Abstract

In this work, we study the wave equations in 2D Euclidian space for a new non-central potential consisting of a Kratzer term and a dipole term $V(r, \theta) = Qr^{-1} + D_r r^{-2} + D_\theta \cos(\theta)r^{-2}$. For Schrodinger equation, we obtain the analytical expressions of the energies and the wave functions of the system. For Klein-Gordon and Dirac equations, we do the study in both spin and pseudo-spin symmetries to get the eigenfunctions and the eigenvalues. We also study the dependence of energies on the parameters D_r and D_θ . We find that the D_θ term tends to dissociate the system, and thus counteracts the Coulomb binding effect, and that the D_r term can either amplify or decrease this effect according to its sign.

1 Introduction

The quantum wave equations, namely Schrödinger, Klein-Gordon and Dirac, are very good tools for the study of atomic and molecular systems. Unfortunately those equations have analytical solutions for very few type of potentials and the majority are central. The complexity of the study of multi-particle systems has forced theorists to use mean-field models and most of them are also central. These central potentials don't correspond to the reality of physical systems, except for the Coulomb potential that matches perfectly the Hydrogen because it is just a two-particle system.

When we study non central potentials, the difficulty already appears in Schrödinger equation, where the separation of variables is only possible when the potential is of the type $V(r) + V(\theta)r^{-2} + V(\varphi)r^{-2}\sin^{-2}(\theta)$ [1, 2, 3, 4], and among them there is only few ones that can be studied analytically [5, 4]. The study of this kind of potential began with the works of Makarov [6] and Hartmann [7] in molecular systems and now they are in focus in various fields, especially in quantum chemistry and nuclear physics. For example they were used for the description of ring-shaped molecules like benzene and also for the interactions between deformed pair of nuclei [8, 9, 10, 11].

The most simple non-central potential is the electric dipole $D \cos(\theta)r^{-2}$ (or pure dipole) and it attracted attention very early because there were experimental clues that it could have bound states only if its moment exceed a critical value [12]. Experiments studies followed and confirmed these results despite the fact that there is no analytical solutions for this system [13]. This potential has also attracted attention in chemistry given its applications in the anionic bounds of polar molecules [14, 15, 16, 17] and also in molecular biology in the study of electron binding mechanisms in DNA and RNA [18] (for a review see [19]).

From a theoretical point of view, the pure dipole potential has been studied in the case of 3D systems [20] and also in 1D and 2D systems [20, 21]. Theoretical studies have also focused on the potential of the non-pure dipole $Qr^{-1} + D \cos(\theta)r^{-2}$, in 3D systems [22] and in 2D ones [23]. For this last potential, both cases showed that the dipole must be below a critical value to have bound states in the system; These results are in the opposite of those of the pure dipole.

The interest for 2D systems comes from the great popularity of graphene (and co. like silicene and manganene) and also from experimental achievements with the realization of quantum gases at low dimensions [24, 25] and before that from quasi-condensate experiments [26]. In 2D systems, pure dipole is present in ultrathin semiconductor layers [27], in spin-polarized atomic hydrogen absorbed on the surface of superfluid helium [28], for charged particles in a plane with perpendicular magnetic field [29] and also in gapped graphene with two charged impurities [30, 31]. On the other hand, non-pure dipole potential was recently found in the case of electron pairing that stems from the spin-orbit interaction in two-dimensional quantum well [32].

In this work we consider a new type of non-central potential consisting of a combination of a Kratzer potential and a dipole term $V(r, \theta) = Qr^{-1} + D_r r^{-2} + D_\theta \cos(\theta)r^{-2}$. Our choice for this potential comes the fact that it is a better generalization of the Coulomb interaction than the non-pure dipole potential considered in [22], [23] and [32] and also for the potential richness of its applications given the number of parameters in its expression. We add a dipole term to the Kratzer

potential to take into account the anisotropy of the distribution of charges and thus generalize the studies already made for central distributions. Our study also aims to add a new non-central system that has analytical solutions to those already presented in the literature [5, 4].

Kratzer potential was introduced to study the regularities in the band spectra of diatomic molecules [33, 34], and since then it has attracted a lot of attention because of its applications in various fields of physics and chemistry such as nuclear physics [35], molecular physics [36], quantum chemistry [37] and chemical physics [38]. It is even used for the study of optical properties in semiconductor quantum dots [39]. The studies the Kratzer potential modified with angular terms followed for their possible applications in ring-shaped organic molecules [40, 41]. Recently, the Kratzer potential has been experimentally justified in 2D systems because Rydberg series of s-type excitonic states in monolayers of semiconducting transition metal dichalcogenides, which are 2D semiconductors, follow a model system of 2D Kratzer type instead of a 2D hydrogen atom [42].

Our work will be structured as follows: after this introduction which constitutes the first section 1, we will first start by a theoretical justification of our choice of the non-central Kratzer potential in the second section 2, then we will solve the Schrödinger equation for this new potential in the case of two-dimensional systems in the third section 3. Finally, after two sections devoted to the results of the relativistic studies 45, will come our conclusions in the sixth section 6.

