COMPONENTWISE LINEARITY OF PROJECTIVE VARIETIES WITH ALMOST MAXIMAL DEGREE

ĐOÀN TRUNG CƯỜNG AND SIJONG KWAK

Abstract. The degree of a projective subscheme has an upper bound in terms of the codimension and the reduction number. If a projective variety has an almost maximal degree, that is, the degree equals to the upper bound minus one, then its Betti table has been described explicitly. We build on this work by showing that for most of such varieties, the defining ideals are componentwise linear and in particular the componentwise linearity is suitable for classifying the Betti tables of such varieties. As an application, we compute the Betti table of all varieties with almost maximal degree and componentwise linear resolution.

1. Introduction

Let \( X \subset \mathbb{P}^{n+e} \) be a non-degenerate closed subscheme of dimension \( n \) and codimension \( e \) over an infinite field \( k \). Let \( I_X \) be the saturated homogeneous defining ideal and \( R_X = k[x_0, \ldots, x_{n+e}]/I_X \) be the homogeneous coordinate ring of \( X \).

Among the important numerical invariants of \( X \) are the degree \( \deg(X) \), the Castelnuovo-Mumford regularity and the reduction number \( r(r(X)) \) (which is defined as the reduction number of \( R_X \)). In particular, the reduction number together with the codimension provides an upper bound for the degree, namely,

\[
\deg(X) \leq \binom{e + r}{r}.
\]

Those projective subschemes attaining the degree upper bound are exactly arithmetically Cohen-Macaulay subschemes with \( (r + 1) \)-linear free resolution (see [2, Theorem 3.1]). The next to the extremal case has been also investigated. We say that \( X \) is a projective subscheme of almost maximal degree if \( \deg(X) = \binom{e + r}{r} - 1 \). As one of the main results of [2], the authors have shown that if a projective variety (i.e., a reduced and irreducible subscheme) is of almost maximal degree, then its arithmetic depth, i.e., the depth of \( R_X \), is at least the dimension of the variety. So it is either arithmetically Cohen-Macaulay (depth\( (R_X) = n + 1 \)) or non-arithmetically Cohen-Macaulay with depth\( (R_X) = n \). This leads to an explicit description of the Betti table of such varieties (see [2, Theorem 5.4, Proposition 4.6]).

In this paper we investigate the structure of the saturated defining ideal of projective varieties of almost maximal degree and show that the componentwise linearity is suitable for our purpose.

Definition 1.1. A homogeneous ideal \( I \) is componentwise linear if the ideal \( I_{(d)} \) generated by degree \( d \) homogeneous polynomials in \( I \) has a linear resolution for all \( d \).

Herzog and Hibi introduced componentwise linear ideals in [8] as a generalization of linear ideals. They showed that a Stanley-Reisner ideal \( I_\Delta \) is componentwise linear if and only if the Alexander dual \( \Delta^* \) is sequentially Cohen-Macaulay, generalizing a well-known theorem of Eagon-Reisner on the equivalence between linearity of \( I_\Delta \) and Cohen-Macaulay of \( \Delta^* \). While componentwise linear monomial ideals are studied extensively by many authors, componentwise linear prime ideals, so varieties, have not been understood well.

In literature, componentwise linearity of curves has been considered by several authors. For examples, the tetrahedral curves with componentwise linear resolutions are characterized by Francisco-Migliore-Nagel in [11, Corollary 4.9]. Almost all curves with maximal Hartshorne-Rao module with respect to their degree and genus are componentwise linear in characteristic zero (see Nagel [11, Corollary 6.2]). A projective subscheme of maximal degree has a linear resolution (see [2, Theorem 3.1]), so it is componentwise linear. By [2, Theorem 4.1], an arithmetically Cohen-Macaulay projective subscheme \( X \) has an almost...
maximal degree if and only if \( \dim_k(\mathcal{I}_X) = 1 \) and the truncated ideal \( (\mathcal{I}_X)_{\geq r+1} \) has a linear resolution where \( r \) is the reduction number of \( R_X \). Consequently \( X \) has a componentwise linear resolution.

Our current research is motivated by the following question of Satoshi Murai.

**Question 1.2.** Are the saturated defining ideals of projective varieties of almost maximal degree componentwise linear?

The main aim of this paper is to give a complete answer to Question 1.2. By the discussion above, it suffices to consider non-arithmetically Cohen-Macaulay projective varieties of almost maximal degree. It is shown by [2, Theorem 5.1] that these varieties have an almost maximal arithmetic depth, say, \( \text{depth}(R_X) = n = \dim(X) \). This property together with the almost maximality of degree enables one to describe explicitly their Betti tables. We will show that most of them have componentwise linear resolutions and at the same time characterize those without componentwise linear resolutions (see Theorem 3.4). We actually enlarge our category to include not only varieties of almost maximal degree but all projective subschemes of almost maximal degree and almost maximal arithmetic depth.

About the structure of the paper, in Section 2 we characterize projective subschemes of almost maximal degree and arithmetic depth in terms of their initial ideal and compute their Betti tables. Componentwise linearity is studied in Section 3 where we present the main result characterizing componentwise linearity of projective subschemes of almost maximal degree and arithmetic depth.

Through this paper, \( k \) is an infinite field and a projective variety is a reduced and irreducible projective subscheme. The computation in this paper is established by using Macaulay 2 (cf. [5]).

## 2. Projective Subschemes of Almost Maximal Degree and Arithmetic Depth

Let \( X \subset \mathbb{P}^{n+e} \) be a non-degenerate projective subscheme of dimension \( n \) and codimension \( e \) over the field \( k \). Denote by \( S_i \) the polynomial ring \( k[x_1, \ldots, x_{n+e}] \) for \( n, e > 0 \) and \( i = 0, 1, \ldots, n + e \). Let \( I_X \subset S_0 \) be the saturated homogeneous defining ideal of \( X \) and \( R_X = S_0/I_X \) be the homogeneous coordinate ring.

Let \( S \) be a \( k \)-subalgebra of \( R_X \) generated by linear forms such that \( S \hookrightarrow R_X \) is a Noether normalization, i.e., \( S \) is a polynomial \( k \)-algebra and \( R_X \) is a finitely generated \( S \)-module. The reduction number of \( R_X \) with respect to \( S \) is the supremum of degree of all homogeneous minimal generators of \( R_X \) as an \( S \)-module, denoted \( r_S(R) \). The reduction number of \( R_X \) is the least \( r_S(R) \) where \( S \) runs over all Noether normalization (see [13]). This number, say \( r \), is also called the reduction number of \( X \).

