Moment Identifiability of Homoscedastic Gaussian Mixtures

Daniele Agostini, Carlos Améndola and Kristian Ranestad

Abstract

We consider the problem of identifying a mixture of Gaussian distributions with same unknown covariance matrix by their sequence of moments up to certain order. Our approach rests on studying the moment varieties obtained by taking special secants to the Gaussian moment varieties, defined by their natural polynomial parametrization in terms of the model parameters. When the order of the moments is at most three, we prove an analogue of the Alexander-Hirschowitz theorem classifying all cases of homoscedastic Gaussian mixtures that produce defective moment varieties. As a consequence, we determine identifiability when the number of mixed distributions is smaller than the dimension of the space. In the two component setting we provide a closed form solution for parameter recovery based on moments up to order four, while in the one dimensional case we interpret the rank estimation problem in terms of secant varieties of rational normal curves.

1 Introduction

In the context of algebraic statistics [16], moments of probability distributions have recently been explored from an algebraic and geometric point of view [1, 4, 9, 10]. The key point for this connection is that in many cases the sets of moments define algebraic varieties, hence called moment varieties. In the case of moments of mixture distributions, there is a natural correspondence to secant varieties of the moment varieties. Studying geometric invariants such as their dimension reveals properties such as model identifiability. One of the main applications for statistical inference is in the context of the method of moments, which matches the distribution’s moments to moment estimates obtained from a sample.

Gaussian mixtures are a prominent statistical model with multiple applications (see [3] and references therein). They are probability distributions on \( \mathbb{R}^n \) with a density that is a convex combination of Gaussian densities:

\[
\lambda_1 f_{\mathcal{N}(\mu_1, \Sigma_1)}(x) + \cdots + \lambda_k f_{\mathcal{N}(\mu_k, \Sigma_k)}(x)
\]

where \( \mu_1, \ldots, \mu_k \in \mathbb{R}^n \) are the \( k \) means, \( \Sigma_1, \ldots, \Sigma_k \in \text{Sym}^2(\mathbb{R}^n) \) are the covariance matrices, and the \( 0 \leq \lambda_i \leq 1 \) with \( \lambda_1 + \cdots + \lambda_k = 1 \) are the mixture weights.
The starting point is thus the Gaussian moment variety $G_{n,d}$, as introduced in [4], whose points are the vectors of all moments of order at most $d$ of an $n$-dimensional Gaussian distribution. The moments corresponding to the mixture density (1) form the secant variety $\text{Sec}_k(G_{n,d})$, and identifiability in this general setting was the focus of [5].

In this work we study special families of Gaussian mixtures, called homoscedastic mixtures, where all the Gaussian components share the same covariance matrix. In other words, a homoscedastic Gaussian mixture has a density of the form

$$\sum_{i=1}^{k} \lambda_i f_{N(\mu_i, \Sigma)}(x)$$

where the Gaussian probability densities $f_{N(\mu_i, \Sigma)}(x)$ have all different means $\mu_i$ and same covariance matrix $\Sigma$. The moments, up to order $d$, of homoscedastic Gaussian mixtures are still polynomials in the parameters (the means and the covariance matrix), and form the moment variety $\text{Sec}_k^H(G_{n,d})$. This is a set of special $k$-secants inside the secant variety $\text{Sec}_k(G_{n,d})$.

The main question we are concerned with is: when can a general homoscedastic $k$-mixture of $n$-dimensional Gaussians be identified by its moments of order $d$? More precisely, denote by $\Theta^H_{n,k}$ the parameter space of means, covariances and mixture weights for homoscedastic mixtures, and the moment map by

$$M_{n,k,d} : \Theta^H_{n,k} \rightarrow \text{Sec}_k^H(G_{n,d}).$$

The mixture parameters of a point on the moment variety $\text{Sec}_k^H(G_{n,d})$ can be uniquely recovered if the fiber of the moment map (3) is a singleton up to natural permutations of the parameters. If this happens for a general point on the moment variety, we say that the mixture is rationally identifiable from its moments up to order $d$. If the fiber of a general point is finite, we say that we have algebraic identifiability. The parameters are not identifiable if the general fiber of the moment map has positive dimension.

If the dimension of the parameter space is larger than the dimension of the space of moments, then one may expect any moment to lie on the moment variety. Clearly the fiber of the moment map must have positive dimension and we cannot have identifiability. We therefore distinguish the unexpected cases: when the dimension of the moment variety is less than the dimension of both the parameter space and the moment space, then we say that the moment variety $\text{Sec}_k^H(G_{n,d})$ is defective. In particular, defectivity implies non-identifiability.

We illustrate with an example:

**Example 1.** Let $n = 2$, $k = 2$ and $d = 3$. That is, we consider moments up to order three for the homoscedastic mixture of two Gaussians in $\mathbb{R}^2$. The Gaussian moment variety $G_{2,3}$ is 5-dimensional with 2 parameters for the mean vector and 3 for the symmetric covariance matrix. The parameters for the homoscedastic mixture are two mean vectors $\mu_1 = \begin{pmatrix} \mu_{11} \\ \mu_{12} \end{pmatrix}$ and $\mu_2 = \begin{pmatrix} \mu_{21} \\ \mu_{22} \end{pmatrix}$, the common covariance $\Sigma = \begin{pmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{12} & \sigma_{22} \end{pmatrix}$ and the mixture weight $\lambda$ of the
first component, in total $2 \times 2 + 3 + 1 = 8$ parameters. On the other hand, there are 9 bivariate moments up to order 3. Explicitly, the map is:

\[
\begin{align*}
m_{10} &= \lambda \mu_{11} + (1 - \lambda) \mu_{21} \\
m_{01} &= \lambda \mu_{12} + (1 - \lambda) \mu_{22} \\
m_{20} &= \lambda (\mu_{11}^2 + \sigma_{11}) + (1 - \lambda)(\mu_{21}^2 + \sigma_{11}) \\
m_{02} &= \lambda (\mu_{12}^2 + \sigma_{22}) + (1 - \lambda)(\mu_{22}^2 + \sigma_{22}) \\
m_{11} &= \lambda (\mu_{11}\mu_{12} + \sigma_{12}) + (1 - \lambda)(\mu_{21}\mu_{22} + \sigma_{12}) \\
m_{30} &= \lambda (\mu_{11}^3 + 3\sigma_{11}\mu_{11}) + (1 - \lambda)(\mu_{21}^3 + 3\sigma_{11}\mu_{21}) \\
m_{03} &= \lambda (\mu_{12}^3 + 3\sigma_{22}\mu_{12}) + (1 - \lambda)(\mu_{22}^3 + 3\sigma_{22}\mu_{22}) \\
m_{21} &= \lambda (\mu_{11}^2\mu_{12} + \sigma_{11}\mu_{12} + 2\sigma_{12}\mu_{12}) + (1 - \lambda)(\mu_{21}^2\mu_{22} + \sigma_{11}\mu_{22} + 2\sigma_{12}\mu_{22}) \\
m_{12} &= \lambda (\mu_{11}\mu_{12}^2 + \sigma_{22}\mu_{12} + 2\sigma_{12}\mu_{12}) + (1 - \lambda)(\mu_{21}\mu_{22}^2 + \sigma_{22}\mu_{21} + 2\sigma_{12}\mu_{21})
\end{align*}
\]

Since we have more moments than parameters, one would expect that the mixture parameters can be recovered. However, the dimension of Sec\textsuperscript{3}_{G_{2,3}} equals 7. This is one less than the expected dimension of 8. Therefore it is defective and we do not have algebraic identifiability. This means that the method of moments is doomed to fail in this setting. However, if one measures moments up to order $d = 4$, it is possible to uniquely recover the mixture parameters.

As is often observed [1, 4, 10], a change of coordinates to cumulants tends to yield simpler representations and faster computations. This is the case here and hence we also study the cumulant varieties of the homoscedastic Gaussian mixtures. For Example 1 above, the moment variety in cumulant coordinates is simply the cone over a twisted cubic curve (see Example 10). This is not a coincidence, as we shall see in Section 3.

Our main results, Theorems 22 and 23, identify the defective homoscedastic moment varieties when $d = 3$ and show that the homoscedastic moment variety is not defective when $k \leq n + 1$. These are analogues of the Alexander-Hirschowitz theorem on secant-defective Veronese varieties [2].

This paper is organized as follows. In Section 2 we present the connection between moments and cumulants. We define the moment varieties corresponding to homoscedastic secants in Section 3. In Section 4 we give general algebraic identifiability considerations and do a careful analysis of the subcases $d = 3$, $k = 2$ and $n = 1$. Finally, we conclude with a summary of our results and list further research directions.

## 2 Moments and Cumulants

To get started, we make some remarks about moments and cumulants from an algebraic perspective. To a sufficiently integrable random variable $X$ on $\mathbb{R}^n$, we can associate its moments $m_{a_1, \ldots, a_n}[X]$ and cumulants $\kappa_{a_1, \ldots, a_n}[X]$ through the generating functions in $\mathbb{R}[u_1, \ldots, u_n]$:

\[
M_X(u) = \sum_{(a_1, \ldots, a_n)} m_{a_1, \ldots, a_n}[X] \frac{u_1^{a_1} \cdots u_n^{a_n}}{a_1! \cdots a_n!}, \quad K_X(u) = \sum_{(a_1, \ldots, a_n)} \kappa_{a_1, \ldots, a_n}[X] \frac{u_1^{a_1} \cdots u_n^{a_n}}{a_1! \cdots a_n!}.
\]
The information obtained from moments is equivalent to the one from cumulants, since they can be obtained from one another through the simple transformations

$$M_X(u) = \exp(K_X(u)), \quad K_X(u) = \log(M_X(u))$$

which are well-defined, because the 0-th moment is always one, whereas the 0-th cumulant is always zero: $m_0[X] = 1, \kappa_0[X] = 0$ for every random variable $X$. In particular, moments and cumulants take values in the affine hyperplanes $A_{n,M}^M$ and $A_{n,K}^K$ of $\mathbb{R}[u_1, \ldots, u_n]$ defined by

$$A_{n,M} = \{m_0 = 1\}, \quad A_{n,K} = \{\kappa_0 = 0\}.$$  

(6)

We call these hyperplanes the moment space and the cumulant space.

If we take only moments up to order $d$, we replace the power series ring $\mathbb{R}[u_1, \ldots, u_n]$ with the truncated ring $\mathbb{R}[u_1, \ldots, u_n]/(u_1, \ldots, u_n)^{d+1}$, and everything goes through. In particular, we have an analogous definition of the affine hyperplanes $A_{n,d,M}^M$ and $A_{n,d,K}^K$ which we denote again by moment space and cumulant space.