2 The Non-Central Kratzer Potential

We consider a system composed of a point charge q in the potential of a charge distribution $Q = \int dq$ (a cluster of point charges dq) such as an ion and a charged particle. The extended charge Q produce the following potential at the position of the test charge q :

$$V(\vec{r}) = \int \frac{1}{4\pi\epsilon_0} \frac{dq_a}{r_a} \quad (1)$$

We choose the origin O of the reference at the center of Q , We denote M the position of q and \vec{r} the corresponding vector. We put \vec{A} or a the position of the elementary charge dq , so the relative position of the point charge q is $\vec{r}_a = \vec{AM} = \vec{OM} - \vec{OA} = \vec{r} - \vec{a}$; Thus we write:

$$V(\vec{r}) = \int \frac{1}{4\pi\epsilon_0} \frac{dq_a}{\|\vec{r} - \vec{a}\|} = \int \frac{1}{4\pi\epsilon_0} dq_a \left[(\vec{r} - \vec{a})^2 \right]^{-1/2} \quad (2)$$

We use Taylor series to write the integral because we consider that the cluster's dimensions characterized by $\|\vec{a}\|$ are small compared to the whole system represented by $\|\vec{r}\|$:

$$V(\vec{r}) = \int \frac{1}{4\pi\epsilon_0} \frac{dq_a}{r} \left[\left(1 - 2\frac{\vec{r} \cdot \vec{a}}{r^2} + \frac{\vec{a}^2}{r^2} \right)^2 \right]^{-1/2} \quad (3)$$

we restrict ourselves to the 1st order of the multipole expansion:

$$\left[\left(1 - 2\frac{\vec{r} \cdot \vec{a}}{r^2} + \frac{\vec{a}^2}{r^2} \right)^2 \right]^{-1/2} = 1 + \frac{\vec{r} \cdot \vec{a}}{r^2} + O\left(\frac{\vec{a}^2}{r^2}\right) \quad (4)$$

and we get:

$$\begin{aligned} V(\vec{r}) &= \frac{1}{4\pi\epsilon_0} \left(\int \frac{dq_a}{r} + \int \frac{dq_a}{r} \frac{\vec{r} \cdot \vec{a}}{r^2} \right) \\ V(\vec{r}) &= \frac{1}{4\pi\epsilon_0} \left(\frac{1}{r} \int dq_a + \frac{1}{r^2} \int a \cos \theta_a dq_a \right) \end{aligned} \quad (5)$$

The volume element in the integral is the one around the position \vec{a} of dq_a , so the position \vec{r} of the point charge q is a constant according to this integration and the potential becomes:

$$V(r) = \frac{1}{4\pi\epsilon_0} \frac{Q}{r} + \frac{1}{4\pi\epsilon_0} \frac{D_r}{r^2} \quad (6)$$

D_r represents the dipole moment of the cluster and it's denoted with the indice r because one can consider it as a "radial" one or a dipole with moment always pointing to the test charge q [43]. The relation 6 is equivalent to the Kratzer expression defined by:

$$V_K(r) = d_e \left(\frac{r_e^2}{r^2} - \frac{2r_e}{r} \right) \quad (7)$$

where we consider that d_e is the dissociation energy and r_e is the equilibrium interatomic separation in the molecule [44, 45, 46].

We see that the potential is central and this may not reflect reality because the distribution is not usually perfectly symmetric. Therefore, we have to take into account the possible anisotropy in the charge distribution and to do this we consider that the positive and the negative centers of charges do not coincide in Q and we denote their positions \vec{a}_+ and \vec{a}_- . This two centers form an electric dipole representing this anisotropy and the potential of such a dipole is just $D_\theta \cos(\theta) r^{-2}$. The dipole moment D_θ is proportional to the distance between the two charge centers and the angle θ defines the orientation of the position \vec{r} according to the dipole axis defined by $\vec{a}_+ - \vec{a}_-$. We call this term the "angular" dipole to differentiate it from the "radial" one.

Adding all the terms together gives us the Coulomb potential with two dipoles and we call it a non-central (N-C) Kratzer potential:

$$V(r, \theta) = \frac{1}{4\pi\epsilon_0} \frac{Q}{r} + \frac{1}{4\pi\epsilon_0} \frac{D_r}{r^2} + \frac{1}{4\pi\epsilon_0} \frac{D_\theta \cos \theta}{r^2} \quad (8)$$

This expression takes into account the non-point character of an ionic system acting on an elementary charge and also the anisotropy in the charge distribution of this ion; It represents the first correction of the Coulomb effect of an extended charge.

