k \leq \mu_k, \tilde{\nu}_k \leq \nu_k$ such that they have the same mass and

$$W(\mu_k, \nu_k) = W(\tilde{\mu}_k, \tilde{\nu}_k) + \|\mu_k - \tilde{\mu}_k\| + \|\nu_k - \tilde{\nu}_k\|.$$

Now we consider a triple $(r, \phi = \{(\mu_k, \nu_k)\}, \vec{x})$. Then we have

$$d_{r, \phi}(\mu, \nu) = \sum_{k=1}^n W(\tilde{\mu}_k, \tilde{\nu}_k) + I_r(\mu - \sum_{k=1}^n \tilde{\mu}_k) + I_r(\nu - \sum_{k=1}^n \tilde{\nu}_k) + 2^{-r} \quad (3.6)$$

and by the subadditivity of $I_r$,

$$I_r(\mu - \sum_{k=1}^n \tilde{\mu}_k) \leq I_r(\mu - \sum_{k=1}^n \mu_k) + I_r(\sum_{k=1}^n \mu_k - \tilde{\mu}_k) \leq I_r(\mu - \sum_{k=1}^n \mu_k) + \sum_{k=1}^n \|\mu_k - \tilde{\mu}_k\| \quad (3.7)$$

Plugging (3.7) into (3.6), we obtain that

$$d_{r, \phi}(\mu, \nu) \leq d_{r, \phi}(\mu, \nu) < d_{r, \phi}(\mu, \nu) + \epsilon,$$

which completes the proof.

### 3.3. Continuity of the conditional update map

Let us equip $\mathcal{P}(\tilde{X})$ with the Wasserstein metric $W$:

$$W(\xi_1, \xi_2) := \inf_{\tilde{X} \times \tilde{X}} \int_{\tilde{X}} \int_{\tilde{X}} d(\mu, \nu) \pi(d\mu, d\nu),$$

where the infimum is taken over all couplings $\pi$ of $(\xi_1, \xi_2)$. In this section, we will prove that $T : (\tilde{X}, d) \to (\mathcal{P}(\tilde{X}), W)$ is continuous. We begin with a useful lemma.
Lemma 3.2. Let
\[ A = \int_{\mathbb{R}^d} e^{\beta Y(u)} \mu * \mathcal{Z}(du) + (1 - \|\mu\|) e^{\lambda(\beta)}. \] (3.8)
Then, for any \( p > 0 \),
\[ \mathbb{E} A^{-p} \leq 2^p e^{\lambda(-p\beta)}. \]

Proof. We consider two cases. If \( \|\mu\| \leq 1/2 \), then by Jensen inequality,
\[ \mathbb{E} A^{-p} \leq \left( (1 - \|\mu\|) e^{\lambda(\beta)} \right)^{-p} \leq 2^p (\mathbb{E} e^{\beta Y(1,0)})^{-p} \leq 2^p \mathbb{E} e^{-p\beta Y(1,0)} = 2^p e^{\lambda(-p\beta)}. \]
If \( \|\mu\| > 1/2 \), then again by Jensen’s inequality,
\[ \mathbb{E} A^{-p} \leq \mathbb{E} \left( \int_{\mathbb{R}^d} e^{\beta Y(u)} \mu * \mathcal{Z}(du) \right)^{-p} \]
\[ \leq \|\mu\|^{-p} \mathbb{E} \int_{\mathbb{R}^d} e^{-p\beta Y(u)} \frac{\mu * \mathcal{Z}(du)}{\|\mu\|} \]
\[ = \|\mu\|^{-p} e^{\lambda(-p\beta)} \int_{\mathbb{R}^d} \frac{\mu * \mathcal{Z}(du)}{\|\mu\|} \leq 2^p e^{\lambda(-p\beta)}. \]

Proposition 3.3. There is a constant \( M > 0 \) such that the following holds true: for any \( \epsilon > 0 \),
there is \( \delta = \delta(\epsilon) > 0 \) such that for \( \mu, \nu \in \bar{X} \)
\[ d(\mu, \nu) < \delta \quad \Rightarrow \quad W(T\mu, T\nu) < M\epsilon. \]

Proof. Let \( \hat{\mu} = \{\hat{\alpha}_j\}, \hat{\nu} = \{\hat{\gamma}_j\} \) be \( \bar{X} \)-valued random variables with laws \( T\mu, T\nu \), respectively. Since
\[ W(T\mu, T\nu) = \min \mathbb{E} d(\hat{\mu}, \hat{\nu}), \] (3.9)
where the minimum is taken over all couplings of \( (\hat{\mu}, \hat{\nu}) \), our goal is to construct a coupling which makes \( \mathbb{E} d(\hat{\mu}, \hat{\nu}) \) as small as possible.

Let \( \epsilon \in (0,1) \) be given. We will determine \( \delta = \delta(\epsilon) > 0 \) later. If \( d(\mu, \nu) < \delta \), there is a triple \( (r, \phi = \{(\mu_k, \nu_k)\}) \) such that
\[ d_{r,\phi,\bar{x}}(\mu, \nu) < \delta. \] (3.10)
We may assume \( \delta \leq 2^{-L} \) so that \( r > L \).

(Step 1) We first assume that for each \( k \), there is at most one \( j = j(k) \) such that \( \mu_j \leq \alpha_k \) and the same condition holds for \( \nu \). By rearranging the order of \( \{\hat{\alpha}_j\}, \{\hat{\gamma}_j\} \) and translating each \( \gamma_i \) if needed, we may assume \( \mu_k \leq \alpha_k, \nu_k \leq \gamma_k \) for \( 1 \leq k \leq n \) and \( \bar{x} = \bar{0} \).

Let us use the same environment \( Y \) to define \( \hat{\alpha}_j, \hat{\gamma}_j \) as in (3.2). In addition to \( A \) defined in (3.8), we introduce
\[ B = \int_{\mathbb{R}^d} e^{\beta Y(u)} \nu * \mathcal{Z}(du) + (1 - \|\nu\|) e^{\lambda(\beta)}, \] (3.11)
\[ \alpha_i^*(dx) = e^{\beta Y(i,x)} \alpha_i * \mathcal{Z}(dx), \]
\[ \gamma_i^*(dx) = e^{\beta Y(i,x)} \gamma_i * \mathcal{Z}(dx). \]
Notice that $\hat{\alpha}_i = \alpha_i^* (dx) / A$, $\hat{\gamma}_i = \gamma_i^* (dx) / B$. Similarly, define
\[
\begin{align*}
\mu_k^* (dx) &= e^{\beta Y (k, x)} \mu_k * Z (dx), \\
\nu_k^* (dx) &= e^{\beta Y (k, x)} \nu_k * Z (dx),
\end{align*}
\] (3.12)

Choosing a $(\hat{\mu}, \hat{\nu})$-g-triple $(r, \hat{\phi} = \{\hat{\mu}_k, \hat{\nu}_k\}_{k=1}^n, \hat{0})$, we have
\[
\mathbf{E} d(\hat{\mu}, \hat{\nu}) \leq \mathbf{E} \left[ \sum_{k=1}^n \hat{W}(\hat{\mu}_k, \hat{\nu}_k) + I_r (\hat{\mu} - \sum \hat{\mu}_k) + I_r (\hat{\nu} - \sum \hat{\nu}_k) + 2^{-r} \right].
\] (3.13)

1. Upper bound for $\mathbf{E} \sum_{k=1}^n \hat{W}(\hat{\mu}_k, \hat{\nu}_k)$

We first observe the generalized Wasserstein distance terms.
\[
\mathbf{E} \hat{W}(\hat{\mu}_k, \hat{\nu}_k) = \mathbf{E} \hat{W} \left( \frac{\mu_k^*}{A}, \frac{\nu_k^*}{B} \right) \leq \mathbf{E} \hat{W} \left( \frac{\mu_k^*}{A}, \frac{\nu_k^*}{A} \right) + \mathbf{E} \hat{W} \left( \frac{\nu_k^*}{A}, \frac{\nu_k^*}{B} \right)
\]
\[
\leq \mathbf{E} \frac{1}{A} \hat{W}(\mu_k^*, \nu_k^*) + \mathbf{E} \left[ \frac{|A - B|}{AB} \left\| \nu_k^* \right\| \right].
\] (3.14)

Summing over $k$ gives
\[
\mathbf{E} \sum_{k=1}^n \hat{W}(\hat{\mu}_k, \hat{\nu}_k) \leq \mathbf{E} \frac{1}{A} \sum_{k=1}^n \hat{W}(\mu_k^*, \nu_k^*) + \mathbf{E} \left[ \frac{|A - B|}{A} \sum_{k=1}^n \left\| \nu_k^* \right\| \right]
\]
\[
\leq \mathbf{E} \frac{1}{A} \sum_{k=1}^n \hat{W}(\mu_k^*, \nu_k^*) + \mathbf{E} \frac{|A - B|}{A}
\]
\[
\leq (EA^{-2})^{1/2} \left( \sum_{k=1}^n \left[ \mathbf{E} \hat{W}(\mu_k^*, \nu_k^*)^2 \right]^{1/2} + \frac{[E(A - B)^2]^{1/2}}{\sqrt{2}} \right). 
\] (3.15)

We need to estimate all the terms on the right-hand side of (3.15). We start with $\mathbf{E} \hat{W}(\mu_k^*, \nu_k^*)$.

1-(i) Upper bound for $\mathbf{E} \left( \hat{W}(\mu_k^*, \nu_k^*)^2 \right)^{1/2}$

We observe that the stationary process $(e^{2\beta X(x)})_{x \in \mathbb{R}^d}$ is uniformly integrable and by the path continuity, a $\lim_{|x| \to 0} e^{\beta X(x)} = e^{\beta X(0)}$ almost surely. It follows that $(e^{\beta X(x)})_{x \in \mathbb{R}^d}$ is $L^2$-continuous, i.e.,
\[
\lim_{|x| \to 0} \mathbf{E} (e^{\beta X(x)} - e^{\beta X(0)})^2 = 0.
\]

Therefore, there is $\delta_1 = \delta_1 (\epsilon) \in (0, 1)$ such that
\[
|x| < \delta_1 \quad \Rightarrow \quad \mathbf{E} (e^{\beta Y(x)} - e^{\beta Y(0)})^2 < \epsilon^2.
\]

Let $\mu_k' = \mu_k * Z$, $\nu_k' = \nu_k * Z$. Let $\pi_k$ be the optimal coupling of $(\mu_k, \nu_k)$ and $\pi_k'$ be the optimal coupling of $(\mu_k', \nu_k')$. One can check that
\[
W(\mu_k', \nu_k') \leq W(\mu_k, \nu_k)
\]
by considering the following coupling of \( (\mu'_k, \nu'_k) \):
\[
\pi'_k(dx, dy) = \int_{w \in \mathbb{R}^d} \mathcal{Z}(dw) \pi_k(d(x-w), d(y-w)).
\]
Since \( \|\mu_k\| (e^{\beta Y(x)} \wedge e^{\beta Y(y)}) \pi'_k \) is an unnormalized sub-coupling of \( (\mu'_k, \nu'_k) \), i.e.,
\[
\|\mu_k\| \int e^{\beta Y(\cdot)} \wedge e^{\beta Y(\cdot)} \pi'_k(\cdot, dy) \leq \mu'_k(\cdot), \quad \|\mu_k\| \int e^{\beta Y(\cdot)} \wedge e^{\beta Y(\cdot)} \pi'_k(dx, \cdot) \leq \nu'_k(\cdot),
\]
we can use it to estimate
\[
\tilde{W}(\mu'_k, \nu'_k) \leq \|\mu_k\| \int d_1(x,y) (e^{\beta Y(x)} \wedge e^{\beta Y(y)}) \pi'_k(dx, dy)
\]
\[
+ \|\mu_k\| \int \left( e^{\beta Y(x)} - e^{\beta Y(y)} \right) \pi'_k(dx, dy) + \|\mu_k\| \int \left( e^{\beta Y(y)} - e^{\beta Y(x)} \right) \pi'_k(dx, dy)
\]
\[
= \|\mu_k\| \int d_1(x,y) (e^{\beta Y(x)} \wedge e^{\beta Y(y)}) \pi'_k(dx, dy) + \|\mu_k\| \int |e^{\beta Y(x)} - e^{\beta Y(y)}| \pi'_k(dx, dy)
\]
\[
\leq \|\mu_k\| \int d_1(x,y) e^{\beta Y(x)} \pi'_k(dx, dy) + \|\mu_k\| \int |e^{\beta Y(x)} - e^{\beta Y(y)}| \pi'_k(dx, dy).
\]
Therefore,
\[
\mathbb{E} \tilde{W}(\mu'_k, \nu'_k)^2
\]
\[
\leq 2 \|\mu_k\|^2 \left[ \mathbb{E} \left( \int d_1(x,y) e^{\beta Y(x)} \pi'_k(dx, dy) \right)^2 + \mathbb{E} \left( \int |e^{\beta Y(x)} - e^{\beta Y(y)}| \pi'_k(dx, dy) \right)^2 \right]
\]
\[
\leq 2 \|\mu_k\|^2 \left[ e^{\lambda(2\beta)} \int d_1(x,y)^2 \pi'_k(dx, dy) + \int \mathbb{E} |e^{\beta Y(x)} - e^{\beta Y(y)}|^2 (1_{|x-y| \geq \delta_1} + 1_{|x-y| < \delta_1}) \pi'_k(dx, dy) \right]
\]
\[
\leq 2 \|\mu_k\|^2 \left[ e^{\lambda(2\beta)} \frac{W(\mu_k, \nu_k)}{\|\mu_k\|} + 4 e^{\lambda(2\beta)} \frac{W(\mu_k, \nu_k)}{\|\mu_k\|\delta_1} + e^2 \right].
\]
Taking the square root and summing over \( k \), we conclude that there is a constant \( C_0 = C_0(\beta) > 0 \) such that
\[
\sum_{k=1}^n \mathbb{E} \tilde{W}(\mu'_k, \nu'_k)^2 \leq C_0 \left( \sqrt{\frac{\delta}{\delta_1}} + \epsilon \right).
\]
\[
(3.16)
\]
1-(ii) Upper bound for \( \mathbb{E}(A - B)^2 \)
To estimate \( (A - B)^2 \), let us define
\[
V(u) = e^{\beta Y(u)} - e^{\lambda(u)}
\]
\[
\mu^a = \{ \tilde{\alpha}_j \} := \mu - \sum_{j=1}^n \mu_j, \quad \nu^a = \{ \tilde{\gamma}_j \} := \nu - \sum_{j=1}^n \nu_j.
\]
One can write
\[
A - e^{\lambda(u)} = \int_{\mathbb{R}^d} V(u) \mu * \mathcal{Z}(du), \quad B - e^{\lambda(u)} = \int_{\mathbb{R}^d} V(u) \nu * \mathcal{Z}(du),
\]
and therefore
\[(A - B)^2 = \left( \int_{\mathbb{R}^d} V(u) \mu * Z(du) - \int_{\mathbb{R}^d} V(u) \nu * Z(du) \right)^2 \]
\[ \leq 3 \sum_{k=1}^{n} \left( \int_{\mathbb{R}^d} V(k, x) \mu_k * Z(dx) - \int_{\mathbb{R}^d} V(k, x) \nu_k * Z(dx) \right)^2 \]
\[ + 3 \left( \int_{\mathbb{R}^d} V(u) \mu^s * Z(du) \right)^2 + 3 \left( \int_{\mathbb{R}^d} V(u) \nu^s * Z(du) \right)^2. \]  
(3.18)