One might change the variables by a linear transformation such that \( S_e = k[x_e, \ldots, x_{n+e}] \to R_X \) is a Noether normalization of \( R_X \) whose reduction number is exactly \( r \). Then we have the upper bounds for degree \( \text{deg}(X) = \text{deg}(R_X) \leq \binom{n+r}{r} \). On the other hand, we always have the upper bound of the arithmetic depth of \( X \), namely, \( \text{depth}(R_X) \leq n + 1 \).

We say that \( X \) is a subscheme of maximal degree if \( \text{deg}(X) = \binom{n+r}{r} \) and that \( X \) is of almost maximal degree if \( \text{deg}(X) = \binom{n+r}{r} - 1 \). If \( \text{depth}(R_X) = n + 1 \) then \( X \) is arithmetically Cohen-Macaulay. If \( \text{depth}(R_X) = n \) then we say that \( X \) has an almost maximal arithmetic depth. A projective variety of maximal degree is always arithmetically Cohen-Macaulay (see, for example, [2, Theorem 3.1]). If a projective variety \( X \) is of almost maximal degree then \( \text{depth}(R_X) \geq \dim(X) \) (see [2, Theorem 5.1]), so \( X \) has at least an almost maximal arithmetic depth. In the sequel, instead of considering only varieties, we enlarge our category to include all projective subschemes with almost maximal degree and almost maximal arithmetic depth.

The first result of this section is a characterization of projective subschemes \( X \) of almost maximal degree and arithmetic depth in terms of their initial ideals.

**Theorem 2.1** (Initial ideal). Let \( X \subset \mathbb{P}^{n+e} \) be a non-degenerate closed subscheme of dimension \( n \), codimension \( e \) and reduction number \( r \). Let \( I_X \subset S_0 \) be the saturated defining ideal of \( X \) and \( R_X = S_0/I_X \). Assume that \( S = S_e = k[x_e, \ldots, x_{n+e}] \) is a Noether normalization of \( R_X \) with reduction number \( r_{S}(R_X) = r \). We fix the degree reverse lexicographic order on the monomials of \( S_0 \). The following statements are equivalent

(a) \( X \) is a subscheme of almost maximal degree and almost maximal arithmetic depth;
(b) \( \text{in}(I_X) = (x_0, \ldots, x_{e-1})^{e+1} + (uv) \), where \( u \in k[x_0, \ldots, x_{e-1}] \) is a monomial of degree \( r \) and \( v \in k[x_e, \ldots, x_{n+e}] \) is a monomial of positive degree.

If it is the case, then \( \text{reg}(R_X) = \text{reg}(S_0/\text{in}(I_X)) = \text{deg}(uv) - 1 \).

**Proof.** (b) \( \Rightarrow \) (a): The degree conclusion follows from the comparison

\[
\text{deg}(R_X) = \text{deg}(S_0/\text{in}(I_X)) = \binom{e+r}{e} - 1.
\]
In order to prove the depth conclusion, let \( J = (x_0, \ldots, x_{e-1}) \). We have a short exact sequence
\[
0 \to S_0/J^{r+1} \to S_0/J^{r+1} \to S_0/\text{in}(I_X) \to 0.
\]
Since \( S_0/J^{r+1} \) is Cohen-Macaulay of dimension \( n + 1 \), we obtain
\[
\text{depth}(S_0/\text{in}(I_X)) \geq n.
\]

Now the Cancellation Principle induces the inequalities of Betti numbers \( \beta^{S_0}_{ij}(S_0/I_X) \leq \beta^{S_0}_{ij}(S_0/\text{in}(I_X)) \) for any \( i, j \) (see [8 Corollary 1.21] or [9 Section 3.3]) which lead to a comparison of the projective dimension
\[
\text{proj.dim}_{S_0}(S_0/I_X) \leq \text{proj.dim}_{S_0}(S_0/\text{in}(I_X)).
\]
The Auslander-Buchsbaum formula then implies that \( \text{depth}(S_0/I_X) \geq \text{depth}(S_0/\text{in}(I_X)) \geq n \). As \( S_0/I_X \) is not Cohen-Macaulay (see [1, Proposition 2.1]), we obtain
\[
\text{proj.dim}_{S_0}(S_0/I_X) = \text{proj.dim}_{S_0}(S_0/\text{in}(I_X)) = n.
\]

(a) \( \Rightarrow \) (b): Suppose \( \deg(X) = \binom{e+r}{e} - 1 \) and \( \text{depth}(R_X) = n \).

The \( S_e \)-module \( R_X \) has a minimal set of generators containing all monomials in \( x_0, \ldots, x_{e-1} \) which are not contained in the ideal \( \text{in}(I_X) + (x_e, \ldots, x_{n+e}) \) (see [2 Lemma 2.4]). Denote this set by \( B_0 \) and its cardinality by \( \mu_{S_e}(R_X) \). The maximal degree of monomials in \( B_0 \) is the reduction number of \( R_X \) (see [14]), so we obtain
\[
\binom{e + r}{e} - 1 \leq \deg(X) = \mu_{S_e}(R_X) \leq \binom{e + r}{e}.
\]
Since \( X \) is not arithmetically Cohen-Macaulay, \( \deg(X) < \mu_{S_e}(R_X) \) and we obtain \( \mu_{S_e}(R_X) = \binom{e + r}{e} \).

This shows that
\[
B_0 = \{ x_0^{n_0} \cdots x_{e-1}^{n_{e-1}} : n_0 + \ldots + n_{e-1} \leq r \}.
\]
Hence the initial ideal \( \text{in}(I_X) \) is minimally generated by a disjoint union of the set \( T_{e+1} \) of all monomials in \( x_0, \ldots, x_{e-1} \) of degree \( r + 1 \) and a set \( M \) of some monomials in \( S_0 \) divided by some \( x_i \) for \( i \geq e \). Write \( M = \{ u_1, v_1, \ldots, u_n, v_n \} \) where \( u_i \in k[x_0, \ldots, x_{e-1}] \) with \( 0 < \deg(u_i) = r \) and \( v_i \in k[x_e, \ldots, x_{n+e}] \) with \( \deg(v_i) > 0 \). We have
\[
\deg(S_0/\text{in}(I_X)) = \deg(S_0/I_X) = \binom{e + r}{e} - 1,
\]
and
\[
\deg(S_0/I_X) = \deg(S_0/(u_1, \ldots, u_n, T_{e+1})).
\]
So \( \deg(S_0/(u_1, \ldots, u_n, T_{e+1})) = \binom{e + r}{e} - 1 \). The degree of \( S_0/(u_1, \ldots, u_n, T_{e+1}) \) is the number of monomials in \( T_0 \cup T_1 \cup \ldots \cup T_r \) which are not in \( \{ u_1, \ldots, u_n \} \). Since \( |T_0 \cup T_1 \cup \ldots \cup T_r| = \binom{e + r}{e} \), it induces the identity \( u_1 = u_2 = \ldots = u_n = u \) with \( \deg(u) = r \).