3 2D Schrödinger Equation for N-C Kratzer Potential

We write the two-dimensional stationary Schrödinger equation for a point charge in the potential 8 and we use the polar coordinates for the Laplacian:

$$\left[\frac{-\hbar^2}{2\mu} \left(\frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{1}{r^2} \frac{\partial^2}{\partial \theta^2} \right) + \frac{q}{4\pi\epsilon_0} \left(\frac{Q}{r} + \frac{D_r}{r^2} + \frac{D_\theta \cos \theta}{r^2} \right) \right] \psi = E\psi \quad (9)$$

We put the equation in the more convenient following form:

$$\left[\left(\frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} - \frac{2\mu q Q}{4\pi\epsilon_0\hbar^2} \frac{1}{r} - \frac{2\mu q D_r}{4\pi\epsilon_0\hbar^2} \frac{1}{r^2} \right) + \frac{1}{r^2} \left(\frac{\partial^2}{\partial \theta^2} - \frac{2\mu q D_\theta}{4\pi\epsilon_0\hbar^2} \cos(\theta) \right) \right] \psi = \frac{-2\mu E}{\hbar^2} \psi \quad (10)$$

and we write the solution as $\psi(r, \theta) = r^{-1/2} R(r) \Theta(\theta)$ to get two separate equations:

$$\left(\frac{\partial^2}{\partial \theta^2} - E_\theta - \frac{2\mu q D_\theta}{4\pi\epsilon_0\hbar^2} \cos(\theta) \right) \Theta(\theta) = 0 \quad (11a)$$

$$\left[\frac{\partial^2}{\partial r^2} + \left(E_\theta + \frac{1}{4} - \frac{2\mu q D_r}{4\pi\epsilon_0\hbar^2} \right) \frac{1}{r^2} - \frac{2\mu q Q}{4\pi\epsilon_0\hbar^2} \frac{1}{r} + \frac{2\mu E}{\hbar^2} \right] R(r) = 0 \quad (11b)$$

We have to solve the angular equation 11a to find the constants E_θ and then we use these angular eigenvalues to solve the radial equation 11b; this will give us the energies E of the system and also the wave functions $\psi(r, \theta)$.

3.1 Solution of Angular Equation

The angular equation can easily be written as a Mathieu equation [47] by defining $\theta = 2z$, $a = -4E_\theta$ and $p = \mu q D_\theta / (\pi\epsilon_0\hbar^2)$:

$$\frac{\partial^2 \Theta(z)}{\partial z^2} + (a - 2p \cos 2z) \Theta(z) = 0 \quad (12)$$

The solutions of this equation are the cosine-elliptic $ce_{2m}(z)$ and the sine-elliptic $se_{2m+2}(z)$ functions where m is a natural number [48]. The solutions of the Mathieu equation are periodic because z has π as a period and this lead us to consider the Floquet's theorem [49] or the Bloch's theorem [50]. They stipulate that, for a given value of the parameter p , the solution is periodic only for certain values of the other parameter a ; They are called characteristic values and denoted $a(2m, p)$ or $a_{2m}(p)$ for the cosine solutions and $b(2m, p)$ or $b_{2m}(p)$ for the sine ones.

There is no analytical expression for the Mathieu characteristic values $a_{2m}(p)$ and $b_{2m}(p)$, so they are usually given either numerically or graphically. This doesn't preclude that we can write approximate analytical expressions for small and large values of p [51]. For small values of p , we can express a and b for $m > 3$ as ($l = 4m^2 - 1$):

$$a_{2m} = b_{2m} \approx 4m^2 + \frac{1}{2l} p^2 + \frac{20m^2 + 7}{32l^3(l-3)} p^4 + \frac{36m^4 + 232m^2 + 29}{64l^5(l-3)(l-8)} p^6 + \mathcal{O}(p^8) \quad (13)$$

The coefficients of the power series of $a_{2m}(p)$ and $b_{2m}(p)$ are the same until the terms in p^{2m-2} .

We have similar polynomials for $m \leq 3$ but with different coefficients for the a 's and the b 's. We note here that there is no sine solutions for $m = 0$ and so there is no $b(m = 0)$.

For large values of p , we get another polynomial ($k = 2n + 1$):

$$a_n = b_{n+1} \approx -2p + 2kp^{1/2} - \frac{1}{8} [k^2 + 1] - [k^3 + 3k] \frac{1}{2^7 p^{1/2}} - [5k^4 + 34k^2 + 9] \frac{1}{2^{12} p} + \mathcal{O}(p^{-3/2}) \quad (14)$$

From now on to simplify the writing, we will use the same symbol $c_{2m}(p)$ for both the characteristic values $a_{2m}(p)$ and $b_{2m}(p)$.

Using the definitions $a = -4E_\theta$ and $p = \mu q D_\theta / (\pi \varepsilon_0 \hbar^2)$ together with the relation of Mathieu parameters enable us to write the angular eigenstates as a function of the angular moment:

$$E_\theta^{(2m)} = -\frac{1}{4} c_{2m} \left(\frac{\mu q}{\pi \varepsilon_0 \hbar^2} D_\theta \right) \quad (15)$$

From 13, we see that for small values of D_θ (or p), the angular solution can be put in the form:

$$E_\theta^{(2m)} = -m^2 + P_m(D_\theta) \quad (16)$$

where $P_m(D_\theta)$ is a polynomial in terms of even power of D_θ starting from 2. This expression will be used to validate our solutions in the limit $D_\theta \rightarrow 0$.