By the independence of \( \{V(i, \cdot)\}_{i \in \mathbb{N}} \), we see that
\[ \mathbb{E} \left[ \sum_{k=1}^{n} \left( \int_{\mathbb{R}^d} V(k, x) \mu_k * Z(dx) - \int_{\mathbb{R}^d} V(k, x) \nu_k * Z(dx) \right)^2 \right] \]
\[ = \sum_{k=1}^{n} \mathbb{E} \left( \int_{\mathbb{R}^d} V(k, x) \mu_k * Z(dx) - \int_{\mathbb{R}^d} V(k, x) \nu_k * Z(dx) \right)^2 \]
\[ = \sum_{k=1}^{n} \mathbb{E} (\| \mu_k^s \| - \| \nu_k^s \|)^2 \leq \sum_{k=1}^{n} \mathbb{E} \tilde{W}(\mu_k^s, \nu_k^s)^2. \]  
(3.19)

Denote \( c_\beta(x) = \mathbb{E} \left[ (e^{\beta X(x)} - e^{\lambda(\beta)}) (e^{\beta X(0)} - e^{\lambda(\beta)}) \right] \). Notice that \( c_\beta(x) \leq e^{\lambda(2\beta)} \) for all \( x \in \mathbb{R}^d \). Let us now give an upper bound for the second term in (3.18):
\[ \mathbb{E} \left( \int_{\mathbb{R}^d} V(u) \mu^s * Z(du) \right)^2 = \sum_{j=1}^{\infty} \mathbb{E} \left( \int_{\mathbb{R}^d} V(j, x) \alpha_j^s * Z(dx) \right)^2 \]
\[ = \sum_{j=1}^{\infty} \mathbb{E} \int_{(\mathbb{R}^d)^2} V(j, x) V(j, \tilde{x}) (\alpha_j^s * Z)^{\otimes 2}(dx, d\tilde{x}) \]
\[ = \sum_{j=1}^{\infty} \int_{(\mathbb{R}^d)^2} c_\beta(x - \tilde{x}) (\alpha_j^s * Z)^{\otimes 2}(dx, d\tilde{x}). \]  
(3.20)

One can see that for any \( \alpha \in \mathcal{M}_{\leq 1} \) and \( r \geq 0 \),
\[ I_r(\alpha * Z) = \sup_{x_0 \in \mathbb{R}^d} \left( \int f_r(x - x_0) \alpha(dy) Z(dx - y) \right) = \sup_{x_0 \in \mathbb{R}^d} \left( \int f_r(x + y - x_0) \alpha(dy) Z(dx) \right) \]
\[ \leq \int \left( \sup_{x_0 \in \mathbb{R}^d} \int f_r(x + y - x_0) \alpha(dy) Z(dx) \right) Z(dx) = I_r(\alpha). \]  
(3.21)

We recall that \( L \) is the radius of dependence of the potential and \( r > L \). Therefore,
\[ \int_{(\mathbb{R}^d)^2} c_\beta(x - \tilde{x}) (\alpha_j^s * Z)^{\otimes 2}(dx, d\tilde{x}) = \int_{|x - \tilde{x}| \leq L} c_\beta(x - \tilde{x}) (\alpha_j^s * Z)^{\otimes 2}(dx, d\tilde{x}) \]
\[ \leq e^{\lambda(2\beta)} \int_{|x - \tilde{x}| < r} (\alpha_j^s * Z)^{\otimes 2}(dx, d\tilde{x}) = e^{\lambda(2\beta)} \int_{\mathbb{R}^d} \alpha_j^s * Z(B_r(x)) \alpha_j^s * Z(dx) \]
\[ \leq e^{\lambda(2\beta)} \sup_{x \in \mathbb{R}^d} \alpha_j^s * Z(B_r(x)) \int_{\mathbb{R}^d} (\alpha_j^s * Z)(dx) \leq e^{\lambda(2\beta)} I_r(\alpha_j^s * Z) \| \alpha_j^s \| < e^{\lambda(2\beta)} \delta \| \alpha_j^s \|. \]  
(3.22)
Combining (3.20) with (3.22) gives
\[
\mathbb{E} \left( \int_{\mathbb{R}^d} V(u) \mu^s \ast \mathcal{Z}(du) \right)^2 \leq \sum_{j=1}^{\infty} e^{\lambda(2\beta)j} \| \alpha_j^s \| \leq e^{\lambda(2\beta)j}. \tag{3.23}
\]
The same upper bound holds for the third term in (3.18). Plugging (3.16), (3.19), and (3.23) into (3.18), we obtain
\[
\left[ \mathbb{E}(A - B) \right]^{1/2} \leq \sqrt{3} \left( \sum_{k=1}^{n} \mathbb{E}W(\mu_k^*, \nu_k^*)^2 + 2e^{\lambda(2\beta)j} \right)^{1/2}
\leq \sqrt{3} \left( \sum_{k=1}^{n} \left( \mathbb{E}W(\mu_k^*, \nu_k^*)^2 \right)^{1/2} + e^{\lambda(2\beta)/2} \sqrt{2\delta} \right) \leq C_1 \left( \sqrt{\frac{\delta}{\delta_1}} + \epsilon \right), \tag{3.24}
\]
where \( C_1 = C_1(\beta) > 0 \) is some constant depending only on \( \beta \).

1-(iii) Summary

Now Lemma 3.2 and relations (3.15), (3.16), (3.24) imply there is a constant \( C_2 = C_2(\beta) > 0 \) such that
\[
\mathbb{E} \left[ \sum_{k=1}^{n} \tilde{W}(\mu_k^*, \nu_k^*) \right] \leq C_2 \left( \sqrt{\frac{\delta}{\delta_1}} + \epsilon \right), \tag{3.25}
\]
an estimate of the first term in (3.13).

2. Upper bound for \( \mathbb{E}I_r(\tilde{\mu} - \frac{1}{n} \sum_{k=1}^{n} \tilde{\mu}_k) \)

Let us estimate the second term on the right-hand side of (3.13). Since \( r > L \), we have
\[
\mathbb{E}I_r(\tilde{\mu} - \frac{1}{n} \sum_{k=1}^{n} \tilde{\mu}_k) = \mathbb{E} \left[ \frac{1}{r} \sup_{u_0} \int_{\mathbb{R}^d} g_r(u - u_0)e^{\beta Y(u)} \mu_s \ast \mathcal{Z}(du) \right]
\leq \mathbb{E} \left[ \sup_{u_0} \int_{\mathbb{R}^d} g_r(u - u_0)e^{2\beta Y(u)} \mu_s \ast \mathcal{Z}(du) \right]^{1/2}
\leq 2e^{\lambda(2\beta)/2} \mathbb{E} \left[ \sup_{u_0} \int_{\mathbb{R}^d} g_r(u - u_0)^{2\mu_s} \ast \mathcal{Z}(du) \right]^{1/2}
\leq 2e^{\lambda(2\beta)/2} \mathbb{E} \left[ \int_{\mathbb{R}^d} e^{2\beta Y(u)} \mu_s \ast \mathcal{Z}(du) \right]^{1/2}
\leq 2e^{\lambda(2\beta)/2}I_r(\mu_s) \left( \frac{\sqrt{\delta}}{\sqrt{\delta_1}} \right) ^{1/2}
\leq 2e^{\lambda(2\beta)+\lambda(2\beta)/2}I_r(\mu_s) \leq 2e^{\lambda(2\beta)+\lambda(2\beta)/2} \sqrt{\delta}, \tag{3.26}
\]
where we used (3.21) in line 6. The same upper bound holds for \( \mathbb{E}I_r(\tilde{\nu} - \sum_{k=1}^{n} \tilde{\nu}_k) \).

3. Conclusion

Finally, based on (3.9), (3.13), (3.25) and (3.26), we conclude that there is a constant \( C_3 = C_3(\beta) > 0 \) such that
\[
\mathcal{W}(\mathcal{T} \mu, \mathcal{T} \nu) \leq \mathbb{E}d(\tilde{\mu}, \tilde{\nu}) < C_3 \left( \sqrt{\frac{\delta}{\delta_1}} + \epsilon \right).
\]
Choosing $\delta = \min(\delta_1 e^2, 2^{-L})$, we complete the proof.

**(Step 2)** We now relax the assumption that $\alpha_k, \gamma_k$ are minorized by at most one $\mu_j, \nu_j$ for each $k$, respectively.

**Lemma 3.4.** Let $\Omega = C[\mathbb{R}^d, \mathbb{R}]$ be the space of all continuous real-valued functions on $\mathbb{R}^d$ with $LU$ topology metrized by a metric

$$
\rho(\omega_1, \omega_2) = \sum_{n=1}^{\infty} \frac{1}{2^n} \left( \sup_{|x| \leq n} |\omega_1(x) - \omega_2(x)| \wedge 1 \right).
$$

Let $\mathbb{P}$ be the probability measure on $(\Omega, \mathcal{F})$ under which the coordinate mapping process $Y_x(\omega) = \omega(x)$ has the same distribution as $X(x)$. Suppose closed sets $U_1, U_2, \ldots, U_n \subset \mathbb{R}^d$ satisfy $\min_{i \neq j} d_0(U_i, U_j) > L$. Then, there is an extended probability space $(\Omega', \mathcal{F}', \mathbb{P}')$ on which we can construct stationary processes $Y^{(1)}, Y^{(2)}, \ldots, Y^{(n)}$ such that

1. $Y^{(1)}, \ldots, Y^{(n)}$ are mutually independent and have the same distribution as $X(\cdot)$;
2. $\mathbb{P}'\{Y^{(i)}_x = Y_x \text{ for all } x \in U_i\} = 1$ for all $i = 1, \ldots, n$.

**Remark 3.5.** Our proof of this lemma uses regular conditional probabilities. Their existence is guaranteed by our choice of $C[\mathbb{R}^d, \mathbb{R}]$ as the space of realizations but in principle we could impose weaker requirements on the potential than continuity in Section 1.1.

**Proof of Lemma 3.4.** It suffices to give a construction for $n = 2$ since then one can iterate it to prove the lemma for general $n$. Let us define $U_0 = U_1 \cup U_2$ and $\mathcal{F}_k = \mathcal{B}(C[\mathbb{U}_k, \mathbb{R}])$, $k = 0, 1, 2$. For $k = 0, 1, 2$, there is a regular conditional probability $Q_k$ defined on $\Omega \times \mathcal{F}$ such that $Q_k(\omega, A) = \mathbb{P}(A|\mathcal{F}_k)(\omega)$. For any $A \in \mathcal{B}(\Omega)$, since $Q_k(\cdot, A)$ is $\mathcal{F}_k$-measurable, $Q_k$ depends only on $u_k := \omega|_{U_k} \in C[\mathbb{U}_k, \mathbb{R}]$. Therefore, $Q_k$ can be viewed as a function defined on $C[\mathbb{U}_k, \mathbb{R}] \times \mathcal{F}$. Let $T_k$ be the projection of $\Omega$ on $C[\mathbb{U}_k, \mathbb{R}]$ and define $\mu_k(du) = \mathbb{P}(T_k^{-1}(du_k))$.

Note that by the $L$-dependence of $Y$, $\mu_0 = \mu_1 \otimes \mu_2$. Let us now take $\Omega' = \Omega^{(0,1,2)}$, $\mathcal{F} = \mathcal{B}(\Omega^{(0,1,2)})$ and define $\mathbb{P}'$ as

$$
\mathbb{P}'(A \times B \times C) = \int Q_0(u_1, u_2, A)Q_1(u_1, B)Q_2(u_2, C)\mu_1(du_1)\mu_2(du_2),
$$

For $i = 0, 1, 2$, we denote the $i$-th marginal distribution of $\mathbb{P}'$ by $\mathbb{P}'_i$ and set $Y^{(i)}_x(\omega) = \omega_i(x)$ for $\omega = (\omega_0, \omega_1, \omega_2) \in \Omega'$. It is easy to check that $\mathbb{P}'_0 = \mathbb{P}'_1 = \mathbb{P}'_2 = \mathbb{P}$. In addition, if we let $\mathbb{P}'_{ij}$ be the marginal distribution of $\mathbb{P}'$ with respect to the $i$-th and $j$-th arguments for $0 \leq i < j \leq 2$, then $\mathbb{P}'_{12} = \mathbb{P}'_1 \otimes \mathbb{P}'_2$, i.e., $Y^{(1)}$ and $Y^{(2)}$ are independent and the proof of part (1) is completed.

Let us define $\bar{\mu}_1(du_1dv) = \mathbb{P}'_0((T_1 \times T_1)^{-1}(du_1dv))$ on $C[\mathbb{U}_1, \mathbb{R}]^2$. For $A, B \in \mathcal{B}(C[\mathbb{U}_1, \mathbb{R}])$, we have

$$
\bar{\mu}_1(A \times B) = \int Q_0(u_1, u_2, T_1^{-1}(A))Q_1(u_1, T_1^{-1}(B))\mu_1(du_1)\mu_2(du_2)
$$

$$
= \int Q_1(u_1, T_1^{-1}(A))Q_1(u_1, T_1^{-1}(B))\mu_1(du_1) = \int 1_A(u_1)1_B(u_1)\mu_1(du_1) = \mu_1(A \cap B),
$$

which implies that all the mass of $\bar{\mu}_1$ lie on the diagonal of $C[\mathbb{U}_1, \mathbb{R}]^2$, i.e.

$$
\bar{\mu}_1\{(u, v) \in C[\mathbb{U}_1, \mathbb{R}]^2 : u = v\} = 1.
$$
Therefore, $Y^{(0)}_x = Y^{(1)}_x \mathbb{P}^\epsilon$-a.s. for all $x \in U_1$. Similarly, we also obtain $Y^{(0)}_x = Y^{(2)}_x \mathbb{P}^\epsilon$-a.s. for all $x \in U_2$. Identifying $Y^{(0)}$ with $Y$ completes the proof.

