MEAN DIMENSION AND METRIC MEAN DIMENSION FOR
NON-AUTONOMOUS DYNAMICAL SYSTEMS

FAGNER B. RODRIGUES AND JEOVANNY M. ACEVEDO

Abstract. In this paper we extend the definitions of mean dimension and metric mean dimension for non-autonomous dynamical systems. We show some properties of this extension and furthermore some applications to the mean dimension and metric mean dimension of single continuous maps.

1. Introduction

In the late 1990’s, M. Gromov in [2] introduced the notion of mean dimension for a topological dynamical system \((X, \phi)\) (\(X\) is a compact topological space and \(\phi\) is a continuous map on \(X\), which is, as well as the topological entropy, an invariant under conjugacy. In [10], Lindestrauss and Weiss showed that the mean dimension is zero if the topological dimension of \(X\) is finite. They gave some examples where the mean dimension is positive. For instance, they proved that the mean dimension of \((([0,1]^m)\mathbb{Z}, \sigma)\), where \(\sigma\) is the two-sided full shift map on \(([0,1]^m)\mathbb{Z}\), which has infinite topological entropy, is equal to \(m\) and that any non-trivial factor of \((([0,1]^m)\mathbb{Z}, \sigma)\) has positive mean dimension.

We say that a dynamical system \((X, \phi)\) can be embedded in a dynamical system \((Y, \psi)\) if there exists an inclusion \(i : X \rightarrow Y\) such that \(\psi \circ i = i \circ \phi\). As any compact metric space \((X, d)\) can be imbedded in \([0,1]^N\) (say by a map \(i : X \rightarrow [0,1]^N\)), then \(x \rightarrow (\ldots, i(\phi^{-1}(x)), i(x), i(\phi(x)), \ldots)\) is an embedding of an invertible dynamical system \((X, \phi)\) in the shift \((([0,1]^N)\mathbb{Z}, \sigma)\). Lindestrauss and Weiss used the mean dimension, denoted by \(\text{mdim}(X, \phi)\), to prove that a necessary condition for an invertible system \((X, \phi)\) to be embedded in the dynamical system \((([0,1]^m)\mathbb{Z}, \sigma)\) is that \(\text{mdim}(X, \phi) < m\) (see [10, Corollary 3.4]). In [11, Theorem 5.1], Lindestrauss proved that if \((X, \phi)\) is an invertible system which is an extension of a minimal system, and \(K\) is a convex set with non-empty interior such that \(\text{mdim}(X, \phi) < \dim K/36\), then \((X, \phi)\) can be embedded in the shift \(((K^Z, \sigma))\). In particular, if \(\text{mdim}(X, \phi) < m/36\), then \((X, \phi)\) can be embedded in \((([0,1]^N)\mathbb{Z}, \sigma)\). More recently, Gutman and Tsukamoto showed in [4, Theorem 1.4], that if \((X, \phi)\) is a minimal system with \(\text{mdim}(X, \phi) < N/2\) then we can embed it into the shift on \((([0,1]^N)\mathbb{Z}, \sigma)\). Furthermore, \(N/2\) is optimal because Lindensrauss and Tsukamoto in [12, Theorem 1.3], constructed a minimal system of mean dimension \(N/2\) which cannot be embedded into \((([0,1]^N)\mathbb{Z}, \sigma)\).

The concept of metric mean dimension for a dynamical system \(\phi : (X, d) \rightarrow (X, d)\) was introduced in [10], where \((X, d)\) is a compact metric space with metric \(d\) and \(\phi\) is a continuous map. It refines the topological entropy for systems with infinite entropy, which, in the case of a manifold of dimension greater than one, form a residual subset of the set consisting of a continuous map defined on the manifold (see [13]). In fact, every system with finite topological entropy has metric mean dimension equal to zero and for any metric \(d'\) equivalent to \(d\) on \(X\) one has \(\text{mdim}(X, \phi) \leq \text{mdim}_M(X, \phi, d')\), where \(\text{mdim}_M(X, \phi, d')\) denotes the metric mean dimension.

Key words and phrases. Sequence of maps, mean dimension, metric mean dimension.
dimension of \((X, \phi)\) with respect to \(d'\) (see [9][10]). The metric mean dimension depends on the metric \(d\), therefore it is not a topological invariant. However, for a metrizable topological space \(X\), \(\text{mdim}_M(X, \phi) = \inf_{d'} \text{mdim}_M(X, \phi, d')\) is invariant under topological conjugacy, where the infimum is taken over all the metrics on \(X\) which generates the topology of \(X\). In [9], Theorem 4.3, the author proved that if \((X, \phi)\) is an extension of a minimal system, then there is a metric \(d'\) on \(X\), equivalent to \(d\), such that \(\text{mdim}(X, \phi) = \text{mdim}_M(X, \phi, d')\). For general dynamical systems, this result is not valid, as we will see in Example 4.7.

More recently, Kloeckner [6] investigates the dynamical system \((\mathcal{P}(S^1), \Phi_{d^*})\), where \(\mathcal{P}(S^1)\) is the space of probability measures on the circle \(S^1\) and \(\Phi_{d^*}\) is the push-forward map induced by a \(d\)-expanding map \(\Phi_{d^*} : S^1 \rightarrow S^1\). The author shows that if one considers the Wasserstein metric with cost function \(|\cdot|^p (p \in [1, \infty))\), denoted by \(W_p\), on \(\mathcal{P}(S^1)\) then \(\text{mdim}_M(\mathcal{P}(S^1), \Phi_{d^*}, W_p) \geq p(d-1)\).

H. Lee in [8] introduced mean dimensions for continuous actions of countable sofic groups on compact metrizable spaces and proves that, in this setting, mean dimension is an important tool for distinguishing continuous actions of countable sofic groups with infinite entropy.

A non-autonomous dynamical system (or a sequential dynamical system) is a collection \(f = (f_n)_{n \in \mathbb{N}}\) of continuous maps \(f_n : X_n \rightarrow X_{n+1}\), where \(X_n\) is a compact topological space for every \(n \in \mathbb{N}\). In the last two decades, several authors have tried to extend some results that are valid for autonomous systems for the non-autonomous case. Kolyada and Snoha in [7] defined the concept of entropy for this setting and prove that, just as in the case of autonomous systems, it is invariant under equiconjugacy and that it is concentrated in the non-wandering set of the dynamics (see [7] and [13]). In a more recent work, Freitas et al [1] have analyzed the existence of Extreme Value Laws in this setting. In [14] Stadelbauer guarantees, under appropriate conditions, the existence of a spectral gap for transference operators associated with sequential systems.

The purpose of this work is to extend these concepts of mean and metric dimension to non-autonomous systems where \(X_n = X\), for all \(n \in \mathbb{N}\). In the following paragraphs we will discuss the structure of the paper and some results obtained.

In the next section we will define the mean dimension for a non-autonomous dynamical system \(f = (f_n)_{n \in \mathbb{N}}\), which will be denoted by \(\text{mdim}(X, f)\). Furthermore, we will prove that some properties that are valid for the entropy of non-autonomous dynamical systems also are valid for the mean dimension (see [7] and [13]). An application of these properties is that, for any continuous maps \(\phi\) and \(\psi\) on \(X\), the compositions \(\phi \circ \psi\) and \(\psi \circ \phi\) have the same mean dimension. (see Corollary 2.3).

In Section 3, we will extend the notion of metric mean dimension (given by Lindenstrauss and Weiss in [10] for single maps) for non-autonomous dynamical systems. In Theorem 3.4 we show that, as the topological entropy, it is concentrated in the non-wandering set of the dynamics. Theorem 3.6 proves that the metric mean dimension is an upper bound for the mean dimension of any non-autonomous dynamical system. Example 4.7 shows that there exists single maps such that their metric mean dimension is biggest that their mean dimension. In Theorem 3.8 we will obtain that if \(f = (f_n)_{n \in \mathbb{N}}\) converges uniformly to a continuous map \(f : X \rightarrow X\), then the limit of the metric mean dimension of \((f_{n+m})_{n \in \mathbb{N}}\) as \(m \rightarrow \infty\) is bounded by the metric mean dimension of \(f\).

We will prove in Section 4 that the metric mean dimension of the shift on \(X^K\) is equal to the box dimension of \(X\) with respect to the metric \(d\), where \(K = \mathbb{Z}\) or \(\mathbb{N}\) (see Theorem 4.4). This facts implies that the box dimension of \(X\) is an upper bound for the metric mean dimension of any non-autonomous dynamical system \((f_n)_{n \in \mathbb{N}}\) uniformly convergent (see Corollary 4.7). However, there exist dynamical systems defined on compact metric spaces with finite box dimension whose metric mean dimension is infinite (see Example 4.8).
As we said above, the mean dimension for single continuous maps, and consequently for non-autonomous dynamical systems (which we denote by \( \text{mdim}_M(X,f,d) \)), depends on the metric \( d \). In Section 5 we prove that with some conditions, \( \text{mdim}_M(X,f) = \inf_d \text{mdim}_M(X,f,d) \) is invariant under topological equicontinuity, where the infimum is taken over all the metrics on \( X \) equivalent to \( d \). Furthermore, we will prove that if each \( f_i \) is a homeomorphism, then \( \text{mdim}_M(X,f) \) is independent on the first homeomorphisms (see Corollaries 5.3 and 5.4). Let \( h_{\text{top}}(f) \) be the topological entropy of \( f = (f_n)_{n \in \mathbb{N}} \). We have that \( h_{\text{top}}(f^{(p)}) \leq p h_{\text{top}}(f) \) and if the sequence \( (f_n)_{n \in \mathbb{N}} \) is equicontinuous, then the equality holds (see [7], Lemmas 4.2 and 4.4 and [13], Proposition 5.2). For the case of the metric mean dimension, we always have that \( \text{mdim}_M(X,f^{(p)},d) \leq p \text{mdim}_M(X,f,d) \), however the inequality can be strict even for single continuous maps (see Remark 5.6).

In the last section we will present additional properties of the metric mean dimension for non-autonomous dynamical systems defined on manifolds.