In order to obtain the desired description of the initial ideal of \( I_X \), it is essential to study the minimal free resolution of \( R_X \) as an \( S_e \)-module.

To start with, we prove that the equivalence classes in \( R_X \) of the monomials in \( B_0 \setminus \{ u \} \) are \( S_e \)-linearly independent. Let’s denote the monomials in \( B_0 \setminus \{ u \} \) by \( u_1, \ldots, u_d \), where \( d = \binom{e + r}{r} - 1 = \deg(R_X) \).

Assume that
\[
f_1 u_1 + \ldots + f_d u_d = 0,
\]
for some polynomials \( f_1, \ldots, f_d \in S_e \) which are not identically zero. Let \( f = f_1 u_1 + \ldots + f_d u_d \in I \). We can assume in addition that \( f_1, \ldots, f_d \) are homogeneous polynomials such that \( f \) is also homogeneous. Obviously \( u_1, \ldots, u_d \in S_e \) are linearly independent over \( S_e \), so \( f \neq 0 \). Write \( \text{in}(f) = \lambda v_1 v_2 \), where \( \lambda \in k^* \) and \( m_1 \in B_0 \setminus \{ u \} \) and \( m_2 \in S_e \). Then this contradicts to the fact that \( \text{in}(f) \) lies in \( \text{in}(I) \) which is minimally generated over \( S_e \) by \( T_{e+1} \cup \{ u v_1, \ldots, u v_s \} \). This shows that \( \overline{u}_1, \ldots, \overline{u}_d \) are \( S_e \)-linearly independent.

Now the Auslander-Buchsbaum formula induces
\[
\text{proj.dim}_{S_e}(R_X) = \text{depth}(S_e) - \text{depth}(R_X) = 1.
\]
Since \( \mu_{S_e}(R_X) = d + 1 \), \( \deg(R_X) = d \), \( R_X \) as an \( S_e \)-module has a minimal graded \( S_e \)-free resolution
\[
0 \leftarrow R_X \leftarrow \bigoplus_{i=1}^{d+1} S_e e_i \leftarrow F_1 \leftarrow S_e g \leftarrow 0,
\]
where \( \{ e_1, \ldots, e_{d+1} \} \) and \( \{ g \} \) are bases of free \( S_e \)-modules and
\[
\phi(e_i) = \begin{cases} v_i & \text{for } i = 1, \ldots, d, \\ 1 & \text{for } i = d + 1, \end{cases}
\]
\[
\psi(g) = \langle h_i e_i \rangle_{i=1, \ldots, d+1} =: \omega \in F_0.
\]
for some homogeneous polynomials \( h_1, \ldots, h_{d+1} \in S_c \). The homomorphism \( \phi \) induces an isomorphism

\[
\overline{\phi} : \bigoplus_{i=1}^{d+1} S_c e_i/(\sum_{i=1}^{d+1} h_i e_i) \cong R_X.
\]

The polynomial \( h_{d+1} \) is particularly non-zero as \( \overline{\pi}_1, \ldots, \overline{\pi}_d \) are \( S_c \)-linearly independent.

Recall that \( T_{r+1} \cup \{uv_1, \ldots, uv_s\} \) is a minimal set of generators of \( \text{in}(I_X) \). Let \( g_i \) be the polynomial in the reduced Gröbner basis of \( I_X \) with \( \text{in}(g_i) = uv_i \), for \( i = 1, \ldots, s \). Then no trailing monomials of \( g_i \) lie in the initial ideal \( \text{in}(I_X) \) and we can write

\[
g_i = uv_i + \sum_{j=1}^{d} u_j g_{ij},
\]

with some homogeneous polynomials \( g_i, g_{ij} \in S_c \) and \( \text{in}(g_i) = v_i \). In the \( S_c \)-module \( F_0 = \bigoplus_{j=1}^{d+1} S_c e_j \) we consider the elements

\[
\omega_i = q_i e_{d+1} + \sum_{j=1}^{d} q_{ij} e_j, i = 1, \ldots, s.
\]

We have \( \phi(\omega_i) = \overline{\pi}_i \neq 0 \), hence \( \omega_i \in \text{Ker}(\phi) = \text{Im}(\psi) = (\omega) \) and we can write \( \omega_i = a_i \omega \) for some polynomial \( a_i \in S_c \). We denote \( h = \sum_{i=1}^{s} h_i u_i + h_{d+1} u \in I_X \), then obviously \( g_i = \phi(\omega_i) = a_i \phi(\omega) = a_i h \).

Since \( g_i \) is in the reduced Gröbner basis of \( I_X \) and \( h \in I_X \), this is possible only if \( a_i \) is a non-zero constant polynomial, i.e., \( a_i \in k^\times \). This deduces that \( s = 1 \) and

\[
\text{in}(I_X) = (T_{r+1}) + (uv_1).
\]

It remains to prove the last conclusion on Castelnuovo-Mumford regularity. Suppose \( X \) satisfies (a) and (b). Recall that \( R_X \) has a minimal graded free \( S_c \)-resolution

\[
0 \leftarrow R_X \leftarrow F_0 = \bigoplus_{i=1}^{d+1} S_c e_i \leftarrow F_1 = S_c g \leftarrow 0,
\]

where \( S_c e_i \simeq S_c[-\deg u_i] \) for \( i = 1, \ldots, d \), \( S_c e_{d+1} \simeq S_c[-\deg u] \) and \( S_c g \simeq S_c[-\deg h] \). Moreover \( \deg(h) = \deg(g_1) = \deg(u_{v_1}) \geq r + 1 \). Hence

\[
\text{reg}(R_X) = \max\{\deg(u_1), \ldots, \deg(u_d), \deg(u), \deg(h) - 1\}
\]

\[
= \deg(h) - 1
\]

\[
= \deg(u) - 1
\]

\[
= \text{reg}(S_0/\text{in}(I_X)).
\]

\[\square\]

Let \( M \) be a graded finitely generated module over a polynomial ring \( S \). The \((i,j)\)-th graded Betti number of \( M \) is \( \beta_{i,j}^{S_0} = \dim_k \text{Tor}^{S_0}_{i,j}(M,k)_{i+j} \). In the next we are going to compute the Betti numbers of projective subschemes satisfying the equivalent conditions in Theorem 2.1. Let’s consider first some examples of such subschemes.

**Example 2.2.** Below are some examples of projective subschemes of almost maximal degree and arithmetic depth.

(i) [2] Theorem 5.1] Projective varieties of almost maximal degree have almost maximal arithmetic depth.