**Example 2** (Dirac distribution). Let $\mu = (\mu_1, \ldots, \mu_n)$ in $\mathbb{R}^n$ be a point. The Dirac distribution $\delta_{\mu}$ with center $\mu$ on $\mathbb{R}^n$ is given by

$$\int_{\mathbb{R}^n} f(x) \delta_{\mu}(x) := f(\mu).$$

Hence, if $X$ is a random variable on $\mathbb{R}^n$ with this distribution, its moment-generating function is

$$M_X(u) = \mathbb{E}[e^{u^t X}] = e^{u^t \mu} = \sum_{(a_1, \ldots, a_n)} \mu_1^{a_1} \cdots \mu_n^{a_n} \frac{u_1^{a_1} \cdots u_n^{a_n}}{a_1! \cdots a_n!}.$$ 

(8)

So that the moments of $X$ are simply the usual monomials evaluated at $\mu$. Instead, for the cumulant generating function we see that

$$K_X(u) = \log M_X(u) = \log e^{u^t \mu} = u^t \mu = \mu_1 u_1 + \cdots + \mu_n u_n,$$

hence the linear cumulants coincide with the coordinates of $\mu$, and the higher order cumulants are all zero.

This has an immediate translation into algebro-geometric terms: the parameter space for all Dirac distributions is the space $\mathbb{R}^n$, and the image of the moment map of degree $d$, $M: \mathbb{R}^n \to A_{n,d}^M$ is the affine $d$-th Veronese variety $V_{n,d} \subseteq A_{n,d}^M$. Instead, the image of the cumulant map $K: \mathbb{R}^n \to A_{n,d}^K$ is the linear subspace given by $\{\kappa_2 = \kappa_3 = \cdots = \kappa_d = 0\}$, where we denote by $\kappa_i$ the degree $i$-part of an element in $A_{n,d}^K$.

**Example 3** (Gaussian distribution). Let $\mu \in \mathbb{R}^n$ be a point, and $\Sigma \in \text{Sym}^2 \mathbb{R}^n$ an $n \times n$ symmetric and positive-definite matrix. The Gaussian distribution on $\mathbb{R}^n$ with mean $\mu$ and covariance matrix $\Sigma$ is given by the density

$$f_{(\mu, \Sigma)}(x) := \frac{1}{\sqrt{\det(2\pi\Sigma)}} e^{-\frac{1}{2}(x-\mu)^t \Sigma^{-1} (x-\mu)}.$$ 

(10)
If $X \sim \mathcal{N}(\mu, \Sigma)$ is a Gaussian random variable with these parameters, its moment-generating function and cumulant-generating function are given by

$$M_X(u) = e^{u^t \mu + \frac{1}{2} u^t \Sigma u}, \quad K_X(u) = u^t \mu + \frac{1}{2} u^t \Sigma u.$$ (11)

The Gaussian moment variety $\mathcal{G}_{n,d} \subseteq \mathbb{A}_{n,d}^M$ consists of all Gaussian moments up to order $d$. Observe that the corresponding cumulant variety is given simply by the linear subspace $\{ \kappa_3 = \cdots = \kappa_d = 0 \} \subseteq \mathbb{A}_{n,d}^K$.

While our focus is on Gaussian distributions, our approach applies to general location families that admit moment and cumulant varieties. We illustrate this with the next example.

**Example 4** (Laplace distribution). The (symmetric) multivariate Laplace distribution has a location parameter $\mu \in \mathbb{R}^n$ and a covariance parameter $\Sigma$, a positive-definite $n \times n$ matrix. Its density function involves the modified Bessel function of the second kind, but it has a much simpler moment generating function:

$$M_X(u) = \exp(u^t \mu) \left( 1 - \frac{1}{2} u^t \Sigma u \right), \quad K_X(u) = u^t \mu - \log \left( 1 - \frac{1}{2} u^t \Sigma u \right).$$ (12)

with radius of convergence such that $|u^t \Sigma u| < 2$.

Moments and cumulants up to order $d = 3$ match with the the Gaussian case. Also note that when $\Sigma = 0$, we recover once more the Dirac moment generating function. However, when $d \geq 4$, the Laplace cumulants are no longer a linear space in the cumulant space.

The multiplicative structure of the power series ring $\mathbb{R}\langle u_1, \ldots, u_n \rangle$ makes it particularly suitable to independence statements with respect to moments. Indeed, if $X,Y$ are two independent random variables on $\mathbb{R}^n$ then

$$M_{X+Y}(u) = \mathbb{E}[e^{u^t(X+Y)}] = \mathbb{E}[e^{u^tX} e^{u^tY}] = \mathbb{E}[u^tX] \cdot \mathbb{E}[u^tY] = M_X(u) \cdot M_Y(u).$$

With cumulants it is even simpler: indeed, we see that

$$K_{X+Y}(u) = \log(M_{X+Y}) = \log(M_X M_Y) = \log(M_X) + \log(M_Y) = K_X(u) + K_Y(u).$$

The group of affine transformations $\text{Aff}(\mathbb{R}^n)$ acts naturally on both moments and cumulants: indeed, for any $A \in GL(n, \mathbb{R})$ and $b \in \mathbb{R}^n$ and a random variable $X$ on $\mathbb{R}^n$, we have

$$M_{AX+b}(u) = M_A M_X(u) \cdot M_b(u) = \mathbb{E}[e^{u^tAX}] \cdot \mathbb{E}[e^{u^tb}] = e^{u^tb} \cdot \mathbb{E}[e^{(A^tu)^tX}] = e^{u^tb} \cdot M_X(A^t u)$$

and

$$K_{AX+b}(u) = \log(M_{AX+b}(u)) = \log(e^{u^tb} M_X(A^t u)) = u^t b + K_X(A^t u).$$

In particular, we see that translations correspond simply to translations in cumulant coordinates, whereas they induce a more complicated expression in moment coordinates.
3 Homoscedastic Secants

When Karl Pearson introduced Gaussian mixtures to model subpopulations of crabs [15], he also proposed the method of moments in order to estimate the parameters. The basic idea is to compute sample moments from observed data, and match them to the theoretical moments (which will be expressions in terms of the unknown parameters). Solving these equations for the parameters gives precisely the method of moments estimator. The method has been largely studied and generalized. A good survey is [13], and a recent ‘denoised’ version for Gaussian mixtures is [18].

The method of moments is very friendly for mixture models because computing moments of mixture densities is straightforward, since for every measurable function $g : \mathbb{R}^n \to \mathbb{R}$

$$
\int_{\mathbb{R}^n} g(x) \left( \sum_{i=1}^{k} \lambda_i f_{(\mu_i, \Sigma_i)}(x) \right) dx = \sum_{i=1}^{k} \lambda_i \int_{\mathbb{R}^n} g(x) f_{(\mu_i, \Sigma_i)}(x) dx,
$$

and thus the moments are just linear combinations of the corresponding Gaussian moments.

As hinted in the introduction, we can rephrase this discussion geometrically: let $G_{n,d} \subseteq A_{M_n,d}$ be the Gaussian moment variety on $\mathbb{R}^n$ of order $d$. Then the moments of mixtures of Gaussians are linear combinations of points in $G_{n,d}$, so that their corresponding variety is the $k$-th secant variety $\text{Sec}_k(G_{n,d})$.

Since our current interest is on homoscedastic Gaussian mixtures, where the Gaussian components share a common covariance matrix, the densities have the form:

$$
\lambda_1 f_{(\mu_1, \Sigma)}(x) + \cdots + \lambda_k f_{(\mu_k, \Sigma)}(x)
$$

where the $\mu_i \in \mathbb{R}^n$ are the mean parameters, the $\Sigma \in \text{Sym}^2 \mathbb{R}^n$ is the common covariance parameters, and the $\lambda_i \in \mathbb{R}$ with $\lambda_1 + \cdots + \lambda_k = 1$ are the mixture parameters. Thus, the parameter space for homoscedastic mixtures is

$$
\Theta_{n,k}^H := (\mathbb{R}^n)^k \times \mathbb{R}^{k-1} \times \text{Sym}^2 \mathbb{R}^n = \{(\mu_1, \ldots, \mu_k), (\lambda_1, \ldots, \lambda_k), \Sigma \mid \lambda_1 + \cdots + \lambda_k = 1\},
$$

and it has dimension

$$
\dim \Theta_{n,k}^H = nk + k - 1 + \frac{n(n+1)}{2} = (n+1) \left(k + \frac{n}{2}\right) - 1.
$$

The moment map for homoscedastic mixtures is then an algebraic map

$$
M_{n,k,d} : \Theta_{n,k}^H \to A_{M_n,d}^d.
$$

Points on the image, the moments of homoscedastic mixtures, are linear combinations of points in $G_{n,d} \subseteq A_{M_n,d}$ which share the same covariance matrix.

**Definition 5.** We define the image of the moment map $M_{n,k,d}$ as the homoscedastic $k$-secant variety, $\text{Sec}_k^H(G_{n,d})$. The fiber dimension $\Delta_{n,k,d}^H$ is the general fiber dimension of the map $M_{n,k,d}$,

$$
\Delta_{n,k,d}^H = \dim \Theta_{n,k}^H - \dim \text{Sec}_k^H(G_{n,d}).
$$

We say that $\text{Sec}_k^H(G_{n,d})$ is algebraically identifiable if and only if $\Delta_{n,k,d}^H = 0$. 

The feasibility of the method of moments is based on computing points on the fibers of the moment map $M_{n,k,d}$. Algebraic identifiability of $\text{Sec}_k^H(G_{n,d})$ means that a general homoscedastic Gaussian mixture of parameters $n, k$ is indeed identifiable from its moments up to order $d$ in the sense that only finitely many Gaussian mixture distributions share the same moments up to order $d$, whereas we reserve the term rationally identifiable if a general fiber consists of a single point, up to label swapping. In case the general fiber is not finite, then it is positive-dimensional, there is no identifiability of the parameters from the moments up to order $d$, and a higher order is needed for identifiability (cf. Remark 16 and [4, Problem 17]).

Since the dimension of $\text{Sec}_k^H(G_{n,d})$ is always bounded by the dimension of the ambient space $\mathbb{A}_{n,d}$, we get a simple estimate for the fiber dimension:

**Lemma 6.** For all $n, d, k$ we have that

$$\Delta^H_{n,k,d} \geq \max \left\{ (n + 1) \left( k + \frac{n}{2} \right) - \left( \frac{n + d}{d} \right), 0 \right\}. \quad (18)$$

**Proof.** The moment space $\mathbb{A}_{n,d}^M$ is an affine hyperplane inside the vector space $\mathbb{R}[[u_1, \ldots, u_n]]/(u_1, \ldots, u_n)^{d+1}$, hence it has dimension

$$\dim \mathbb{A}_{n,d}^M = \dim \mathbb{R}[[u_1, \ldots, u_n]]/(u_1, \ldots, u_n)^{d+1} - 1 = \left( \frac{n + d}{d} \right) - 1. \quad (19)$$

Since $\text{Sec}_k^H(G_{n,d}) \subseteq \mathbb{A}_{n,d}^M$ we see that

$$\Delta^H_{n,k,d} = \dim \Theta_{n,k}^H - \dim \text{Sec}_k^H(G_{n,d}) \geq \dim \Theta_{n,h}^H - \dim \mathbb{A}_{n,d}^M \quad (20)$$

which is exactly the inequality in the statement. □

We expect that in general situations the inequality \cite{18} is in fact an equality. Hence, we define the defect to be

$$\delta^H_{n,k,d} := \Delta^H_{n,k,d} - \max \left\{ (n + 1) \left( k + \frac{n}{2} \right) - \left( \frac{n + d}{d} \right), 0 \right\}. \quad (21)$$

We say that $\text{Sec}_k^H(G_{n,d})$ is defective if and only if $\delta^H_{n,k,d} > 0$. As observed earlier, defectivity implies non-identifiability.