2. Mean dimension for non-autonomous dynamical systems

Let \( X \) be a compact metric space. In this section we will suppose that \( f = (f_n)_{n \in \mathbb{N}} \) is a non-autonomous dynamical system, where \( f_n : X \rightarrow X \) is a continuous map for all \( n \geq 1 \). We write \((X,f,d)\) to denote a non-autonomous dynamical system \( f \) on \( X \) endowed with the metric \( d \). For \( n,k \in \mathbb{N} \) define

\[
f_n^{(0)} := I_X := \text{the identity on } X \quad \text{and} \quad f_n^{(k)}(x) := f_n \circ \cdots \circ f_1(x) \quad \text{for } k \geq 1.
\]

Set

\[
\mathcal{C}(X) = \{(f_n)_{n \in \mathbb{N}} : f_n : X \rightarrow X \text{ is a continuous map}\}.
\]

Given \( \alpha \) an open cover of \( X \) define

\[
\alpha_n^{-1} = \alpha \vee f_1^{-1}(\alpha) \vee (f_1^2)^{-1}(\alpha) \vee \cdots \vee (f_1^n)^{-1}(\alpha)
\]

and set

\[
\text{ord}(\alpha) = \sup_{x \in X} \sum_{U \in \alpha} 1_U(x) - 1 \quad \text{and} \quad D(\alpha) = \min_{\beta < \alpha} \text{ord}(\beta),
\]

where \( 1_U \) is the indicator function and \( \beta < \alpha \) means that \( \beta \) is a partition of \( X \) finer than \( \alpha \).

**Definition 2.1.** The **mean dimension** of \( f \in \mathcal{C}(X) \) is defined to be

\[
\text{mdim}(X,f) = \sup_{\alpha} \lim_{n \to \infty} \frac{D(\alpha_n^{-1})}{n}.
\]

By Corollary 2.5 of [10] we have that \( D(\alpha \vee \beta) \leq D(\alpha) + D(\beta) \), for any open covers \( \alpha \) and \( \beta \). It follows that the limit that defines the mean dimension is well defined.

**Remark 2.2.** We present a list of some important properties about the mean dimension for both autonomous and non autonomous dynamical systems:

1. For a non-autonomous dynamical system given by the iterates of a single continuous map \( f : X \rightarrow X \), i.e., \( f = (f_n)_{n \in \mathbb{N}} \), the definition of mean dimension coincides with the one presented in [10], that is, \( \text{mdim}(X,(f_n)_{n \in \mathbb{N}}) = \text{mdim}(X,f) \).

2. Recall that for a topological space \( X \), the **topological dimension** is defined as

\[
\dim(X) = \sup_{\alpha} D(\alpha)
\]

where \( \alpha \) runs the open covers of \( X \). If \( \dim(X) < \infty \), then \( D(\alpha_n^{-1}) \leq \dim(X) \) for all \( n \in \mathbb{N} \) and so, \( \text{mdim}(X,f) = 0 \) for any \( f \in \mathcal{C}(X) \).

3. In [10], Proposition 3.1, is proved that \( \text{mdim}(X^Z,\sigma) \leq \dim(X) \), where \( \sigma \) is the shift on \( X^Z \). We can prove analogously that \( \text{mdim}(X^N,\sigma) \leq \dim(X) \).
Proof. Let \( h \) (see [7], Lemma 4.2). In general, the equality always holds for the mean dimension. Denote by \( \text{mdim}(X) \) which implies that \( \text{mdim}(X, f) \leq \text{mdim}(X, \phi) \). We can define the mean dimension for any \( X \subseteq X \) as follows: take \( \alpha \) open cover of \( X \) and consider \( \alpha Y = \{ U \cap Y : U \in \alpha \} \), the open cover of \( Y \) given by the restriction of \( \alpha \) to \( Y \). Then define

\[
\text{mdim}(Y, f|_Y) = \sup_{\alpha} \lim_{n \to \infty} \frac{\mathcal{D}((\alpha Y)^n)}{n},
\]

It is clear from the definition that \( \text{mdim}(Y, f|_Y) \leq \text{mdim}(X, f) \).

(6) A necessary condition for an invertible dynamical system \( \phi : X \to X \) to be imbeddable in \(((0,1]^m, \sigma)\) is that \( \text{mdim}(X, \phi) \leq m \) (see [10], Corollary 3.4).

(7) Any nontrivial factor of \(((0,1]^2, \sigma)\) has positive mean dimension (see [10], Theorem 3.6).

We will show some properties of the mean dimension which are valid for the topological entropy. Denote by \( h_{\text{top}}(f) \) the topological entropy of \( f \) (see [7], [13]). For any \( p \geq 1 \), set \( f^{(p)} = \{ f^{(p)}_1, f^{(p)}_2, f^{(p)}_3, \ldots \} \). We have

\[
h_{\text{top}}(f^{(p)}) \leq p h_{\text{top}}(f) \quad \text{for any } p \geq 1
\]

(see [7], Lemma 4.2). In general, the equality \( h_{\text{top}}(f^{(p)}) = p h_{\text{top}}(f) \) is not valid. The equality holds if the sequence \( f = (f_n)_{n \in \mathbb{N}} \) is equicontinuous (see [7], Lemma 4.4). On the other hand, the equality always holds for the mean dimension.

**Proposition 2.3.** For any \( f = (f_n)_{n \in \mathbb{N}} \in \mathcal{C}(X) \) and \( p \in \mathbb{N} \) we have

\[
\text{mdim}(X, f^{(p)}) = p \text{mdim}(X, f).
\]

**Proof.** Let \( \alpha \) be an open cover of \( X \). Then we notice that, for \( k \in \mathbb{N} \),

\[
\lim_{k \to \infty} \frac{\mathcal{D}(\alpha \vee (f_1^{(1)})^{-1}(\alpha) \vee \cdots \vee (f_1^{((k-1)p)})^{-1}(\alpha))}{k} \leq \lim_{k \to \infty} \frac{\mathcal{D}(\alpha_0^{(k-1)p})}{k} \leq p \lim_{k \to \infty} \frac{\mathcal{D}(\alpha_0^{(kp-1)})}{kp},
\]

which implies that \( \text{mdim}(X, f^{(p)}) \leq p \text{mdim}(X, f) \). For the converse, note that

\[
\alpha_0^{kp-1} = \alpha_0^{p-1} \vee (f_1^{(1)})^{-1} \vee (f_1^{(2p)})^{-1} \vee \cdots \vee (f_1^{((k-1)p)})^{-1} \alpha_0^{p-1},
\]

and so

\[
\text{mdim}(X, f) = \sup_{\alpha} \lim_{k \to \infty} \frac{\mathcal{D}(\alpha_0^{(kp-1)})}{kp} \leq \frac{\text{mdim}(X, f^{(p)})}{p},
\]

which proves the proposition.

In [7], Lemma 4.5, Kolyada and Snoha proved that

\[
h_{\text{top}}(\sigma^i(f)) \leq h_{\text{top}}(\sigma^j(f)) \quad \text{for any } i \leq j,
\]

where \( \sigma \) is the right shift \( \sigma((f_n)_{n \in \mathbb{N}}) = (f_{n+1})_{n \in \mathbb{N}} \). Furthermore, in [13], Corollary 5.6, the author showed that if each \( f_i \) is an homeomorphism then the equality holds, that is, the topological entropy for non-autonomous dynamical systems is independent on the first maps on a sequence of homeomorphisms \( f = (f_n)_{n \in \mathbb{Z}} \). Next proposition shows that these properties also hold for the mean dimension.

**Proposition 2.4.** Let \( i, j \) be two positive integers with \( i \leq j \). Then

\[
\text{mdim}(X, \sigma^i(f)) \leq \text{mdim}(X, \sigma^j(f)).
\]

If each \( f_i \) is a homeomorphism then the equality holds.
Proof. It is enough to prove the proposition for $i = 0$ and $j = 1$. For any open cover $\alpha$ of $X$ we have
\[
\mathcal{D}(\alpha_{0}^{n-1}) \leq \mathcal{D}(\alpha) + \mathcal{D}(f_{1}^{-1}(\alpha) \lor (f_{2}^{-1}(\alpha) \lor (f_{2}^{(2)})^{-1}(\alpha) \lor \ldots \lor (f_{2}^{(n-2)})^{-1}(\alpha))
\]
\[
= \mathcal{D}(\alpha) + \mathcal{D}(\alpha \lor (f_{2}^{-1}(\alpha) \lor (f_{2}^{(2)})^{-1}(\alpha) \lor \ldots \lor (f_{2}^{(n-2)})^{-1}(\alpha)).
\]
Thus
\[
\lim_{n \to \infty} \frac{\mathcal{D}(\alpha_{0}^{n-1})}{n} \leq \lim_{n \to \infty} \frac{\mathcal{D}(\alpha)}{n} + \lim_{n \to \infty} \frac{\mathcal{D}(\alpha \lor (f_{2}^{-1}(\alpha) \lor (f_{2}^{(2)})^{-1}(\alpha) \lor \ldots \lor (f_{2}^{(n-2)})^{-1}(\alpha))}{n}
\]
\[
= \lim_{n \to \infty} \frac{n - 1}{n} \mathcal{D}(\alpha \lor (f_{2}^{-1}(\alpha) \lor (f_{2}^{(2)})^{-1}(\alpha) \lor \ldots \lor (f_{2}^{(n-2)})^{-1}(\alpha)) \leq \mathcal{D}(\alpha \lor (f_{2}^{-1}(\alpha) \lor (f_{2}^{(2)})^{-1}(\alpha) \lor (f_{2}^{(3)})^{-1}(\alpha) \lor \ldots).
\]
Hence $\mathcal{M}(X, \sigma(f)) \leq \mathcal{M}(X, f)$. □

If the $f_{i}$’s are not necessarily homeomorphisms, then the inequality above can be strict. In fact, take $f_{n} = f : X \to X$ for any $n \geq 2$, where $f$ is any continuous map with positive mean dimension and $f_{1} : X \to X$ a constant map. Then $\mathcal{M}(X, f) = 0$ and $\mathcal{M}(X, \sigma(f)) = \mathcal{M}(X, f)$.

Applying Proposition 2.3 and Proposition 2.4 we obtain the following:

**Corollary 2.5.** Let $f = (f, g, f, g, \ldots)$ and $g = (g, f, g, f, \ldots)$, where $f, g : X \to X$ are continuous maps. Then
\[
\mathcal{M}(X, f) = \mathcal{M}(X, g).
\]

Therefore,
\[
\mathcal{M}(X, f \circ g) = \mathcal{M}(X, g \circ f).
\]

**Proof.** It follows directly from Proposition 2.4 that $\mathcal{M}(X, f) = \mathcal{M}(X, g)$. Now, by Proposition 2.3 we have
\[
\mathcal{M}(X, f \circ g) = \mathcal{M}(X, f^{(2)}) = 2\mathcal{M}(X, f) = 2\mathcal{M}(X, g)
\]
\[
= \mathcal{M}(X, g^{(2)}) = \mathcal{M}(X, g \circ f),
\]
which proves the corollary. □

It follows directly from Corollary 2.5 that if $f$ and $g$ are topologically conjugate continuous maps, then
\[
\mathcal{M}(X, f) = \mathcal{M}(X, g),
\]
since if $\phi$ is a topological conjugacy between $f$ and $g$, that is, $\phi$ is a homeomorphism and $\phi \circ f = g \circ \phi$, then
\[
\mathcal{M}(X, f) = \mathcal{M}(X, \phi^{-1} \circ \phi \circ f) = \mathcal{M}(X, \phi \circ f \circ \phi^{-1}) = \mathcal{M}(X, g).
\]

For any $f = (f_{n})_{n \in \mathbb{N}} \in \mathcal{C}(X)$ one can consider the asymptotic mean dimension as the limit
\[
\mathcal{M}(X, f)^{*} = \lim_{n \to \infty} \mathcal{M}(X, \sigma^{n}(f)),
\]
which exists by Proposition 2.4.
Theorem 2.6. Let \( f = (f_n)_{n \in \mathbb{N}} \in C(X) \). If \( f \) converges uniformly to a continuous map \( f : X \to X \), then
\[
\operatorname{mdim}(X, f)^* \leq \operatorname{mdim}(X, f).
\]
In particular, \( \operatorname{mdim}(X, f) \leq \operatorname{mdim}(X, f) \).