3.2 Solution of Radial Equation

Using the asymptotic behavior of the solutions to solve the radial equation 11b, we start with the transformation $R(r) = r^\lambda e^{-\beta r} f(r)$, so we get a new differential equation for $f(r)$:

$$\left[r \frac{d^2}{dr^2} + 2(\lambda - \beta r) \frac{d}{dr} - 2 \left(\frac{\mu q Q}{4\pi \varepsilon_0 \hbar^2} + \lambda \beta \right) \right] f(r) = 0 \quad (17)$$

Because parameters β and λ are free ones, we chose them as follows to simplify the equation:

$$\beta^2 = -\frac{2\mu E}{\hbar^2} \text{ \& } \lambda(\lambda - 1) + E_\theta^{(m)} - \frac{2\mu q D_r}{4\pi \varepsilon_0 \hbar^2} + \frac{1}{4} = 0 \quad (18)$$

As $\psi(r, \theta)$ must be convergent, the accepted solutions for these parameters that let $R(r)$ non-singular at $r = 0$ are:

$$\beta = \sqrt{-\frac{2\mu E}{\hbar^2}} \text{ \& } \lambda = \frac{1}{2} + \sqrt{-E_\theta^{(m)} + \frac{2\mu q D_r}{4\pi \varepsilon_0 \hbar^2}} \quad (19)$$

We can reduce 17 to a confluent hypergeometric type by defining a new variable $z = 2\beta r$:

$$\left[z \frac{d^2}{dz^2} + (2\lambda - z) \frac{d}{dz} - \left(\frac{\mu q Q}{4\pi \varepsilon_0 \hbar^2} \frac{1}{\beta} + \lambda \right) \right] f(z) = 0 \quad (20)$$

The solution here is just the confluent hypergeometric function:

$$f(z) = N_1 F_1 \left(\lambda + \frac{\mu q Q}{4\pi \varepsilon_0 \hbar^2} \beta^{-1}, 2\lambda, 2\beta r \right) \quad (21)$$

and the wave function of the system follows:

$$\psi(r, \theta) = N r^{\lambda - \frac{1}{2}} e^{-\beta r} \Theta(\theta)_1 F_1 \left(\lambda + \frac{\mu q Q}{4\pi \varepsilon_0 \hbar^2} \beta^{-1}, 2\lambda, 2\beta r \right) \quad (22)$$

We compute the normalization constant N from the condition $\int |\psi(r, \theta)|^2 r dr d\theta = 1$ and we recall that Mathieu functions are normalized by definition to π [48]:

$$N = \frac{2^\lambda \beta^{\lambda + \frac{1}{2}}}{(2\lambda - 1)! \pi} \left(\frac{(n_r + 2\lambda - 1)!}{n_r! (n_r + 2\lambda)!} \right)^{1/2} \quad (23)$$

Here we have used Laguerre polynomials of degree n_r [48]:

$$L_{n_r}^{2\lambda-1}(2\beta r) = \frac{(n_r + 2\lambda - 1)!}{n_r!(2\lambda - 1)!} {}_1F_1(-n_r, 2\lambda, 2\beta r) \quad (24)$$

and the identity [48]:

$$\int_0^\infty e^{-q} q^{k+1} [L_n^k(q)]^2 dq = \frac{(n+k)!}{n!} (2n+k+1) \quad (25)$$

One can also use the Appell's double series F_2 to get the same normalized constant [52].

From the asymptotic behavior of the confluent series ($r \rightarrow \infty \implies {}_1F_1 = 0$) which leads to $\psi \rightarrow 0$ for $r \rightarrow \infty$, we find the condition of quantization:

$$\lambda + \frac{\mu q Q}{4\pi\epsilon_0 \hbar^2} \beta^{-1} = -n_r, \quad n_r = 0, 1, 2, \dots \quad (26)$$

and we use this condition with the relation 19 to obtain the spectrum of the discrete energy levels of our system:

$$E_{n_r, m} = - \left[\left(\frac{4\pi\epsilon_0 \hbar^2}{2\mu q Q} \sqrt{\frac{\hbar^2}{2\mu}} \right) \left(n_r + \frac{1}{2} + \sqrt{-E_\theta^{(m)} + \frac{2\mu q D_r}{4\pi\epsilon_0 \hbar^2}} \right) \right]^{-2} \quad (27)$$

Starting from this expression, we can get the solutions of the usual 2D Kratzer potential [53, 54] by taking the limit $D_\theta \rightarrow 0$, so $P_m(D_\theta) \rightarrow 0$ which lead to $E_\theta^{(m)} = -m^2$ from 16:

$$E_{n_r, m}^{(Kratzer)} = - \left[\left(\frac{4\pi\epsilon_0 \hbar^2}{2\mu q Q} \sqrt{\frac{\hbar^2}{2\mu}} \right) \left(n_r + \frac{1}{2} + \sqrt{m^2 + \frac{2\mu q D_r}{4\pi\epsilon_0 \hbar^2}} \right) \right]^{-2} \quad (28)$$

If we add the limit $D_r \rightarrow 0$, we find the 2D Coulomb solutions [55, 56]:

$$E_{n_r, m}^{(Coulomb)} = - \left(\frac{4\pi\epsilon_0 \hbar^2}{2\mu q Q} \sqrt{\frac{\hbar^2}{2\mu}} \right) \left(n_r + |m| + \frac{1}{2} \right)^{-2} \quad (29)$$