### 3.1 Cumulant representation

We explore how homoscedastic secants become in some sense simpler in cumulant coordinates, and how this representation can be used to check identifiability.

First we rephrase the situation in terms of random variables: let $Z = Z_\Sigma$ be a Gaussian random variable with mean 0 and covariance matrix $\Sigma$, and let $B = B_{(\mu_1, \ldots, \mu_k), (\lambda_1, \ldots, \lambda_k)}$ an independent random variable with distribution given by a mixture of Dirac distributions:

$$\lambda_1 \delta_{\mu_1}(x) + \cdots + \lambda_k \delta_{\mu_k}(x). \quad (22)$$
Then, the random variable $Z + B$ has density given precisely by the homoscedastic mixture $[1]$. Moreover, if $m = \mu_1 \lambda_1 + \cdots + \mu_k \lambda_k$ is the mean of $B$, we can write $B = A + m$, where $A$ is a centered mixture of Dirac distributions.

We can compute cumulants of this random variable as follows:

$$K_{B+Z}(u) = K_B(u) + K_Z(u) = K_A(u) + m^t u + \frac{1}{2} u^t \Sigma u$$

and this suggests to parametrize the homoscedastic secants in cumulant coordinates as follows:

$$K : \Theta^0_{n,k} \times \mathbb{R}^n \times \text{Sym}^2 \mathbb{R}^n \to \mathbb{A}^K_{n,d}, \quad (A, m, \Sigma) \mapsto K_A(u) + m^t u + \frac{1}{2} u^t \Sigma u$$

where $\Theta^0_{n,k}$ parametrizes the centered mixtures of Dirac distributions

$$\Theta^0_{n,k} = \{ (\mu_1, \ldots, \mu_k), (\lambda_1, \ldots, \lambda_k) \mid \lambda_1 \mu_1 + \cdots + \lambda_k \mu_k = 0, \lambda_1 + \cdots + \lambda_k = 1 \}$$

The cumulant homoscedastic secant variety $\log(\text{Sec}^H_k (G_{n,d}))$ is by construction the image of the map above. However, we observe that in the image of the map, every possible value of the first cumulants and the second cumulants is allowed, since we can freely translate by the elements in $\mathbb{R}^n$ and $\text{Sym}^2(\mathbb{R}^n)$, so the only constraints are in the cumulants of order three and higher. We summarize this discussion in the following lemma.

**Lemma 7.** Let $\mathbb{A}^{K,3}_{n,d}$ be the space of cumulants of order at least three and at most $d$, let

$$\phi = \phi_{n,k,d} : \Theta^0_{n,k} \to \mathbb{A}^{K,3}_{n,d}, \quad A \mapsto K_A(u)_3 + K_A(u)_4 + \cdots + K_A(u)_d$$

be the cumulant map and let $C^0_{n,k,d}$ denote the closure $\overline{\phi(\Theta^0_{n,k})}$. Then the cumulant homoscedastic secant variety $\log(\text{Sec}^H_k (G_{n,d}))$ is the cone over $C^0_{n,k,d}$.

**Remark 8.** In particular, the equations for the cumulant homoscedastic secant variety $\log(\text{Sec}^H_k (G_{n,d}))$ inside $\mathbb{A}^{K,3}_{n,d}$ are exactly the same as the equations for $C^0_{n,k,d}$ inside $\mathbb{A}^{K,3}_{n,d}$.

The fiber dimension $\Delta^H_{n,k,d}$ can also be computed as the fiber dimension of the map $\phi$:

**Lemma 9.** The fiber dimension $\Delta^H_{n,k,d}$ is equal to the fiber dimension of $\phi$. In other words

$$\Delta^H_{n,k,d} = \dim \Theta^0_{n,k} - \dim C^0_{n,k,d} = (k - 1)(n + 1) - \dim C^0_{n,k,d}.$$  

**Proof.** The fiber dimension $\Delta^H_{n,k,d}$ is the difference $\dim \Theta^H_{n,k} - \dim \log(\text{Sec}^H_k (G_{n,d}))$. We know that $\Theta^H_{n,k} \cong \Theta^0_{n,k} \times \mathbb{R}^n \times \text{Sym}^2 \mathbb{R}^n$. Moreover, Lemma 7 tells us that $\log(\text{Sec}^H_k (G_{n,d}))$ is the cone over $C^0_{n,k,d}$, which is precisely $\mathbb{R}^n \times \text{Sym}^2 \mathbb{R}^n \times C^0_{n,k,d}$, so that the first equality follows. For the second equality, the dimension of $\Theta^0_{n,k}$ can be computed as $nk + k - 1 - n = (n+1)(k-1)$.  $\square$
**Example 10** \( (n = k = 2, \ d = 3) \). Revisiting Example 1 from the introduction, we concluded that \( \text{Sec}^H_2(G_{2,3}) \subset A^M_{n,3} \cong A^0 \) is expected to be a hypersurface but it is actually of codimension 2. The ideal of \( \text{Sec}^H_2(G_{2,3}) \) is Cohen-Macaulay and determinantal (generated by the maximal minors of a \( 6 \times 5 \)-matrix) as described in [4, Proposition 19]. The homoscedastic cumulant variety \( \log(\text{Sec}^H_2(G_{2,3})) \) is defined by the vanishing of the \( 2 \times 2 \) minors of 

\[
\begin{pmatrix}
k_{30} & k_{21} & k_{12} \\
k_{21} & k_{12} & k_{03}
\end{pmatrix}.
\]

Note that indeed the first and second order cumulants \( k_{10}, k_{01}, k_{20}, k_{11}, k_{22} \) do not appear in the equations above, so that the cumulant variety is the cone over the twisted cubic curve.

**Remark 11.** We also see that to estimate the mixture parameters from the cumulants we can limit ourselves again to the map \( \phi \) of Lemma 7. Indeed, suppose that we have a homoscedastic mixture with parameters \( (((\lambda_1, \ldots, \lambda_k), (\mu_1, \ldots, \mu_k)), m, \Sigma) \in \Theta^0_{n,k} \times \mathbb{R}^n \times \text{Sym}^2 \mathbb{R}^n \) and suppose that we know its cumulants, that we can write in polynomial form as

\[
\begin{align*}
\kappa_1(u) &= m^t u \\
\kappa_2(u) &= K_A(u)_2 + \frac{1}{2} u^t \Sigma u \\
\kappa_3(u) &= K_A(u)_3 \\
\kappa_4(u) &= K_A(u)_4 \\
&\vdots
\end{align*}
\]

Then we see that to recover the parameters we can first try to recover the \( \lambda_i \) and the \( \mu_i \) from the cumulants of order three and higher, and then compute \( m \) and \( \Sigma \) from the cumulants of order one and two.

### 3.2 Veronese secants

We briefly observe that we can recast the above discussion in a way that makes apparent the connection to mixtures of Dirac distributions and, hence, to secants of Veronese varieties. To work with classical secant varieties, this time we work in moment coordinates. We have seen that every homoscedastic mixture is the distribution of a random variable of the form \( Z + B \), where \( B \) is a mixture of Dirac distributions and \( Z \) is a centered Gaussian of covariance \( \Sigma \), independent from \( B \). Thus the moment generating function of this variable is

\[
M_{Z+B}(u) = M_Z(u)M_B(u) = e^{\frac{1}{2} u^t \Sigma u} \cdot M_B(u).
\]

We see that in this way we can decouple the role of the covariance parameter from the others: in particular, we see that for \( \Sigma = 0 \), we get precisely the moment variety for mixtures of Dirac distributions, and we know that this is precisely the \( k \)-secant to the Veronese variety \( \text{Sec}_k(V_{n,d}) \). Then, we observe that the additive group \( \text{Sym}^2 \mathbb{R}^n \) acts on the moment space \( A^M_{n,d} \) by

\[
\text{Sym}^2 \mathbb{R}^n \times A^M_{n,d} \to A^M_{n,d}, \quad (\Sigma, M(u)) \mapsto e^{\frac{1}{2} u^t \Sigma u} \cdot M(u)
\]
and then (29) tells us precisely that \( \text{Sec}^H_k(G_{n,d}) \) is the union of all the orbits of the points in \( \text{Sec}_k(V_{n,d}) \) under this action.

This is useful because we can exploit well-known results on secants of Veronese varieties to address identifiability. First, let \( \Delta^V_{n,k,d} \) denote the fiber dimension of the \( k \)-secants to the Veronese variety \( \text{Sec}_k(V_{n,d}) \subseteq \mathbb{P}^{M_{n,d}} \): by definition, this is

\[
\Delta^V_{n,k,d} := nk + k - 1 - \dim \text{Sec}_k(V_{n,d}).
\]  

A basic estimate for the dimension of \( \text{Sec}_k(V_{n,d}) \) is given by the dimension of the ambient space \( \dim A^{M_{n,d}} = \binom{n+d}{d} - 1 \), hence we see that

\[
\Delta^V_{n,k,d} \geq \max \left\{ (n+1)k - \binom{n+d}{d}, 0 \right\}
\]

(32)

so that we can define the defect for the \( k \)-th secant of the Veronese variety as

\[
\delta^V_{n,k,d} := \Delta^V_{n,k,d} - \max \left\{ (n+1)k - \binom{n+d}{d}, 0 \right\}.
\]

(33)

This number was famously computed by Alexander and Hirschowitz [2]:

**Theorem 12** (Alexander-Hirschowitz). The defect for the Veronese variety is always zero, except in the following exceptional cases

\[
\begin{align*}
d = 2, 2 \leq k & \leq n \quad \Delta^V_{n,k,2} = \frac{k(k - 1)}{2} \\
n = 2, d = 4, k = 5 \quad \delta^V_{2,5,4} = 1 \\
n = 3, d = 4, k = 9 \quad \delta^V_{3,9,4} = 1 \\
n = 4, d = 3, k = 7 \quad \delta^V_{4,7,3} = 1 \\
n = 4, d = 4, k = 14 \quad \delta^V_{4,14,4} = 1
\end{align*}
\]

Moreover, for a general point \( M(u) \in \text{Sec}_k(V_{n,d}) \), let us consider the closed subset of \( \text{Sym}^2 \mathbb{R}^n \) given by

\[
D(M) := \{ \Sigma \in \text{Sym}^2 \mathbb{R}^n \mid e_1^2 u^t \Sigma u \cdot M(u) \in \text{Sec}_k(V_{n,d}) \}.
\]

(35)

Then we have the following relation between the fiber dimensions (17) and (31):

**Proposition 13.** It holds that

\[
\Delta^H_{n,k,d} = \Delta^V_{n,k,d} + \dim D(M)
\]

(36)

where \( M \in \text{Sec}_k(V_{n,d}) \) is a general point.
Proof. By the previous discussion, the moment map for homoscedastic mixtures factors as a composition of two surjective maps

$$\Theta^H_{n,k} \rightarrow \text{Sym}^2(\mathbb{R}^n) \times \text{Sec}_k(\mathcal{V}_{n,d}) \rightarrow \text{Sec}_k^H(\mathcal{G}_{n,d}).$$

(37)

Hence, the fiber dimension of the composite map is the sum of the fiber dimensions of the two factors. For the first one this is precisely $\Delta^V_{n,k,d}$ so it remains to consider the second. Denote it temporarily by $\rho: \text{Sym}^2(\mathbb{R}^n) \times \text{Sec}_k(\mathcal{V}_{n,d}) \rightarrow \text{Sec}_k^H(V_{n,d})$ and let $(\Sigma_o, M_o(u)) \in \text{Sym}^2(\mathbb{R}^n) \times \text{Sec}_k(\mathcal{V}_{n,d})$ be a general point. We need to compute the dimension of the fiber

$$\rho^{-1}(\rho(\Sigma_o, M_o(u))) = \{(\Sigma, M(u)) | e^{\frac{1}{2}u^t\Sigma u} \cdot M(u) = e^{\frac{1}{2}u^t\Sigma_o u} \cdot M_o(u)\}$$

$$= \{\Sigma \in \text{Sym}^2(\mathbb{R}^n) | e^{\frac{1}{2}u^t(\Sigma_o - \Sigma) u} \cdot M_o(u) \in \text{Sec}_k(\mathcal{V}_{n,d})\}$$

(38)

$$= \Sigma_o - \{\Sigma' \in \text{Sym}^2(\mathbb{R}^n) | e^{\frac{1}{2}u^t(\Sigma_o - \Sigma) u} \cdot M_o(u) \in \text{Sec}_k(\mathcal{V}_{n,d})\} \cong D^K(M_o)$$

and we are done.