Proof. Let \( (x_n)_{n \in \mathbb{N}} \) be a sequence of mutually different point converging to a point \( x_0 \). Define the map \( F : \{x_n : n = 0, 1, \ldots\} \times X \to \{x_n : n = 0, 1, \ldots\} \times X \) by \( F : (x, y) \mapsto (\phi(x), \psi(x, y)) \), where
\[
\phi(x_n) = \begin{cases} x_0, & \text{if } n = 0 \\ x_{n+1}, & \text{if } n > 0 \end{cases} \quad \text{and} \quad \psi(x_n, y) = \begin{cases} f(y), & \text{if } n = 0 \\ f_n(y), & \text{if } n > 0 \end{cases}
\]
Note that the non wandering set of \( F \), \( \Omega(F) \), is a subset of the fix fiber \( x_0 \times X \) and as
\[
\operatorname{mdim}(\{x_n : n = 0, 1, \ldots\} \times X, F) = \operatorname{mdim}(\{x_0\} \times X, F).
\]
(by [3 Lemma 7.2]), we have that
\[
\operatorname{mdim}(\{x_n : n = 0, 1, \ldots\} \times X, F) = \operatorname{mdim}(\{x_0\} \times X, F).
\]
Therefore,
\[
\operatorname{mdim}(\{x_m : m \geq k\} \times X, F) \leq \operatorname{mdim}(\{x_0\} \times X, F) = \operatorname{mdim}(\{x_n : n = 0, 1, \ldots\} \times X, F),
\]
for all \( k > 0 \) (see Remark 2.2 item (3)). Now we notice that by the definition of the map \( F \) we have that
\[
\operatorname{mdim}(\{x_m : m \geq k\} \times X, F) = \operatorname{mdim}(X, \sigma^k(f)), \quad \text{for } k > 0,
\]
and \( \operatorname{mdim}(\{x_0\} \times X, F) = \operatorname{mdim}(X, f) \). Hence, \( \operatorname{mdim}(X, \sigma^k(f)) \leq \operatorname{mdim}(X, f) \), for all \( k \). \qed

Next example proves that the inequality above can be strict.

Example 2.7. Let \( \phi : I^n \to I^n \) be a continuous map with positive mean dimension. For each \( n \geq 1 \), set \( f_n : I^n \times I^n \to I^n \times I^n \) defined by
\[
f_n((x_1)_{i \in \mathbb{N}}, (y_1)_{i \in \mathbb{N}}) = ((\lambda_n x_i)_{i \in \mathbb{N}}, (x_i \phi(y))_{i \in \mathbb{N}}),
\]
where \( \lambda_n \to 1 \) and \( \lambda_n \cdots \lambda_1 \to 0 \) as \( n \to \infty \). Note that \( f_n \) converges uniformly on \( I^n \times I^n \) to \( f((x_1)_{i \in \mathbb{N}}, (y_1)_{i \in \mathbb{N}}) = ((x_i \phi(y))_{i \in \mathbb{N}}) \) as \( n \to \infty \) and
\[
\operatorname{mdim}(I^n \times I^n, f) \geq \operatorname{mdim}(\{\ldots , 1, 1, \ldots \} \times I^n, f) = \operatorname{mdim}(I^n, \phi) > 0.
\]
On the other hand, note that \( f^n_\phi(x, y) \to (0, 0) \) as \( n \to \infty \) for any \( (x, y) \in I^n \times I^n \) and \( k \geq 1 \). Hence \( \operatorname{mdim}(I^n \times I^n, \sigma^k(f)) = 0 \) for any \( k \geq 1 \), where \( f = (f_n)_{n \in \mathbb{N}} \) and therefore \( \operatorname{mdim}(I^n \times I^n, f)^* = 0 \).

3. Metric mean dimension for non-autonomous dynamical systems

Throughout this section, we will fix \( f = (f_n)_{n \in \mathbb{N}} \in C(X) \) where \( X \) is a compact metric space with metric \( d \). For any non-negative integer \( n \) we define \( d_n : X \times X \to [0, \infty) \) by
\[
d_n(x, y) = \max\{d(x, y), d(f_1(x), f_1(y)), \ldots, d(f_1^{(n-1)}(x), f_1^{(n-1)}(y))\}.
\]
It is not difficult to see that \( d_n \) is a metric for all \( n \) and generates the same topology as \( d \) generates. Fix \( \varepsilon > 0 \). We say that \( A \subset X \) is a \((n, f, \varepsilon)\)-separated set if \( d_n(x, y) > \varepsilon \), for any two distinct points \( x, y \in A \). We denote by \( \operatorname{sep}(n, f, \varepsilon) \) the maximal cardinality of a \((n, f, \varepsilon)\)-separated subset of \( X \). Furthermore, let \( \operatorname{cov}(n, f, \varepsilon) \) denotes the minimum number of \( \varepsilon \)-balls in the \( d_n \)-metric to cover \( X \). We say that \( E \subset X \) is a \((n, f, \varepsilon)\)-spanning set if for any \( x \in X \) there exists \( y \in E \) so that \( d_n(x, y) < \varepsilon \). Let \( \operatorname{span}(n, f, \varepsilon) \) be the minimum cardinality of \((n, f, \varepsilon)\)-spanning subset of \( X \). Given an open cover \( \alpha \), we say that \( \alpha \) is a \((n, f, \varepsilon)\)-cover if the \( d_n \)-diameter of any element of \( \alpha \) is less than \( \varepsilon \). Let \( \operatorname{cov}(n, f, \varepsilon) \) denote the minimum cardinality of a \((n, f, \varepsilon)\)-cover. By the compactness of \( X \), \( \operatorname{sep}(n, f, \varepsilon) \), \( \operatorname{span}(n, f, \varepsilon) \) and \( \operatorname{cov}(n, f, \varepsilon) \) are finite real numbers.
Definition 3.1. We define the lower metric mean dimension of \((X, f, d)\) and the upper metric mean dimension of \((X, f, d)\) by

\[
\underline{\text{mdim}}_M(X, f, d) = \liminf_{\varepsilon \to 0} \frac{\text{sep}(f, \varepsilon)}{|\log \varepsilon|} \quad \text{and} \quad \overline{\text{mdim}}_M(X, f, d) = \limsup_{\varepsilon \to 0} \frac{\text{sep}(f, \varepsilon)}{|\log \varepsilon|},
\]

respectively, where \(\text{sep}(f, \varepsilon) = \limsup_{n \to \infty} \frac{1}{n} \log \text{sep}(n, f, \varepsilon)\).

It is not difficult to see that

\[
\underline{\text{mdim}}_M(X, f, d) = \liminf_{\varepsilon \to 0} \frac{\text{span}(f, \varepsilon)}{|\log \varepsilon|} = \liminf_{\varepsilon \to 0} \frac{\text{cov}(X, \varepsilon)}{|\log \varepsilon|},
\]

where \(\text{span}(f, \varepsilon) = \limsup_{n \to \infty} \frac{1}{n} \log \text{span}(n, f, \varepsilon)\) and \(\text{cov}(f, \varepsilon) = \limsup_{n \to \infty} \frac{1}{n} \log \text{cov}(n, f, \varepsilon)\). The same holds for the upper metric mean dimension.

Remark 3.2. Following the definition of topological entropy for non-autonomous dynamical systems introduced in [7] one can see that if the topological entropy of the system \((X, f, d)\) is finite then its metric mean dimension is zero.

Definition 3.3. We say that \(x \in X\) is a nonwandering point for \(f\) if for every neighbourhood \(U\) of \(x\) there exist positive integers \(k\) and \(n\) with \(f^{(k)}_n(U) \cap U \neq \emptyset\). We denote by \(\Omega(f)\) the set consisting of the nonwandering points of \(f\).

It is well-known that for any continuous map \(\phi : X \to X\) he have \(h_{\text{top}}(\phi) = h_{\text{top}}(\phi|_{\Omega(\phi)})\). The same holds for a non-autonomous system (see [7]). In our next result we prove that the equality also holds for the metric mean dimension.

Theorem 3.4. We have

\[
\underline{\text{mdim}}_M(X, f, d) = \underline{\text{mdim}}_M(\Omega(f), f, d).
\]

Proof. It is clear that \(\underline{\text{mdim}}_M(X, f, d) \geq \underline{\text{mdim}}_M(\Omega(f), f, d)\). Fix \(\varepsilon > 0\) and \(n \in \mathbb{N}\). Let \(\alpha\) be an open \((n, f, \varepsilon)\)-cover of \(X\) with minimum cardinality. Take \(\beta\) a minimal finite open subcover of \(\Omega(f)\), chosen from \(\alpha\) (note that \(\beta\) is an \((n, f, \varepsilon)\)-cover of \(\Omega(f)\)). By the minimality of \(\alpha\) we have that \(\beta\) is an \((n, f, \varepsilon)\)-cover of \(\Omega(f)\) with minimum cardinality, which we denote by \(\text{Card}(\beta) = \text{cov}(\Omega(f), n, f, \varepsilon)\).