Our goal is to reduce the problem to that studied in (Step 1). To that end, we will find $\mu'$ and $\nu'$ in $\mathcal{X}$ such that, on the one hand, $T\mu'$ and $T\nu'$ are close to $T\mu$ and $T\nu$, respectively, and on the other hand, $\mu'$ and $\nu'$ satisfy the conditions of (Step 1).

First, we choose $M > 0$ such that $Z(B_{M}(0)^c) < \epsilon$ and introduce $Z_1, Z_2$ via

$$Z = \mathbb{1}_{B_M(0)^c} + \mathbb{1}_{B_M(0)^c} Z := Z_1 + Z_2.$$ 

Recalling that $n$ and $(\mu_i)_{i=1}^n$ were defined just before (3.10), we define $\mu' = \{\tilde{\alpha}'_i\} \in \mathcal{X}$ as follows:

$$\tilde{\alpha}'_i = \begin{cases} \mu_i, & i \leq n, \\ \alpha_{i-n} - \sum_{j:p_j \leq \alpha_{i-n}} \mu_j, & i > n. \end{cases}$$

We also define a function $J : \{1, \cdots, n\} \rightarrow \mathbb{N}$ as

$$J(k) = l \Leftrightarrow \mu_{k} \leq \alpha_l.$$ 

We denote by $\tilde{\mu}'$ a $\mathcal{X}$-valued random variable whose law is $T\mu'$. To estimate $\mathcal{W}(T\mu, T\mu')$, we need to introduce a coupling of $(\tilde{\mu}, \tilde{\mu}')$. To this end, let $Y, W$ be independent random fields with the same law as $X$ and let us use $Y$ to define $\tilde{\mu}$.

We fix $j$ in the range of $J$. For $k \in J^{-1}(j)$,

$$U_k = \{x \in \mathbb{R}^d : x \in \bar{B}_M(y) \forall y \in \text{supp}(\mu_k)\}.$$ 

If we impose $\delta < 2^{-\max(L, M)-M}$ (i.e., $r > \max(L, M) + M$), then by the definition of a $(\mu, \nu)$-triple, for all $k \neq l$,

$$d_0(\text{supp}(\mu_k), \text{supp}(\mu_l)) \geq \text{deg}(\phi) > 2(\max(L, M) + M),$$

which implies that $\min_{k \neq l} d_0(U_k, U_l) > 2\max(L, M) > L$. Therefore, we can apply Lemma 3.4 to $Y(j, \cdot)$ and $(U_k)_{k \in J^{-1}(j)}$ to construct $(Y^{(k)})_{k \in J^{-1}(j)}$ satisfying conditions (1) and (2) in the Lemma.

We now set

$$Y'(k, \cdot) = \begin{cases} Y^{(k)}, & 1 \leq k \leq n, \\ W(k, \cdot), & k > n, \end{cases}$$

and use it to define $\tilde{\mu}'$. We remark that

$$Y(J(k), x) = Y'(k, x) \mathbb{P} \text{-a.s. for all } x \in U_k.$$ 

Similarly to (3.12) and (3.8), let us define $\mu'^{v}_{k, j}, \mu'_k, \mu'^{v}$ and $A'$ with the environment $Y'$ and introduce for $j \in \{1, 2\}$,

$$\mu'^{v}_{k, j} = e^{\beta Y^{(v)}(k, x)} \mu_k * Z_j(dx), \quad \mu'^{v}_{k, j} = \mu'^{v}_{k, j} / A',$$

$$\mu'_k = e^{\beta Y'(k, x)} \mu_k * Z_j(dx), \quad \mu'_{k, j} = \mu'_{k, j} / A'.$$

Choosing a $(\hat{\mu}, \hat{\mu}')$-g-triple

$$r_0 = \frac{r}{2}, \quad \varphi = (\hat{\mu}_{k, 1}, \hat{\mu}'_{k, 1})_{k=1}^n, \quad \bar{\gamma} = \bar{\delta},$$

(3.28)
where $V$ and $C > (\text{supp})$ gives
\[
\mathcal{W}(T\mu, T\mu') \leq E[d(\hat{\mu}, \hat{\mu}')] \leq \mathbb{E}\left[\sum_{k=1}^{n} \hat{W}(\hat{\mu}_{k,1}, \hat{\mu}'_{k,1}) + I_{r_0}(\hat{\mu} - \sum_{k=1}^{n} \hat{\mu}_{k,1}) + I_{r_0}(\hat{\mu}' - \sum_{k=1}^{n} \hat{\mu}'_{k,1}) + 2^{-r_0}\right]. \tag{3.29}
\]

We estimate the first term on the right-hand side in (3.29). Similarly to (3.14) and (3.15),
\[
E \sum_{k=1}^{n} \hat{W}(\hat{\mu}_{k,1}, \hat{\mu}'_{k,1}) \leq (EA^{-2})^{1/2} \left(\mathbb{E}\left[\hat{W}(\mu^*_{k,1}, \mu'^*_{k,1})^2\right]\right)^{1/2} + \left(\mathbb{E}(A - A')^2\right)^{1/2}. \tag{3.30}
\]
It follows from supp($\mu_k * Z_1$) $\in U_k$ and (3.27) that
\[
\mu^*_{k,1} = \mu'^*_{k,1} \text{ P-a.s., } \Rightarrow \hat{W}(\hat{\mu}_{k,1}, \hat{\mu}'_{k,1}) = 0,
\]
and
\[
E \left(\int |e^{\beta Y(J(k), x)} - e^{\beta Y'(k, x)}|\mu_k * Z(dx)\right)^2 = E \left(\int |e^{\beta Y(J(k), x)} - e^{\beta Y'(k, x)}|\mu_k * Z_2(dx)\right)^2
\]
\[
\leq ||\mu_k * Z_2|| E \int \left(e^{\beta Y(J(k), x)} - e^{\beta Y'(k, x)}\right)^2 \mu_k * Z_2(dx) \leq 2e^{\lambda(2\beta)} ||\mu_k||^2 \epsilon^2. \tag{3.31}
\]
Similarly to (3.18), we have
\[
(A - A')^2 \leq 3 \left[\sum_{k=1}^{n} \int_{\mathbb{R}^d} (e^{\beta Y(J(k), x)} - e^{\beta Y'(k, x)}) \mu_k * Z(dx)\right]^2
\]
\[
+ 3 \left(\int_{\mathbb{R}^d} V(u) \mu^* * Z(du)\right)^2 + 3 \left(\int_{\mathbb{R}^d} V'(u) \mu'^* * Z(du)\right)^2, \tag{3.32}
\]
where $V'(u) = e^{\beta Y'(u)} - e^{\lambda(\beta)}$ and $\mu'^* = \mu' - \sum \mu_k$ as in (3.17). Plugging (3.31) and (3.32) into (3.32), we have
\[
E(A - A')^2 \leq 6e^{\lambda(2\beta)}(\epsilon^2 + \delta). \tag{3.33}
\]
Plugging (3.31) and (3.33) into (3.30) and using Lemma 3.2, we obtain
\[
E \sum_{k=1}^{n} \hat{W}(\hat{\mu}_{k,1}, \hat{\mu}'_{k,1}) \leq 2e^{(\lambda(-2\beta) + \lambda(2\beta))/2} \cdot \sqrt{6}(\epsilon + \sqrt{\delta}). \tag{3.34}
\]
As for the $I_{r_0}$ terms on the right-hand side of (3.29), we repeat the computation of (3.26) to obtain
\[
E I_{r_0} \left(\hat{\mu} - \sum_{k=1}^{n} \hat{\mu}_{k,1}\right) \leq EI_r \left(\hat{\mu} - \sum_{k=1}^{n} \hat{\mu}_{k,1}\right) + EI_r \left(\sum_{k=1}^{n} \hat{\mu}_{k,2}\right)
\]
\[
\leq 2e^{(\lambda(-2\beta) + \lambda(2\beta))/2} \left[I_r(\mu^* * Z)^{1/2} + I_r(\sum \mu_k * Z^2)^{1/2}\right]
\]
\[
\leq 2e^{(\lambda(-2\beta) + \lambda(2\beta))/2} \left(\sqrt{\delta} + \sqrt{\epsilon}\right). \tag{3.35}
\]
Combining (3.29), (3.34), (3.35) and recalling that $2^{-r_0} = 2^{-r/2} < \sqrt{\delta}$ due to (3.28) and (3.10), we conclude that there is a constant $C > 0$ such that if $\delta < \min(\delta_0, e^2, 2^{-\max(L, M) - M})$, then
\[
\mathcal{W}(T\mu, T\mu') \leq 2e^{(\lambda(-2\beta) + \lambda(2\beta))/2} \left(\sqrt{6}(\epsilon + \sqrt{\delta}) + 2(\sqrt{\delta} + \sqrt{\epsilon})\right) + \sqrt{\delta} < C \epsilon.
\]
The same result holds for $\nu$ so that there is $\nu'$ such that $W(T\nu, T\nu') < C\epsilon$. One can check that $d_{r, \phi', \bar{x}}(\mu', \nu') = d_{r, \phi, \bar{x}}(\mu, \nu) < \delta$, where $\phi' = \{(\alpha'_i, \gamma'_i)\}_{i=1}^n$. Thus, (Step 1) can be now applied to estimate $W(T\mu', T\nu')$. Finally, the triangle inequality

$$W(T\mu, T\nu) \leq W(T\mu, T\mu') + W(T\mu', T\nu') + W(T\nu', T\nu),$$

completes the proof in the general case. □

3.4. Lifting the update map. We discussed in (3.5) that $T\nu(d\mu) = \Gamma(\nu, d\mu)$ can be understood as a transition kernel for the Markov chain $(\rho_i)_{i \geq 0}$. Integrating $\Gamma(\nu, d\mu)$ over the initial conditions $\nu$, we can extend $T$ to an operator $T$ on $\mathcal{P}(\tilde{X})$:

$$T\xi(d\mu) = \int_{\tilde{X}} T\nu(d\mu)\xi(d\nu). \quad (3.36)$$

Therefore, $T$ maps the law of $\rho_i$ to the law of $\rho_{i+1}$.

**Proposition 3.6.** $T : \mathcal{P}(\tilde{X}) \to \mathcal{P}(\tilde{X})$ is (uniformly) continuous

**Proof.** Let $\epsilon > 0$ and $\xi_1, \xi_2 \in \mathcal{P}(\tilde{X})$ be given. We would like to show that there is $\delta > 0$ such that

$$W(\xi_1, \xi_2) < \delta \implies W(T\xi_1, T\xi_2) < \epsilon.$$

By Proposition 3.3, there is $\delta_1 > 0$ such that

$$d(\mu, \nu) < \delta_1 \implies W(T\mu, T\nu) < \epsilon/2.$$

Let us assume $W(\xi_1, \xi_2) < \delta := \delta_1 \epsilon/4$ and let $\Pi$ be the optimal coupling of $(\xi_1, \xi_2)$. Moreover, for $\mu, \nu \in \tilde{X}$, let $\Pi_{\mu, \nu}$ be the optimal coupling of $(T\mu, T\nu)$. Then, one can check that

$$\Pi'(d\eta, d\tau) = \int_{\tilde{X} \times \tilde{X}} \Pi_{\mu, \nu}(d\eta, d\tau)\Pi(d\mu, d\nu)$$

is a coupling of $(T\xi_1, T\xi_2)$. Therefore,

$$W(T\xi_1, T\xi_2) \leq \int d(\eta, \tau)\Pi'(d\eta, d\tau) = \int \int d(\eta, \tau)\Pi_{\mu, \nu}(d\eta, d\tau)\Pi(d\mu, d\nu)$$

$$= \int W(T\mu, T\nu)\Pi(d\mu, d\nu) \leq \int W(T\mu, T\nu)(1_{{d(\mu, \nu) \geq \delta_1}} + 1_{{d(\mu, \nu) < \delta_1}})\Pi(d\mu, d\nu)$$

$$\leq \frac{2}{\delta_1} \int d(\mu, \nu)\Pi(d\mu, d\nu) + \frac{\epsilon}{2} = \frac{2}{\delta_1} W(\xi_1, \xi_2) + \frac{\epsilon}{2} < \epsilon,$$

which completes the proof. □

**Remark 3.7.** Based on the definition of $T$, one can readily check that $T\nu = T\delta_{\nu}$. Therefore, (3.36) can be rewritten as

$$T\xi(d\mu) = \int_{\tilde{X}} T\delta_{\nu}(d\mu)\xi(d\nu),$$

and by iteration, one has that for $T^i = T \circ \ldots \circ T$, $i \geq 1$,

$$T^i\xi(d\mu) = \int_{\tilde{X}} T^i\delta_{\nu}(d\mu)\xi(d\nu). \quad (3.37)$$
4. Convergence of empirical measure

4.1. The convergence to fixed points of the update map. Let us denote the empirical probability measure of the endpoint distributions on \( \tilde{X} \) by

\[
\psi_n := \frac{1}{n+1} \sum_{i=0}^{n} \delta_{\rho_i}.
\]

The goal of this part is to study the asymptotic behavior of \( \psi_n \). We will prove that \( \psi_n \) converges to a set \( K \) of fixed point of \( T \) and introduce an “energy functional” \( R \) which maps \( \psi_n-1 \) to a value close to the quenched free energy \( F_n \). The functional \( R \) allows us to improve the former result by replacing \( K \) with a subset \( K_0 \) of \( K \) with the minimal energy state.