Remark 14. In particular, in the range $(n+1)(k+\frac{n}{2}) \leq (n+d)$ where we expect identifiability for homoscedastic Gaussian mixtures, we see that $\Delta^V_{n,k,d} = \delta^V_{n,k,d}$, and Alexander-Hirschowitz tells us that $\Delta^V_{n,k,d} = \delta^V_{n,k,d} = 0$. Hence Proposition 13 yields

$$\delta^H_{n,k,d} = \dim D(M)$$

(39)

4 Moment Identifiability

Now we start to determine identifiability in various cases. To do so, it will be convenient to change notation slightly: we will replace the location parameter $\mu = (\mu_1, \ldots, \mu_n)$ with the corresponding linear polynomial $u^t\mu = \mu_1 u_1 + \cdots + \mu_n u_n$ and we will replace the covariance parameter $\Sigma$ with the quadric $\frac{1}{2}u^t\Sigma u$. Of course, the two representations are equivalent, but the polynomial formalism is better suited to the cumulant space and the moment space. In particular, the linear polynomials live in the dual vector space $V = \text{Hom}(\mathbb{R}^n, \mathbb{R})$, whereas the quadratic polynomials live in $\text{Sym}^2 V$.

The next inequality reflects the fact that increasing the order of moments (or cumulants) measured results in better identifiability:

Lemma 15. For the fiber dimension, it holds that:

$$\Delta^H_{n,k,d} \geq \Delta^H_{n,k,d+1}.$$  

(40)

Proof. By definition, the fiber dimension $\Delta^H_{n,k,d}$ is the dimension of a general nonempty fiber of the moment map $M_{n,k,d}: \Theta^H_{n,k,d} \to \mathcal{A}_{n,d}$. However, this map is the composition of the map $M_{n,k,d+1}: \Theta^H_{n,k,d} \to \mathcal{A}_{n,d+1}$ and the projection map $\mathcal{A}_{n,d+1} \to \mathcal{A}_{n,d}$, that forgets the moments of order $d + 1$, so that the conclusion follows.

\[\square\]
Remark 16. Since Gaussian mixtures are identifiable from finitely many moments (see e.g. [4]), the sequence
\[ \Delta_{n,k,1}^H \geq \Delta_{n,k,2}^H \geq \cdots \geq \Delta_{n,k,d}^H \geq \Delta_{n,k,d+1}^H \geq \cdots \]
must stabilize at 0 for some \( D \gg 0 \).

The following observation is less trivial: it tells us that if the number \( k \) of mixed distribution is less than the dimension \( n \) of the space plus one, then we can reduce to the case \( n = k - 1 \).

Proposition 17. Suppose that \( d \geq 3 \) and \( n \geq k - 1 \), then
\[ \Delta_{n,k,d}^H = \Delta_{k-1,k,d}^H. \] (41)

Proof. We use Lemma \( \Box \) which tells us that the fiber dimension \( \Delta_{n,k,d}^H \) is equal to the fiber dimension of the map
\[ \phi_{n,k,d} : \Theta_{n,k}^0 \to \Lambda_{n,d}^{K,3}. \] (42)
This dimension can be computed by looking at the differential of the map at a general point. Recall that the parameter space is defined (in our new polynomial notation) as
\[ \Theta_{n,k}^0 = \left\{ ((\lambda_1, \ldots, \lambda_k), (L_1, \ldots, L_k)) \in \mathbb{R}^k \times V^k \mid \sum_{i=1}^k \lambda_i = 1, \sum_{i=1}^k \lambda_i L_i = 0 \right\}. \] (43)

Let \( p = ((\lambda_1, \ldots, \lambda_k), (L_1, \ldots, L_k)) \in \Theta_{n,k}^0 \) be a general point. Then the tangent space to \( \Theta_{n,k}^0 \) at the point is given by
\[ T_p \Theta_{n,k}^0 = \left\{ ((\varepsilon_1, \ldots, \varepsilon_k), (H_1, \ldots, H_k)) \in \mathbb{R}^k \times V^k \mid \sum_{i=1}^k \varepsilon_i = 0, \sum_{i=1}^k (\varepsilon_i L_i + \lambda_i H_i) = 0 \right\}. \]

The fiber dimension of \( \phi_{n,k,d} \) coincides with the dimension of the kernel of the differential \( d\phi_{n,k,d} \) at the general point \( p \). In particular, since the point is general and \( n \geq k - 1 \), we can suppose that \( L_i = u_i \) for \( i = 1, \ldots, k - 1 \) and that all the \( \lambda_i \) are nonzero. In particular \( L_k \) is a linear combination of \( u_1, \ldots, u_{k-1} \). Now, we claim that if \( ((\varepsilon_1, \ldots, \varepsilon_k), (H_1, \ldots, H_k)) \) is in the kernel of \( d\phi_{n,k,d} \) then the only variables appearing in the \( H_i \) are \( u_1, \ldots, u_k \). If this is true, then we are done, because the kernel of \( d\phi_{n,k,d} \) will coincide with the kernel of \( d\phi_{k-1,k,d} \) at the point \( ((\lambda_1, \ldots, \lambda_k), (L_1, \ldots, L_k)) \in \Theta_{k-1,k}^0 \).

To prove the claim, observe that the map is given by the cumulant functions \( \phi = (\kappa_3, \kappa_4, \ldots, \kappa_d) \), so it is enough to prove the analogous claim for the kernel of the differential of \( \kappa_3 \). Since our distribution has mean zero by construction, the third cumulant coincides with the third moment
\[ \kappa_3 = \lambda_1 L_1^3 + \cdots + \lambda_k L_k^3. \] (44)

Hence the differential is the linear map
\[ d\kappa_{3,p} : T_p \Theta_{n,k}^0 \to \Lambda_{n,d}^{K,3}, \quad ((\varepsilon_1, \ldots, \varepsilon_k), (H_1, \ldots, H_k)) \mapsto \sum_{i=1}^k (3 \lambda_i H_i + \varepsilon_i L_i) L_i^2 \] (45)
and if \(((\varepsilon_1, \ldots, \varepsilon_k), (H_1, \ldots, H_k))\) is in the kernel, then we must have
\[
\sum_{i=1}^{k} h_i L_i^2 = 0, \quad \text{where } h_i = 3\lambda_i H_i + \varepsilon_i L_i. \tag{46}
\]
Since \(\lambda_k \neq 0\), this is equivalent to \(\sum_{i=1}^{k} h_i (\lambda_i L_i)^2 = 0\) and since \(\lambda_1 L_1 + \cdots + \lambda_k L_k = 0\), we see that
\[
\sum_{i=1}^{k} h_i (\lambda_i L_i)^2 = \sum_{i=1}^{k-1} h_i (\lambda_i L_i)^2 + h_k \left( \sum_{i=1}^{k-1} \lambda_i L_i \right)^2 \tag{46}
\]
\[
= \sum_{i=1}^{k-1} (\lambda_i^2 h_i + \lambda_k^2 h_k) L_i^2 + 2h_k \left( \sum_{1 \leq i < j \leq k-1} \lambda_i \lambda_j L_i L_j \right). \tag{46}
\]
Recalling our assumption that \(L_i = u_i\) for \(i = 1, \ldots, k - 1\), this last expression is equal to zero if and only if we have an equality
\[
\sum_{i=1}^{k-1} (\lambda_i^2 h_i + \lambda_k^2 h_k) u_i^2 = -2h_k \left( \sum_{1 \leq i < j \leq k-1} \lambda_i \lambda_j u_i u_j \right). \tag{47}
\]
If this is true, then we see that there cannot be a variable different from \(u_1, \ldots, u_{k-1}\) in \(h_k\). Indeed, if there is such a variable \(y\), then on the right hand side we have the monomial \(yu_1 u_2\), while there cannot be such a monomial on the left hand side. Suppose also that a variable \(y\) appears in one of the \(h_i\) for \(i = 1, \ldots, k - 1\): then on the left hand side there would be a monomial of the form \(yu_i^2\), while there is no such monomial on the right hand side.

Hence, this shows that the \(h_i\) are polynomials in the \(u_1, \ldots, u_k\), and, by definition of the \(h_i\), it follows that the same holds for the \(H_i\). This proves our claim and we are done. \(\Box\)

Thanks to this proposition, we will be able to completely characterize identifiability whenever \(n \geq k - 1\).

### 4.1 Moments up to order \(d = 3\)

When \(d = 3\) we can determine the defect and the fiber dimension \(\Delta_{n,k,3}^H\) in all cases. To carry out the analysis for each \(n\) and \(k\) our strategy is to use Lemma 9. First we observe that when \(d = 3\), the space \(A_{n,d}^{K,3}\) is identified with the space \(\text{Sym}^3 V\) of homogeneous polynomials of degree three. Moreover, as we observed in the proof of Proposition 17, the third cumulants coincide with the third moments, so that the map \(\phi\) of Lemma 9 is:
\[
\phi: \Theta_{n,k}^0 \to \text{Sym}^3 V \quad \left( (L_1, \ldots, L_k), (\lambda_1, \ldots, \lambda_k) \right) \mapsto \lambda_1 L_1^3 + \cdots + \lambda_k L_k^3. \tag{48}
\]
We can compute the closure \(C_{n,k,d}^0\) of the image fairly explicitly.