The set \(K = X \setminus \bigcup_{U \in \beta} U\) is compact and consists of wandering points. We can cover \(K\) by a finite number of wandering subsets, each of them contained in some element of \(\alpha\). The sets defined before together with \(\beta\) form a finite open cover \(\gamma(n) = \gamma\) of \(X\), finer than \(\alpha\). Consider, for each \(k\), the open cover \(\gamma(k, f^{(n)})\) associated to the sequence \(f^{(n)}\). Note that each element of \(\gamma(k, f^{(n)})\) is of the form

\[
A_0 \cap (f_1^{(n)})^{-1}(A_1) \cap (f_1^{(n)})^{-1}(A_2) \cap \cdots \cap (f_1^{(n)})^{-1} \circ \cdots \circ (f_{(k-2)n+1}^{(n)})^{-1}(A_{k-1}),
\]

where \(A_i \in \gamma, \text{ for } i = 0, \ldots, k-1\). It implies that \(\gamma(k, f^{(n)})\) is a \((k, f^{(n)}, \varepsilon)\)-cover of \(X\). Let \(A_i\) and \(A_j\) be nonempty open sets of \(\gamma(k, f^{(n)})\) for some \(i < j\). If \(A_i = A_j\), then

\[
(f_{(j-i)n+1}^{(n)})^{-1}(A_i) = f_{m+1}^{(n)}(A_i)
\]

intersects \(A_i = A_j\). In that case \(A_i\) does not contain non-wandering points for \(f\) (and hence \(A_i \in \beta\)). Now we estimate the number of elements of \(\gamma(k, f^{(n)})\). Setting

\[
j := \text{Card}(A_i : i = 0, 1, \ldots, k-1) \quad \text{and} \quad m := \text{Card}(\gamma(k, f^{(n)}) \setminus \beta),
\]

we have \(0 \leq j \leq m\). In this case we have \(\binom{m}{j}\) possibilities of the choice of a \(j\)-element subset of \(\gamma(k, f^{(n)}) \setminus \beta\) and then these sets can appear as various \(A_i's\) in \(k \cdot (k-1) \cdots (k-j+1) = k!/(k-j)!\)
ways. For the rest of $A$’s we can choose any element of $\beta$. So, the number of elements of $\gamma(k; f(n))$ is bounded by
\[ \sum_{j=0}^{m} \binom{m}{j} \frac{k!}{(k-j)!} \cdot (\text{Card}(\beta))^{k-j}. \]
Since $k!/(k-j)! \leq k^m$ and $\binom{m}{j} \leq m!$, this number is not larger than $(m+1) \cdot m! \cdot k^m \cdot (\text{Card}(\beta))^k$.
Thus, using the fact that $\text{cov}(k, \mathbf{f}(n), \varepsilon) \leq \text{Card}(\gamma(k; f(n)))$, we have
\[ \limsup_{k \to \infty} \frac{1}{k} \log \text{cov}(k, \mathbf{f}(n), \varepsilon) \leq \limsup_{k \to \infty} \frac{1}{k} \log (m+1) \cdot m! \cdot k^m \cdot (\text{Card}(\beta))^k = \log(\text{Card}(\beta)). \]
As
\[ \limsup_{k \to \infty} \frac{1}{k} \log \text{cov}(k, \mathbf{f}(n), \varepsilon) = \frac{1}{n} \log \text{cov}(\Omega(f), n, f, \varepsilon), \]
it follows that
\[ \limsup_{k \to \infty} \frac{1}{k} \log \text{cov}(k, \mathbf{f}(n), \varepsilon) \leq \frac{1}{n} \log \text{cov}(\Omega(f), n, f, \varepsilon). \]
Taking the limsup as $n \to \infty$ we obtain
\[ \text{cov}(f, \varepsilon) \leq \limsup_{n \to \infty} \frac{1}{n} \log \text{cov}(\Omega(f), n, f, \varepsilon) := \text{cov}(\Omega(f), f, \varepsilon). \]
So,
\[ \text{mdim}_M(X, f, d) = \lim_{\varepsilon \to 0} \inf \frac{\text{cov}(f, \varepsilon)}{|\log \varepsilon|} \leq \lim_{\varepsilon \to 0} \inf \frac{\text{cov}(\Omega(f), f, \varepsilon)}{|\log \varepsilon|} = \text{mdim}_M(\Omega(f), f, d), \]
which proves the theorem. \hfill \Box

**Definition 3.5.** A continuous map $\psi : X \to Y$ will be called $\alpha$-compatible if it is possible to find a finite open cover $\beta$ of $\psi(X)$ such that $\psi^{-1}(\beta) \succ \alpha$.

The proof of the following proposition, which will be used to prove our next result, can be found in [10] Proposition 2.4.

**Proposition 3.6.** If $\alpha$ is an open cover of $X$, then $D(\alpha) \leq k$ if and only if there exists an $\alpha$-compatible continuous map $\psi : X \to K$, where $K$ has topological dimension $k$.

The next result is inspired in the Theorem 4.2 of [10] and shows that the metric mean dimension is an upper bound for the mean dimension.

**Theorem 3.7.** For any metric $d$ on $X$ compatible with the topology of $X$ we have that
\[ \text{mdim}(X, f) \leq \text{mdim}_M(X, f, d). \]

**Proof.** Let $\alpha$ be an open cover of $X$. We can assume that $\alpha$ is of the form
\[ \alpha = \{U_1, V_1\} \cup \cdots \cup \{U_\ell, V_\ell\}, \]
where each $\{U_i, V_i\}$ is an open cover of $X$ with two elements. For each $1 \leq i \leq \ell$ define $\omega_i : X \to [0, 1]$ by
\[ \omega_i(x) = \frac{d(x, X \setminus V_i)}{d(x, X \setminus U_i) + d(x, X \setminus V_i)}. \]
It is not difficult to see that $\omega_i$ is Lipschitz, $U_i = \omega_i^{-1}([0, 1))$ and $V_i = \omega_i^{-1}(]0, 1]).$

Let $C$ be a common bound for the Lipschitz constants of all $\omega_i$. For each positive integer $N$ define $F(N, \cdot) : X \to [0, 1]^N$ by
\[ F(N, x) = (\omega_1(x), \omega_\ell(x), \omega_1(f_1(x)), \omega_\ell(f_1(x)), \omega_1(f_1^{(N)}(x)), \omega_\ell(f_1^{(N)}(x))). \]
As $U_i = \omega_i^{-1}([0, 1))$ and $V_i = \omega_i^{-1}(]0, 1])$ we have that $F(N, \cdot) \succ \alpha_0^{N-1}$. 

Now for each $S \subset \{1, \ldots, \ell N\}$, for $x \in X$, denote by $F(N, x)_S$ the projection of $F(N, x)$ to the coordinates of the index set $S$.

**Claim.** Let $\varepsilon > 0$ and $D = \mdim_M(X, f, d)$. There exists $N(\varepsilon) > 0$ so that, for all $N > N(\varepsilon)$ there exists $\xi \in (0, 1)^{\ell N}$ which satisfies

$$\xi_S \notin F(N, X)_S,$$

for any subset $S \subset \{1, \ldots, \ell N\}$ that satisfies $|S| > (D + \varepsilon)N$.

**Proof.** Let $\delta > 0$ such that

$$\delta < (2^N (2C)^D)^{-2\varepsilon} \quad \text{and} \quad \frac{\text{sep}(f, \delta)}{\log \delta} = \frac{\mdim_M(X, f, d)}{4}. $$

We notice that for $N$ sufficiently large we can cover $X$ by $\delta^{-(D + \varepsilon/2)^N}$ dynamical balls $B(x, N, \delta) = \{y \in X : d_N(x, y) < \delta\}$. Using the fact that $C$ is the common Lipschitz constant for all $\omega_i$ we conclude that

$$F(N, B(x, \delta, N)) \subset \{a \in [0, 1]^{\ell N} : \|F(N, x) - a\|_\infty < C\delta\},$$

where $\|(a_1, \ldots, a_{\ell N}) - (b_1, \ldots, b_{\ell N})\|_\infty = \sup_i |a_i - b_i|$. It implies that $F(N, X)$ can be covered by $\delta^{-(D + \varepsilon/2)^N}$ balls in the $\|\cdot\|_\infty$ norm of radius $C\delta$. Let $B(1), \ldots, B(K)$ be these balls, with $K = \delta^{-(D + \varepsilon/2)^N}$.

Choose $\xi \in [0, 1]^{\ell N}$ with uniform probability and notice that

$$\mathbb{P}(\xi \in F(N, X)_S) \leq \sum_{j=1}^K \mathbb{P}(\xi \in B(j)_S) \leq \delta^{-(D + \varepsilon/2)^N} (2C\delta)^{|S|},$$

and so

$$\mathbb{P}(\exists S : |S| > (D + \varepsilon)N \text{ and } \xi_S \in F(N, X)_S) \leq \sum_{|S| > (D + \varepsilon)N} \mathbb{P}(\xi_S \in F(N, X)_S) \leq (2^N (2C)^D)^{\varepsilon/2} \delta^{-(D + \varepsilon/2)^N} (2C\delta)^{D + \varepsilon} N \leq 2^{\ell N} ((2C)^D \delta^{(D + \varepsilon/2)})^N \ll 1. $$

Hence, with high probability, a random $\xi$ will satisfies the requirements. \hfill \square

**Claim.** If $\pi : F(N, X) \to [0, 1]^{\ell N}$ satisfies for both $a = 0$ and $a = 1$, and all $\xi \in [0, 1]^{\ell N}$,

$$\{1 \leq k \leq \ell N : \xi_k = a\} \subset \{1 \leq k \leq \ell N : \pi(\xi)_S = a\},$$

then $\pi \circ F(N, X)$ is compatible with $a_0^{N-1}$.

**Proof.** Given $\xi \in [0, 1]^{\ell N}$, define for $0 \leq j < N$ and $1 \leq i < \ell$

$$W_{i,j} = \begin{cases} (f_1^{(j)})^{-1}(U_i), & \text{if } \xi_{j+1} = 0, \\ (f_1^{(j)})^{-1}(V_i), & \text{otherwise}. \end{cases}$$

By the definition of $W_{i,j}$ we have that $(\pi \circ F(N, \cdot))^{-1}(\xi) \subset \bigcap_{1 \leq i \leq \ell, 0 \leq j < N} W_{i,j} \in a_0^{N-1}$. It follows that $\pi \circ F(N, X)$ is compatible with $a_0^{N-1}$. \hfill \square

For a fixed $\varepsilon > 0$, consider $\tilde{\xi}$ and $N$ as in the first Claim. Set

$$\Phi = \{\xi \in [0, 1]^{\ell N} : \xi_k = \xi_k \text{ for more than } (D + \varepsilon)N \text{ indexes } k\}.$$

Then, $F(N, X) \subset \Phi^C = [0, 1]^{\ell N} \setminus \Phi$.