**Proposition 4.1.** As \( n \to \infty \), \( \mathcal{W}(\psi_n, T\psi_n) \to 0 \) \( \mathbb{P} \)-a.s.

**Proof.** We use martingale analysis similar to that in the proof of Proposition 4.1 in [BC16]. Let

\[
\mathcal{L} = \{ h : \tilde{X} \to \mathbb{R} : |h(\mu) - h(\nu)| \leq d(\mu, \nu) \text{ for all } \mu, \nu \in \tilde{X}, h(0) = 0 \}
\]

and

\[
\psi'_n := \frac{1}{n+1} \sum_{i=1}^{n+1} \delta_{\rho_i}.
\]

Using \( \frac{1}{n+1} (\delta_{(\rho_0,\rho_{n+1})} + \sum_{i=1}^{n} \delta_{(\rho_i,\rho_i)}) \) as a coupling of \( (\psi_n, \psi'_n) \) and applying (2.15) we conclude that \( \mathcal{W}(\psi_n, \psi'_n) \leq 2/(n+1) \). Therefore, it suffices to prove that

\[
\mathcal{W}(\psi'_n, T\psi_n) \to 0. \tag{4.1}
\]

It follows from (2.10) that

\[
\mathcal{W}(\psi'_n, T\psi_n) = \sup_{h \in \mathcal{L}} \frac{M_n(h)}{n+1},
\]

where

\[
M_n(h) = \sum_{i=0}^{n} \left( h(\rho_{i+1}) - \mathbb{E}[h(\rho_{i+1})|\mathcal{G}_i] \right)
\]

is a martingale. Since \( |h| \leq 2 \), we can apply the Burkholder–Davis–Gundy inequality to see that there is a constant \( C > 0 \) such that

\[
\mathbb{E}M_n(h)^4 \leq C\mathbb{E} \left( \sum_{i=0}^{n} \left( h(\rho_{i+1}) - \mathbb{E}[h(\rho_{i+1})|\mathcal{G}_i] \right)^2 \right)^2 \leq 16C(n+1)^2,
\]

which implies \( \mathbb{E} \left( M_n(h)/(n+1) \right)^4 \leq 16C(n+1)^{-2} \) and hence, by the Borel–Cantelli lemma,

\[
\lim_{n \to \infty} \frac{|M_n(h)|}{n+1} = 0 \quad \mathbb{P}-\text{a.s.} \tag{4.2}
\]

On the other hand, we observe

\[
\|h - h'\|_\infty < \epsilon \quad \Rightarrow \quad \left| \frac{M_n(h)}{n+1} - \frac{M_n(h')}{n+1} \right| < 2\epsilon,
\]

\[
\]
which tells us that $(M_n(\cdot)/(n+1))_{n\geq 0}$ is an equicontinuous sequence of functions on $\mathcal{L}$. By Arzela–Ascoli theorem, the limit in (4.2) is uniform in $h \in \mathcal{L}$, which completes the proof. \hfill \Box

Proposition 4.1 suggests that $(\psi_n)_{n\geq 0}$ will be close to the set of fixed points of $\mathcal{T}$ as $n$ becomes large. We denote the set of fixed points of $\mathcal{T}$ by

$$\mathcal{K} = \{\xi \in \mathcal{P}(\bar{X}) : \mathcal{T}\xi = \xi\}.$$ 

Notice that $\mathcal{K}$ is nonempty since $\mathcal{T}\delta_0 = \delta_0$. By applying the same argument as in Corollary 4.3 and Proposition 4.4 in [BC16], we can prove the following:

**Proposition 4.2.** As $n \to \infty$, $\mathcal{W}(\psi_n, \mathcal{K}) \to 0$ P-a.s.

**Proof.** Suppose that $\mathcal{W}(\psi_n, \mathcal{K}) \to 0$. Then, there is $\epsilon > 0$ and a subsequence $(\psi_{n_k})_{k \geq 1}$ such that $\mathcal{W}(\psi_{n_k}, \mathcal{K}) > \epsilon$ for all $k \geq 1$. Since $\mathcal{P}(\bar{X})$ is compact, we may assume $\lim_{k \to \infty} \psi_{n_k} = \psi$ for some $\psi \in \mathcal{P}(\bar{X})$, if needed, by choosing a further subsequence. On the other hand,

$$\mathcal{W}(\psi, \mathcal{T}\psi) \leq \mathcal{W}(\psi, \psi_{n_k}) + \mathcal{W}(\psi_{n_k}, \mathcal{T}\psi_{n_k}) + \mathcal{W}(\mathcal{T}\psi_{n_k}, \mathcal{T}\psi),$$

and as $k \to \infty$, each term in the right-hand side converges to 0 due to the convergence of $\psi_{n_k}$, Proposition 4.1, and continuity of $\mathcal{T}$, respectively. It follows $\mathcal{T}\psi = \psi$, i.e., $\psi \in \mathcal{K}$, which contradicts the assumption that $\psi_{n_k}$ is $\epsilon$-away from $\mathcal{K}$. \hfill \Box

**Proposition 4.3.** If $\xi \in \mathcal{K}$, $\xi\{\mu \in \bar{X} : 0 < ||\mu|| < 1\} = 0$.

**Proof.** Let $\xi \in \mathcal{K}$ and let $\mu$ be a $\bar{X}$-valued random variable whose law is $\xi$. Let us suppose, to derive a contradiction, that $\xi\{\mu \in \bar{X} : 0 < ||\mu|| < 1\} > 0$. Recalling that $T\mu$ is the law of the $\bar{X}$-valued random variable $\tilde{\mu}$ defined as in (3.4), we have, by Jensen’s inequality applied to the concave function $x \mapsto x/(x + (1 - ||\mu||)e^{\lambda(\beta)})$,

$$E ||\tilde{\mu}|| = E \frac{\int_{\mathbb{R}^d} e^{\beta Y(u)} \mu * \mathcal{Z}(du)}{\int_{\mathbb{R}^d} e^{\beta Y(u)} \mu * \mathcal{Z}(dw) + (1 - ||\mu||)e^{\lambda(\beta)}} \leq \frac{E \int_{\mathbb{R}^d} e^{\beta Y(u)} \mu * \mathcal{Z}(du)}{E \int_{\mathbb{R}^d} e^{\beta Y(u)} \mu * \mathcal{Z}(du) + (1 - ||\mu||)e^{\lambda(\beta)}} \leq \frac{e^{\lambda(\beta)} ||\mu||}{e^{\lambda(\beta)}} = ||\mu||,$$

where equality holds if and only if $\int_{\mathbb{R}^d} e^{\beta Y(u)} \mu * \mathcal{Z}(du)$ is a constant P-a.s. However, since $Y$ is non-degenerate, we have a strict inequality. Combining this fact and the assumption that we made, we see that

$$\int ||\tilde{\mu}|| \mathcal{T}\xi(d\tilde{\mu}) = \int \int ||\mu|| T\mu(d\tilde{\mu})\xi(d\mu) < \int \int ||\mu|| T\mu(d\tilde{\mu})\xi(d\mu) = \int ||\mu|| \mathcal{T}\xi(d\mu),$$

which is a contradiction. \hfill \Box

### 4.2. Variational formula for the free energy.

We observe that

$$F_n(\beta) := \frac{1}{n} \log Z_n(\beta) = \frac{1}{n} \sum_{i=0}^{n-1} \log \frac{Z_{i+1}}{Z_i} = \frac{1}{n} \sum_{i=0}^{n-1} \log \left( \int_{\mathbb{R}^d} e^{\beta X(i+1,x)} \rho_i * \mathcal{Z}(dx) \right).$$
Conditioning the $i$-th term on $\mathcal{G}_i$, we have

$$EF_n = \frac{1}{n} \sum_{i=0}^{n-1} ER(\rho_i), \quad (4.3)$$

where

$$R(\rho_i) := \mathbb{E} \left[ \log \left( \int_{\mathbb{R}^d} e^{\beta X(i+1,x)} \rho_i * Z(dx) \right) \big| \mathcal{G}_i \right].$$

It is useful to extend this to a functional on $\mathcal{X}$ as follows:

$$R(\mu) := \mathbb{E} \log \left( \int_{\mathbb{R}^d} e^{\beta Y(u)} \mu * Z(du) + (1 - \|\mu\|) e^{\lambda(\beta)} \right), \quad \mu \in \mathcal{X}, \quad (4.4)$$

where $Y$ has the same law as $X$.

**Proposition 4.4.** The functional $R : (\mathcal{X}, d) \to (\mathbb{R}, d_0)$ in (4.4) is well-defined and continuous.

**Proof.** It is easy to check that the right-hand side of (4.4) does not depend on the choice of the representative of $\mu$. We need to prove that $R(\mu)$ is finite. For any positive random variable $K$, one has

$$|\mathbb{E} \log K| \leq \max\{\log \mathbb{E} K, \log \mathbb{E} K^{-1}\} = \log \left( \max\{\mathbb{E} K, \mathbb{E} K^{-1}\} \right) \quad (4.5)$$

by Jensen’s inequality. On the other hand, we see that

$$\mathbb{E} \left[ \int_{\mathbb{R}^d} e^{\beta Y(u)} \mu * Z(du) + (1 - \|\mu\|) e^{\lambda(\beta)} \right] = e^{\lambda(\beta)} \quad (4.6)$$

and by Lemma 3.2,

$$\mathbb{E} \left( \int_{\mathbb{R}^d} e^{\beta Y(u)} \mu * Z(du) + (1 - \|\mu\|) e^{\lambda(\beta)} \right)^{-1} \leq 2 e^{\lambda(-\beta)}. \quad (4.7)$$

Combining (4.5), (4.6), and (4.7) gives $|R(\mu)| < \infty$.

We now prove the continuity of $R$. We will show that there is a constant $M > 0$ with the following property: for any $\epsilon > 0$ there is $\delta = \delta(\epsilon) > 0$ such that

$$d(\mu, \nu) < \delta \quad \Rightarrow \quad |R(\mu) - R(\nu)| < M \epsilon.$$  

Let us define $A, B$ by (3.8) and (3.11). Notice that for any $x > 0$,

$$|\log x| \leq |x - 1| + \left| \frac{1}{x} - 1 \right|.$$  

Combining this with Lemma 3.2 and (3.24), we have

$$|R(\mu) - R(\nu)| = \left| \mathbb{E} \log \frac{A}{B} \right| \leq \mathbb{E} \left| \frac{A}{B} - 1 \right| + \mathbb{E} \left| \frac{B}{A} - 1 \right|$$

$$\leq \left( \left( \mathbb{E} B^{-2} \right)^{1/2} + \left( \mathbb{E} A^{-2} \right)^{1/2} \right) \left( \mathbb{E} (A - B)^2 \right)^{1/2} \leq M \epsilon,$$

where the constant $M$ does not depend on $\mu, \nu$, which completes the proof. \qed

**Proposition 4.5.** The map $\mathcal{R} : (\mathcal{P}(\mathcal{X}), \mathcal{W}) \to (\mathbb{R}, d_0)$ defined by

$$\mathcal{R}(\xi) := \int R(\mu) \xi(d\mu), \quad \xi \in \mathcal{P}(\mathcal{X}),$$

is continuous.
is uniformly continuous.

**Proof.** Let \( \epsilon > 0 \) be given and let \( M := \max_{\mu \in \tilde{X}} |R(\mu)| \). It is sufficient to show that there is \( \delta > 0 \) such that

\[
W(\xi_1, \xi_2) < \delta \quad \Rightarrow \quad |R(\xi_1) - R(\xi_2)| < (2M + 1)\epsilon.
\]

By Proposition 4.4, there is \( \delta_1 > 0 \) such that

\[
d(\mu, \nu) < \delta_1 \quad \Rightarrow \quad |R(\mu) - R(\nu)| < \epsilon.
\]

Set \( \delta = \delta_1 \epsilon \) and let \( \Pi \) be the optimal coupling of \( (\xi_1, \xi_2) \). Then, for any \( \xi_1, \xi_2 \in \mathcal{P}(\tilde{X}) \) with \( W(\xi_1, \xi_2) < \delta \), we have

\[
|R(\xi_1) - R(\xi_2)| \leq \int |R(\mu) - R(\nu)| \Pi(d\mu, d\nu) \\
= \int |R(\mu) - R(\nu)| (1_{d(\mu, \nu) \geq \delta_1} + 1_{d(\mu, \nu) < \delta_1}) \Pi(d\mu, d\nu) \\
\leq \frac{2M}{\delta_1} \int d(\mu, \nu) \Pi(d\mu, d\nu) + \epsilon = \frac{2M}{\delta_1} W(\xi_1, \xi_2) + \epsilon < (2M + 1)\epsilon,
\]

completing the proof. \( \square \)

We can rewrite (4.3) as

\[
\mathbf{EF}_n = \frac{1}{n} \sum_{i=0}^{n-1} \mathbf{ER}(\rho_i) = \mathbf{E}[R(\psi_{n-1})].
\]

(4.8)

In fact, not only the expectations but the random variables themselves are close:

**Proposition 4.6.** As \( n \to \infty \), \( F_n - R(\psi_{n-1}) \to 0 \ P\text{-a.s.} \)

**Proof.** Let

\[
V_i = \int_{\mathbb{R}^d} e^{\beta X(i+1,x)} \rho_i \ast \mathcal{Z}(dx), \quad U_i = \log V_i.
\]

We have \( \mathbf{E}[U_i|\mathcal{F}_i] = R(\rho_i) \) and therefore

\[
M_n := n(F_n - R(\psi_{n-1})) = \sum_{i=0}^{n-1} (U_i - \mathbf{E}[U_i|\mathcal{F}_i])
\]

is a martingale.

We claim that \( \mathbf{E}(U_i - \mathbf{E}[U_i|\mathcal{F}_i])^4 \) is bounded. It suffices to show that \( \mathbf{EU}_i^4 \) is bounded. To this end, we observe that

\[
\mathbf{EV}_i^2 \leq \mathbf{E} \int_{\mathbb{R}^d} e^{2\beta X(i+1,x)} \rho_i \ast \mathcal{Z}(dx) = e^{\lambda(2\beta)}
\]

Similarly, we obtain \( \mathbf{E}[V_i^{-2}] \leq e^{\lambda(-2\beta)} \). Using the inequality \( (\log x)^4 < x^2 + 1/x^2 \), we have

\[
\mathbf{EU}_i^4 < \mathbf{EV}_i^2 + \mathbf{E}V_i^{-2} \leq e^{\lambda(2\beta)} + e^{\lambda(-2\beta)}.
\]
Using the Burkholder–Davis–Gundy inequality, we obtain
\[ EM_n^4 \leq C_2 E \left( \sum_{i=0}^{n-1} (U_i - E[U_i|G_i])^2 \right)^2 \leq C n^2, \]
which implies \( E(M_n/n)^4 \leq C n^{-2} \) and hence, by the Borel–Cantelli lemma,
\[ \lim_{n \to \infty} |F_n - R(\psi_{n-1})| = \lim_{n \to \infty} \frac{|M_n|}{n} = 0 \quad \text{P-a.s.}, \]
completing the proof.

4.3. A representation of convergence of \( F_n \) via \( R \) and \( T \). The goal of this section is to prove Theorem 4.7 and Theorem 4.10.

Theorem 4.7.
\[ \lim_{n \to \infty} F_n = \inf_{\xi \in K} R(\xi) \quad \text{P-a.s.} \quad (4.9) \]

We already discussed in (1.2) that \( |F_n - E F_n| \to 0 \) almost surely and in \( L_p \) for all \( p \geq 1 \). Hence, it is sufficient to show
\[ \lim_{n \to \infty} E F_n = \inf_{\xi \in K} R(\xi). \]
To that end, we need two following propositions.