(ii) [2] Lemma 5.3] Let \( S_0 = k[x_0, \ldots, x_{n+e}] \) and \( J = (x_0, \ldots, x_{e-1}) \). Let \( u \in J \) be a monomial of degree \( r \) and \( v \) be a non-constant monomial in \( x_1, \ldots, x_{n+e} \). Put \( I = (uv) + J^{r+1} \). Then \( I \) defines a closed subscheme in \( \mathbb{P}^{n+r} \) which satisfies the equivalent conditions in Theorem 2.1. The Betti numbers of \( I \) are as follows:

(a) If \( \deg(uv) = r + 1 \) then

\[
\beta_{i,j}^{S_0}(I) = \begin{cases} (e+r)(r+1)(e+r) & \text{if } 0 \leq i < e, j = r + 1, \\
0 & \text{otherwise.}
\end{cases}
\]

(b) If \( \deg(uv) > r + 1 \) then

\[
\beta_{i,j}^{S_0}(I) = \begin{cases} (e+r)(r+1)(e+r) & \text{if } 0 \leq i < e, j = r + 1, \\
(e+r)(e+r) & \text{if } 0 \leq i < e, j = \deg(uv), \\
0 & \text{otherwise.}
\end{cases}
\]
Corollary 2.3. Let \( X \subseteq \mathbb{P}^{n+e} \) be a non-degenerate closed subscheme of dimension \( n \), codimension \( e \) and reduction number \( r \). Let \( R_X = S_0/I_X \) be the homogeneous coordinate ring of \( X \). Suppose \( S = S_e \to R_X \) is a Noether normalization with reduction number \( r(S(R_X)) = r \). The following statements are equivalent:

(a) \( X \) is of almost maximal degree and almost maximal arithmetic depth;
(b) \( R_X \), as an \( S \)-module, has the graded Betti numbers

\[
\beta^S_{i,j}(R_X) = \begin{cases} 
(e^{+j}-1)/j & \text{if } i = 0, 0 \leq j \leq r, \\
1 & \text{if } i = 1, j = \text{reg}(R), \\
0 & \text{if } i = 1, j \neq \text{reg}(R) \text{ or } i > 1.
\end{cases}
\]

(c) \( R_X \), as an \( S \)-module, has the Betti numbers

\[
\beta^S_i(R_X) = \begin{cases} 
(e+r)/r & \text{if } i = 0, \\
1 & \text{if } i = 1, \\
0 & \text{if } i > 1;
\end{cases}
\]

**Proof.** The implications (b) \( \Rightarrow \) (c) \( \Rightarrow \) (a) are obvious. We are going to show (a) \( \Rightarrow \) (b).

Assume that \( X \) has \( \text{deg}(X) = (e^+) - 1 \) and \( \text{depth}(R_X) = n \). Due to the proof for Theorem 2.1, we have

\[
\beta^{S}_{0,j}(R_X) = 1 \quad \text{ if } i = 1, j = \text{reg}(R),
\]

\[
= 0 \quad \text{ if } i > 1 \text{ or } i = 1, j \neq \text{reg}(R).
\]

Now we compute \( \beta^{S}_{0,j}(R_X) \). We have seen in the proof of Theorem 2.1 that \( R_X \) is minimally generated over \( S_e \) by all monomials in \( x_0, \ldots, x_{e-1} \) of degree from 0 to \( r \). Consequently, we have

\[
\sum_{j=0}^{r} \beta^{S}_{0,j}(R) = \binom{e + r}{r}.
\]

On the other hand, \( \beta^{S}_{0,j}(R) \) is bounded above by the number of monomials in \( x_0, \ldots, x_{e-1} \) of degree \( j \), i.e.,

\[
\beta^{S}_{0,j}(R) \leq \binom{e + j - 1}{j}.
\]

This implies that

\[
\beta^{S}_{0,j}(R) = \binom{e + j - 1}{j},
\]

for all \( j = 0, 1, \ldots, r \).

As an immediate consequence, we get information on Hilbert polynomial and arithmetic genus.

Corollary 2.4. Let \( X \subseteq \mathbb{P}^{n+e} \) be a non-degenerate closed subscheme of dimension \( n \), codimension \( e \) and reduction number \( r \). Let \( R_X = S_0/I_X \) be the homogeneous coordinate ring of \( X \). The Hilbert polynomial of \( X \) is

\[
P_{R_X}(T) = \sum_{j=0}^{r} \binom{e - 1 + j}{e - 1} \left( T + n - j \right) - \binom{T - \text{reg}(R_X) - 1 + n}{n}.
\]

The arithmetic genus of \( X \) is

\[
g(X) = (-1)^n(P_{R_X}(0) - 1) = \sum_{j=n+1}^{r} \binom{e - 1 + j}{e - 1} \left( j - 1 \right) - \binom{\text{reg}(R_X)}{n} + (-1)^{n+1}.
\]

In particular, if \( r \leq \dim(X) \) then

\[
g(X) = -\binom{\text{reg}(R_X)}{n} + (-1)^{n+1}.
\]

So over the Noether normalization \( S = S_e \), the Betti table of \( X \) is described precisely. From this table we can recover the Betti table of \( X \) over the ring \( S_0 \).

**Theorem 2.5 (Betti table).** Let \( X \subseteq \mathbb{P}^{n+e} \) be a non-degenerate closed subscheme of dimension \( n \), codimension \( e \) and reduction number \( r \). Let \( I_X \subseteq S_0 \) be the defining ideal of \( X \) and \( R_X = S_0/I_X \). Then \( X \) if of almost maximal degree and arithmetic depth if and only if the Betti table (over \( S_0 \)) of \( R_X \) has one of the following shapes (in the following tables, we write only rows with some possibly non-zero entries):
(a) \( \text{reg}(R_X) = r \):
where for \( 1 \leq i \leq e + 1 \),
\[
\beta_{i,r} = \binom{e + r}{i + r} \left( \binom{r + i - 1}{r} \right) + \binom{e}{i - 1}.
\]

(b) \( \text{reg}(R_X) = r + 1 \):
\[
\begin{array}{cccccc}
0 & 1 & \cdots & i & \cdots & e & e + 1 \\
r & 0 & \beta_{1,r} & \cdots & \beta_{i,r} & \cdots & \beta_{e,r} & 1 \\
r + 1 & 0 & \beta_{1,r+1} & \cdots & \beta_{i,r+1} & \cdots & \beta_{e,r+1} & 1 \\
\end{array}
\]
where for \( 1 \leq i \leq e + 1 \),
\[
\beta_{i,r} - \beta_{i-1,r+1} = \binom{e + r}{i + r} \left( \binom{r + i - 1}{r} \right) - \binom{e}{i - 2},
\]
and
\[
\beta_{i,r} \leq \binom{e + r}{i + r} \left( \binom{r + i - 1}{r} \right), \quad \beta_{i-1,r+1} \leq \binom{e}{i - 2}.
\]