**Lemma 18.** The set \(C_{n,k,d}^0\) is the Zariski closure of
\[
\{ H_1(u)^3 + \cdots + H_k(u)^3 \mid H_1(u), \ldots, H_k(u) \in \mathbb{R}^n \text{ linearly dependent } \}. \tag{49}
\]
\textbf{Proof.} Recall that
\[ \Theta^0_{n,k} = \{((L_1, \ldots, L_k), (\lambda_1, \ldots, \lambda_k)) \in V^k \times \mathbb{R}^{k-1} \mid \lambda_1 + \cdots + \lambda_k = 1, \lambda_1 L_1 + \cdots + \lambda_k L_k = 0 \}. \]
To compute the Zariski closure, we can suppose that all the $\lambda_i$ are strictly positive, so that in particular we can write
\[ L_k = \frac{-\lambda_1}{\lambda_k} L_1 - \cdots - \frac{-\lambda_{k-1}}{\lambda_k} L_{k-1}. \quad (50) \]
Since cubic roots are well defined over $\mathbb{R}$, we can write
\[
\begin{align*}
\lambda_1 L_1^3 + \cdots + \lambda_k L_k^3 &= \lambda_1 L_1^3 + \cdots + \lambda_k L_k^3 - \lambda_k \left( \frac{\lambda_1}{\lambda_k} L_1 + \cdots + \frac{\lambda_{k-1}}{\lambda_k} L_{k-1} \right)^3 \\
&= (\sqrt[3]{\lambda_1} L_1)^3 + \cdots + (\sqrt[3]{\lambda_k} L_k)^3 - \left[ \left( \frac{\sqrt[3]{\lambda_1}}{\sqrt[3]{\lambda_k}} \right)^2 \cdot 3 \sqrt[3]{\lambda_1} L_1 + \cdots + \left( \frac{\sqrt[3]{\lambda_k}}{\sqrt[3]{\lambda_k}} \right)^2 \cdot 3 \sqrt[3]{\lambda_{k-1}} L_{k-1} \right]^3 \\
&= H_1^3 + \cdots + H_{k-1}^3 - \left[ \left( \frac{\sqrt[3]{\lambda_1}}{\sqrt[3]{\lambda_k}} \right)^2 \cdot H_1 + \cdots + \left( \frac{\sqrt[3]{\lambda_k}}{\sqrt[3]{\lambda_k}} \right)^2 \cdot H_{k-1} \right]^3 \\
&= H_1^3 + \cdots + H_{k-1}^3 + H_k^3 \quad (52)
\end{align*}
\]
where $H_i := \sqrt[3]{\lambda_i} L_i$ for $i = 1, \ldots, k - 1$, and $H_k := -\sum_{i=1}^{k-1} \left( \frac{\sqrt[3]{\lambda_i}}{\sqrt[3]{\lambda_k}} \right)^2 L_i$. In particular, this shows immediately that $\lambda_1 L_1^3 + \cdots + \lambda_k L_k^3$ can be written as a sum of cubic powers of linearly dependent linear forms.

For the converse, let $H_1, \ldots, H_k$ be linearly dependent linear forms: since we are interested just in the Zariski closure, we can assume that $H_k = -\beta_1 H_1 - \cdots - \beta_{k-1} H_{k-1}$ for some general $\beta_1, \ldots, \beta_{k-1} \in \mathbb{R}$ strictly positive. We want to write
\[ \beta_i = \left( \frac{\sqrt[3]{\lambda_i}}{\sqrt[3]{\lambda_k}} \right)^2 \quad (51) \]
for some $\lambda_1, \ldots, \lambda_k \in \mathbb{R}$ positive such that $\lambda_1 + \cdots + \lambda_k = 1$. If we can find such $\lambda_i$, then the previous computations tell us that
\[ H_1^3 + \cdots + H_k^3 = \lambda_1 L_1^3 + \cdots + \lambda_k L_k^3 \quad (52) \]
where $L_i = \frac{1}{\sqrt[3]{\lambda_i}} H_i$ for $i = 1, \ldots, k - 1$ and $L_k = -\frac{\lambda_1}{\lambda_k} L_1 - \cdots - \frac{\lambda_{k-1}}{\lambda_k} L_{k-1}$, so that $\lambda_1 L_1 + \cdots + \lambda_k L_k = 0$, which is what we want to prove.

To conclude, we need to show that the equations (51) have a solution: these equations are equivalent to
\[ (\sqrt[3]{\beta_i})^3 = \frac{\lambda_i}{1 - \lambda_1 - \cdots - \lambda_{k-1}} \quad \text{for } i = 1, \ldots, k - 1. \quad (53) \]
Observe that the square roots are well defined since $\beta_i > 0$ for all $i = 1, \ldots, k-1$. Moreover, if $\lambda_1, \ldots, \lambda_{k-1}$ is a solution to this equation, then it is easy to see that all the $\lambda_i$ must be strictly positive: indeed, since the $\beta_i$ are positive, $\lambda_i$ and $1 - \lambda_1 - \cdots - \lambda_{k-1}$ have the same sign. Thus, if one of the $\lambda_i$ is negative, then all the $\lambda_i$ are negative, but then $1 - \lambda_1 - \cdots - \lambda_{k-1} > 0$ which is absurd.

Now, setting $b_i = \sqrt[3]{\beta_i}$, we can rewrite the equations as the linear system

$$
\begin{pmatrix}
1 + b_1 & b_1 & b_1 & \ldots & b_1 \\
 b_2 & 1 + b_2 & b_2 & \ldots & b_2 \\
 b_3 & b_3 & 1 + b_3 & \ldots & b_3 \\
 \vdots & \vdots & \vdots & \ddots & \vdots \\
 b_{k-1} & b_{k-1} & b_{k-1} & \ldots & 1 + b_{k-1}
\end{pmatrix}
\begin{pmatrix}
\lambda_1 \\
 \lambda_2 \\
 \lambda_3 \\
 \vdots \\
 \lambda_{k-1}
\end{pmatrix}
= 
\begin{pmatrix}
 b_1 \\
 b_2 \\
 b_3 \\
 \vdots \\
 b_{k-1}
\end{pmatrix}
$$

The Matrix Determinant Lemma gives that $\det(I + b \cdot 1^T) = 1 + 1^Tb = 1 + b_1 + \cdots + b_{k-1}$, which is positive since the $\beta_i$ are positive. This means the system (54) has a unique solution.

**Remark 19.** The proof of Lemma 18 gives actually more: indeed, it shows that the image of the positive part

$$
\Theta_{n,k}^{0,+} = \{((L_1, \ldots, L_k), (\lambda_1, \ldots, \lambda_k)) \in \Theta_{n,d}^0 | \lambda_i > 0 \text{ for all } i = 1, \ldots, k\},
$$

which is the one relevant in statistics, coincides with the set of sums $\{H_1(u)^3 + \cdots + H_k(u)^3\}$, where the $H_i$ are positively linearly dependent, meaning that there are coefficients $\beta_1, \ldots, \beta_k > 0$ such that

$$
\beta_1 H_1 + \cdots + \beta_k H_k = 0.
$$

**Remark 20.** The set of sums of cubes of $k$ dependent linear forms has a natural interpretation in terms of the projective Veronese variety: indeed consider the third Veronese embedding of $\mathbb{P}(V) = \mathbb{P}^{n-1}$:

$$
v_3: \mathbb{P}(V) \hookrightarrow \mathbb{P}(\text{Sym}^3 V), \quad [L] \mapsto [L^3].
$$

For each $(k-2)$-dimensional linear subspace $\Pi \subseteq \mathbb{P}^{n-1}$ we can take the $k$-th secant variety $\text{Sec}_k(v_3(\Pi)) \subseteq \mathbb{P}(\text{Sym}^3 V)$, and then Lemma 18 is telling us that $C_{n,k,d}^0$ is the affine cone over the union of these secants:

$$
C_{n,k,d}^0 = \text{Cone} \left( \bigcup_{\Pi \subseteq \mathbb{P}^{n-1}} \text{Sec}^k(v_3(\Pi)) \right).
$$

The dimension of this variety can be computed explicitly. We divide our approach in the cases $k \leq n + 1$ and $k \geq n + 1$:

**Proposition 21.**

i) If $k \geq n + 1$, then

$$
\dim C_{n,k,d}^0 = \min \left\{ kn, \binom{n+2}{3} \right\}
$$

except in the case $n = 5, k = 7$, where $\dim C_{3,7,3}^0 = 34$.  

15
ii) If \( k \leq n + 1 \), then
\[
\Delta^H_{n,4,3} = 2, \quad \Delta^H_{n,3,3} = 2, \quad \Delta^H_{n,2,3} = 1. \tag{60}
\]
and when \( k \geq 5 \),
\[
\Delta^H_{n,k,3} = 0. \tag{61}
\]

Proof. i) Since \( k \geq n + 1 \), Remark [20] shows that \( C^0_{n,k,3} \) is simply the cone over the \( k \)-th secant variety \( \text{Sec}_k(v_3(\mathbb{P}^{n-1})) \). The dimension of this variety is computed by the Alexander-Hirschowitz theorem, so that we get:
\[
\text{dim } C^0_{n,k,3} = \min \left\{ kn, \left( \frac{n+2}{3} \right) \right\} \tag{62}
\]
with the single exception of \( n = 5, k = 7 \), where the dimension is one less than the expected, hence \( \text{dim } C^0_{5,7,3} = 34 \).

ii) Since \( k \leq n + 1 \), Proposition [17] shows that \( \Delta^H_{n,k,3} = \Delta^H_{k-1,k,3} \). Hence, for \( k = 2, 3, 4 \) we can see directly from Table [1] that
\[
\Delta^H_{3,4,3} = 2, \quad \Delta^H_{2,3,3} = 2, \quad \Delta^H_{1,2,3} = 1. \tag{63}
\]
For \( k \geq 5 \) instead, we follow the proof of Proposition [17] and try to show that the differential of \( \phi_{k-1,k,3} : \Theta^0_{k-1,k,3} \to \text{Sym}^3 V \) at a general point is injective. We know that the kernel of the differential at a point \( p = ((\lambda_1, \ldots, \lambda_k), (L_1, \ldots, L_k)) \) consists of elements \( ((\varepsilon_1, \ldots, \varepsilon_k), (H_1, \ldots, H_k)) \in \mathbb{R}^k \times V^k \) such that \( \varepsilon_1 + \cdots + \varepsilon_k = 0, \varepsilon_1 L_1 + \cdots + \varepsilon_k L_k + \lambda_1 H_1 + \cdots + \lambda_k H_k = 0 \) and
\[
\sum_{i=1}^{k-1} \ell_i L_i^2 + 2h \left( \sum_{1 \leq i < j \leq k-1} \lambda_i \lambda_j L_i L_j \right) = 0, \tag{64}
\]
where \( \ell_i = \lambda_i^2 (3\lambda_i H_i + \varepsilon_i L_i) + \lambda_i^2 (3\lambda_k H_k + \varepsilon_k L_k) \) and \( h = 3\lambda_k H_k + \varepsilon_k L_k \). Now choose the specific point \( p \) given by \( \lambda_i = \frac{1}{k} \) for each \( i = 1, \ldots, k \), \( L_i = u_i \) for \( i = 1, \ldots, k-1 \) and \( L_k = -u_1 - \cdots - u_{k-1} \). Then the equation above becomes
\[
\sum_{i=1}^{k-1} \ell_i u_i^2 + \frac{2}{k^2} \cdot h \left( \sum_{1 \leq i < j \leq k-1} u_i u_j \right) = 0. \tag{65}
\]
Let us write \( h = h_1 u_1 + \cdots + h_{k-1} u_{k-1} \). In (65), we see that the coefficient of \( u_au_bu_c \) is \( \frac{2}{k^2} (h_a + h_b + h_c) \) for all \( 1 \leq a < b < c \leq k-1 \). Hence we get the equations
\[
h_a + h_b + h_c = 0, \quad \text{for all } 1 \leq a < b < c \leq k-1. \tag{66}
\]
Let \( 1 \leq a < b < c < d \leq k - 1 \) be any four distinct indexes between 1 and \( k - 1 \). Then the previous equations translate into the linear system
\[
\begin{pmatrix}
1 & 1 & 1 & 0 \\
1 & 1 & 0 & 1 \\
1 & 0 & 1 & 1 \\
0 & 1 & 1 & 1
\end{pmatrix}
\begin{pmatrix}
h_a \\
h_b \\
h_c \\
h_d
\end{pmatrix} = 0. \tag{67}
\]
The matrix appearing in the linear system is invertible, so \( h_a = h_b = h_c = h_d = 0 \). Since this holds for an arbitrary choice of four distinct indexes, it follows that \( h = 0 \). Now, relation (65) tells us that \( \sum_{i=1}^{k-1} u_i^2 \ell_i = 0 \), but since \( u_1^2, \ldots, u_{k-1}^2 \) form a complete intersection of quadrics, they do not have linear syzygies, which implies that \( \ell_i = 0 \) for each \( i \). From the definitions of \( \ell_i \) and \( h_i \), it follows that \( 3\lambda_i H_i + \varepsilon_i L_i = 0 \) for each \( i \) but then the other two relations \( \sum_i \varepsilon_i = 0 \) and \( \sum_i (\lambda_i H_i + \varepsilon_i L_i) = 0 \) imply that \( H_i = 0, \varepsilon_i = 0 \) for all \( i \), which is what we needed.