Proposition 4.8.
\[ \liminf_{n \to \infty} E F_n \geq \inf_{\xi \in K} R(\xi) \quad \text{P-a.s.} \quad (4.10) \]

Proof. By Proposition 4.2 and 4.5,
\[ \liminf_{n \to \infty} R(\psi_n) \geq \inf_{\xi \in K} R(\xi) \quad \text{P-a.s.} \]
The conclusion follows from Proposition 4.6 and Fatou’s Lemma.

Proposition 4.9.
\[ \limsup_{n \to \infty} E F_n \leq \inf_{\xi \in K} R(\xi) \quad \text{P-a.s.} \quad (4.11) \]

Proof. We claim that for any \( \mu^{(0)} \in \tilde{X} \) and \( n \in \mathbb{N} \),
\[ \sum_{i=0}^{n-1} R(T^i \delta_{\mu^{(0)}}) \geq E \log Z_n. \quad (4.12) \]
First, let us use this claim to derive (4.11). For any \( \xi \in \mathcal{P}(\tilde{X}) \), it follows from (3.37) that
\[ R(T^i \xi) = \int R(\nu) T^i \xi(\nu) d\nu = \int \int R(\nu) T^i \delta_{\mu}(d\nu) \xi(\nu) d\mu = \int R(T^i \delta_{\mu}) \xi(d\mu). \]
Moreover, if \( \xi \in K \), then (4.12) implies
\[ R(\xi) = \frac{1}{n} \sum_{i=0}^{n-1} R(T^i \xi) = \int \frac{1}{n} \sum_{i=0}^{n-1} R(T^i \delta_{\mu}) \xi(d\mu) \geq \int \frac{E \log Z_n}{n} \xi(d\mu) = E F_n. \]
Taking infimum over $\xi \in \mathcal{K}$ and $\limsup$, we complete the proof.

Let us prove the claim (4.12). For $i \geq 1$, let $\mu^{(i)} = \{\alpha_j^{(i)}\}_{j \in \mathbb{N}}$ be defined inductively by

\[ \mu^{(i)}(du) = \frac{\int_{\mathbb{N} \times \mathbb{R}^d} e^{\beta Y^{(i)}(u)} \mu^{(i-1)} \ast \mathcal{Z}(du)}{\int_{\mathbb{N} \times \mathbb{R}^d} e^{\beta Y^{(i)}(v)} \mu^{(i-1)} \ast \mathcal{Z}(dv) + (1 - \|\mu^{(i-1)}\|) e^{\lambda(\beta)}}, \tag{4.13} \]

where $(Y^{(i)})$ are i.i.d. random fields whose law is the same as $X$. By induction, we see that the law of $\mu^{(i)}$ is $\mathcal{T}^i \delta_{\mu^{(0)}}$. Hence,

\[ \mathcal{R}(\mathcal{T}^i \delta_{\mu^{(0)}}) = \mathbb{E} \log \left( \int_{\mathbb{N} \times \mathbb{R}^d} e^{\beta Y^{(i+1)}(u)} \mu^{(i)} \ast \mathcal{Z}(du) + (1 - \|\mu^{(i)}\|) e^{\lambda(\beta)} \right) = \mathbb{E} \log D_{i+1}, \]

where

\[ D_i = \int_{\mathbb{N} \times \mathbb{R}^d} e^{\beta Y^{(i)}(u)} \mu^{(i-1)} \ast \mathcal{Z}(du) + (1 - \|\mu^{(i-1)}\|) e^{\lambda(\beta)} \]

\[ = \int_{(\mathbb{N} \times \mathbb{R}^d)^2} e^{\beta Y^{(i)}(u)} P_1^{n}(du_1) \mu^{(i-1)}(dv) + (1 - \|\mu^{(i-1)}\|) e^{\lambda(\beta)}, \quad i \geq 0. \tag{4.14} \]

Here, we can consider $P_k^{u}$ as a probability measure on $(\mathbb{N} \times \mathbb{R}^d)^k$ by extending $P_k$ defined on $(\mathbb{R}^d)^k$ as follows: for any $u_i = (m_i, x_i) \ (0 \leq i \leq k)$ given,

\[ P_k^{u_0}(du_1, \ldots, du_k) = \mathbb{1}_{\{m_0 = m_1 = \cdots = m_k\}} P_k^{x_0}(dx_1, \ldots, dx_k). \]

Notice that

\[ \sum_{i=0}^{n-1} \mathcal{R}(\mathcal{T}^i \delta_{\mu^{(0)}}) = \mathbb{E} \log \prod_{i=1}^{n} D_i. \]

Iterating (4.13) for $i = n - 1, \cdots, 1$, we have

\[ \int_{(\mathbb{N} \times \mathbb{R}^d)^2} e^{\beta Y^{(n)}(u)} P_1^{n-1}(du) \mu^{(n-1)}(dv) \]

\[ = \frac{1}{D_{n-1}} \int_{(\mathbb{N} \times \mathbb{R}^d)^3} e^{\beta (Y^{(n)}(u) + Y^{(n-1)}(u_n-1))} P_2^{n-2}(du, dv) \mu^{(n-2)}(dv) \]

\[ = \cdots \]

\[ = \prod_{i=1}^{n-1} D_i \int_{(\mathbb{N} \times \mathbb{R}^d)^n} \mu^{(0)}(dv_0) \int_{(\mathbb{N} \times \mathbb{R}^d)^n} \exp \left( \sum_{i=1}^{n} \beta Y^{(i)}(u_i) \right) P_n^{u_0}(du), \tag{4.15} \]

where $\bar{u} = (u_1, \cdots, u_n)$. Integrating over $u$ in (4.13), we have

\[ 1 - \|\mu^{(i)}\| = \frac{(1 - \|\mu^{(i-1)}\|) e^{\lambda(\beta)}}{D_i}. \]

Iterating this relation for $i = n - 1, \cdots, 1$, we obtain

\[ (1 - \|\mu^{(n-1)}\|) e^{\lambda(\beta)} = \frac{(1 - \|\mu^{(0)}\|) e^{n\lambda(\beta)}}{\prod_{i=1}^{n-1} D_i} = \frac{(1 - \|\mu^{(0)}\|) \mathbb{E} Z_n}{\prod_{i=1}^{n-1} D_i}. \tag{4.16} \]
Combining (4.14) for \( i = n \), (4.15), and (4.16), we obtain
\[
\prod_{i=1}^{n} D_i = \int \mu^{(0)}(du_0) \int \exp \left( \sum_{i=1}^{n} \beta Y^{(i)}(u_i) \right) P_n^{u_0}(d\bar{u}) + (1 - \|\mu^{(0)}\|) \mathbf{E} Z_n, 
\]
and by Jensen’s inequality,
\[
\log \prod_{i=1}^{n} D_i \geq \int \mu^{(0)}(du_0) \log \left( \int \exp \left( \sum_{i=1}^{n} \beta Y^{(i)}(u_i) \right) P_n^{u_0}(d\bar{u}) \right) + (1 - \|\mu^{(0)}\|) \log \mathbf{E} Z_n
\]
\[
\geq \int \mu^{(0)}(du_0) \log \left( 1 - \|\mu^{(0)}\| \right) \mathbf{E} \log Z_n
\]
\[
= \int \mu^{(0)}(du_0) \log Z_{n,u_0} + (1 - \|\mu^{(0)}\|) \mathbf{E} \log Z_n. 
\]

Since \( (Y^{(i)}(j,x))_{j \geq 1} \) is stationary in \( x \), \( \log Z_{n,u} \overset{d}{=} \log Z_n \) for all \( u \in \mathbb{N} \times \mathbb{R}^d \). In particular, \( \mathbf{E} \log Z_{n,u} = \mathbf{E} \log Z_n \). Taking expectation on both sides of (4.17), we obtain
\[
\sum_{i=0}^{n-1} \mathcal{R}(T^i \delta_{\mu^{(0)}}) = \mathbf{E} \left[ \log \prod_{i=1}^{n} D_i \right] \geq \int \mu^{(0)}(du_0) \mathbf{E} \log Z_n + (1 - \|\mu^{(0)}\|) \mathbf{E} \log Z_n = \mathbf{E} \log Z_n, 
\]
completing the proof of (4.12) and the entire proposition. □

Let us denote
\[
\mathcal{K}_0 = \{ \xi_0 \in \mathcal{K} : \mathcal{R}(\xi_0) = \inf_{\xi \in \mathcal{K}} \mathcal{R}(\xi) \}. 
\]

Since \( \mathcal{R} \) is continuous on the compact space \( \mathcal{P}(\bar{X}) \), the infimum is attained and \( \mathcal{K}_0 \) is also compact. Proposition 4.2, Proposition 4.6, and Theorem 4.7 suggest that one can strengthen Proposition 4.2 by taking a subset \( \mathcal{K}_0 \) of \( \mathcal{K} \).

**Theorem 4.10.** As \( n \to \infty \), \( \mathcal{W}(\psi_n, \mathcal{K}_0) \to 0 \) \( \mathbf{P} \)-a.s.

We omit the proof. It is identical to that of Theorem 4.11 in [BC16] and is based on compactness of \( \mathcal{K} \), continuity of \( \mathcal{R} \), Proposition 4.6, and Theorem 4.7.

5. Characterization of high/low temperature regimes

5.1. Existence of phase transitions. We recall that the critical inverse temperature \( \beta_c \) was introduced in Theorem B.

**Theorem 5.1.**

(a) \( 0 \leq \beta \leq \beta_c \), then \( \mathcal{K} = \mathcal{K}_0 = \{ \delta_0 \} \).

(b) If \( \beta > \beta_c \), then \( \xi(\{ \mu \in \bar{X} : \|\mu\| = 1 \}) = 1 \) for all \( \xi \in \mathcal{K}_0 \), so \( \mathcal{K} \) has an element other than \( \delta_0 \).

We refer the proof to Lemma 5.1 and Theorem 5.2 in [BC16]. The proof is based on the definition of Lyapunov exponent (1.3), Theorem B, Proposition 4.3 and Theorem 4.7.

**Lemma 5.2.** For any \( r \geq 0 \), the map \( I_r : \bar{X} \to [0, 1] \), defined in (2.12), is continuous.
Proof. Let $\epsilon > 0$, $r \geq 0$ and $\mu = \{\tilde{\alpha}_i\} \in \tilde{\mathcal{X}}$ be given. We need to show that there is $\delta(\epsilon, r) > 0$ such that

$$d(\mu, \nu) < \delta \quad \Rightarrow \quad |I_r(\mu) - I_r(\nu)| < \epsilon.$$  

We set $\delta = \min(\epsilon/2, 2^{-r})$ and take any $\nu \in \tilde{\mathcal{X}}$ such that $d(\mu, \nu) < \delta$. There is a $(\mu, \nu)$-triple $(r_0, \phi = \{(\mu_k, \nu_k)\}_{k=1}^n, \bar{x})$ such that $d_{r_0, \phi, \bar{x}}(\mu, \nu) < \delta$. By the choice of $\delta$, we have $r_0 > r$. From the subadditivity of $I_r$, we have

$$I_r\left(\sum_{k=1}^n \mu_k\right) \leq I_r(\mu) \leq I_r\left(\sum_{k=1}^n \mu_k\right) + I_r\left(\mu - \sum_{k=1}^n \mu_k\right)$$

$$I_r\left(\sum_{k=1}^n \nu_k\right) \leq I_r(\nu) \leq I_r\left(\sum_{k=1}^n \nu_k\right) + I_r\left(\nu - \sum_{k=1}^n \nu_k\right).$$

It follows from $\deg(\phi) > 2r_0 > 2r$ that

$$\left|I_r\left(\sum_{k=1}^n \mu_k\right) - I_r\left(\sum_{k=1}^n \nu_k\right)\right| = \left|\sup_k I_r(\mu_k) - \sup_k I_r(\nu_k)\right|.$$  

Combining all these estimates, we conclude that

$$|I_r(\mu) - I_r(\nu)| \leq \left|I_r\left(\sum_{k=1}^n \mu_k\right) - I_r\left(\sum_{k=1}^n \nu_k\right)\right| + \max\left\{I_r\left(\mu - \sum_{k=1}^n \mu_k\right), I_r\left(\nu - \sum_{k=1}^n \nu_k\right)\right\}$$

$$\leq \sup_k |I_r(\mu_k) - \inf_k I_r(\nu_k)| + \delta \leq \sup_k |I_r(\mu_k) - I_r(\nu_k)| + \delta$$

$$\leq \sup_k W(\mu_k, \nu_k * \delta_{x_k}) + \delta < 2\delta \leq \epsilon,$$

which completes the proof.  

\[\square\]

**Theorem 5.3.**

(a) If $0 \leq \beta \leq \beta_c$, then

$$\lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \sup_{x \in \mathbb{R}^d} \rho_i(B_1(x)) = 0.$$  

(b) If $\beta > \beta_c$, then there is $c > 0$ such that

$$\liminf_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \sup_{x \in \mathbb{R}^d} \rho_i(B_1(x)) \geq c.$$  

**Proof.** By the (uniform) continuity of the map $\xi \mapsto \int I_r(\mu)\xi(d\mu)$ on the compact space $\mathcal{P}(\tilde{\mathcal{X}})$, for any $\epsilon > 0$, we can choose some $\delta > 0$ such that

$$W(\xi, \mathcal{K}_0) < \delta \quad \Rightarrow \quad \inf_{\xi \in \mathcal{K}_0} \int I_r(\mu)\xi(d\mu) \leq \int I_r(\mu)\xi(d\mu) \leq \sup_{\xi \in \mathcal{K}_0} \int I_r(\mu)\xi(d\mu) + \epsilon.$$  

Theorem 4.10 implies that

$$\inf_{\xi \in \mathcal{K}_0} \int I_r(\mu)\xi(d\mu) \leq \liminf_{n \to \infty} \int I_r(\mu)\psi_n(d\mu).$$
\[ \leq \limsup_{n \to \infty} \int I_r(\mu)\psi_n(d\mu) \leq \sup_{\xi \in K_0} \int I_r(\mu)\xi(d\mu). \] (5.1)

If \( 0 \leq \beta \leq \beta_c \) (or equivalently \( K_0 = \{ \delta_0 \} \)), we have \( \sup_{\xi \in K_0} \int I_1(\mu)\xi(d\mu) = 0 \) and together with (2.13), we obtain
\[ \limsup_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \sup_{x \in \mathbb{R}^d} \rho_i(B_1(x)) \leq \limsup_{n \to \infty} \int I_1(\mu)\psi_n(d\mu) = 0. \]

If \( \beta > \beta_c \), by Theorem 5.1, every \( \xi \in K_0 \) is supported on \( \{ \mu : \|\mu\| = 1 \} \). Therefore, we have
\[ \int I_0(\mu)\xi(d\mu) > 0 \quad \text{for all} \quad \xi \in K_0. \]

This and compactness of \( K_0 \) imply that there is \( c > 0 \) such that
\[ \inf_{\xi \in K_0} \int I_0(\mu)\xi(d\mu) \geq c. \]

Combining this with (5.1) and (2.13) completes the proof of (b). \( \square \)

6. Asymptotic clusterization

6.1. Definitions and sufficient conditions.

**Definition 6.1.** A sequence of probability measures \((\alpha_i)_{i \geq 0}\) on \( \mathbb{R}^d \) is said to be “asymptotically clustered at level \( r > 0 \)” if for every sequence \((\epsilon_i)_{i \geq 0}\) tending to 0, we have
\[ \lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \alpha_i(A_{\alpha_i}(r)) = 1 \quad \text{P.-a.s.}, \]
where \( A_{\alpha_i}(r) := \{ x \in \mathbb{R}^d : \alpha(B_r(x)) > \epsilon V_d r^d \} \) and \( V_d \) is the volume of the unit ball in \( \mathbb{R}^d \).