(c) \( \text{reg}(R_X) > r + 1 \):
\[
\begin{array}{cccccc}
0 & 1 & \cdots & i & \cdots & e & e + 1 \\
r & 0 & \beta_{1,r} & \cdots & \beta_{i,r} & \cdots & \beta_{e,r} & 1 \\
\text{reg}(R) & 0 & \left( \binom{e}{0} \right) & \cdots & \left( \binom{e}{i-1} \right) & \cdots & \left( \binom{e}{e-1} \right) & \left( \binom{e}{e} \right) \\
\end{array}
\]
where for \( 1 \leq i \leq e + 1 \),
\[
\beta_{i,r} = \binom{e + r}{i + r} \left( \binom{i + r - 1}{r} \right),
\]
\[
\beta_{i,\text{reg}(R)} = \binom{e}{i - 1}.
\]

Proof. Suppose \( S = S_e \to R_X \) is a Noether normalization of \( R_X \) with reduction number \( r_S(R_X) = r \). For the proof we make use of the relation between Betti numbers of \( R_X \) over \( S_0 \) and over \( S \). For each \( m \in \mathbb{Z} \), denote
\[
\lambda^S_{\lambda^S_0}(M) = \sum_{j=0}^{m} (-1)^j \beta_{m-j,j}^S(M).
\]

Necessary condition: The proof of necessary condition is similar to the proof of Theorem 5.4 in [2] which treats varieties rather subschemes as in the present paper. Suppose \( X \) is of almost maximal degree and almost maximal depth. Fix the degree reverse lexicographic order on monomials of \( S_0 \). Due to Theorem 2.1, the initial ideal of \( I_X \) has the explicit description
\[
\text{in}(I_X) = (x_0, \ldots, x_{e-1})^{r+1} + (uv),
\]
for some monomials \( u \) in \( x_0, \ldots, x_{e-1} \) of degree \( r \) and \( v \) in \( x_e, \ldots, x_n + e \) of positive degree.

The Cancellation Principle (see [3, Corollary 1.21] or [3, Section 3.3]) gives rise to the comparison
\[
0 \leq \beta^S_{ij}(R_X) \leq \beta^S_{ij}(S_0/\text{in}(I_X)).
\]

Now using the computation in Example (ii) of Lemma 2.2 we obtain
\[
\beta^S_{ij}(R_X) = 0,
\]
for all \( (i, j) \not\in \{ (0, 0), (1, r), \ldots, (e, r), (1, \text{reg}(R_X)), \ldots, (e + 1, \text{reg}(R_X)) \} \).

By definition, we always have \( \text{reg}(R_X) \geq r \). If \( \text{reg}(R_X) = r \) or \( \text{reg}(R_X) \geq r + 2 \) then we get
\[
\beta^S_{ij}(R_X) = \beta^S_{ij}(S_0/\text{in}(I_X)),
\]
for all \( i, j \), the conclusion then follows.
Suppose $\text{reg}(X) = r + 1$, then
\[
\chi_m^S(R_X) = (-1)^m \beta_{m-r-1,r}^S(R_X) + (-1)^{r+1}\beta_{m-r-1,r+1}^S(R_X).
\]
For the Betti number of $R_X$ over the Noether normalization $S$, from Corollary 2.3 we have
\[
\chi_m^S(R_X) = \begin{cases} 
(-1)^m \left(\begin{array}{c} e + m - 1 \\ e - 1 \end{array}\right) & \text{if } 0 \leq m \leq r, \\
1 & \text{if } m = \text{reg}(R_X) + 1, \\
0 & \text{otherwise}.
\end{cases}
\]
Following Corollary 2.7(a)], we have
\[
\chi_m^S(R_X) = \sum_{j=0}^e \binom{e}{j} \chi_{m-j}^S(R_X) = (-1)^m \left(\begin{array}{c} e + r \\ i + r \end{array}\right) \left(\begin{array}{c} r + i - 1 \\ r \end{array}\right) + (-1)^{r+1} \left(\begin{array}{c} e \\ i - 2 \end{array}\right).
\]
Sufficient condition: From the Betti table, $R_X$ has projective dimension $e + 1$ over $S_0$. The Auslander-Buchsbaum formula then gives us $\text{depth}(R_X) = n$. Furthermore, we also have
\[
\chi_m^S(R_X) = \sum_{j=0}^e \binom{e}{j} \chi_{m-j}^S(R_X) = (-1)^m \left(\begin{array}{c} e + r \\ i + r \end{array}\right) \left(\begin{array}{c} r + i - 1 \\ r \end{array}\right) + (-1)^{\text{reg}(R_X)-r} \left(\begin{array}{c} e \\ i - 1 - \text{reg}(R_X) + r \end{array}\right).
\]
Now using again the relation between Betti numbers over $S_0$ and $S$ in Corollary 2.7(a)], we obtain
\[
\chi_m^S(R_X) = \begin{cases} 
(-1)^m \left(\begin{array}{c} e + m - 1 \\ e - 1 \end{array}\right) & \text{if } 0 \leq m \leq r, \\
1 & \text{if } m = \text{reg}(R_X) + 1, \\
0 & \text{otherwise}.
\end{cases}
\]
Hence
\[
\text{deg}(R_X) = \sum_{m=0}^e (-1)^m \chi_m^S(R_X) = \sum_{m=0}^e \left(\begin{array}{c} e + m - 1 \\ e - 1 \end{array}\right) - 1 = \left(\begin{array}{c} e + r \\ e \end{array}\right) - 1.
\]
Therefore $X$ has an almost maximal degree. \hfill \Box

3. Componentwise linearity

For a homogeneous ideal $I \subset S_0$, we denote by $I(d)$ the ideal generated by all homogeneous polynomials of degree $d$ in $I$. Following Herzog-Hibi [8], we say that $I$ has a componentwise linear resolution if for each $d > 0$, the ideal $I(d)$ has a linear minimal free resolution. There are several characterizations of ideals with componentwise linear resolution, mostly by the equality between the Betti numbers of the ideal and its initial ideal with respect to certain monomial orders.

The main aim of this section is to answer Question 1.2 by showing that most of the projective sub-schemes of almost maximal degree and arithmetic depth have componentwise linear resolution.

The following simple lemma is very useful in the sequel.

Lemma 3.1. Let $I \subset S_0$ be a homogeneous ideal with a linear minimal free resolution. Then so is $(x_0, \ldots, x_{e+n})I$.