Now, for each $m = 1, 2, \ldots$, denote by $J_m$ the set

$$J_m = \{\xi \in [0, 1]^{\ell N} : \xi_i \in \{0, 1\} \text{ for at least } m \text{ indexes } 1 \leq i \leq \ell N\}.$$
Since $\bar{\xi}$ is in the interior of $[0, 1]^{\ell N}$, one can define $\pi_1 : [0, 1]^{\ell N} \setminus \{\bar{\xi}\} \to J_1$ by mapping each $\xi$ to the intersection of the ray starting at $\xi$ and passing through $\xi$ and $J_1$. For each of the $(\ell N - 1)$-dimensional cubes $I^t$ that comprises $J_1$ we can define a retraction on $I^t$ in a similar fashion using as a center the projection of $\bar{\xi}$ on $I^t$. This will define a continuous retraction $\pi_2$ of $\Phi^C$ onto $J_2$. As long as there is some intersection of $\Phi$ with the cubes in $J_n$ this process can be continued, thus we finally get a continuous projection $\pi$ of $\Phi^C$ onto $J_{m_0}$, a space of topological dimension equals to $m_0$, with

$$m_0 \leq |D + \varepsilon|N + 1,$$

where $|x| = \max\{k \in \mathbb{Z} : k \leq x\}$. By construction, $\pi$ satisfies the hypotheses of the second claim. Thus $\pi \circ F(N, \cdot) \geq \alpha_0^{N-1}$. Moreover, since $F(N, X) \subset \Phi^C$, we have $\pi(F(N, X)) \subset J_{m_0}$.

Putting all together, we have constructed a $\alpha_0^{N-1}$ compatible function from $X$ to a space of topological dimension less or equal to $|D + \varepsilon|N + 1$, and so

$$\frac{D(\alpha_0^{N-1})}{N} \leq \frac{|D + \varepsilon|N + 1}{N}.$$ 

As $\varepsilon$ goes to zero we get that $\text{mdim}(X, f) \leq D$. \hfill $\Box$

In Example 4.7, we will prove that the inequality on Theorem 4.3 can be strict. In [9], Theorem 4.3, is proved that if a continuous map $\phi : X \to X$ is an extension of a minimal system, then there is a metric $d'$ on $X$, equivalent to $d$, such that

$$\text{mdim}(X, \phi) = \text{mdim}_M(X, \phi, d').$$

We can consider the asymptotic metric mean dimension as the following limit

$$\text{mdim}_M(X, f, d)^* = \limsup_{i \to \infty} \text{mdim}_M(X, \sigma^i(f), d).$$

Applying the same idea as the one used to prove Theorem 2.7 and using Theorem 3.4, we obtain that:

**Theorem 3.8.** If $f = (f_n)_{n \in \mathbb{N}}$ converges uniformly to a continuous map $f : X \to X$, then, for any $k \geq 1$,

$$\text{mdim}_M(X, \sigma^k(f), d) \leq \text{mdim}_M(X, f, d).$$

Consequently,

$$\text{mdim}_M(X, f, d)^* \leq \text{mdim}_M(X, f, d).$$

We can prove, as in Example 2.7, that the inequality above can be strict.

**Remark 3.9.** All the above results are valid for the upper metric mean dimension of $(X, f, d)$.

### 4. Upper bound for the metric mean dimension

As we saw in Remark 2.2, we have $\text{mdim}(X^K, \sigma) \leq \dim(X)$, where $K = \mathbb{Z}$ or $\mathbb{N}$. Furthermore, if $X = I^k$, then $\text{mdim}(X^Z, \sigma) = k$. In this section we will prove that the metric dimension of the shift on $X^K$ is equal to the box dimension of $X$ with respect to the metric $d$, which will be defined below. This fact implies that the metric dimension of any continuous map $\phi : X \to X$ is less or equal to the box dimension of $X$ with respect to the metric $d$ (see Proposition 4.3). Therefore, by Theorem 3.8 we will have that both $\text{mdim}_M(X, f, d)^*$ and $\text{mdim}_M(X, f, d)^*$ are bounded by the box dimension of $X$ with respect to the metric $d$ for any convergent sequence $f = (f_n)_{n \in \mathbb{N}}$.

Consider the metric $\tilde{d}$ on $X^K$ defined by

$$\tilde{d}(\bar{x}, \bar{y}) = \sum_{i \in K} \frac{1}{2^{|i|}}d(x_i, y_i),$$

for $\bar{x} = (x_i)_{i \in K}, \bar{y} = (y_i)_{i \in K} \in X^K$. (4.1)
Take $X = [0, 1]$, endowed with the metric $d(x, y) = |x - y|$ for $x, y \in X$. In [11], Example E, it is proved that $\text{mdim}(X^Z, \sigma, d) = 1$. Using the same idea, in the next lemma we prove that $\text{mdim}(X^N, \sigma, d) = 1$.

**Lemma 4.1.** Take $X = [0, 1]$ endowed with the metric $d(x, y) = |x - y|$ for $x, y \in X$. Thus

$$\text{mdim}(X^N, \sigma, \tilde{d}) = 1.$$ 

**Proof.** Fix $\varepsilon > 0$ and take $l = \lceil \log(4/\varepsilon) \rceil$, where $\lceil x \rceil = \min\{k \in \mathbb{Z} : x \leq k\}$. Note that $\sum_{n \geq l} 2^{-n} \leq \varepsilon/2$. Consider the open cover of $X$ given by

$$I_k = \left( \frac{(k - 1)\varepsilon}{12}, \frac{(k + 1)\varepsilon}{12} \right), \quad \text{for } 0 \leq k \leq \lceil 12/\varepsilon \rceil.$$ 

Note that $I_k$ has length $\varepsilon/6$. Let $n \geq 1$. Next, consider the following open cover of $X^N$:

$$I_{k_1} \times I_{k_2} \times \cdots \times I_{k_{n+l}} \times X \times X \times \cdots,$$

where $0 \leq k_1, k_2, \ldots, k_{n+l} \leq \lceil 12/\varepsilon \rceil$.

Each open set has diameter less than $\varepsilon$ with respect to the distance $\tilde{d}_n$ (see [11,II]). Therefore

$$\text{cov}(n, \sigma, \varepsilon) \leq (1 + \lfloor 12/\varepsilon \rfloor)^{n+l} = (2 + 12/\varepsilon)^{n+1+12/\varepsilon}.$$ 

Hence

$$\text{cov}(\sigma, \varepsilon) = \lim_{n \to \infty} \frac{\log \text{cov}(n, \sigma, \varepsilon)}{n} \leq \lim_{n \to \infty} \frac{(n + 1 + 12/\varepsilon) \log(2 + 12/\varepsilon)}{n} = \log(2 + 12/\varepsilon).$$

Thus

$$\text{mdim}(X^N, \sigma, \tilde{d}) = \lim_{\varepsilon \to 0} \frac{\text{cov}(\sigma, \varepsilon)}{\log |\varepsilon|} \leq 1.$$ 

On the other hand, any two distinct points in the sets

$$\{(x_i)_{i \in \mathbb{N}} \in X^N : x_i \in \{0, \varepsilon, 2\varepsilon, \ldots, [1/\varepsilon] \varepsilon\} \text{ for all } 0 \leq i < n\}$$

have distance $\geq \varepsilon$ with respect to $d_n$. It follows that

$$\text{cov}(n, \sigma, \varepsilon) \geq (1 + [1/\varepsilon])^n \geq (1/\varepsilon)^n.$$ 

Therefore

$$\text{cov}(\sigma, \varepsilon) \geq \lim_{n \to \infty} \frac{\log \text{cov}(n, \sigma, \varepsilon)}{n} = |\log \varepsilon|.$$ 

Hence $\text{mdim}_M(X^N, \sigma, d) = 1$. □

**Definition 4.2.** For $\varepsilon > 0$, let $N(\varepsilon)$ be the minimum number of closed balls of radius $\varepsilon$ needed to cover $X$. The numbers

$$\overline{\dim}_B(X, d) = \limsup_{\varepsilon \to 0} \frac{\log N(\varepsilon)}{|\log \varepsilon|} \quad \text{and} \quad \underline{\dim}_B(X, d) = \liminf_{\varepsilon \to 0} \frac{\log N(\varepsilon)}{|\log \varepsilon|}$$

are called, respectively, the upper Minkowski dimension (or upper box dimension) of $X$ and the lower Minkowski dimension (or lower box dimension) of $X$, with respect to $d$.

For any metric space $(X, d)$ we have

$$\dim(X) \leq \dim_H(X, d) \leq \overline{\dim}_B(X, d),$$

where $\dim_H(X, d)$ is the Hausdorff dimension of $X$ with respect to $d$ (see [3, Section II, A]). If $X = [0, 1]$, then $\dim(X) = \dim_H(X, d) = \underline{\dim}_B(X, d) = 1$. However, there exist sets such that the above inequalities can be strict, as we will see in the next example, which also proves that neither $\dim(X)$ nor $\dim_H(X, d)$ are upper bounds for $\text{mdim}_M(X^Z, \sigma, d)$. 

Example 4.3. Let $A = \{0\} \cup \{1/n : n \geq 1\}$ endowed with the metric $d(x, y) = |x - y|$ for $x, y \in A$. In [15], Lemma 3.1, is proved that $\dim_H(A) = 0$ while $\dim_B(A) = 1/2$. Furthermore, we have

$$ \mdim_M(A^Z, \sigma, \tilde{d}) = \dim_B(A) = 1/2 $$

(see [11], Section VII).

Using the Classical Variational Principle, in [15], Theorem 5, the authors claim to have proven that for any $(X, d)$

$$ \mdim_M(X^Z, \sigma, \tilde{d}) = \dim_B(X, d). $$

We will generalize the ideas given in [11], Example E, to prove that the metric mean dimension of the shift map is equal to the box dimension of $X$.

Theorem 4.4. For $K = \mathbb{Z}$ or $\mathbb{N}$ we have

$$ \mdim_M(X^K, \sigma, \tilde{d}) = \dim_B(X, d) \quad \text{and} \quad \mdim_M(X^K, \sigma, \tilde{d}) = \dim_B(X, d). $$

Proof. We will prove the case $K = \mathbb{Z}$ (the case $K = \mathbb{N}$ can be proved analogously as in Lemma [11]). Fix $\varepsilon > 0$ and take $l$ big enough such that $\sum_{n \geq l} 2^{-n} \text{diam}(X) \leq \varepsilon/2$. Let $m = N(\varepsilon)$ be the minimum number of closed $\varepsilon$-balls $X_1, \ldots, X_m$ needed to cover $X$. Consider the open cover of $X^Z$ given by the open sets

$$ \cdots \times X \times X_{k-1} \times X_{k-1+1} \times \cdots \times X_{k+n-1} \times X \times \cdots, $$

where $1 \leq k_1, k_1+1, \ldots, k_{n+l} \leq m$.