</table>

Table 1: Moment varieties of homoscedastic Gaussian mixtures with \( d = 3 \)

Now we are ready for a complete classification of defectivity when \( d = 3 \):

**Theorem 22.** For \( d = 3 \), the defect \( \delta_{n,k,3}^H = 0 \) for any \( k \) and \( n \), with the following exceptions:

- \( n \geq k \) and \( k = 2 \), where \( \delta_{n,2,3}^H = 1 \).
- \( n \geq k \) and \( k = 3, 4 \), where \( \delta_{n,k,3}^H = 2 \).
- \( n = 5 \) and \( k = 7 \), where \( \delta_{5,7,3}^H = 1 \).
- \( 5 \leq n + 1 < k \leq \frac{n^2 + 2n + 6}{6} \leq \frac{n^2 + 3n + 2}{6} \) where \( \delta_{n,k,3}^H = k - n - 1 \).
- \( 5 \leq n + 1 \leq \frac{n^2 + 2n + 6}{6} \leq k < \frac{n^2 + 3n + 2}{6} \) where \( \delta_{n,k,3}^H = n \left( \frac{n^2 + 3n + 2}{6} - k \right) \).
Table 1 records all instances $\text{Sec}^H_{G,3}(n)$ for $n = 1, \ldots, 7$ and range of $k$ that covers all defective cases (‘par’ denotes the number of parameters and ‘exp’ the expected dimension).

**Proof.** First we consider the case when $n \geq k$: then Proposition 21 (ii) gives us $\Delta^H_{n,k,3}$ and then it is straightforward to check that in all these cases we have $\delta^H_{n,k,3} = \Delta^H_{n,k,d}$, which is what we want.

Now we consider the cases where $k \geq n + 1$. Let’s consider first the exceptional case $n = 5, k = 7$: then Proposition 21 (i) gives that $\dim_{\phi_3}(\Theta_{0,5}) = 34$, and then we get from Lemma 9 that $\Delta^H_{5,7,3} = 2$ and $\delta^H_{5,7,3} = 1$.

Now let us consider the other cases, then Proposition 21 (i) gives that $\dim_{\phi_3}(\Theta_{n,k}) = \min\{nk, \left(\frac{n+2}{3}\right)\}$ (68) and then Lemma 9 shows that $\delta^H_{n,k,3} = (k - 1)(n + 1) - \min\{nk, \left(\frac{n+2}{3}\right)\} = \max\{k - n - 1, k - n - 1 + n\left(\frac{n^2 + 3n + 2}{6}\right)\}$

so that $\delta^H_{n,k,3} = \max\{k - n - 1, k - n - 1 + n\left(\frac{n^2 + 3n + 2}{6}\right)\} - \max\{0, (n + 1)\left(\frac{n^2 + 2n + 6}{6}\right)\}$.

Suppose first that $n = 1, 2, 3$: then we get that $k \geq n + 1 \geq \frac{n^2 + 2n + 6}{6} \geq \frac{n^2 + 3n + 2}{6}$ so that $\delta^H_{n,k,3} = k - n - 1 + n\left(\frac{n^2 + 3n + 2}{6}\right) - (n + 1)\left(\frac{n^2 + 2n + 6}{6}\right) = 0$. (69)

Now let’s suppose that $n \geq 4$. Then we see that $5 \leq n + 1 \leq \frac{n^2 + 2n + 6}{6} \leq \frac{n^2 + 3n + 2}{6}$ and we have three possibilities for $k$: if $k \geq \frac{n^2 + 3n + 2}{6}$, then $\delta^H_{n,k,3} = k - n - 1 + n\left(\frac{n^2 + 3n + 2}{6}\right) - (n + 1)\left(\frac{n^2 + 2n + 6}{6}\right) = 0$. (70)

If instead $\frac{n^2 + 2n + 6}{6} \leq k < \frac{n^2 + 3n + 2}{6}$, then $\delta^H_{n,k,3} = k - n - 1 - (n + 1)\left(\frac{n^2 + 2n + 6}{6}\right) = n\left(\frac{n^2 + 3n + 2}{6} - k\right)$ (71)

which is strictly positive. Finally, if $n + 1 \leq k < \frac{n^2 + 2n + 6}{6}$ we see that $\delta^H_{n,k,3} = k - n - 1$, (72)

which is positive if and only if $k > n + 1$. 

As a consequence, we completely characterize identifiability whenever $k \leq n + 1$: 

\[\square\]
Theorem 23. Suppose $k \leq n + 1$. If $k \geq 5$ then a general homoscedastic mixture is identifiable from the moments or cumulants up to order 3, if instead $k = 2, 3, 4$ then a general homoscedastic mixture is identifiable from the moments up to order $d = 4$.

Proof. When $k \geq 5$ this follows immediately from Theorem 22 and Lemma 15. If instead $k = 2, 3, 4$, thanks to Proposition 17 it is enough to set $n = k - 1$ and check the first $d$ for which we have identifiability: these are a finite number of cases that can be done by direct computation (e.g. in Macaulay2 [1]), and we find that such a $d$ is 4.

4.2 Mixtures with $k = 2$ components

When $k = 2$ we can completely characterize the rational identifiability as well. Since the case $d = 3$ is already covered, we consider only $d \geq 4$.

Theorem 24. The homoscedastic secant $\text{Sec}_2^H(G_{n,4})$ is algebraically identifiable. If $d \geq 5$, the homoscedastic secant $\text{Sec}_2^H(G_{n,d})$ is also rationally identifiable.

Proof. We want to use Lemma 9 and Remark 11. So, we have the parameter space $\Theta^0_{n,2} = \{((L_1, L_2), (\lambda_1, \lambda_2)) | \lambda_1 + \lambda_2 = 1, \lambda_1 L_1 + \lambda_2 L_2 = 0\}$ and the map

$$\phi_d: \Theta^0_{n,2} \rightarrow C^0_{n,2,d} \subseteq \mathbb{A}^{K,3}_{n,d}.$$ (73)

We want to compute the general fiber of this map: since we are assuming $d \geq 4$, we know from Theorem 23 and its proof that the map has finite fibers, hence to compute a general fiber we can restrict to the open subset $\lambda_2 \neq 0$, where we can write $L_2 = -\frac{\lambda_1}{\lambda_2} L_1 = -\frac{\lambda}{1 - \lambda} L_1$. Thus, we want to compute the fibers of the induced map

$$F_d: \mathbb{C} \times (\mathbb{R} \setminus \{1\}) \rightarrow \mathbb{A}^{K,3}_{n,d}, \quad (L, \lambda) \mapsto \phi_d \left( (\lambda, 1 - \lambda), \left( L, -\frac{\lambda}{1 - \lambda} L \right) \right).$$ (74)

In explicit terms, this map is given by the the terms from degree 3 to degree $d$ of the logarithm $\log(\lambda e^L + (1 - \lambda) e^{-\frac{\lambda}{1 - \lambda} L})$. A computation shows that the first terms are:

$$\log(\lambda e^L + (1 - \lambda) e^{-\frac{\lambda}{1 - \lambda} L}) = f_3(\lambda) L^3 + f_4(\lambda) L^4 + f_5(\lambda) L^5 + \ldots$$

$$f_3(\lambda) = \frac{\lambda(1 - \lambda)(1 - 2\lambda)}{6(1 - \lambda)^3}, \quad f_4(\lambda) = \frac{\lambda(1 - \lambda)(1 - 6\lambda(1 - \lambda))}{24(1 - \lambda)^4}, \quad f_5(\lambda) = \frac{\lambda(1 - \lambda)(1 - 2\lambda)(1 - 12\lambda(1 - \lambda))}{120(1 - \lambda)^5}.$$ (75)

Now suppose that $d = 4$, and let $L \in V$ and $\lambda \in \mathbb{R} \setminus \{1\}$ be general elements. More precisely, it will be enough to assume $L \neq 0$ and $\lambda \neq 0, 1, \frac{1}{2}, \frac{1}{3}$, so that $\kappa_3 = f_3(\lambda) L^3 \neq 0$. We want to compute the fiber of the point $(\kappa_3, \kappa_4) = F_4(L, \lambda)$: in statistical terms, we have the data of the cumulants $\kappa_3, \kappa_4$ and we try to recover the parameters $\lambda, L$. 19
We will give an explicit algorithm to do so. First we observe that \( \kappa_3 = f_3(\lambda_0)L_0^3 = (\sqrt[3]{f_3(\lambda_0)}L_0)^3 \) and that the polynomial \( L_0 := \sqrt[3]{f_3(\lambda)}L \) can be computed explicitly: indeed if we write

\[
\kappa_3 = \kappa_{300.0} u_1^3 + \kappa_{030.0} u_2^3 + \cdots + \kappa_{00.03} u_n^3 + ( \text{ terms with mixed monomials } )
\]  

then we see that it must be

\[
L_0 = \sqrt[3]{\kappa_{300.0}} u_1 + \sqrt[3]{\kappa_{030.0}} u_2 + \cdots + \sqrt[3]{\kappa_{00.03}} u_n.
\]  

In particular, we get that \( L = f_3(\lambda)^{-\frac{1}{3}} L_0 \), so that the equation \( \kappa_4 = f_4(\lambda)L^4 \) translates into \( \frac{f_4(\lambda)}{f_3(\lambda)^{\frac{1}{3}}} = \frac{a^4}{L_0^4} \). Observe that \( a := \frac{a^4}{L_0^4} \) is a constant that can be computed explicitly by comparing a single nonzero coefficient of \( L_0^4 \) with the corresponding coefficient of \( \kappa_4 \): for example, if \( \sqrt[3]{\kappa_{300.0}} \neq 0 \), then

\[
a = \frac{\kappa_{400.0}}{(\sqrt[3]{\kappa_{300.0}})^4}.
\]  

Now, we see that the equation \( \frac{f_4(\lambda)}{f_3(\lambda)^{\frac{1}{3}}} = a \) is equivalent to \( \frac{f_4(\lambda)^3}{f_3(\lambda)^4} = a^3 \), which we can write explicitly as

\[
\frac{3}{32} \cdot \frac{(1 - 6\lambda(1 - \lambda))^3}{\lambda(1 - \lambda)(1 - 4\lambda(1 - \lambda))^2} = a^3.
\]  

We observe this expression is invariant under exchanging \( \lambda \) with \( 1 - \lambda \), as it is to be expected from the symmetry of the situation. Hence, we can set \( \gamma := \lambda(1 - \lambda) \) and we can rewrite this expression as

\[
\frac{3}{32} \cdot \frac{(1 - 6\gamma)^3}{\gamma(1 - 4\gamma)^2} = a^3.
\]  

Since this is a cubic equation there are three possible solutions for \( \gamma \), so that we do not have rational identifiability. However, in a statistical setting, \( \gamma \) can be recovered uniquely: see Corollary \([23]\) below.