Comparing with these results, we use the notations of the 2D hydrogen atom $n = n_r + |m|$ and we write the energy eigenvalues of the system ($E_\theta^{(m)}$ is replaced from 15):

$$E_{n, m} = - \left[\left(\frac{4\pi\epsilon_0 \hbar^2}{\mu q Q} \sqrt{\frac{\hbar^2}{2\mu}} \right) \left(n - |m| + \frac{1}{2} + \sqrt{\frac{1}{4} c_{2m} \left(\frac{\mu q}{\pi\epsilon_0 \hbar^2} D_\theta \right) + \frac{2\mu q D_r}{4\pi\epsilon_0 \hbar^2}} \right) \right]^{-2} \quad (30)$$

For our numerical computations, we use the same considerations as those of molecular systems. So we choose the extended charge as a positive ion and the point charge is an electron, and we get two opposite charges equal in magnitude $q = -Q = -e$. We use the Hartree atomic units where $\hbar = e = \mu = 4\pi\epsilon_0 = 1$ and the energies become:

$$E_{n, m} = -2 \left(n - |m| + \frac{1}{2} + \sqrt{\frac{1}{4} c_{2m} (4D_\theta) + 2D_r} \right)^{-2} \quad (31)$$

Figure 1: $E(1,0)$ vs D_{θ} for $D_r = 0.3, 0.6$ and 0.9

Figure 2: $E(n,0)$ vs D_{θ} for $D_r = 0.5$ and $n = 1, 2, 3, 4$ and 5

We note in this relation of the energies, that the angular dipole removes the degeneracy of the sine and cosine states for $m \neq 0$. This degeneracy is restored when the angular momentum vanishes since the two Mathieu's characteristic parameters a_{2m} and b_{2m} have the same limit in this case 13. The result restores those of the ordinary Kratzer potential (or Coulomb potential) where the wave function of each level $E_{n,m}$ is a linear combination of both sine and cosine states. For the s -states ($m = 0$), we only find the cosine solutions because the sine solutions are absent in this case.

Through the expression 31, we see that the behavior of the energies follows essentially that of the Mathieu's parameters and thus the angular momentum, whereas the effect of the radial moment merely shifts the energies to larger or smaller values according to its sign. The sign of the angular momentum doesn't affect the results because the parameters c_{2m} are even functions. Of course, the energies increase with the n and decrease with the m but the main effect of the m is to extend the allowed region for the values of the angular momentum. We also note that the energies corresponding to the $ce_{2m}(z)$ solutions are larger than the $se_{2m}(z)$ ones and this is caused by the fact that the a_{2m} are bigger than the b_{2m} . (see figures 1234 where dashed lines are for sine solutions).

The main remark that can be drawn from 31 is that there is an essential condition for the system to have bound states:

$$\frac{1}{4}c_{2m}(4D_{\theta}) + 2D_r > 0 \quad (32)$$

Figure 3: $E(n, 1)$ vs D_{θ} for $D_r = 0.5$ and $n = 1, 2, 3$

Figure 4: $E(3, m)$ vs D_{θ} for $D_r = 0.5$ and $m = 0, 1, 2$ and 3

Figure 5: Forbidden regions of D_r and D_θ for $m = 0, 1, 2$

$D_r \backslash m$	0	1	2	3
-0.3	—	1.925	8.004	17.462
+0.0	—	2.662	8.679	18.132
+0.3	0.543	3.284	9.323	18.782
+0.6	0.923	3.851	9.942	19.420
+0.9	1.284	4.385	10.543	20.046

Table 1: Critical values for D_θ

This condition shows that there are critical values for the two dipole moments, depending only on the quantum number m , that make the corresponding bound state no longer exists. If we put $D_r = 0$, all the s -states ($m = 0$) are absent because the critical value for D_θ here is zero. We say here that the presence of radial dipole is essential for s -states to exist, otherwise the angular momentum make them disappear. The same observation is made concerning the other m -states ($m > 0$), but the critical value of the angular momentum is positive in all these cases and these critical values increase with m and also with the values of D_r (fig5). This critical value is smaller for the sine states and this causes the spread of the spectrum of these states to be less than that of the cosine states on the axis of the angular momentum (figures 4 and 5 where the indice a is for cosine solutions and the b for sine ones). So the radial dipole has two effects, it moves the energies to higher values while enlarging the region of possible values of angular momentum (fig6).

The table 1 shows the critical values of D_θ for different values of D_r and m when we consider cosine solutions.

4 2D Relativistic Equations for N-C Kratzer Potential

We start by considering the general case of the non-central potential $V(r, \theta) = V(r) + V(\theta)/r^2$ in 2D systems. There are no analytical solutions for the Klein-Gordon and Dirac equations for this potentials, but both equations reduce to the same Schrödinger type equation if we consider the cases of spin and pseudo-spin symmetries. These symmetries have been considered for the first time in shell models of nuclear physics, where protons and neutrons are treated in the same way [57, 58]. Then they became essential symmetries in relativistic theories [59, 60] and since then their studies have increased considerably in these systems [61]. These symmetries were also used to study the relativistic theory of both central and ring-shaped Kratzer potentials [62, 63].