Note that each one of these open sets has diameter less than $4\varepsilon$ with respect to the distance $\tilde{d}_n$ on $X^Z$. Therefore $\text{cov}(n, \sigma, 4\varepsilon) \leq n^{n+2l+1}$ and hence

$$ \text{cov}(\sigma, 4\varepsilon) = \lim_{n \to \infty} \frac{\log \text{cov}(n, \sigma, 4\varepsilon)}{n} \leq \lim_{n \to \infty} \frac{(n+2l+1) \log(m)}{n} = \log N(\varepsilon), $$

which implies that

$$ \mdim_M(X^Z, \sigma, \tilde{d}) = \limsup_{\varepsilon \to \infty} \frac{\text{cov}(\sigma, 4\varepsilon)}{\log 4\varepsilon} \leq \limsup_{\varepsilon \to \infty} \frac{\log N(\varepsilon)}{\log 4\varepsilon} = \limsup_{\varepsilon \to \infty} \frac{\log N(\varepsilon)}{\log 4 + \log \varepsilon} = \dim_B(X, d), $$

and

$$ \mdim_M(X^Z, \sigma, \tilde{d}) = \liminf_{\varepsilon \to \infty} \frac{\text{cov}(\sigma, 4\varepsilon)}{\log 4\varepsilon} \leq \dim_B(X, d). $$

To prove the converse inequality, for $\varepsilon > 0$ let $\{x_1, x_2, \ldots, x_{N(\varepsilon)}\}$ be a maximal set of points in $X$ which are $\varepsilon$-separated. For $n \geq 1$, consider the set

$$ \{(y_i)_{i \in \mathbb{Z}} : y_i \in \{x_1, x_2, \ldots, x_{N(\varepsilon)}\} \text{ for all } -l \leq i \leq n + l\} $$

and notice that it is $(\sigma, n, \varepsilon)$-separated and its cardinality is bounded from below by $N(\varepsilon)n^{n+2l+1}$. So

$$ \text{sep}(\sigma, \varepsilon) \geq \lim_{n \to \infty} \frac{\log N(\varepsilon)n^{n+2l+1}}{n} = \log N(\varepsilon), $$

and it implies that

$$ \mdim_M(X^Z, \sigma, \tilde{d}) \geq \dim_B(X, d), $$

which proves the theorem. \qed

The idea of the proof for the following proposition is given in [15], Remark 4.

Proposition 4.5. For any continuous map $\phi : X \to X$ we have

$$ \mdim_M(X, \phi, d) \leq \dim_B(X, d) \quad \text{and} \quad \mdim_M(X, \phi, d) \leq \dim_B(X, d). $$

In particular, if $X = [0, 1]$, then

$$ \mdim_M(X, \phi, d) \leq \mdim_M(X, \phi, d) \leq 1. $$
Proof. Consider the embedding $\psi : X \to X^N$, defined by $x \mapsto \psi(x) = (x, \phi(x), \phi^2(x), \ldots)$. We have $\sigma \circ \psi = \psi \circ \phi$. Therefore, $Y = \psi(X)$ is a closed subset of $X^N$ invariant by $\sigma$. Take the metric $d_\psi$ on $X$ defined by $d_\psi(x, y) = d(\psi(x), \psi(y))$, for any $x, y \in X$. Clearly $d(x, y) \leq d_\psi(x, y)$ for any $x, y \in X$, therefore any $(n, \phi, \varepsilon)$-separated subset of $X$ with respect to $d$ is a $(n, \phi, \varepsilon)$-separated subset of $X$ with respect to $d_\psi$. Hence

$$\text{mdim}_M(X, \phi, d) \leq \text{mdim}_M(X, \phi, d_\psi) = \text{mdim}_M(Y, \sigma[y, \tilde{d}) \leq \text{mdim}_M(X^N, \sigma, \tilde{d}) \leq \dim_B(X, d).$$

and, analogously, $\text{mdim}_M(X, \phi, d) \leq \dim_B(X, d)$.

Theorem 3.3 and Proposition 4.5 imply that

**Corollary 4.6.** If $f = (f_n)_{n \in \mathbb{N}}$ converges uniformly to a continuous map on $X$, then

$$\text{mdim}_M(X, f, d)^* \leq \dim_B(X, d) \quad \text{and} \quad \text{mdim}_M(X, f, d)^* \leq \dim_B(X, d).$$

In particular, if $X = [0, 1]$, then $\text{mdim}_M(X, f, d)^* \leq 1$.

In the next example we prove that there exist dynamical systems $\phi : X \to X$ such that $\text{mdim}_M(X, \phi, d) = \dim_B(X, d)$.

**Example 4.7.** Take $g : [0, 1] \to [0, 1]$, defined by $x \mapsto |1 - 3|x - 1||$, and $0 = a_0 < a_1 < \cdots < a_n < \cdots$, where $a_n = \sum_{k=1}^{n} 6/\pi^2 k^2$ for $n \geq 1$. For each $n \geq 1$, let $T_n : J_n := [a_{n-1}, a_n] \to [0, 1]$ be the unique increasing affine map from $J_n$ (which has length $6/\pi^2 n^2$) onto $[0, 1]$ and take any strictly increasing sequence of natural numbers $m_n$. Consider the continuous map $\phi : [0, 1] \to [0, 1]$ such that, for each $n \geq 1$, $\phi_{J_n} = T_n^{-1} \circ g^{m_n} \circ T_n$.

Fix $n \geq 1$. Note that $J_n$ can be divided into $3^{m_n}$ intervals with the same length $J_n(1), \ldots, J_n(3^{m_n})$, such that

$$\phi(J_n(i)) = J_n \quad \text{for each } i \in \{1, \ldots, 3^{m_n}\}.$$

Next, $J_n(i)$ can be divided into $3^{m_n}$ intervals with the same length $J_n(i, 1), \ldots, J_n(i, 3^{m_n})$ such that

$$\phi(J_n(i, s)) = J_n(i) \quad \text{for } i = 1, \ldots, 3^{m_n} \quad \text{and } s = 1, \ldots, 3^{m_n}.$$

Inductively we can prove that, for all $k \geq 1$ and $(i_1, \ldots, i_k)$, where $i_j \in \{1, \ldots, 3^{m_n}\}$, we can divide $J_n(i_1, \ldots, i_k)$ into $3^{m_n}$ intervals with the same length $J_n(i_1, \ldots, i_k, 1), \ldots, J_n(i_1, \ldots, i_k, 3^{m_n})$ such that

$$\phi(J_n(i_1, \ldots, i_k, i)) = J_n(i_1, \ldots, i_k) \quad \text{for } i = 1, \ldots, 3^{m_n}.$$

Furthermore, each $J_n(i_1, \ldots, i_k)$ has length $|J_n|/3^{m_n}$ for each $k \geq 1$.

Take $\varepsilon_n = |J_n|/3^{m_n} = 3/\pi^2 n^2 3^{m_n}$ for each $n \geq 1$. If $x \in J_n(i_1, \ldots, i_k)$ and $y \in J_n(j_1, \ldots, j_k)$ where $(i_1, \ldots, i_k) \neq (j_1, \ldots, j_k)$ and each $i_1, \ldots, i_k, j_1, \ldots, j_k$ is odd, then

$$d_{n+k}(x, y) \geq \varepsilon_n.$$

For each $k \geq 1$, there are more than $(3^{m_n}/2)^k$ intervals $J_n(i_1, \ldots, i_k)$ with $i_s$ odd, $s = 1, \ldots, k$.

Hence $\text{sep}(n, k, \phi, \varepsilon_n) \geq (3^{m_n}/2)^k$ and then

$$\text{sep}(\phi, \varepsilon_n) \geq \lim_{k \to \infty} \frac{\log \text{sep}(n+k, \phi, \varepsilon_n)}{k} \geq \log(3^{m_n}/2).$$

Therefore

$$\text{mdim}_M([0, 1], \phi, | \cdot |) \geq \lim_{n \to \infty} \frac{\log(3^{m_n}/2)}{-\log \varepsilon_n} = \lim_{n \to \infty} \frac{\log(3^{m_n}/2)}{-\log(3/\pi^2 n^2)} = \lim_{n \to \infty} \frac{\log(3^{m_n}) + \log 2}{\log(\pi^2 n^2/3) + \log(3^{m_n})} = 1,$$

hence $\text{mdim}_M([0, 1], \phi, | \cdot |) \geq 1$. It follows from Proposition 4.5 that $\text{mdim}_M([0, 1], \phi, | \cdot |) \leq 1$. Therefore $\text{mdim}_M([0, 1], \phi, | \cdot |) = 1.$
In the above example, for each $n \geq 1$, take $m_n = n$ and
\[
 f_n(x) = \begin{cases} 
 \phi(x), & \text{if } x \in [0, a_{n+1}], \\
 a_{n+1}, & \text{if } x \in [a_{n+1}, 1]. 
\end{cases}
\]
Thus $f_n$ converges uniformly to $\phi$ as $n \to \infty$. In [7], Figure 3, is proved that the topological entropy $h_{top}((f_{n+k})_{n=1}^{\infty}) = k \log 3$ for each $k \geq 1$. Hence, $\text{mdim}_M([0, 1], (f_{n+k})_{n=1}^{\infty}, \cdot, \cdot) = 0$ and therefore $\text{mdim}_M([0, 1], (f_n)_{n=1}^{\infty}, \cdot, \cdot) = 0 < \text{mdim}_M([0, 1], \phi, \cdot, \cdot) = 1$.

On the other hand, the sequence
\[
 g_n(x) = \begin{cases} 
 \phi(x), & \text{if } x \in [0, a_{n+1}], \\
 x, & \text{if } x \in [a_{n+1}, 1]. 
\end{cases}
\]
also converges uniformly to $\phi$ as $n \to \infty$. Note that $g^{(n+k)}_n |J_n = \phi^k |J_n$, for $n \geq 1, k \geq 1$. Therefore, a dynamical system with positive metric mean dimension can be approximated by a sequence of continuous maps with metric mean dimension equal to zero.

Next example proves that the box dimension is not an upper bound for the metric mean dimension of sequences that are not convergent. In particular, there exist non-autonomous dynamical systems with infinite metric mean dimension.