**Definition 6.2.** We say that \((\alpha_i)_{i \geq 0}\) is “asymptotically locally clustered” if for any sequence \((\epsilon_i)_{i \geq 0}\) tending to 0, we have
\[ \lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \alpha_i(A_{\alpha_i}^c) = 1 \quad \text{P.-a.s.}, \]
where \( A_{\alpha_i}^c = \{ x \in \mathbb{R}^d : \liminf_{r \downarrow 0} \frac{\alpha(B_r(x))}{V_d r^d} > \epsilon \} \).

**Remark 6.3.** If every \( \alpha_i \) is absolutely continuous with respect to the Lebesgue measure, then, due to the Lebesgue differentiation theorem, the asymptotically local clustering property is equivalent to clustering of densities:
\[ \lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \alpha_i(B_{\alpha_i}^c) = 1 \quad \text{P.-a.s.}, \]
where \( B_{\alpha_i}^c = \{ x \in \mathbb{R}^d : \frac{\alpha}{dx}(x) > \epsilon \} \).

The above definitions are extensions of the notion of asymptotic pure atomicity that was introduced first by Vargas in [Varg07] and modified by Bates and Chatterjee in [BC16] in their studies of endpoint distributions for discrete polymers. Moreover, asymptotic clustering at positive
levels was studied in [BM18] still under the name of asymptotic pure atomicity. However, we think that our definitions and terminologies are better tuned to the continuous setting. Roughly speaking, \((\alpha_i)_{i \geq 0}\) is asymptotically clustered at level \(r\) if the mass of \(\alpha_i\) concentrates on few balls of radius \(r\) for large \(i\).

We state a sufficient condition for asymptotic clusterization that is simpler to verify because it is stated in terms of fixed \(\epsilon\) instead of sequences \((\epsilon_i)_{i \geq 0}\).

**Lemma 6.4** (Lemma 6.2 in [BC16]). Let \(r > 0\) be given. If for every \(c > 0\), there is \(\epsilon = \epsilon(r, c) > 0\) such that

\[
\liminf_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \alpha_i(A^\epsilon_{\alpha_i}(r)) > 1 - c \quad \text{P-a.s.},
\]  

(6.1)

then \((\alpha_i)_{i \geq 0}\) is asymptotically clustered at level \(r\).

The proof of this lemma repeats the proof of Lemma 6.2 of [BC16] word for word. The discreteness of \(\mathbb{Z}^d\) plays no role in this argument.

### 6.2. Auxiliary functionals.

For any \(\epsilon > 0\), let us define \(f_\epsilon : \mathbb{R}_+ \to [0, 1]\) by

\[
f_\epsilon(t) = \begin{cases} 
0 & \text{for } 0 \leq t < \epsilon, \\
\frac{1}{\epsilon}(t - \epsilon) & \text{for } \epsilon \leq t \leq 2\epsilon, \\
1 & \text{otherwise}.
\end{cases}
\]

One can see that \(f_\epsilon\) is \(1/\epsilon\)-Lipschitz continuous and can be interpreted as an approximation of a step function \(g_\epsilon(t) = \mathbb{1}_{(\epsilon, \infty)}(t)\) for small \(\epsilon\).

For any \(\mu = (\alpha_i)_{i \in \mathbb{N}} \in \mathcal{X}\) and \(r > 0\), let us define a functional \(D_r\) on \(\mathcal{X} \times (\mathbb{N} \times \mathbb{R}^d)\) as

\[
D_r(\mu, u) = \frac{1}{V_{dr^d}} \int \left(1 - \frac{|u - v|}{r}\right)^+ \mu(dv) = \frac{1}{V_{dr^d}} \int \left(1 - \frac{|x - y|}{r}\right)^+ \alpha_i(dy),
\]

where \(u = (i, x)\) and \(a^+ = \max(a, 0)\). Comparing this with the definition of \(I_r\), one has that

\[
\sup_{u \in \mathbb{N} \times \mathbb{R}^d} D_r(\mu, u) \leq \frac{1}{V_{dr^d}} I_r(\mu).
\]

We also observe that

\[
|D_r(\mu, u_1) - D_r(\mu, u_2)| \leq \frac{1}{V_{dr^d}} \int \left| \left(1 - \frac{|v - u_1|}{r}\right)^+ - \left(1 - \frac{|v - u_2|}{r}\right)^+ \right| \mu(dv)
\]

\[
\leq \frac{1}{V_{dr^d}} \int \frac{|u_1 - u_2|}{r} \mu(dv) \leq \frac{|u_1 - u_2|}{V_{dr^{d+1}}},
\]

so \(D_r\) is \(1/V_{dr^{d+1}}\)-Lipschitz continuous in \(u\). Using the embedding of \(\mathcal{M}_{\leq 1}\) into \(\mathcal{X}\), we can naturally define \(D_r\) on \(\mathcal{M}_{\leq 1} \times \mathbb{R}^d\). Combining (2.10) with the fact that \(y \mapsto (1 - |x - y|/r)^+\) is \(1/r\)-Lipschitz for every \(x \in \mathbb{R}^d\), we obtain

\[
|D_r(\alpha, x) - D_r(\gamma, x)| \leq \frac{1}{V_{dr^{d+1}}} W(\alpha, \gamma), \quad \alpha, \gamma \in \mathcal{M}_1, \ x \in \mathbb{R}^d.
\]  

(6.2)
Let us define a functional $J_{r,\epsilon} : \mathcal{X} \to [0, 1]$ by

$$J_{r,\epsilon}(\mu) = \int f_\epsilon \circ D_{r,\mu}(u) \mu(du) = \sum_{j \in \mathbb{N}} \int f_\epsilon \circ D_{r,\alpha_j}(x) \alpha_j(dx),$$

where we denoted $D_r(\mu, \cdot)$ by $D_{r,\mu}(\cdot)$. $J_{r,\epsilon}$ is well-defined on $\tilde{\mathcal{X}}$ due to the following observation

$$\int f_\epsilon \circ D_{r,\alpha \delta_y}(x)(\alpha * \delta_y)(dx) = \int f_\epsilon \circ D_{r,\alpha}(x) \alpha(dx), \quad \alpha \in \mathcal{M}_{\leq 1}, \ y \in \mathbb{R}^d.$$

**Proposition 6.5.** For any $r, \epsilon > 0$, $J_{r,\epsilon} : \tilde{\mathcal{X}} \to [0, 1]$ is continuous.

**Proof.** Let $\mu \in \tilde{\mathcal{X}}$ and $\delta_2 > 0$ be given. We claim that

$$d(\mu, \nu) < \delta_1 := \min \left( \frac{\epsilon \delta_2 V_d r^d (r + 1)}{6}, 2^{-2r} \right) \Rightarrow |J_{r,\epsilon}(\mu) - J_{r,\epsilon}(\nu)| < \delta_2.$$ Fix $\nu \in \tilde{\mathcal{X}}$ satisfying $d(\mu, \nu) < \delta_1$. Then, we can find a triple $(r', \phi = \{ (\mu_k, \nu_k) \}_{k=1}^n, \bar{x})$ such that

$$r' > 2r \quad \text{and} \quad d_{r', \phi, \bar{x}}(\mu, \nu) < \delta_1.$$ Let us denote

$$\mu^\delta = \{ \bar{\alpha}^\delta_j \} = \mu - \sum_{j=1}^n \mu_j, \quad \nu^\delta = \{ \bar{\gamma}^\delta_j \} = \nu - \sum_{j=1}^n \nu_j, \quad \nu'_k = \nu_k + \delta_{x_k}.$$

Then, we have

$$|J_{r,\epsilon}(\mu) - J_{r,\epsilon}(\nu)| \leq \sum_{k=1}^n \left| \int f_\epsilon \circ D_{r,\mu}(u) \mu_k(du) - \int f_\epsilon \circ D_{r,\nu}(u) \nu_k(du) \right|$$

$$+ \int f_\epsilon \circ D_{r,\mu}(u) \mu^\delta(du) + \int f_\epsilon \circ D_{r,\nu}(u) \nu^\delta(du). \quad (6.3)$$

In order to derive the upper bound for the first term in the right-hand side of (6.3), we observe

$$\left| \int f_\epsilon \circ D_{r,\mu}(u) \mu_k(du) - \int f_\epsilon \circ D_{r,\nu}(u) \mu_k(du) \right|$$

$$= \left| \int f_\epsilon D_{r, \mu_k}(u) + D_{r, \mu_k}(u) \mu_k(du) - \int f_\epsilon D_{r, \mu_k}(u) \mu_k(du) \right|$$

$$\leq \frac{1}{\epsilon} \int D_{r, \mu_k}(u) \mu_k(du) = \frac{1}{\epsilon} \int D_{r, \mu_k}(u) \mu_k(du)$$

$$\leq \frac{1}{\epsilon V_d r^d} \int I_r(\mu^\delta) \mu_k(du) \leq \frac{1}{\epsilon V_d r^d} \|I_r(\mu^\delta)\| \mu_k(du) \leq \frac{\delta_1}{\epsilon V_d r^d} \|\mu_k\|.$$ In the second equality, we used the fact that $d_0(\text{supp}(\mu_k), \text{supp}(\mu_l)) > 2r' > 4r$ for all $l \neq k$, which implies $D_{r, \mu_k} = D_{r, \mu^\delta_k}$ on $\text{supp}(\mu_k)$. Combining this with the triangle inequality, we have

$$\sum_{k=1}^n \left| \int f_\epsilon \circ D_{r,\mu}(u) \mu_k(du) - \int f_\epsilon \circ D_{r,\nu}(u) \nu_k(du) \right|$$

$$\leq \sum_{k=1}^n \left| \int f_\epsilon \circ D_{r,\mu_k}(x) \mu_k(dx) - \int f_\epsilon \circ D_{r,\nu_k}(x) \nu_k(dx) \right| + \frac{2\delta_1}{\epsilon V_d r^d}. \quad (6.4)$$
On the other hand, we can use (6.2), (2.10), and the $1/\varepsilon$-Lipschitz continuity of $f_\varepsilon$ to write

$$
\left| \int f_\varepsilon \circ D_{r,\mu_k}(x) \mu_k(dx) - \int f_\varepsilon \circ D_{r,\nu_k}(x) \nu_k(dx) \right| = \left| \int f_\varepsilon \circ D_{r,\mu_k}(x) \mu_k(dx) - \int f_\varepsilon \circ D_{r,\nu_k'}(x) \nu_k'(dx) \right|
$$

$$
\leq \left| \int f_\varepsilon \circ D_{r,\mu_k}(x) \mu_k(dx) - \int f_\varepsilon \circ D_{r,\nu_k'}(x) \mu_k(dx) \right| + \left| \int f_\varepsilon \circ D_{r,\nu_k'}(x) \mu_k(dx) - \int f_\varepsilon \circ D_{r,\nu_k'}(x) \nu_k'(dx) \right|
$$

$$
\leq \frac{1}{\varepsilon} \int |D_{r,\mu_k}(x) - D_{r,\nu_k'}(x)| \mu_k(dx) + \frac{1}{\varepsilon V_d r^d} W(\mu_k, \nu_k') \leq \frac{2}{\varepsilon V_d r^d} W(\mu_k, \nu_k').
$$

Summing over $k$ on both sides gives

$$
\sum_{k=1}^{\infty} \left| \int f_\varepsilon \circ D_{r,\mu_k}(x) \mu_k(dx) - \int f_\varepsilon \circ D_{r,\nu_k}(x) \nu_k(dx) \right| \leq \frac{2}{\varepsilon V_d r^d} \sum_{k=1}^{\infty} W(\mu_k, \nu_k') < \frac{2\delta_1}{\varepsilon V_d r^d}. \quad (6.5)
$$

Let us estimate the second and the third terms in the right-hand side of (6.3).

$$
\int f_\varepsilon \circ D_{r,\mu}(u) \mu^s(du) = \int_{\{u : D_{r,\mu}(u) > \varepsilon\}} f_\varepsilon \circ D_{r,\mu}(u) \mu^s(du)
$$

$$
\leq \mu^s\{u : D_{r,\mu}(u) > \varepsilon\} \leq \mu^s\{u : \mu(B_r(u)) > \varepsilon V_d r^d\}. \quad (6.6)
$$

Let $C = \{u : \mu(B_r(u)) > \varepsilon V_d r^d\}$. Then, we can choose a finite number of disjoint balls

$$
C = \{B_r(u_i) : u_i \in C, 1 \leq i \leq N\}
$$

such that every ball $B_r(u), u \in C$ has non-empty intersection with $\bigcup_{i=1}^{N} B_r(u_i)$. The disjointness of $C$ gives $N \leq \frac{1}{\varepsilon V_d r^d}$ and

$$
C \subset \bigcup_{i=1}^{N} B_{2r}(u_i) \subset \bigcup_{i=1}^{N} B_{r'}(u_i).
$$

Using this and $\mu^s(B_{r'}(u)) \leq I_{r'}(\mu^s) < \delta_1$ for all $u \in \mathbb{N} \times \mathbb{R}^d$, (6.6) can be continued as

$$
\int f_\varepsilon \circ D_{r,\mu}(u) \mu^s(du) \leq \mu^s(C) \leq \mu^s\left(\bigcup_{i=1}^{N} B_{r'}(u_i)\right) < N\delta_1 \leq \frac{\delta_1}{\varepsilon V_d r^d}. \quad (6.7)
$$

Combining (6.3), (6.4), (6.5), and (6.7) completes the proof. \hfill \Box

### 6.3. Asymptotic clusterization of polymer endpoint distributions

In this section, we prove the following theorem which is a reformulation of relations (1.4) and (1.6) in Theorem 1.1.