Proof. The ideal $I$ has a set of generators consisting of homogeneous polynomials of the same degree $d = \text{reg}(I)$. Let $t$ be the minimal number of generators of $I$, then $I/mI \simeq k[-d]^t$, where $m = (x_0, \ldots, x_{e+n}) \subset S_0$. From the short exact sequence
\[
0 \to k[-d]^t \to S_0/mI \to S_0/I \to 0,
\]
we obtain $\text{reg}(S_0/mI) \leq \max\{\text{reg}(S_0/I), d\} = d$. On the other hand, $mI$ is generated by degree $d + 1$ homogeneous elements, so $\text{reg}(S_0/mI) = d$ and $mI$ has a $(d + 1)$-linear resolution (see Theorem 1.2)]. \hfill \Box

Corollary 3.2. Let $u$ be a monomial in $x_0, \ldots, x_{e-1}$ of degree $r$ and $v$ be a monomial in $x_e, \ldots, x_{e+n}$ of positive degree. Put $I = (x_0, \ldots, x_{e-1})^{r+1} + (uv)$. Then $I$ has a componentwise linear minimal free resolution.

Proof. If $\text{deg}(v) = 1$ then $I$ is generated by degree $(r + 1)$ homogeneous polynomials. Due to Theorem 3.4, $I$ has a linear resolution.

Let’s assume $\text{deg}(v) > 1$. It is clear that $I_{(r+1)} = (x_0, \ldots, x_{e-1})^{r+1}$ has an $(r + 1)$-linear resolution. For $1 \leq s < \text{deg}(v)$, the ideal $I_{(r+s)} = m^{s-1}(x_0, \ldots, x_{e-1})^{r+1}$ has a linear resolution due to Lemma 3.4. For $s \geq \text{deg}(v)$, we have $r + s \geq \text{deg}(uv) = \text{reg}(I)$ and therefore $I_{(r+s)}$ has a linear resolution (see Proposition 1.1)]. \hfill \Box
Proposition 3.3. Let $I \subset S_0$ be a saturated homogeneous ideal such that $R = S_0/I$ has dimension $n + 1$ and reduction number $r$. Suppose $\deg(R) = \binom{r + n}{r} - 1$ and depth$(R) = n$. Then

(a) $I_{(r + 1)}$ has a linear resolution if and only if either

(i) $\reg(R) = r$, or

(ii) $\reg(R) = r + 1$ and $\beta^S_{1,r+1}(R) = 1$, or

(iii) $\reg(R) \geq r + 2$.

When (ii) or (iii) is the case, $S_0/I_{(r+1)}$ is Cohen-Macaulay.

(b) $I_{(r+1)}$ does not have a linear resolution if and only if $\reg(R) = r + 1$, $\beta^S_{1,r+1}(R) = 0$.

When it is the case, $\beta^S_{1,r+1}(S_0/\in(I_{(r+1)})) = 1$ and $I$ is generated by degree $r + 1$ homogeneous polynomials.

Proof. If $\reg(R) = r$ then following Theorem 2.3 (a), $I_{(r+1)}$ has an $(r + 1)$-linear resolution.

Let us assume that $\reg(R) > r$. Changing the variables by a linear transformation, we may assume that $S = S_0 = k[x_r, \ldots, x_{n+e}]$ is a Noether normalization of $R$ with reduction number $r_S(R) = r$. We fix the degree reverse lexicographic order on the monomials of $S_0$. Due to Theorem 2.1 the initial ideal of $I$ has a simple form

$$\in(I) = (x_0, \ldots, x_{e-1})^{r+1} + (uv),$$

where $u$ is a monomial in $x_0, \ldots, x_{e-1}$ of degree $r$ and $v$ is a monomial in $x_e, \ldots, x_{n+e}$ of degree at least 2. Let $g_1, \ldots, g_t$ be a reduced Gröbner basis of $I$ such that $\{\in(g_1), \ldots, \in(g_t)\}$ is a minimal set of generators of $(x_0, \ldots, x_{e-1})^{r+1}$ and $\in(g) = uv$. In particular, $I_{(r+1)} = (g_1, \ldots, g_t)$.

Now we prove the equivalence in (b). Suppose $I_{(r+1)}$ does not have a linear resolution. We have

$$(x_0, \ldots, x_{e-1})^{r+1} \subseteq \in(I_{(r+1)}) \subseteq \in(I) = (x_0, \ldots, x_{e-1})^{r+1} + (uv),$$

with $\deg(uv) \geq r + 2$. If $\in(I_{(r+1)}) = (x_0, \ldots, x_{e-1})^{r+1}$ then $\in(I_{(r+1)})$ is $(r + 1)$-linear, so $I_{(r+1)}$ is $(r + 1)$-linear, a contradiction. Then $\in(I_{(r+1)})$ must have a minimal generator of degree at least $r + 2$. Following [12] Lemma 2.2, $\beta^S_{0,r+2}(\in(I_{(r+1)})) \neq 0$. This occurs only if $\deg(uv) = r + 2$ and

$$\in(I_{(r+1)}) = (x_0, \ldots, x_{e-1})^{r+1} + (uv) = \in(I)$$

Thus $\beta^S_{0,r+2}(\in(I_{(r+1)})) = \beta^S_{0,r+2}(\in(I)) = 1$.

Put $m = (x_0, \ldots, x_{e+n})$. We have

$$\beta^S_{0,r+2}(\in(I)) = \dim_k \in(I)_{(r+2)} - \dim_k (m \in(I))_{(r+2)}$$

$$= \dim_k \in(I)_{(r+2)} - \dim_k (\in(I_{(r+1)}))_{(r+2)}$$

$$= \dim_k (I_{(r+2)}) - (\dim_k (\in(I_{(r+1)}))_{(r+2)} - \beta^S_{0,r+2}(\in(I_{(r+1)}))).$$

Hence

$$\beta^S_{0,r+2}(\in(I)) - \beta^S_{0,r+2}(\in(I_{(r+1)})) = \dim_k (I_{(r+2)}) - \dim_k (\in(I_{(r+1)}))_{(r+2)}.$$ 

On the other hand, we have

$$\beta^S_{0,r+2}(I) = \dim_k (I_{(r+2)}) - \dim_k (mI)_{(r+2)}$$

$$= \dim_k (I_{(r+2)}) - \dim_k ((mI)_{(r+1)})_{(r+2)}$$

$$= \dim_k (I_{(r+2)}) - \dim_k (I_{(r+1)})_{(r+2)}$$

$$= \dim_k (I_{(r+2)}) - \dim_k (\in(I_{(r+1)}))_{(r+2)}.$$ 

This deduces that $\beta^S_{0,r+2}(I) = \beta^S_{0,r+2}(\in(I)) - \beta^S_{0,r+2}(\in(I_{(r+1)})) = 0$.