**Example 4.8.** Let $X = \{0, 1\}^\mathbb{N}$ with its usual metric and consider $f = (f_i)_{i \in \mathbb{N}}$, where $f_i : \{0, 1\}^\mathbb{N} \to \{0, 1\}^\mathbb{N}$ given by $f_i(\omega) = \sigma^i(\omega)$, for any positive integer $i$. We notice that $f_1^{(n)}(\omega) = \sigma^{2^{n+i}}(\omega)$. We claim that $\text{mdim}_M(X, f, d)$ is infinite. Fix $\varepsilon > 0$. Take a positive integer $k$ so that $2^{-(k+1)} \leq \varepsilon < 2^{-k}$. Now consider $A \subset \{0, 1\}^\mathbb{N}$ a $(2^{n+1} - 2, \varepsilon)$-separated set for the shift map $\sigma$ of maximum cardinality and notice that $A$ is a $(n, \varepsilon)$-separated set for $f$. So, $\text{sep}(n, f, \varepsilon) \geq 2^{n+1} - 2 + k$ and then
\[
 \frac{\log \text{sep}(n, f, \varepsilon)}{n \log \varepsilon} \geq \frac{(2^{n+1} - 2 + k) \log 2}{nk}.
\]
So, by the definition of the upper metric mean dimension,
\[
 \text{mdim}_M(X, f, d) = \limsup_{\varepsilon \to 0} \limsup_{n \to \infty} \frac{\log \text{sep}(n, f, \varepsilon)}{n \log \varepsilon} = \infty.
\]

5. **Uniform equiconjugacy and metric mean dimension**

We say that the systems $f = (f_n)_{n \in \mathbb{N}}$ on $(X, d)$ and $g = (g_n)_{n \in \mathbb{N}}$ on $(Y, d')$ are uniformly equiconjugate if there exists a equicontinuous sequence of homeomorphisms $h_n : X \to Y$ so that $h_{n+1} \circ f_n = g_n \circ h_n$, for all $n \in \mathbb{N}$, that is, the following diagram
\[
\begin{array}{ccc}
X & \xrightarrow{f_1} & X & \xrightarrow{f_2} & \cdots & \xrightarrow{f_n} & X \\
\downarrow h_1 & & \downarrow h_2 & & \cdots & & \downarrow h_{n+1} \\
Y & \xrightarrow{g_1} & Y & \xrightarrow{g_2} & \cdots & \xrightarrow{g_n} & Y
\end{array}
\]
is commutative for all $n \in \mathbb{N}$. In the case where $h_n = h$, for all $n \in \mathbb{N}$, we say that $f$ and $g$ are uniformly conjugate.

Note that the notion of uniform equiconjugacy does not depend on the metric on $X$ and $Y$. Indeed, if $d^*$ is other metric on $X$ and $d'^*$ is other metric on $Y$, then $(X, f, d)$ and $(X, f, d^*)$ are uniformly equiconjugate by the sequence $(I_X)_{n \in \mathbb{N}}$ and $(Y, g, d')$ and $(Y, g, d'^*)$ are uniformly
equi conjugate by the sequence \((I_Y)_{n \in \mathbb{N}}\). Hence, if \((X, f, d)\) and \((Y, g, d')\) are uniformly equi conjugate by the sequence \((h_n)_{n \in \mathbb{N}}\), then \((X, f, d')\) and \((Y, g, d')\) are uniformly equi conjugate by the sequence \((I_Y \circ h_n \circ I_X)_{n \in \mathbb{N}}\).

Topological entropy for non-autonomous dynamical systems is invariant under uniform equi conjugacy (see [2] and [13]). Metric mean dimension for single dynamical systems depends on the metric \(d\) on \(X\). Consequently, it is not an invariant under conjugacy and therefore it is not an invariant for uniformly equi conjugate non-autonomous dynamical systems. Set

\[ B = \{ \rho : \rho \text{ is a metric on } X \text{ equivalent to } d \} \]

and take

\[ \text{mdim}_M(X, f) = \inf_{\rho \in B} \text{mdim}_M(X, f, \rho). \]

**Theorem 5.1.** Let \(f = (f_n)_{n \in \mathbb{N}}\) and \(g = (g_n)_{n \in \mathbb{N}}\) be two non-autonomous dynamical systems defined on the metric spaces \((X, d)\) and \((Y, d')\) respectively.

1. If \(f\) and \(g\) are uniformly conjugate then

\[ \text{mdim}(X, f) = \text{mdim}(X, g). \]

2. If \((X, f)\) and \((Y, g)\) are uniformly equi conjugate by a sequence of homeomorphisms \((h_n)_{n \in \mathbb{N}}\) that satisfies \(\inf_n \{d(h_n^{-1}(y_1), h_n^{-1}(y_2))\} > 0\) for any \(y_1, y_2 \in Y\), then

\[ \text{mdim}_M(X, f) \geq \text{mdim}_M(Y, g). \]

3. If \((X, f)\) and \((Y, g)\) are uniformly equi conjugate by a sequence of homeomorphisms \((h_n)_{n \in \mathbb{N}}\) that satisfies \(\inf_n \{d(h_n(x_1), h_n(x_2))\} > 0\) for any \(x_1, x_2 \in X\), then

\[ \text{mdim}_M(X, f) \leq \text{mdim}_M(Y, g). \]

4. If \((X, f)\) and \((Y, g)\) are uniformly equi conjugate by a sequence of homeomorphisms \((h_n)_{n \in \mathbb{N}}\) that satisfies \(\inf_n \{d(h_n^{-1}(y_1), h_n^{-1}(y_2)), d'(h_n(x_1), h_n(x_2))\} > 0\) for any \(y_1, y_2 \in Y\) and \(x_1, x_2 \in X\), then

\[ \text{mdim}_M(X, f) = \text{mdim}_M(Y, g). \]

**Proof.**

1. Let \(h : X \to Y\) be a homeomorphism which conjugate \(f\) and \(g\), i.e., \(h \circ f_1^{(n)} = g_1^{(n)} \circ h\) for all \(n \in \mathbb{N}\). For an open cover \(\alpha\) of \(X\), consider \(\beta = h(\alpha)\), which is an open cover of \(Y\). Now we notice that

\[ \rho_0^{-1} = h(\alpha) \vee g_1^{-1}(h(\alpha)) \vee \cdots \vee (g_1^{-1})^{(n-1)}(h(\alpha)) \]

\[ = h(\alpha) \vee (h \circ f_1^{-1} \circ h^{-1})(h(\alpha)) \vee \cdots \vee (h \circ (f_1^{-1})^{(n-1)} \circ h^{-1})(h(\alpha)) \]

\[ = h(\alpha_0^{-1}). \]

It implies that \(D(h(\alpha_0^{-1})) = D(\alpha_0^{-1})\). Since, for any open cover \(\beta\) of \(Y\) is of the form \(h(\alpha)\), for some open cover \(\alpha\) of \(X\),

\[ \text{mdim}(X, f) = \sup_{\alpha} \lim_{n \to \infty} \frac{D(\alpha_0^{-1})}{n} = \sup_{\beta} \lim_{n \to \infty} \frac{D(\beta_0^{-1})}{n} = \text{mdim}(Y, g). \]

2. Let \((h_n)_{n \in \mathbb{N}}\) be the sequence of equicontinuous homeomorphisms that equi conjugates \(f\) and \(g\). So,

\[ f_n \circ \cdots \circ f_1 = h_{n+1}^{-1} \circ g_n \circ \cdots \circ g_1 \circ h_1. \]

By assumption we have

\[ \inf_n \{d(h_n^{-1}(y_1), h_n^{-1}(y_2))\} > 0, \text{ for any } y_1 \neq y_2 \in Y. \] (5.1)

Hence, we can define on \(Y\) the metric

\[ d'(y_1, y_2) := \inf_n \{d(h_n^{-1}(y_1), h_n^{-1}(y_2))\}. \]
In particular, if $S \subset X$ is a $(m, f, \varepsilon)$-spanning set of $X$ in the metric $d$ and $x_1, x_2 \in S$, then
\[
d_m^*(h_1(x_1), h_1(x_2)) = \max\{d^*(h_1(x_1), f_1(x_2)), \ldots, d^*(g_1^{m-1}(h_1(x_1)), g_1^{m-1}(h_1(x_2)))\}
\leq \max\{d(x_1, x_2), d(h_2^{-1}(g_1(h_1(x_1))), h_2^{-1}(g_1(h_1(x_2)))), \\
\ldots, d(h_m^{-1}(g_1^{m-1}(h_1(x_1))), h_m^{-1}(g_1^{m-1}(h_1(x_2))))\}
= d_m^*(x_1, x_2) \leq \varepsilon.
\]
It follows that $h_1(S)$ is an $(m, g, \varepsilon)$-spanning set of $Y$ in the metric $d^*$. So we obtain that
\[
\dim M(X, f, d) \geq \dim M(Y, g, d^*),
\]
and therefore $\dim M(X, f) \geq \dim M(Y, g)$.

By an analogous argument we can prove (iii). Item (iv) follows from (ii) and (iii). \hfill \Box

The following corollaries follow from Theorem 5.1.

**Corollary 5.2.** If $\phi : X \to X$ and $\psi : X \to X$ are topologically conjugate continuous maps, then
\[
\dim M(X, \phi) = \dim M(X, \psi).
\]

**Corollary 5.3.** If $f_1, \ldots, f_n, g_1, \ldots, g_i$ are homeomorphisms, $f = (f_1, \ldots, f_{i+1}, f_{i+2}, \ldots)$ and $g = (g_1, \ldots, g_i, f_{i+1}, f_{i+2}, \ldots)$, then
\[
\dim M(X, f) = \dim M(Y, g).
\]

**Proof.** Note that the following diagram is commutative
\[
\begin{array}{cccccc}
X & \xrightarrow{f_1} & X & \xrightarrow{f_2} & \ldots & \xrightarrow{f_i} & X & \xrightarrow{f_{i+1}} & X & \xrightarrow{f_{i+2}} & X \\
& h_1 & \downarrow & h_2 & \ldots & h_i & \downarrow & Id_X & \downarrow & Id_X & \downarrow \\
X & \xrightarrow{g_1} & X & \xrightarrow{g_2} & \ldots & \xrightarrow{g_i} & X & \xrightarrow{g_{i+1}} & X & \xrightarrow{g_{i+2}} & X \\
& & & & & & & & & & \\
\end{array}
\]
where $I_X$ is the identity of $X$ and $h_i = g_i^{-1} \circ f_i, h_{i-1} = g_{i-1}^{-1} \circ h_i \circ f_{i-1}, \ldots, h_1 = g_1^{-1} h_2 f_1$. Furthermore, $(h_1, h_2, \ldots, h_i, I_X, I_X, \ldots)$ is an equicontinuous sequence of homeomorphisms. Therefore, $f$ and $g$ are uniformly equiconjugate. The corollary follows from Theorem 5.1 since the infimum $\inf_n (d(h_n^{-1}(y_1), h_n^{-1}(y_2)), d(h_n(x_1), h_n(x_2))) > 0$ is taken over a finite set.

Next corollary means that if $f$ is a sequence of homeomorphisms then $\dim M$ is independent on the firsts elements in the sequence $f$.

**Corollary 5.4.** Let $f = (f_n)_{n \in \mathbb{N}}$ be a non-autonomous dynamical system consisting of homeomorphisms. For any $i, j \in \mathbb{N}$ we have
\[
\dim M(X, \sigma^i(f)) = \dim M(X, \sigma^j(f)).
\]

**Proof.** It is sufficient to prove that $\dim M(X, \sigma^i(f)) = \dim M(X, f)$ for all $i \in \mathbb{N}$. Fix $i \in \mathbb{N}$. Take $g = (g_n)_{n \in \mathbb{N}}$, where, for each $n \leq i$, $g_n = I$ is the identity on $X$ and $g_n = f_n$ for $n > i$. It follows from Corollary 5.3 that
\[
\dim M(X, f) = \dim M(X, g).
\]
For each $x, y \in X$ and $n > i$ we have
\[
\max\{d(x, y), d(g_1^{(i-1)}(x), g_1^{(i-1)}(y)), \ldots, d(g_1^{(n-1)}(x), g_1^{(n-1)}(y))\}
= \max\{d(x, y), d(g_i(x), g_i(y)), \ldots, d(g_i^{(n-i)}(x), g_i^{(n-i)}(y))\}
= \max\{d(x, y), d(f_i(x), f_i(y)), \ldots, d(f_i^{(n-i)}(x), f_i^{(n-i)}(y))\}.
\]
Hence
\[
\dim M(X, f) = \dim M(X, g) = \dim M(X, \sigma^i(f)).
\]
which proves the corollary.