Then, for rational identifiability we need consider also the cumulants \( \kappa_5 \) of order 5: this adds the data \( \kappa_5 \) and the condition \( \kappa_5 = f_5(\lambda)L^5 \). In the above notation we have that \( L = f_3(\lambda)^{-\frac{1}{5}} L_0 \), so that the condition \( \kappa_5 = f_5(\lambda)L^5 \) becomes \( \frac{f_5(\lambda)}{f_3(\lambda)^{\frac{1}{5}}} = \frac{\kappa_5}{L_0^5} \). As before, we see that \( b := \frac{\kappa_5}{L_0^5} \) is a constant that can be computed explicitly by comparing a single nonzero coefficient of \( L_0^5 \) with the corresponding coefficient of \( \kappa_5 \): for example, if \( \sqrt[3]{\kappa_{300.0}} \neq 0 \), then

\[
b = \frac{\kappa_{500.0}}{(\sqrt[3]{\kappa_{300.0}})^5}.
\]  

Now, we see that the equation \( \frac{f_5(\lambda)}{f_3(\lambda)^{\frac{1}{5}}} = a \) is equivalent to \( \frac{f_5(\lambda)^3}{f_3(\lambda)^5} = b^5 \): as before, we can write this explicitly, and under the substitution \( \gamma = \lambda(1 - \lambda) \) we get the equation

\[
\frac{15}{128} \cdot \frac{(1 - 6\gamma)^5}{\gamma(1 - \gamma)^3(1 - 12\gamma)} = b^3.
\]  

20
Hence, we obtain rational identifiability if we can show that the two equations (80) and (82) have a unique common solution $\gamma$. This is like saying that the map $\mathbb{R} \to \mathbb{R}^2, \gamma \mapsto (g(\gamma), h(\gamma))$ is generically injective. We see that this map extends to

$$\mathbb{R} \to \mathbb{P}^2, \left[ \frac{3}{32}(1 - 6\gamma)^3(1 - \gamma)^3(1 - 12\gamma), \frac{15}{128}(1 - 6\gamma)^5(1 - 4\gamma)^2, \gamma(1 - 4\gamma)(1 - \gamma)^3(1 - 12\gamma) \right].$$

Since this map is defined by polynomials of degree 7, it is generically injective if and only if the closure of its image is a plane curve of degree 7. We can check that this is true with Macaulay2 [7]: indeed the resulting curve is given by the equation

$$849346560x^5y^2 - 679477248x^4y^3 - 29491200x^5yz + 2674483200x^4y^2z - 2439217152x^3y^3z + 256000x^5z^2 + 79744000x^4yz^2 + 2415168000x^3y^2z^2 - 2616192000x^2y^3z^2 + 499500000x^2y^2z^3 - 406500000xy^3z^3 + 474609375y^3z^4 = 0.$$  

\[\square\]

Figure 1: Plot of the real-valued function $a(\gamma)$ in (83)

**Corollary 25.** For $k = 2$, the statistical mixture parameters can be recovered uniquely with moments up to order $d = 4$.

**Proof.** This is equivalent to saying that the equation (80) has a unique statistically relevant solution in $\gamma = \lambda(1 - \lambda)$. Note that since $\lambda \in (0, 1) \setminus \{\frac{1}{2}\}$, we have that $\gamma \in (0, \frac{1}{4})$. Consider the real valued function coming from (80):

$$a(\gamma) = \frac{\sqrt{3}(1 - 6\gamma)}{2\sqrt{4\gamma(1 - 4\gamma)^2}}.$$  

(83)
Its derivative, \( a'(\gamma) = -\frac{1}{2\sqrt[3]{3\gamma(1-4\gamma)}}\), is always negative for \( 0 < \gamma < \frac{1}{4} \) so that the function \( a(\gamma) \) is strictly decreasing and, in particular, injective in this statistically meaningful interval. A plot is presented in Figure 1. The corresponding inverse is given by the cubic equation in \( \gamma \)

\[
(256a^3 + 324)\gamma^3 - (128a^3 + 162)\gamma^2 + (16a^3 + 27)\gamma - \frac{3}{2} = 0. \tag{84}
\]

The discriminant of (84) is \( \Delta = -3072a^6(64a^3 + 81) \). It is zero precisely when \( a = -\frac{3\sqrt[3]{3}}{4} \), which corresponds the horizontal asymptote in the graph. If \( a < -\frac{3\sqrt[3]{3}}{4} \), there exist 3 real solutions, but one is negative and the other one is larger than \( \frac{1}{4} \). The remaining solution is also the unique real solution when \( a > -\frac{3\sqrt[3]{3}}{4} \), given explicitly by

\[
\gamma = \frac{4a^3}{3\eta} + \frac{\eta}{3(64a^3 + 81)} + \frac{1}{6}. \tag{85}
\]

where

\[
\eta = (-4096a^9 - 10368a^6 - 6561a^3 + 9\sqrt{262144a^{15}} + 995328a^{12} + 1259712a^9 + 531441a^6)^{\frac{1}{3}}.
\]

This proof also gives us an explicit algorithm to recover the parameters of a homoscedastic mixture of two Gaussians from the cumulants up to order four.

**Algorithm 1:** Recovery of parameters for a homoscedastic mixture of two Gaussians.

**Data:** Data coming from a homoscedastic mixture of two Gaussian distributions.

**Result:** The parameters \( \lambda_1, \lambda_2, \mu_1, \mu_2, \Sigma \) of the mixture.

**begin**

Estimate the mean vector \( \kappa_1 \);

Estimate the covariance matrix \( \kappa_2 \);

Estimate the principal third cumulants \( \kappa_{300..0}, \kappa_{030..0}, \ldots, \kappa_{00..03} \);

For one of the principal third cumulant that is nonzero, estimate the corresponding fourth cumulant: in the following, we will assume that \( \kappa_{300..0} \neq 0 \), so that we estimate \( \kappa_{400..0} \);

Compute \( a = \frac{\kappa_{400..0}}{(3\sqrt[3]{\kappa_{300..0}})} \);

Compute \( \gamma \) as in (85);

Compute the two solutions \( \lambda_1, \lambda_2 \) of \( \lambda(1 - \lambda) = \gamma \);

Compute \( \mu'_1 = f_3(\lambda_1)^{-\frac{1}{3}}(\sqrt[3]{\kappa_{300..0}}, \sqrt[3]{\kappa_{030..0}}, \ldots, \sqrt[3]{\kappa_{00..03}}) \) and \( \mu'_2 = \frac{\lambda_1}{\lambda_2} \mu'_1 \);

Compute \( \mu_1 = \mu'_1 + \kappa_1 \) and \( \mu_2 = \mu'_2 + \kappa_1 \);

Compute \( \Sigma = 2(\kappa_2 - (\lambda_1\mu_1 + \lambda_2\mu_2)^3(\lambda_1\mu_1 + \lambda_2\mu_2)) \);

**end**

Observe that this algorithm needs all the cumulants of order one, all the cumulants of order two, \( n \) cumulants of order three, and one cumulant of order four. Hence, it needs in total \( n + \frac{n(n+1)}{2} + n + 1 \) cumulants.

**Remark 26.** We briefly comment on the geometry of the homoscedastic secant \( \text{Sec}_2^H(\mathcal{G}_{n,d}) \) in cumulant coordinates: we have seen in Remark 20 that this is exactly the cone over
$C^0_{n,2,d} \subseteq A_{n,d}^3$. Up to taking the Zariski closure, the proof of Theorem 24 shows that $C^0_{n,2,d}$ is the image of the map

$$F_d: V \times \mathbb{R} \setminus \{1\} \to A_{n,d}^3, \quad (L, \lambda) \mapsto f_3(\lambda)L^3 + f_4(\lambda)L^4 + f_5(\lambda)L^5 + f_6(\lambda)L^6 + \ldots \quad (86)$$

For $\lambda$ constant, then we get a projected $d$-th Veronese variety of $V$. If instead $L$ is constant, then we get a rational curve, essentially given by $(f_3(\lambda), f_4(\lambda), \ldots, f_d(\lambda))$. In particular, we see that the $f_i(\lambda)$ are independent from the dimensional parameter $n$. In conclusion, the image of this map can be seen as a kind of scroll: indeed, it is a union of Veronese varieties connected by rational curves.

### 4.3 The univariate case $n = 1$

We use the standard notation $\sigma^2$ for the variance $\sigma_{11}$ when $n = 1$.

For $n = 1$, the moment variety $\text{Sec}_k^H(G_{1,d})$ is never defective. The moment map

$$M_{1,k,2k}: \Theta_{1,k}^H \to A_{1,2k}^M$$

is finite to one. In the statistics literature it is known that in the case of homoscedastic secants, one may recover the mixture parameters from given moments (i.e. compute the fiber of the map above), with an algorithm closely related to the well-known Prony’s method [17]. This procedure was introduced by Lindsay as an application of moment matrices [12] and we briefly recall the algorithm here.

First, how does one recover the locations $\mu_i$ and weights $\lambda_i$ of the $k$ components of a Dirac mixture from $2k - 1$ moments? This is known as the quadrature rule and it works as follows. Given the moment sequence $m = (m_1, m_2, \ldots, m_{2k-1})$ one considers the polynomial resulting from the following $(k+1) \times (k+1)$ determinant

$$P_k(t) = \det \begin{pmatrix} 1 & m_1 & \ldots & m_{k-1} & 1 \\ m_1 & m_2 & \ldots & m_k & t \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ m_k & m_{k+1} & \ldots & m_{2k-1} & t^k \end{pmatrix}.$$  

(87)

The $k$ roots $\mu_1, \mu_2, \ldots, \mu_k$ of $P_k(t)$ are precisely the sought locations. This follows since the equations of the secant varieties of the rational normal curve are classically known to be given by the minors of the moment matrices. For a modern reference see [11].