Conversely, if $\beta^S_{0,r+2}(I) = 0$ then by Theorem 2.3 (b), $I_{(r+1)} = I$ which does not have a linear resolution. This proves (b). It also proves the equivalence in (a) since $\beta^S_{0,r+2}(I) \leq 1$ due to Theorem 2.3 (b).

It remains to show that $S_0/I_{(r+1)}$ is Cohen-Macaulay provided one of the conditions (ii), (iii) in (a). To see this, we use [8] Lemma 1.2 and Theorem 2.3 (b), (c) to obtain the vanishing of certain Betti numbers, namely

$$\beta_{i,r}(S_0/I_{(r+1)}) = \beta_{i,r}(S_0/I) = 0,$$

for all $i > e$. Then the linearity of $I_{(r+1)}$ induces the estimate $\proj \dim^S_{S_0/I_{(r+1)}}(S_0/I_{(r+1)}) \leq e$. Using the Auslander-Buchsbaum formula we obtain $\depth(S_0/I_{(r+1)}) = n + 1$ and therefore $S_0/I_{(r+1)}$ is Cohen-Macaulay.

Now we are ready to state the main theorem.

Theorem 3.4. Let $X \subset \mathbb{P}^{n+e}$ be a non-degenerate closed subscheme of codimension $e$ and reduction number $r$. Let $I_X \subset S_0$ be the defining ideal of $X$ and $R_X = S_0/I_X$. Suppose $X$ is of almost maximal degree and arithmetic depth. The following hold true.
(a) $I_X$ has a componentwise linear resolution if and only if either
(i) $\text{reg}(R_X) = r$, or
(ii) $\text{reg}(R_X) = r + 1$ and $\beta^S_{1,r+1}(R_X) = 1$, or
(iii) $\text{reg}(R_X) \geq r + 2$.

(b) $I_X$ does not have a componentwise linear resolution if and only if
$$\text{reg}(R_X) = r + 1 \quad \text{and} \quad \beta^S_{1,r+1}(R_X) = 0.$$ 

Proof. (a) If $I_X$ has a componentwise linear resolution then $(I_X)_{(r+1)}$ has a linear resolution, the necessary conditions hence follows from Proposition 3.3(a).

Conversely, assume either (i), (ii), or (iii). If $\text{reg}(R_X) = r$ then $I_X = (I_X)_{(r+1)}$ has a linear resolution due to Theorem 2.5(a), therefore is componentwise linear. If $\text{reg}(R_X) > r$ then $(I_X)_{(r+1)}$ has a linear resolution by Proposition 3.3. Furthermore, note that $I_X$ has a set of generators consisting of a form of degree equal to $\text{reg}(R_X)$ and forms of degree $r+1$ (cf. Theorem 2.5). Hence for $1 \leq s < \text{reg}(I_X) - r$, we have $(I_X)_{(r+s)} = m^{s-1}(I_X)_{(r+1)}$ which has a linear resolution by Lemma 3.1. For $s \geq \text{reg}(I_X) - r$, the ideal $(I_X)_{(r+s)}$ has a linear resolution (see [3] Proposition 1.1).

(b) We have
$$\beta^S_{1,r+1}(R_X) \leq \beta^S_{1,r+1}(S_0/\text{in}(I_X)) = 1.$$ 

The later equality follows from Theorem 2.5(b) and Corollary 3.2. Hence if $\beta^S_{1,r+1}(R_X) \neq 1$, it means that $\beta^S_{1,r+1}(R_X) = 0$. Now (b) is immediate from (a).

Corollary 3.5. Let $X \subset \mathbb{P}^{n+e}$ be a non-degenerate almost maximal projective variety of codimension $e$ and reduction number $r$. Let $I_X \subset S_0$ be the saturated defining ideal of $X$ and $R_X = S_0/I_X$ be the homogeneous coordinate ring. Then $X$ has a componentwise linear resolution if and only if either
(i) $\text{reg}(R_X) = r$, or
(ii) $\text{reg}(R_X) = r + 1$ and $\beta^S_{1,r+1}(R_X) = 1$, or
(iii) $\text{reg}(R_X) \geq r + 2$.

Assuming either (ii) or (iii), there is an embedding $X \subset Y \subset \mathbb{P}^{n+e}$ where $Y$ is an $(r+1)$-linear arithmetically Cohen-Macaulay projective subscheme of the same dimension as $X$.

Proof. An almost maximal variety has an almost maximal arithmetic depth (cf. [2] Theorem 5.1]). Then the first conclusion follows immediately from Theorem 3.3.

For the second conclusion, assuming (ii) or (iii). Since $I_X$ is componentwise linear, $(I_X)_{(r+1)}$ is $(r+1)$-linear and $S_0/(I_X)_{(r+1)}$ is Cohen-Macaulay by Proposition 3.3(a). Let $Y = \text{Proj}(S_0/(I_X)_{(r+1)})$ then the conclusion follows.

We have seen in Theorem 2.4 an explicit description of the Betti table of a projective subscheme of almost maximal degree and arithmetic depth. In case $\text{reg}(R_X) \neq r + 1$, each Betti number is computed precisely. It is natural to ask for the case $\text{reg}(R) = r + 1$. As an application of the componentwise linearity, we give in the next corollary a partial answer to this question.

Corollary 3.6. Let $X \subset \mathbb{P}^{n+e}$ be a projective subscheme as in Theorem 2.4, in particular $X$ is of almost maximal degree and almost maximal arithmetic depth. We assume further that $X$ has a componentwise linear resolution. The Betti table of the homogeneous coordinate ring of $X$ is

|       | 0   | 1   | $\cdots$ | $i$ | $\cdots$ | $e$ | $e + 1$
|-------|-----|-----|----------|-----|----------|-----|--------
| 0     | 1   |     |          |     |          |     |        
| $r$   | -   | $\beta_r$ | $\beta_{ir}$ | $\beta_{e,r}$ | $\beta_{e+1,r}$ | $\beta_{e+1}$ | $\beta_{e+1}$ |
| $r + 1$ | $\binom{e}{0}$ | $\binom{e}{i-1}$ | $\binom{e}{i-1}$ | $\binom{e}{i} | $\binom{e}{i}$ |

where for $1 \leq i \leq e + 1$,

$$\beta_{i,r} = \binom{e + r}{i + r} \binom{i + r - 1}{r},$$

$$\beta_{e+1,r+1} = \binom{e}{i - 1}.$$ 

Proof. We have seen in Theorem 2.5(b) that the Betti table of $R_X$ has the shape as above, where

$$\beta_{i,r} - \beta_{i-1,r+1} = \binom{e + r}{i + r} \binom{r + i - 1}{r} - \binom{e}{i - 2}.$$
On the other hand, due to Proposition 3.3, the ring $S_0/I_{(r+1)}$ is Cohen-Macaulay and has an $r$-linear resolution. Hence $S_0/I_{(r+1)}$ has a maximal degree by [2] Theorem 3.1. Now we use again [3] Lemma 1.2 together with [2] Corollary 3.2 to obtain
\[
\beta_{ir}(R_X) = \beta_{ir}(S_0/(I_X)(r+1)) = \binom{e+r}{i+r}(i+r-1)^r,
\]
for all $1 \leq i \leq e$. This proves the corollary. 
\[\square\]