We will consider the Klein-Gordon equation first then the Dirac equation and we start with the spin symmetry case and then the pseudo-spin one.

4.1 Klein-Gordon Equation

The stationary Klein-Gordon equation for a single charge q in both scalar $S(\vec{r})$ and vector $U(\vec{r})$ potentials is written as:

$$\left[c^2 p^2 - (E - U(\vec{r}))^2 + (\mu c^2 + S(\vec{r}))^2 \right] \psi(\vec{r}) = 0 \quad (33)$$

The denominations vector potential is used for the energy U but it isn't vectorial in any way. The vectorial potential $\vec{A}(\vec{r})$ comes with the momentum \vec{p} and is zero in our case.

Spin or pseudo-spin symmetry are defined by $S(\vec{r}) = \pm U(\vec{r})$ and the two reduce the wave equation 33 to the following second order equation:

$$\left[c^2 p^2 + 2(E \pm \mu c^2) U(\vec{r}) - (E^2 - \mu^2 c^4) \right] \psi(\vec{r}) = 0 \quad (34)$$

The equation is easily written as a Schrödinger equation with the transformations:

$$\left(\frac{E}{\mu c^2} \pm 1 \right) U(\vec{r}) \longrightarrow U(\vec{r}) \quad \& \quad \frac{1}{2} \left(\frac{E^2}{\mu c^2} - \mu c^2 \right) \longrightarrow E \quad (35)$$

Here we get a system where the potential depends on the energy. These energy dependant potentials have been considered for a long time when the relativistic effects began to be taken into account in quantum physics [64, 65, 66]. Recently a lot of works were devoted to this type of potentials [67, 68, 69] (and the references therein).

4.2 Dirac Equation

We consider now the stationary Dirac equation:

$$[c\vec{\alpha} \cdot \vec{p} + \beta (\mu c^2 + S(\vec{r})) - (E - U(\vec{r}))] \psi(\vec{r}) = 0 \quad (36)$$

and we use the Pauli-Dirac representation:

$$\vec{p} = -i\hbar\vec{\nabla}; \quad \vec{\alpha} = \begin{pmatrix} 0 & \vec{\sigma} \\ \vec{\sigma} & 0 \end{pmatrix}; \quad \beta = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix} \quad (37)$$

where $\vec{\sigma}$ is the vector of Pauli matrices and I is the 2×2 identity matrix.

We write the wave function as a two component vector of the Pauli-Dirac representation:

$$\psi(\vec{r}) = \begin{pmatrix} \varphi(\vec{r}) \\ \chi(\vec{r}) \end{pmatrix} \quad (38)$$

and we obtain two coupled differential equations:

$$\begin{aligned} c\vec{\alpha} \cdot \vec{p} \chi(\vec{r}) &= [E - U(\vec{r}) - \mu c^2 - S(\vec{r})] \varphi(\vec{r}) \\ c\vec{\alpha} \cdot \vec{p} \varphi(\vec{r}) &= [E - U(\vec{r}) + \mu c^2 + S(\vec{r})] \chi(\vec{r}) \end{aligned} \quad (39)$$

If we consider spin symmetry, where $S(\vec{r}) = U(\vec{r})$, the system is decoupled by writing:

$$\chi(\vec{r}) = \frac{c\vec{\alpha} \cdot \vec{p}}{E + \mu c^2} \varphi(\vec{r}) \quad (40)$$

and we get the following second order equation:

$$[c^2 p^2 + 2(E + \mu c^2)U(\vec{r}) - (E^2 - \mu^2 c^4)] \varphi(\vec{r}) = 0 \quad (41)$$

In the same way, using pseudo-spin symmetry relation $S(\vec{r}) = -U(\vec{r})$, we write:

$$\varphi(\vec{r}) = \frac{c\vec{\alpha} \cdot \vec{p}}{E - \mu c^2} \chi(\vec{r}) \quad (42)$$

The system is then decoupled and we get the following second order equation:

$$[c^2 p^2 + 2(E - \mu c^2)U(\vec{r}) - (E^2 - \mu^2 c^4)] \chi(\vec{r}) = 0 \quad (43)$$

We see that the two equations 39 and 41 are equivalent to the equations 34.

We start by studying the spin-symmetry case and then we deduce the solutions for pseudo-spin symmetry by using the transformation $E \rightarrow -E$ (and we add $\chi \leftrightarrow \varphi$ for Dirac equation).