Once the locations are known, the weights $\lambda_i$ are found by solving the $k \times k$ Vandermonde linear system

$$\begin{pmatrix} 1 & 1 & \ldots & 1 \\ \mu_1 & \mu_2 & \ldots & \mu_k \\ \vdots & \vdots & \ddots & \vdots \\ \mu_1^{k-1} & \mu_2^{k-1} & \ldots & \mu_k^{k-1} \end{pmatrix} \begin{pmatrix} \lambda_1 \\ \lambda_2 \\ \vdots \\ \lambda_k \end{pmatrix} = \begin{pmatrix} 1 \\ m_1 \\ \vdots \\ m_{k-1} \end{pmatrix}. \quad (88)$$

Back to the Gaussian case, if we knew the value of the common variance $\sigma^2$, we can reduce to the above instance. In terms of the Gaussian moment generating function:
\[ e^{-\frac{1}{2}\sigma^2 u^2} M_X(u) = e^{\mu u}. \] (89)

This corresponds to a linear change of coordinates on the vector of moments \( m \) to obtain \( \tilde{m} \). Explicitly, for \( 1 \leq j \leq 2k - 1 \)

\[
\tilde{m}_j(\sigma) = \sum_{i=0}^{\lfloor j/2 \rfloor} \frac{j!}{(-2)^i i!(j-2i)!} m_{j-2i}\sigma^{2i}. \] (90)

Then one would apply the quadrature rule to the vector \( \tilde{m} = (\tilde{m}_1, \tilde{m}_2, \ldots, \tilde{m}_{2k-1}) \) to obtain the means \( \mu_1, \mu_2, \ldots, \mu_k \).

However, \( \sigma \) is unknown. In that case, we now have the first \( 2k \) moments \( m = (m_1, m_2, \ldots, m_{2k}) \). If \( \tilde{m} = (\tilde{m}_1, \tilde{m}_2, \ldots, \tilde{m}_{2k}) \) comes from a mixture of \( k \) Dirac measures, then

\[
D_k = \det \begin{pmatrix}
1 & \tilde{m}_1 & \ldots & \tilde{m}_{k-1} & \tilde{m}_k \\
\tilde{m}_1 & \tilde{m}_2 & \ldots & \tilde{m}_k & \tilde{m}_{k+1} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
\tilde{m}_k & \tilde{m}_{k+1} & \ldots & \tilde{m}_{2k-1} & \tilde{m}_{2k}
\end{pmatrix} = 0. \] (91)

One thus treats \( \sigma \) as a variable and substitutes expressions (90) into (91). This results in a polynomial \( D_k(\sigma) \) of degree \( \binom{k+1}{2} \) in \( \sigma^2 \) and the estimator \( \hat{\sigma}^2 \) is obtained as its smallest non-negative root [12, Theorem 5B]. So the algebraic degree for estimating \( \sigma^2 \) is \( \binom{k+1}{2} \). With \( \sigma^2 \) specified, one proceeds as above.

More generally, the moment variety \( \text{Sec}_k^H(G_1,d) \) with \( k \leq d/2 \) is a union

\[
\text{Sec}_k^H(G_1,d) = \bigcup_{\sigma} \text{Sec}_k(V_{1,d}^\sigma),
\]

where \( V_{1,d}^\sigma \) is the translation of the moment curve \( V_{1,d} \) by the variance \( \sigma^2 \) as defined by the Gaussian moments. The secant variety \( \text{Sec}_k(V_{1,d}^\sigma) \) is defined for each \( \sigma \) by the \( (k+1) \times (k+1) \) minors of

\[
M_{k,d} = \det \begin{pmatrix}
1 & \tilde{m}_1 & \ldots & \tilde{m}_{d-k-1} & \tilde{m}_{d-k} \\
\tilde{m}_1 & \tilde{m}_2 & \ldots & \tilde{m}_{d-k} & \tilde{m}_{d-k+1} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
\tilde{m}_k & \tilde{m}_{k+1} & \ldots & \tilde{m}_{d-1} & \tilde{m}_d
\end{pmatrix} = 0. \] (92)

The curves \( V_{1,d}^\sigma \) are distinct, therefore also their \( k \)-th secant varieties. The variety \( \text{Sec}_k(V_{1,d}^\sigma) \) has dimension \( 2k - 1 \), so the union \( \text{Sec}_k^H(G_1,d) \) has dimension \( 2k \). Given the moments \( m_i \) up to degree \( d \) of a point on a homoscedastic \( k \)-secant, the \( (k+1) \times (k+1) \) minors of \( M_{k,d} \) are polynomials in \( \sigma^2 \) with a zero at the common variance. Given the variance the means can be inferred as above.

When \( d = 2k + 1 \), then the variety \( \text{Sec}_k^H(G_1,d) \subset \mathbb{A}_{1,2k+1}^M \) is a hypersurface, defined by the resultant of minors of \( M_{k,d} \), the polynomial obtained by elimination of \( \sigma^2 \) in the ideal
defined by the \((k + 1) \times (k + 1)\) minors. Denote this polynomial by \(P_{2k+1}\). It is a polynomial in \(m_1, ..., m_{2k+1}\). For example,

\[
P_3 = 2m_1^3 - 3m_1m_2 + m_3,
\]

\[
P_5 = 108m_1^6m_2^6 - 432m_1^7m_3m_4 + 432m_1^8m_2^2m_3^2 + 216m_1^8m_2^3m_4 - 432m_1^9m_3m_4 + 108m_1^{10}m_2^2 - 216m_1^5m_2^5m_3 + 864m_1^6m_2^3m_3^2 - 864m_1^7m_2m_3m_4 + 432m_1^8m_3m_4 - 216m_1^9m_4m_5 + 32m_1^7m_2^3m_3 - 172m_1^8m_2m_3^2 + 62m_1^9m_3m_4 - 144m_1^{10}m_4m_5 - 36m_1^6m_2^3m_3^2 + 96m_1^7m_2^2m_3^3 - 172m_1^8m_2^2m_4^3 + 464m_1^9m_3^4 - 68m_1^5m_2^3m_3^3 + 206m_1^6m_2^2m_3^4 + 192m_1^7m_2m_3^5 - 333m_1^8m_4m_5 + 216m_1^9m_2^2m_4m_5 + 132m_1^{10}m_3m_5 - 441m_1^6m_2^2m_3^2m_5 - 1944m_1^7m_2m_3^3m_5 - 864m_1^8m_3^2m_5^2 - 520m_1^9m_4m_5 + 1152m_1^6m_2m_3m_4m_5 - 216m_1^7m_2^2m_3m_4m_5 - 18m_1^8m_2^3m_5^2 + 144m_1^9m_2^2m_3^2m_5 + 80m_1^{10}m_2m_3^3 - 504m_1^6m_2^3m_4m_5 - 264m_1^7m_2^2m_3^2m_4 + 1856m_1^8m_2m_3^3m_4 - 96m_1^9m_3m_4m_5 - 1386m_1^5m_2^3m_3m_4^2 + 162m_1^7m_2^2m_3^2m_4 + 147m_1^6m_3m_5^2 + 180m_1^5m_2m_3m_4m_5 - 1248m_1^6m_2^2m_3^2m_5 + 848m_1^7m_2m_3^3m_5 + 450m_1^8m_3m_4m_5 + 612m_1^9m_2^2m_3m_4m_5 + 96m_1^{10}m_2m_3^4m_5 + 135m_1^6m_2^2m_3^2m_5^2 - 198m_1^7m_2m_3^3m_5^2 - 324m_1^8m_3m_4m_5^2 - 18m_1^9m_4m_5^2 + 108m_1^5m_3m_5^3 - 360m_1^6m_2m_3m_4m_5 + 188m_1^7m_2^2m_3^2m_5 + 204m_1^8m_2m_3^3m_5 + 92m_1^9m_3m_4m_5 - 120m_1^10m_2m_3^4m_5 - 120m_1^5m_2^3m_3m_4m_5 - 144m_1^6m_2^2m_3^2m_4m_5 - 184m_1^7m_2m_3^3m_4m_5 - 21m_1^8m_3m_4m_5^2 + 2m_1^9m_4m_5^2 - 32m_1^5m_3m_5^3 + 36m_1^6m_2m_3m_4m_5^2 + 10m_1^7m_2^2m_3^2m_5^2 - 30m_1^8m_2m_3^3m_5^2 + 6m_1^9m_3m_5^3 + 7m_1^6m_2^3m_3m_4m_5 - 3m_1^7m_2^2m_3^2m_4m_5 - m_1^8m_2m_3^3m_4m_5 + m_1^9m_3m_4^2m_5 + m_3m_5^3.
\]

**Question 27.** What is the degree of \(P_{2k+1}\)? Computations when \(k = 1, 2, 3, 4\) show that the degree is \(k(k + 1)(k + 2)/2\). Does this formula hold for any \(k\)?

If \(P_{2k+1}\) vanishes on a the set \((m_1, ..., m_{2k+1})\) of moments, and \(P_{2l+1}\) does not vanish on \((m_1, ..., m_{2l+1})\) for any \(l < k\), then the moments lie on a homosedastic \(k\)-secant but not on any \(l\) secant for \(l < k\). This property means that this could be the basis for a hypothesis test contrasting the number of components in a homosedastic Gaussian mixture (compare to the rank test proposed in [12], Section 3.1] for the known variance case).
5 Conclusion

We have completely classified all defective cases for the moment varieties associated to homoscedastic Gaussian mixtures whenever $k < n + 1$, $d = 3$, $k = 2$ or $n = 1$. The question concerning a complete classification for all $n,d,k$ remains open, although our computations did not reveal any further defective examples.

Our identifiability results also cover special structure in the covariance matrix, by Remark 11. For example, a common mixture submodel involves isotropic Gaussians, which means that the covariance matrix is a scalar multiple of the identity, $\Sigma = \sigma I$. The homoscedastic and isotropic case is closely related to the $k$-means algorithm used in clustering. In [8], Hsu and Kakade consider the learning of mixtures of isotropic Gaussians from the moments up to order $d = 3$ when $k \leq n + 1$. They prove identifiability for the homoscedastic isotropic submodel (see [6, Theorem 3.2]), and in order to solve the moment equations, they propose to find orthogonal decompositions of the second and third order moment tensors.

On the other hand, in [14] Lindsay and Basak proposed a ‘fast consistent’ method of moments for homoscedastic Gaussian mixtures in the multivariate case, based on a ‘primary axis’ to which the one-dimensional case presented in Section 4.3 is applied. This means that the method will use some moments of order $2k$. Knowing that in some cases there are explicit equations for secants of higher dimensional Veronese varieties [11], an alternative method with minimal order based on these should be possible.

Finally, a similar approach can be made to study moment varieties of homoscedastic mixtures of other location families. In the case of Example 4, we saw that Gaussian moments and Laplacian moments coincide up to $d = 3$. This means that Theorem 22 applies verbatim to homoscedastic mixtures of Laplace distributions.