**Theorem 6.6.**

(a) If $\beta > \beta_c$, then for all $r > 0$, $(\rho_i)_{i \geq 0}$ is asymptotically clustered at level $r$.

(b) If $\beta \leq \beta_c$, then for all $r > 0$, $(\rho_i)_{i \geq 0}$ is not asymptotically clustered at level $r$. Moreover, for any $r > 0$, there is a sequence $(\epsilon_i)_{i \geq 0}$ tending to 0 as $i \to \infty$, such that

$$
\lim_{n \to \infty} \sum_{i=0}^{n-1} \rho_i(A_{\rho_i}^{\epsilon_i}(r)) = 0 \quad \text{P-a.s.} \quad (6.8)
$$
Proof. (a) Suppose $\beta > \beta_c$. Our goal is to show (6.1). To this end, for any $r, \epsilon > 0$, let us define a functional $\mathcal{J}_{r, \epsilon}$ on $\mathcal{P}(\mathcal{X})$ as

$$
\mathcal{J}_{r, \epsilon}(\xi) := \int J_{r, \epsilon}(\mu)\xi(d\mu).
$$

Notice that the continuity of $J_{r, \epsilon}$ passes on to the continuity of $\mathcal{J}_{r, \epsilon}$. We also observe that

$$
J_{r, \epsilon}(\rho_i) = \int_{\{x : D_r, \rho_i(x) > \epsilon\}} f_c \circ D_r, \rho_i(x) \rho_i(dx) \leq \int \mathcal{A}_{\rho_i}(r) f_c \circ D_r, \mu(x) \rho_i(dx) \leq \rho_i(\mathcal{A}_{\rho_i}^c(r)).
$$

Hence,

$$
\frac{1}{n} \sum_{i=0}^{n-1} \rho_i(\mathcal{A}_{\rho_i}^c) \geq \frac{1}{n} \sum_{i=0}^{n-1} J_{r, \epsilon}(\rho_i) = \mathcal{J}_{r, \epsilon}(\psi_{n-1}).
$$

On the other hand, for any $\mu \in \mathcal{X}$ with $\|\mu\| = 1$, we have

$$
\lim_{\epsilon \downarrow 0} J_{r, \epsilon}(\mu) = 1
$$

because $\mu\{u : D_r, \mu(u) > 0\} = 1$ and $J_{r, \epsilon}(\mu) \geq \mu\{u : D_r, \mu(u) > 2\epsilon\}$. Using this along with Theorem 5.1 (2), we obtain that for every $\xi \in \mathcal{K}_0$,

$$
\lim_{\epsilon \downarrow 0} \mathcal{J}_{r, \epsilon}(\xi) = 1.
$$

Since each $\mathcal{J}_{r, \epsilon}$ is continuous on the compact set $\mathcal{K}_0$ and $(\mathcal{J}_{r, \epsilon})_{\epsilon > 0}$ is monotone increasing as $\epsilon \downarrow 0$, the convergence above is uniform in $\xi$ by the Dini’s theorem.

Let now $c > 0$ be given. By the uniform convergence of $(\mathcal{J}_{r, \epsilon})_{\epsilon > 0}$, we can choose $\epsilon = \epsilon(r, c) > 0$ such that

$$
\mathcal{J}_{r, \epsilon}(\xi) > 1 - c \quad \text{for all} \ \xi \in \mathcal{K}_0
$$

and, for such $\epsilon$, we can also find $\delta > 0$ such that

$$
\mathcal{W}(\zeta, \mathcal{K}_0) < \delta \quad \Rightarrow \quad \mathcal{J}_{r, \epsilon}(\zeta) > 1 - c.
$$

Combining Theorem 4.10, (6.9), and (6.10), we complete the proof of (a).

(b) Suppose $\beta \leq \beta_c$ and let $r > 0, \epsilon > 0$ be given. We claim that

$$
\lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \rho_i(\mathcal{A}_{\rho_i}^c(r)) = 0.
$$

To see this, we observe that for any $x \in \mathcal{A}_{\mu}^c(r)$ and $\mu \in \mathcal{X}$,

$$
D_{2r, \mu}(u) = \frac{1}{V_d(2r)^d} \int (1 - |u - v|)^{+} \mu(dv) \geq \frac{1}{V_d(2r)^d} \int \frac{1}{2 \beta r(u)(v)} \mu(dv) = \frac{\mu(B_r(u))}{2^{d+1} V_d d^d} > 2\epsilon',
$$

where $\epsilon' = \epsilon/2^{d+2}$. Therefore, we have

$$
J_{2r, \epsilon'}(\mu) \geq \int_{\{D_{2r, \mu}(u) > 2\epsilon'\}} f_c \circ D_{2r, \mu}(u) \mu(du) = \mu\{D_{2r, \mu}(u) > 2\epsilon'\} \geq \mu(\mathcal{A}_{\mu}^c(r)),
$$

where $\mathcal{A}_{\mu}^c(r)$ is the complement of $\mathcal{A}_{\mu}(r)$. This completes the proof of (b).
which implies that
\[
\frac{1}{n} \sum_{i=0}^{n-1} \rho_i(A_{\rho_i}^r(r)) \leq \frac{1}{n} \sum_{i=0}^{n-1} J_{2r,\epsilon'}(\rho_i) = J_{2r,\epsilon'}(\psi_{n-1}).
\] (6.12)

By Theorem 5.1 (1) and the continuity of \( J_{2r,\epsilon'} \), we conclude
\[
\lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \rho_i(A_{\rho_i}^r(r)) \leq J_{2r,\epsilon'}(\delta_0) = 0.
\]

Fix \( r > 0 \) and let us now construct a sequence \( (\epsilon_i)_{i \geq 0} \) tending to 0 and satisfying (6.8). By (6.11), we see that for each \( k \in \mathbb{N} \), there is \( N_k \) such that
\[
\frac{1}{n} \sum_{i=0}^{n-1} \rho_i(A_{1/k}^{1/k}(r)) < \frac{1}{k} \quad \text{for all } n \geq N_k.
\]
We may assume \( N_{k+1} > N_k \) for all \( k \). Set \( \epsilon_i = 1 \) for \( i < N_k \) and \( \epsilon_i = 1/k \) for \( N_k \leq i < N_{k+1} \). Then, we see that for each \( n \in \mathbb{N} \), there is \( k = k(n) \) such that \( N_k \leq n < N_{k+1} \) and hence
\[
\frac{1}{n} \sum_{i=0}^{n-1} \rho_i(A_{\rho_i}^r(r)) \leq \frac{1}{n} \sum_{i=0}^{n-1} \rho_i(A_{1/k}^{1/k}(r)) < \frac{1}{k}.
\]
Since \( \lim_{n \to \infty} k(n) = \infty \), letting \( n \to \infty \) on the both side above completes the proof of (b). \( \square \)

6.4. Asymptotic local clustering of the endpoint distribution. In this section, we prove the following reformulation of relation (1.5) in Theorem 1.1:

**Theorem 6.7.** If \( \beta > \beta_c \), then \( (\rho_i)_{i \geq 0} \) is asymptotically locally clustered. In particular, for these values of \( \beta \), clusterization of densities (see Remark 6.3) holds if the reference random walk step distribution \( Z(dx) \) is absolutely continuous.

Before we prove this, we recall the Besicovitch covering theorem and its related lemma which will be used later.

**Theorem 6.8. (Besicovitch covering theorem)** There is a constant \( N_d \), depending only on the dimension \( d \), with the following property:
Let \( F = \{ B_{r_\sigma}(x_\sigma) : \sigma \in \mathcal{I} \} \) be any collection of open balls in \( \mathbb{R}^d \) with \( \mathrm{sup} \{ r_\sigma : \sigma \in \mathcal{I} \} < \infty \). Let us denote \( A = \{ x_\sigma : \sigma \in \mathcal{I} \} \). Then, there is a countable subcollection \( \mathcal{G} \) of \( F \) such that \( \mathcal{G} \) is a cover of \( A \) and every \( x \in \bigcup_{B \in \mathcal{G}} B \) belongs to at most \( N_d \) different balls from the subcover \( \mathcal{G} \).

We remark that in [FL94], the lower bound and the upper bound for \( N_d \) were provided:
\[
(2.065 + o(1))^d \leq N_d \leq (2.691 + o(1))^d.
\]
We now state a lemma which is based on the Besicovitch covering theorem.
Lemma 6.9 (Lemma 1.2. in [EG15]). Let $\mu, \nu$ be Radon measures on $\mathbb{R}^d$ and define
\[
D_\mu \nu(x) = \begin{cases} 
\liminf_{r \downarrow 0} \frac{\mu(B_r(x))}{\nu(B_r(x))} & \text{if } \mu(B_r(x)) > 0 \text{ for all } r > 0, \\
+\infty & \text{otherwise.}
\end{cases}
\]

Let $\epsilon > 0$ be given. Then, for any Borel $A \subset \{ x \in \mathbb{R}^d : D_\mu \nu(x) \leq \epsilon \}$, we have
\[
\nu(A) \leq \epsilon \mu(A).
\]

By substituting $\mu = m$ (Lebesgue measure on $\mathbb{R}^d$) and $\nu = \alpha$, we obtain
\[
\alpha(A) \leq \epsilon m(A), \quad \forall \text{ Borel } A \subset (A^\epsilon) = \{ x \in \mathbb{R}^d : D_\alpha \alpha(x) \leq \epsilon \}. \tag{6.13}
\]

Proposition 6.10. Let $\epsilon, c, r > 0$ be given and let us assume that $\alpha \in \mathcal{M}_1$ satisfies
\[
\alpha(A^\epsilon) > 1 - c. \tag{6.14}
\]

Then, there is $\epsilon_1 = \epsilon_1(\epsilon, c, d) > 0$, independent of $\alpha$, such that
\[
\alpha((A^\epsilon)^c) > 1 - 2c.
\]

Proof. Let $\epsilon > 0$ be given. For any $t \in (0, 1)$, let us set $s = (1 - t) / (V_d r^d)$ and
\[
\epsilon_1 = s \epsilon = \frac{1 - t}{V_d r^d} \epsilon. \tag{6.15}
\]

We will determine the value of $t$ later.

Let $x \in A^\epsilon$ and suppose $\alpha(A^\epsilon \cap B_r(x)) \leq t \alpha(B_r(x))$. Then, we see that
\[
\alpha(B_r(x)) = \alpha(A^\epsilon \cap B_r(x)) + \alpha((A^\epsilon)^c \cap B_r(x)) \\
\leq t \alpha(B_r(x)) + \epsilon_1 m((A^\epsilon)^c \cap B_r(x)) \leq t \alpha(B_r(x)) + s \epsilon V_d r^d.
\]

In the first inequality above, we used (6.13). By (6.15), we have
\[
\alpha(B_r(x)) \leq \frac{s \epsilon V_d r^d}{1 - t} = \epsilon,
\]

which contradicts $x \in A^\epsilon$. Therefore, we obtain
\[
\alpha((A^\epsilon)^c \cap B_r(x)) > t \alpha(B_r(x))
\]
or, equivalently,
\[
\alpha((A^\epsilon)^c \cap B_r(x)) \leq (1 - t) \alpha(B_r(x)). \tag{6.16}
\]

Let us now apply Theorem 6.8 with $F = \{ B_r(x) : x \in A^\epsilon \}$ and $A = A^\epsilon$. Then, we can find a countable subset $A \subset A^\epsilon$ such that $G = \{ B_r(x) : x \in A \}$ is a cover of $A^\epsilon$ and every $x \in \bigcup_{y \in A} B_r(y)$ is covered by at most $N_d$ balls from $G$. Therefore, due to (6.16), we have
\[
\alpha((A^\epsilon)^c \cap A^\epsilon) \leq \alpha \left( (A^\epsilon)^c \cap \bigcup_{x \in A} B_r(x) \right) \leq \sum_{x \in A} \alpha((A^\epsilon)^c \cap B_r(x)) \leq (1 - t) \sum_{x \in A} \alpha(B_r(x))
\]
\[
\leq N_d(1-t)\alpha \left( \bigcup_{x \in A} B_r(x) \right) \leq N_d(1-t). \tag{6.17}
\]

Therefore, due to (6.17) and (6.14),
\[
\alpha \left( (A^c) \cap \bigcup_{x \in A} B_r(x) \right) \leq N_d(1-t) + \alpha((A_\alpha^c(r))^c) < N_d(1-t) + c.
\]

Choosing \( t = 1 - \frac{c}{N_d} \left( s = \frac{c}{t} \right) \) completes the proof. \( \square \)

**Proof of Theorem 6.7.** Suppose \( \beta > \beta_c \). Let \( (\epsilon_i)_{i \geq 0} \) tending to 0 be given. For any \( c > 0 \), let us denote \( s = \frac{c}{N_d} \) and

\[
F_c = \{ i \geq 0 : \rho_i(A^c/1) > 1 - c/2 \}, \quad F'_c = \{ i \geq 0 : \rho_i(A^c/1) > 1 - c \}.
\]

By Theorem 6.6 (a), \( (\rho_i)_{i \geq 0} \) is asymptotically clustered at level 1. This can be rewritten as

\[
\lim_{n \to \infty} \frac{1}{n} |F_c \cap [0, n-1]| = 1.
\]

Since Proposition 6.10 implies \( F_c \subset F'_c \), the same relation holds for \( F'_c \) and hence

\[
\liminf_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \alpha_i(A^c_{\alpha_i}) \geq 1 - c \quad \text{P-a.s.}
\]

Letting \( c \downarrow 0 \) completes the proof. \( \blacksquare \)

**7. Geometric localization**

Adapting the terminology from [BC16], we say that a sequence \( (\alpha_n)_{n \geq 0} \) of probability measures on \( \mathbb{R}^d \) is **geometrically localized with positive density** if for any \( \delta > 0 \), there exist \( K < \infty \) and \( \theta > 0 \) such that

\[
\liminf_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \mathbb{1}_{\{\alpha_i \in G_{\delta,K} \}} \geq \theta \quad \text{P-a.s.}, \tag{7.1}
\]

where

\[
G_{\delta,K} = \{ \alpha \in \mathcal{M} : \max_{x \in \mathbb{R}^d} \alpha(B_K(x)) > 1 - \delta \}.
\]

If \( \theta \) can be taken equal to 1, then the sequence would be **geometrically localized with full density**. A full density localization is an open question. In this section, we will prove that \( (\rho_i)_{i \geq 0} \) is geometrically localized with positive density if and only if \( \beta > \beta_c \).