5 Solutions of the Schrödinger Type Equation

5.1 The Spin Symmetry Case

The Schrödinger type equation for the spin-symmetry case is 39:

$$[c^2 p^2 + 2(E + \mu c^2) U(\vec{r}) - (E^2 - \mu^2 c^4)] \psi(\vec{r}) = 0 \quad (44)$$

with the potential energy:

$$U(r, \theta) = eV(r, \theta) = -Z \frac{e^2}{r} + e \frac{D_r}{r^2} + e \frac{D_\theta \cos \theta}{r^2} \quad (45)$$

We use the polar coordinates and the same transformation as before $\psi(r, \theta) = r^{-1/2} R(r) \Theta(\theta)$ to get two separate equations:

$$\left(\frac{d^2}{d\theta^2} - 2 \frac{E + \mu c^2}{\hbar^2 c^2} e D \cos \theta \right) \Theta(\theta) = E_\theta \Theta(\theta) \quad (46a)$$

$$\left[\frac{d^2}{dr^2} + \left(E_\theta - 2 \frac{E + \mu c^2}{\hbar^2 c^2} e D_r + \frac{1}{4} \right) \frac{1}{r^2} + 2 \frac{E + \mu c^2}{\hbar^2 c^2} Z e^2 \frac{1}{r} \right] R(r) = - \frac{E^2 - \mu^2 c^4}{\hbar^2 c^2} R(r) \quad (46b)$$

These equations are equivalent to those of the non-relativistic case 11a and 11b but we have to consider the shifts 35. So we use the same steps to solve 46a and 46b and we get two new eigenvalues relations coming from both angular and radial equations:

$$E_\theta^{(2m)} = -\frac{1}{4} c_{2m} \left(4 \frac{E_{n,m} + 2\mu c^2}{\hbar^2 c^2} e D_\theta \right) \quad (47a)$$

$$E_\theta^{(2m)} = 2 \frac{E_{n,m} + 2\mu c^2}{\hbar^2 c^2} e D_r - \left(n - |m| + \frac{1}{2} - Z \alpha \frac{E_{n,m} + 2\mu c^2}{\sqrt{\mu^2 c^4 - (E_{n,m} + \mu c^2)^2}} \right)^2 \quad (47b)$$

We used the non-relativistic energies $E - \mu c^2$ and we denoted them $E_{n_r, m}$ or $E_{n, m}$ where $n = n_r + |m|$ (α is the fine structure constant).

For the wavefunctions we get the same relation as 22 but with the new parameters β and λ :

$$\beta^2 = -\frac{E^2 - \mu^2 c^4}{\hbar^2 c^2} \text{ \& } \lambda = \frac{1}{2} + \sqrt{-E_\theta^{(2m)} + 2 \frac{E + \mu c^2}{\hbar^2 c^2} e D_r} \quad (48)$$

The same relations are used in the expression of the normalization constant 23.

The non-relativistic limit is obtained by neglecting the term $E_{n, m}$ beside the factor $2\mu c^2$ in 47a, then we replace in 47b and we use the Taylor series according to α^2 :

$$E_{n, m} = -\frac{8\mu c^2 Z \alpha^2}{\left(2n_r + 2\sqrt{-E_\theta^{(2m)} + 4 \frac{\mu \alpha c}{e \hbar} D_r} + 1 \right)^2} + \frac{32\mu c^2 Z^2 \alpha^4}{\left(2n_r + 2\sqrt{-E_\theta^{(2m)} + 4 \frac{\mu \alpha c}{e \hbar} D_r} + 1 \right)^4} + O(\alpha^6) \quad (49)$$

This result generalizes the one found in the non-relativistic case 31 and the ones found for non-relativistic non-pure dipole by putting $D_r = 0$ [23]. One can also found the energies of the

relativistic Kratzer potential using $D_\theta = 0$ or $E_\theta^{(2m)} = -m^2$ [71]. The two conditions $D_r = 0$ and $D_\theta = 0$ together give the energies of the Coulomb potential [72, 2].

We use the Hartree units ($\mu = e = 4\pi\epsilon_0 = \hbar = 1$ and $c = 1/\alpha$) for the numerical computations and we apply for $Z = 1$:

$$E_\theta^{(2m)} = -\frac{1}{4}c_{2m} (4 (E_{n,m}\alpha^2 + 2) D_\theta) \quad (50a)$$

$$E_\theta^{(2m)} = 2 (E_{n,m}\alpha^2 + 2) D_r - \left(n - |m| + \frac{1}{2} - Z\alpha \frac{E_{n,m}\alpha^2 + 2}{\sqrt{1 - (E_{n,m}\alpha^2 + 1)^2}} \right)^2 \quad (50b)$$

And the non-relativistic limit becomes:

$$E_{n,m} = -\frac{2}{\left(n_r + \frac{1}{2} + \sqrt{\frac{1}{4}c_{2m}(8D_\theta) + 4D_r}\right)^2} + \frac{8\alpha^2}{\left(n_r + \frac{1}{2} + \sqrt{\frac{1}{4}c_{2m}(8D_\theta) + 4D_r}\right)^4} + O(\alpha^6) \quad (51)$$

We see here that 51 differs from 31 by a factor of 2 in front of the dipoles moments D_θ and D_r . This factor comes from the addition of scalar and vector potentials in spin-symmetry case which gives a Schrödinger equation with a potential $2V$ instead of V in ordinary theory [73, 74].

We cannot solve the system of equations 50a and 50b analytically because Mathieu characteristics don't have inverse functions. Nevertheless, this system can be solved using graphical methods by seeking the intersection points of the graphs representing the two equations.