Example 3.7. Let $C$ be the smooth rational curve in $\mathbb{P}^3$ defined by $(s,t) \mapsto (s^5, s^4t + s^3t^2, st^4, t^5)$. The curve $C$ has reduction number $r = 2$, Castelnuovo-Mumford regularity $\text{reg}(C) = 4$ and degree $\text{deg}(C) = 5 = \left(\frac{2+3}{2}\right) - 1$. In particular, $C$ is of almost maximal degree. The Betti table of $C$ is

\[
\begin{array}{cccc}
0 & 1 & 2 & 3 \\
0 & 1 & - & - & - \\
1 & - & - & - & - \\
2 & - & 4 & 3 & - \\
3 & - & 1 & 2 & 1 \\
\end{array}
\]

By Theorem 3.4(a), $C$ has a componentwise linear resolution. This can be also shown by direct computation. Indeed, using Macaulay 2 we can find the Betti table of $S_0/I_{(3)}$

\[
\begin{array}{cccc}
0 & 1 & 2 \\
0 & 1 & - & - \\
1 & - & - & - \\
2 & - & 4 & 3 \\
\end{array}
\]

In particular, $S_0/I_{(3)}$ is Cohen-Macaulay. Furthermore, $S_0/I_{(4)}$ has depth zero and its Betti table is

\[
\begin{array}{cccccc}
0 & 1 & 2 & 3 & 4 \\
0 & 1 & - & - & - & - \\
1 & - & - & - & - & - \\
2 & - & - & - & - & - \\
3 & - & 14 & 26 & 17 & 4 \\
\end{array}
\]

In [2] Examples 5.6, 5.7, 5.8, it is shown that all cases (i), (ii), (iii) in part (a) of Theorem 3.4 actually occur. In the next example, we will see a rational curve in $\mathbb{P}^3$ satisfying all conditions in part (b) of Theorem 3.4

Example 3.8. Let $C$ be a smooth rational curve in $\mathbb{P}^3$ defined by $(s,t) \mapsto (s^9, s^4t^5 + s^5t^4, s^4t^5 + s^7t^2, t^9)$. Let $I_C \subset S_0 = k[x, y, z, w]$ be its defining ideal and $R_C = S_0/I_C$. We have $R/(x, w) \simeq S_0/(x, w) + (y, z)^4$, so the reduction number of $R$ is $r = 3$. The curve $C$ is of almost maximal degree with $\text{deg}(C) = 9 = \left(\frac{2+3}{2}\right) - 1$. On the other hand, the Betti table of $R$ is

\[
\begin{array}{cccc}
0 & 1 & 2 & 3 \\
0 & 1 & - & - & - \\
1 & - & - & - & - \\
2 & - & - & - & - \\
3 & - & 5 & 3 & - \\
4 & - & 2 & 1 & - \\
\end{array}
\]

The curve $C$ satisfies all conditions in part (b) of Theorem 3.4 and its minimal free resolution is not componentwise linear.

If the codimension and reduction number are fixed, the size of the Betti tables of projective varieties of almost maximal degree are bounded. While the projective dimension equals to the codimension plus one, the Castelnuovo-Mumford regularity has the following bound.

Proposition 3.9. Let $X \subset \mathbb{P}^{e+n}$ be a projective variety of codimension $e$ and reduction number $r$. Suppose $X$ is of almost maximal degree. Then

\[
\text{reg}(X) \leq \text{deg}(X) - e + 1.
\]
Proof. Let $I_X \subset S_0 = k[x_0, \ldots, x_{e+n}]$ be the saturated defining ideal of $X$ and $R_X = S_0/I_X$ be the homogeneous coordinate ring. Then $R_X$ has depth $n$ by [2] Theorem 5.4.

Since $k$ is infinite, we apply the Bertini irreducibility theorem [10] Theorem 6.3(4)] to choose appropriate linear forms $x_1, \ldots, x_{e+n}$ such that
(a) $x_{e+1}, \ldots, x_{e+n}$ is a regular sequence on $R_X$;
(b) $S = k[x_{e+1}, \ldots, x_{e+n}] \to R$ is a Noether normalization with reduction number $r_S(R) = r$;
(c) $R/X(x_{e+2}, \ldots, x_{e+n})$ is a domain.

We have $\text{reg}(R_X) = \text{reg}(R_X/(x_{e+2}, \ldots, x_{e+n}))$, $r = r(R_X/(x_{e+2}, \ldots, x_{e+n}))$ and
\[\text{deg}(R_X) = \text{deg}(R_X/(x_{e+2}, \ldots, x_{e+n})).\]

Now a famous result of L. Gruson, R. Lazarsfeld and C. Peskine [7, Theorem 1.1] shows that
\[\text{reg}(R_X/(x_{e+2}, \ldots, x_{e+n})) \leq \text{deg}(R_X/(x_{e+2}, \ldots, x_{e+n})) - e = \text{deg}(R_X) - e.\]

Therefore,
\[\text{reg}(X) \leq \text{deg}(R_X) - e + 1 = \left(\frac{e + r}{e}\right) - e.\]

For a projective variety $Y \subset \mathbb{P}^{c+n}$ we have $\text{reg}(Y) \geq 2$. The equality occurs if and only if $r(Y) = 1$ if and only if $Y$ has minimal degree (see [2] Corollary 3.7)]. Projective varieties of almost maximal degree as in Proposition 3.9 do not have minimal degree, so we have the inequalities
\[3 \leq r + 1 \leq \text{reg}(X) \leq \left(\frac{e + r}{e}\right) - e.\]

These lower and upper bounds for the regularity of an almost maximal degree variety are sharp. Indeed, we have seen in Examples 5.5, 5.7 of [2] a smooth elliptic curve $C$ and a smooth rational curve $C'$ in $\mathbb{P}^3$ both of reduction number 2 and of almost maximal degree 5. The Castelnuovo-Mumford regularity of each curve is
\[\text{reg}(C) = 3 = r + 1, \text{ reg}(C') = 4 = \left(\frac{e + r}{e}\right) - e.\]

Acknowledgments. The authors thank Satoshi Murai for raising Question 1.2 which has initially inspired this work. They also thanks Nguyễn Đăng Hợp for helpful discussion on Macaulay 2, especially for his help to find Example 3.8.