**7.1. Useful functionals.** Let \( \mu = \{\alpha_i\} \in \tilde{X} \) be given. Recalling (2.2), let us define a functional \( N \) on \( \tilde{X} \) by

\[
N(\mu) = |S_\mu|.
\]

To describe \( G_{\delta,K} \) in the language of \( (\tilde{X}, d) \), we need to consider

\[
W_\delta(\mu) = \inf \{ r \geq 0 : I_r(\mu) > 1 - \delta \}
\]
and
\[ \mathcal{V}_{\delta,K} = \{ \mu \in \tilde{X} : W_\delta(\mu) < K \}. \]
Using (2.13) and the natural embedding of \( \tilde{M}_1 \) into \( \tilde{X} \), we obtain
\[ \mathcal{G}_{\delta,K} \subset \mathcal{V}_{\delta,K} \cap \{ \mu \in \tilde{X} : N(\mu) = 1, \|\mu\| = 1 \} \subset \mathcal{G}_{\delta,K+1}. \] (7.2)
We also define functionals
\[ Q(\mu) = \sum_{i \in \mathbb{N}} \|\alpha_i\|, \]
\[ m(\mu) = \max_{i \in \mathbb{N}} \|\alpha_i\|. \]
One can check that \( N, W_\delta, Q \) are well-defined.

**Proposition 7.1.**

(a) \( W_\delta \) is upper semi-continuous.

(b) \( m \) is lower semi-continuous.

(c) \( Q \) is lower semi-continuous.

**Proof.** (a) Let \( \mu \in \tilde{X} \) and \( \epsilon > 0 \) be given. Then, \( I_{W_\delta(\mu)+\epsilon}(\mu) > 1 - \delta \). By Lemma 5.2, there is \( \delta_1 > 0 \) such that
\[ d(\mu, \nu) < \delta_1 \implies |I_{W_\delta(\mu)+\epsilon}(\mu) - I_{W_\delta(\mu)+\epsilon}(\nu)| < \epsilon', \]
where \( \epsilon' = \frac{1}{2}(I_{W_\delta(\mu)+\epsilon}(\mu) - 1 + \delta) \). For such \( \nu \), we obtain \( I_{W_\delta(\mu)+\epsilon}(\nu) > 1 - \delta \), which implies
\[ W_\delta(\nu) \leq W_\delta(\mu) + \epsilon. \]

(b) Fix \( \mu \in \tilde{X} \) and \( 0 < \epsilon_2 < m(\mu) \). We must show that there is \( \epsilon_1 > 0 \) such that
\[ d(\mu, \nu) < \epsilon_1 \implies m(\nu) > m(\mu) - \epsilon_2. \]
Without loss of generality, we may assume \( \|\alpha_1\| = m(\mu) \). There is \( R = R(\epsilon_2) > 0 \) such that \( \mu(B_R(1,0)) = \alpha_1(B_R(0)) > m(\mu) - \epsilon_2/2 > \epsilon_2/2 \). Choose \( \epsilon_1 = \min(\epsilon_2, 2^{-R}) \). Then, assuming \( d(\mu, \nu) < \epsilon_1 \), there is a triple \( (r, \phi = \{ (\mu_k, \nu_k) \}_{k=1}^n, \vec{x}) \) such that \( d_{r,\phi,\vec{x}}(\mu, \nu) < \epsilon_1 \). Since \( \deg(\phi) > 2r > 2R \), there is at most one \( \mu_k \) whose support intersects with \( B_R((1,0)) \). If there is no \( \mu_k \) whose support intersects with \( B_R((1,0)) \), then \( 1_{B_R((1,0))} \leq \mu - \sum_{k=1}^n \mu_k \). It follows
\[ d_{r,\phi,\vec{x}}(\mu, \nu) > I_r \left( \mu - \sum_{k=1}^n \mu_k \right) \geq \alpha_1(B_R(0)) > \epsilon_2/2 \geq \epsilon_1, \]
which is a contradiction. Therefore, we may assume \( \mu_1 \) is a unique sub-measure of \( \alpha_1 \) whose support overlaps with \( B_R(0) \). Since \( 1_{B_R((1,0))} \leq \mu - \sum_{k=1}^n \mu_k \), we have
\[ (\mu - \mu_1)(B_R(1,0)) \leq I_R \left( \mu - \sum_{k=1}^n \mu_k \right) \leq I_r \left( \mu - \sum_{k=1}^n \mu_k \right). \]
Therefore,
\[ m(\nu) \geq \|\nu_1\| = \|\mu_1\| \geq \mu_1(B_R(1,0)) \]
\[ \geq \mu(B_R(1,0)) - I_r \left( \mu - \sum_{k=1}^n \mu_k \right) > \left( \|\alpha_1\| - \frac{\epsilon_2}{2} \right) - \frac{\epsilon_2}{2} = m(\mu) - \epsilon_2. \] (7.3)

(c) Fix \( \mu \in \tilde{X} \). If \( Q(\mu) = \infty \) (i.e. \( m(\mu) = 1 \)), then for any \( L > 0 \), by part (b), we can find \( \epsilon_1 > 0 \) such that
\[ d(\mu, \nu) < \epsilon_1 \quad \Rightarrow \quad m(\nu) > 1 - \frac{1}{L+1} \quad \Rightarrow \quad Q(\nu) > L. \]

Now consider the case \( Q(\mu) < \infty \) and fix \( \epsilon_2 > 0 \). First, we can find \( N \) such that
\[ \sum_{i>N} \|\alpha_i\| < \frac{\epsilon_2}{2} + \epsilon_2. \]

Since for any nonnegative \( x_1, x_2, \ldots \) satisfying \( \sum_i x_i < 1 \), we see that
\[ \sum_i \frac{x_i}{1 - x_i} \leq \sum_i \frac{x_i}{1 - \sum_j x_j} = \sum_i \frac{x_i}{1 - \sum_i x_i}, \]
which implies \( \sum_{i>N} \frac{\|\alpha_i\|}{1 - \|\alpha_i\|} < \epsilon_2/2. \)

We may assume \( \|\alpha_i\| \geq \|\alpha_{i+1}\| \) for \( i \leq N - 1 \). Let
\[ N_1 = \sup \left\{ i \in \{1, \ldots, N\} : \|\alpha_i\| > \frac{\epsilon_2}{2N + \epsilon_2} \right\} \vee 0. \]

We can choose \( R = R(\epsilon_2) > 0 \) such that
\[ \max_{1 \leq i \leq N_1} \alpha_i(B_R(0)) < \frac{\epsilon_2}{4N + 2\epsilon_2}. \]

Applying the argument that we used in (7.3), we can find \( \epsilon_1 > 0 \) such that \( d(\mu, \nu) < \epsilon_1 \) guarantees the existence of \((\mu, \nu)\)-matching \( \{(\mu_k, \nu_k)\}_{k=1}^n \) such that \( n \geq N_1 \) and
\[ \|\nu_k\| \geq \|\alpha_k\| - \frac{\epsilon_2}{2N + \epsilon_2} \]
for all \( 1 \leq k \leq N_1 \). It follows that
\[ \frac{\|\nu_k\|}{1 - \|\nu_k\|} \geq \frac{\|\alpha_k\|}{1 - \|\alpha_k\|} - \frac{\epsilon_2}{2N + \epsilon_2} \geq \frac{\|\alpha_k\|}{1 - \|\alpha_k\|} - \frac{\epsilon_2}{2N} \quad \text{for } 1 \leq k \leq N_1. \]

On the other hand, by the definition of \( N_1 \), we have
\[ \frac{\|\alpha_k\|}{1 - \|\alpha_k\|} \leq \frac{\epsilon_2}{2N} \quad \text{for } N_1 < k \leq N. \]

Therefore, we conclude
\[ Q(\nu) \geq \sum_{k=1}^n \frac{\|\nu_k\|}{1 - \|\nu_k\|} \geq \sum_{k=1}^{N_1} \left( \frac{\|\alpha_k\|}{1 - \|\alpha_k\|} - \frac{\epsilon_2}{2N} \right) + \sum_{k=N_1+1}^N \left( \frac{\|\alpha_k\|}{1 - \|\alpha_k\|} - \frac{\epsilon_2}{2N} \right) \]
\[ > \sum_{k=1}^N \frac{\|\alpha_k\|}{1 - \|\alpha_k\|} - \frac{\epsilon_2}{2} > Q(\mu) - \epsilon_2. \]
\[ \square \]
Lemma 7.2. Assume $\beta > \beta_c$. Then, for any $\xi \in \mathcal{K}_0$,
\[ \int Q(\mu)\xi(d\mu) = \infty. \tag{7.4} \]

Proof. Let $\xi \in \mathcal{K}_0$ be given. Notice that $\xi\{\mu \in \tilde{X} : \|\mu\| = 1\} = 1$ by part (2) of Theorem 5.1. Suppose, towards a contradiction, that
\[ \int Q(\mu)\xi(d\mu) < \infty. \tag{7.5} \]
This implies $\xi\{\mu \in \tilde{X} : N(\mu) = 1\} = 0$. Let $\eta$ be a $\tilde{X}$-valued random variable whose law is $\xi$ and $Y$ be a random field with the same law as $X$ and independent of $\eta$. Since $T\eta = \eta$, the law of $\hat{\eta}(du) = \frac{e^{\beta Y(\mu)}\eta * Z(du)}{\int_{\mathbb{R}^d} e^{\beta Y(\mu)}\eta * Z(dw)}$ is also $\xi$. We observe that
\[
E[Q(\hat{\eta})|\eta] = \sum_{i \in \mathbb{N}} E\left[ \int e^{\beta Y(i,x)}\alpha_i * Z(dx) \middle| \eta \right]
\]
\[
= \sum_{i \in \mathbb{N}} E\left[ \int e^{\beta Y(i,x)}\alpha_i * Z(dx) \middle| \eta \right] E\left[ \frac{1}{\int_{\mathbb{R}^d} e^{\beta Y(j,x)}\alpha_j * Z(dx)} \middle| \eta \right]
\]
\[
> \sum_{i \in \mathbb{N}} \frac{E\left[ \int e^{\beta Y(i,x)}\alpha_i * Z(dx) \middle| \eta \right]}{\sum_{j \neq i} \int_{\mathbb{R}^d} e^{\beta Y(j,x)}\alpha_j * Z(dx)} = \sum_{i \in \mathbb{N}} \|\alpha_i\| = Q(\eta),
\]
which is a contradiction. \qed

The following result is a reformulation of Theorem 1.2:

Theorem 7.3.
(a) If $\beta > \beta_c$, then $(\rho_i)_{i \geq 0}$ is geometrically localized with positive density.
(b) If $\beta \leq \beta_c$, then for any $\delta \in (0, 1)$ and any $K > 0$,
\[ \lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} 1_{\{\rho_i \in G_{\delta,K}\}} = 0 \quad \mathbb{P}\text{-a.s.} \tag{7.6} \]

Proof. (a) Let $\delta > 0$ be given. The left-hand side of (7.1) can be expressed in terms of the empirical measure $\psi_n$:
\[ \frac{1}{n} \sum_{i=0}^{n-1} 1_{\{\rho_i \in G_{\delta,K}\}} = \frac{1}{n} \sum_{i=0}^{n-1} \delta_{\rho_i}(G_{\delta,K}) = \psi_{n-1}(G_{\delta,K}). \]
Therefore, it suffices to show that there are $K > 0$ and $\theta > 0$ such that
\[ \liminf_{n \to \infty} \psi_n(G_{\delta,K}) \geq \theta. \tag{7.7} \]
To see this, let us define

\[ U_\delta := \{ \mu \in \mathcal{X} : m(\mu) > 1 - \delta \} = \bigcup_{K=1}^{\infty} V_{\delta,K}. \] (7.8)

By Lemma 7.2, for all \( \xi \in K_0 \),

\[ \xi(U_\delta) > 0. \] (7.9)

The lower semi-continuity of \( m \) implies that \( U_\delta \) is an open set, so the map \( \xi \to \xi(U_\delta) \) is also lower semi-continuous. Together with the compactness of \( K_0 \), we have

\[ \theta := \inf_{\xi \in K_0} \xi(U_\delta) > 0. \] (7.10)

For each \( \xi \in K_0 \), we can use (7.8) and monotonicity of \( V_{\delta,K} \) in \( K \) to choose \( K = K_\xi < \infty \) such that

\[ \xi(V_{\delta,K}) > (1 - \epsilon)\theta. \] (7.11)

The upper semi-continuity of \( W_\delta \) implies that the map \( \xi \to \xi(V_{\delta,K}) \) is lower semi-continuous. Hence, there is \( r_\xi > 0 \) such that

\[ \inf_{\zeta \in B(\xi,r_\xi)} \zeta(V_{\delta,K_\xi}) > (1 - \epsilon)\theta. \]

Since \( K_0 \) is compact and \( \{ B(\xi_i,r_{\xi_i}/2) \}_{\xi_i \in K_0} \) is an open covering of \( K_0 \), we can choose a finite subcovering \( \{ B(\xi_i,r_{\xi_i}/2) \}_{i=1}^n \). Now let \( K = \max_{1 \leq i \leq n} \{ K_{\xi_i} \} \), \( r = \min_{1 \leq i \leq n} \{ r_{\xi_i}/2 \} \). Using the finite open covering of \( K_0 \) above and (7.2), we have

\[ W(\xi,K_0) < r \Rightarrow \xi(V_{\delta,K}) > (1 - \epsilon)\theta \Rightarrow \xi(G_{\delta,K+1}) > (1 - \epsilon)\theta. \]

Notice that \( \lim_{n \to \infty} W(\psi_n,K_0) \to 0 \) from Theorem 4.10. Therefore, letting \( \epsilon \downarrow 0 \), we obtain (7.7).

(b) Suppose \( \beta \leq \beta_c \) and let \( \delta \in (0,1) \), \( K > 0 \), and \( \epsilon > 0 \) be given. We write

\[ G_n = \left\{ i \in \{0, \ldots, n-1\} : \max_{x \in \mathbb{R}^d} \rho_i(B_K(x)) > 1 - \delta \right\}. \]

Then, (7.6) is equivalent to

\[ \lim_{n \to \infty} \frac{|G_n|}{n} = 0 \quad \mathbb{P}-a.s. \] (7.11)

Recalling Theorem 5.3, we can write

\[ \lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \max_{x \in \mathbb{R}^d} \rho_i(B_K(x)) = 0 \quad \mathbb{P}-a.s. \]

Therefore, there is \( N \in \mathbb{N} \) such that

\[ \frac{1}{n} \sum_{i=0}^{n-1} \max_{x \in \mathbb{R}^d} \rho_i(B_K(x)) < (1 - \delta)\epsilon \quad \text{for all } n \geq N, \]

and for such \( n \), we have \( |G_n|/n < \epsilon. \) Letting \( n \to \infty \) and then \( \epsilon \downarrow 0 \), we obtain (7.11). □