Equation 50b shows that E_θ has an inverted and non-symmetric parabolic shape and the intersection point with the plots representing 50a can not exceed its maximum; This limitation gives the critical dipole moments for each quantum numbers. Unlike the non-relativistic case where D_{crit} depends only of the value of m , its values are here weakly dependent on the other quantum number n . This dependence on n comes from the presence of the energies $E_{n,m}$ with D in the angular eigenvalues 50a and these energies depend on n as can be seen from 50b. The weakness of this dependence comes from the presence of the factor α^2 with $E_{n,m}$.

The study of the dependence of the energies according to the values of D_θ shows that this moment increases the energies of the system to a maximum value and then its effect is transformed into a decrease thereof; This shape follows that of the c_{2m} and it is common to all levels but decreases with increasing n . The effect of D_r can be summarized in a shift of the energies to larger or smaller values depending on its sign (Figures 7 and 8).

We mention here that the non-relativistic approximation 51 can be used as a quasi-analytical solution since it gives results in excellent agreement with those computed numerically (fig9).

5.2 The Pseudo-Spin Symmetry Case

The Schrödinger type equation for the pseudo-spin-symmetry case is 43:

$$[c^2 p^2 + 2 (E - Mc^2) U(\vec{r}) - (E^2 - M^2 c^4)] \psi(\vec{r}) = 0 \quad (52)$$

Following the same procedure as that of the spin case, we end up with two relations that come from the eigenvalues of radial and angular equations. We find the following relations for the non-

Figure 7: Relativistic $E(n, 1)$ vs D_θ for $D_r = 0.3$ and $n = 1, 2$ and 3

Figure 8: $E(2, 1)$ vs D_θ for $D_r = 0, 0.3$ and 0.6

Figure 9: Relativistic and Non-Relativistic $E(1, 1)$, $E(2, 1)$ and $E(3, 1)$ vs D_θ for $D_r = 0.3$

relativistic energies of the system $E_{n,m} = E - \mu c^2$ in Hartree units:

$$E_{\theta}^{(2m)} = -\frac{1}{4}c_{2m} (4E_{n,m}\alpha^2 D) \quad (53a)$$

$$E_{\theta}^{(2m)} = 2E_{n,m}\alpha^2 D_r - \left(n - |m| + \frac{1}{2} - Z\alpha \frac{E_{n,m}\alpha^2}{\sqrt{1 - (E_{n,m}\alpha^2 + 1)^2}} \right)^2 \quad (53b)$$

The main difference between these equations and those of the spin symmetry case (50a, 50b) is the absence of factor 2 in front of the α^2 term. This means that the graphs representing the radial solution 53b are almost linear and that the parameter p inside the Mathieu characteristics 53a is very small. Our calculations show that we have to consider very large radial moments ($D_r > 100a.u.$) to find solutions higher than $-200a.u.$. These results are outside the regions of interest for the energies of the atomic systems and support those of works that consider only the case of spin symmetry in their studies [71, 74, 75].

6 Discussion

In this work, we studied the potential $V(r, \theta) = Qr^{-1} + D_r r^{-2} + D_{\theta} \cos(\theta) r^{-2}$ for $2D$ quantum systems in both non-relativistic and relativistic cases. We solved the Schrödinger equation analytically and studied the relativistic spectrum for Klein-Gordon and Dirac equations in both spin and pseudo-spin symmetry cases.

In the non-relativistic case, the spectrum shows that the energies follow mainly the behavior of Mathieu's characteristic parameters and thus the angular moment D_{θ} , whereas the effect of the radial moment D_r is merely a shift in these energies to larger or smaller values according to its sign. We have showed also that there is an essential condition for bound states to exist, which is: $c_{2m}(4D_{\theta}) + 8D_r > 0$. This condition imposes a critical value for the angular moment D_{θ} , depending on the value of m , otherwise the corresponding bound state disappears. These critical values of D_{θ} depend also on the value of D_r and the negative value of this moment which makes $c_{2m}(4D_{\theta}) + 8D_r = 0$ is also a critical value for the radial moment. So we see that by increasing, the radial dipole displaces the energies towards the larger values while widening the region of the possible values of the angular moment.

In the relativistic cases the eigenfunctions are determined analytically but the energies can only be calculated using graphical methods. Only the spin symmetry has given results corresponding to atomic systems. The behavior of the energies is the same as that of the Schrödinger spectrum but it is shifted because the Schrödinger type equation of the relativistic systems has $2V$ as a potential instead of the potential V in the ordinary Schrödinger equation. We also note that the critical values of the dipole moments D_r and D_{θ} depend on the two quantum numbers n and m in the relativistic case instead of just m in the case of non-relativistic systems.

We have found that the angular term removes the degeneracy found in the $\exp(im\theta)$ part of the solutions for central potentials. This is equivalent to the effect of a constant magnetic field in $3D$ systems, where its action removes the degeneracy of the $\exp(im\varphi)$ solutions too. In both cases, the privileged direction of the interaction (dipole axis in $2D$ and field direction in $3D$) removes the degeneracy that existed due to the isotropy of the action before.

Acknowledgement

The authors would like to thank Pr Y. Delenda for his help in writing this work and also Dr. Y. Gindikin for his comment which has enriched it.