**Proposition 5.5.** For any \( f = (f_n)_{n \in \mathbb{N}} \) and \( p \in \mathbb{N} \), we have
\[
\text{mdim}_M(X, f^{(p)}, d) \leq p \text{ mdim}_M(X, f, d).
\]
Consequently,
\[
\text{mdim}_M(X, f^{(p)}) \leq p \text{ mdim}_M(X, f).
\]

**Proof.** We notice that, for any positive integer \( m \),
\[
\max_{0 \leq j < m} d(f_1^{(j)}(x), f_1^{(j)}(y)) \leq \max_{0 \leq j < mp} d(f_1^{(j)}(x), f_1^{(j)}(y)).
\]
If follows that \( \text{span}(m, f^{(p)}, \varepsilon) \leq \text{span}(mp, f, \varepsilon) \), so
\[
\text{span}(f^{(p)}, \varepsilon) = \limsup_{m \to \infty} \frac{1}{m} \log \text{span}(m, f^{(p)}, \varepsilon) \leq \limsup_{m \to \infty} \frac{1}{mp} \log \text{span}(m, f, \varepsilon) = p \text{ span}(f, \varepsilon)
\]
and then \( \text{mdim}_M(X, f^{(p)}, d) \leq p \text{ mdim}_M(X, f, d) \).

**Remark 5.6.** In Example [4,7] we prove that there exists a continuous map \( \phi : [0, 1] \to [0, 1] \) such that \( \text{mdim}_M([0, 1], \phi, d) = 1 \), where \( d(x, y) = |x - y| \) for \( x, y \in [0, 1] \). It follows from Proposition 4.5 that for any \( f : [0, 1] \to [0, 1] \) we have \( \text{mdim}_M([0, 1], f, d) \leq 1 \). Consequently, \( \text{mdim}_M([0, 1], \phi^n, d) \leq 1 \) for any \( n \geq 1 \), which proves that the inequality in Proposition 5.5 can be strict for autonomous systems and therefore for non-autonomous systems.

Next corollary follows from Corollary 5.4 and Proposition 5.5 (see the proof of Corollary 2.5).

**Corollary 5.7.** For any homeomorphisms \( f \) and \( g \) defined on \( X \), we have
\[
\text{mdim}_M(X, f \circ g) = \text{mdim}_M(X, g \circ f).
\]

Before we finish this section we would like to emphasize that all results obtained for the lower metric mean dimension also hold for the upper metric mean dimension.

## 6. Additional Properties of the Metric Mean Dimension

In this section we will show some additional properties of the metric mean dimension of sequences of diffeomorphisms defined on a manifold. For any \( r \geq 0 \), set
\[
\mathcal{C}^r(X) = \{(f_n)_{n \in \mathbb{N}} : f_n : X \to X \text{ is a } C^r \text{-map} \} = \prod_{i=1}^{+\infty} C^r(X),
\]
where \( C^r(X) = \{ \phi : X \to X : \phi \text{ is a } C^r \text{-map} \} \). Hence \( \mathcal{C}^r(X) \) can be endowed with the **product topology**, which is generated by the sets
\[
\mathcal{U} = \bigcup_{i=1}^{j} C^r(X) \times \prod_{i=j+1}^{j+m} U_i \times \prod_{i=j+m}^{+\infty} C^r(X),
\]
where \( U_i \) is an open subset of \( C^r(X) \), for \( j + 1 \leq i \leq j + m \), for some \( j, m \in \mathbb{N} \). The space \( \mathcal{C}^r(X) \) with the product topology will be denoted by \( (\mathcal{C}^r(X), \tau_{\text{prod}}) \). We can consider the map
\[
\text{mdim}_M : (\mathcal{C}^r(X), \tau_{\text{prod}}) \to \mathbb{R} \cup \{+\infty\}
\]
\( f \to \text{mdim}_M(f, X) \).

Clearly, if \( \text{mdim}_M \) is a constant map, then is continuous.

**Proposition 6.1.** If \( \text{mdim}_M : (\mathcal{C}^r(X), \tau_{\text{prod}}) \to \mathbb{R} \cup \{+\infty\} \) is not constant then is discontinuous at any \( f \in \mathcal{C}^r(X) \).

\footnote{If \( r \geq 1 \) we assume that \( X \) is a Riemannian manifold}
Proof. Fix $f = (f_i)_{i \in \mathbb{N}} \in C^r(X)$. Since $\text{mdim}_M$ is not constant, there exists $g = (g_i)_{i \in \mathbb{N}} \in C^r(X)$ such that $\text{mdim}_M(X, g) \neq \text{mdim}_M(X, f)$. Let $\mathcal{V} \in \tau_{\text{prod}}$ be any open neighborhood of $f$. For some $k \in \mathbb{N}$, the sequence $j = (j_i)_{i \in \mathbb{N}}$, defined by

$$j_i = \begin{cases} f_i & \text{if } i = 1, \ldots, k \\ g_i & \text{if } i > k, \end{cases}$$

belongs to $\mathcal{V}$, by definition of $\tau_{\text{prod}}$. It is follow from Corollary 6.3 that $\text{mdim}_M(X, j) = \text{mdim}_M(X, g)$, which proves the proposition. \hfill \Box

Suppose that the Hausdorff dimension of $X$ is finite. For $f = (f_i)_{i \in \mathbb{N}} \in C^r(X)$, let $h_{\text{top}}(f)$ be the topological entropy of $f$ (see [7], [13]). We have that if $h_{\text{top}}(f) < \infty$ then $\text{mdim}_M(X, f, d) = 0$. Therefore, if $\sup_{i \in \mathbb{N}} L(f_i) < \infty$, where $L(f_i)$ is the Lipschitz constant of $f_i$, we have that $h_{\text{top}}(f) < \infty$ and hence $\text{mdim}_M(X, f, d) = 0$. Thus:

**Proposition 6.2.** If $\sup_{i \in \mathbb{N}} L(f_i) < \infty$, then $\text{mdim}_M(X, f, d) = 0$.

In particular, if $X$ is a compact Riemannian manifold and $f = (f_i)_{i \in \mathbb{N}}$ is a sequence of differentiable maps that $\sup_{i \in \mathbb{N}} \|Df_i\| < \infty$, where $Df_i$ is the derivative of $f_i$, we have that $h_{\text{top}}(f) < \infty$ and hence $\text{mdim}_M(X, f, d) = 0$.

Let $d^1(\cdot, \cdot)$ be a $C^1$-metric on $C^1(X)$. Suppose that $\sup_{i \in \mathbb{N}} \|Df_i\| < \infty$. For any $K > 0$, if $d^1(g_i, f_i) < K$, then $\sup_{i \in \mathbb{N}} \|Dg_i\| < \infty$ and therefore $\text{mdim}_M(X, g, d) = 0$. On the other hand, if $\sup_{i \in \mathbb{N}} \|Df_i\| = \infty$, then $\text{mdim}_M(X, f, d)$ is not necessarily zero.

In [13], Section 6, is proved that:

**Proposition 6.3.** If $f = (f_i)_{i \in \mathbb{N}}$ is a sequence of $C^1$-diffeomorphisms, there exists a sequence of positive numbers $(\delta_i)_{i \in \mathbb{N}}$ such that every sequence of diffeomorphisms $g = (g_i)_{i \in \mathbb{N}}$ with $d^1(f_i, g_i) < \delta_i$ for each $i \geq 1$, is uniformly equiconjuge to $f$ by a sequence $(h_i)_{i \in \mathbb{N}}$ such that $h_i \to I_X$ as $i \to \infty$.

Note that, if $h_i \to I_X$ as $i \to \infty$, then for any $x_1 \neq x_2 \in X$ and $y_1 \neq y_2 \in Y$ we have $\inf_i \{d(h_i^{-1}(y_1), h_i^{-1}(y_2)), d(h_i(x_1), h_i(x_2))\} > 0$. Hence, it follows from Theorems [54] and Proposition 6.3 that

**Corollary 6.4.** Given a sequence of diffeomorphisms $f = (f_i)_{i \in \mathbb{N}}$, there exists a sequence of positive numbers $(\delta_i)_{i \in \mathbb{N}}$ such that if $g = (g_i)_{i \in \mathbb{N}}$ is a sequence of diffeomorphisms such that $d^1(f_i, g_i) < \delta_i$ for each $i \geq 0$, then

$$\text{mdim}_M(X, g) = \text{mdim}_M(X, f).$$

Roughly, Corollary 6.3 means that if $d^1(f_i, g_i)$ converges very quickly to zero as $i \to 0$, then

$$\text{mdim}_M(X, f) = \text{mdim}_M(X, g).$$

For each sequence of diffeomorphisms $f = (f_i)_{i \in \mathbb{N}}$ and a sequence of positive numbers $\varepsilon = (\varepsilon_i)_{i \in \mathbb{N}}$, a strong basic neighborhood of $f$ is the set

$$B^r(f, \varepsilon) = \{g = (g_i)_{i \in \mathbb{N}} : g_i \text{ is a } C^r\text{-diffeomorphism and } d(f_i, g_i) < \varepsilon_i, \text{ for all } i \in \mathbb{N}\}.$$

The strong topology (or Whitney topology) on $C^r(X)$ is generated by the strong basic neighborhoods of each $f \in C^r(X)$. The space $C^r(X)$ with the strong topology will be denoted by $(C^r(X), \tau_{\text{str}})$.

**Corollary 6.5.** For $r \geq 1$, let $D^r(X) \subseteq C^r(X)$ be the set consisting of diffeomorphisms. Then

$$\text{mdim}_M : (D^r(X), \tau_{\text{str}}) \to \mathbb{R} \cup \{+\infty\}$$

is a continuous map.
Proof. Let $f \in D^s(X)$. It follows from Theorem 6.3 that there exists a strong basic neighborhood $B^s(f, (\delta_i)_{i \in \mathbb{N}})$ such that every $g \in B^s(f, (\delta_i)_{i \in \mathbb{N}})$ is uniformly equiconjugate to $f$. Thus, from Theorem 5.1 we have $\text{mdim}_M(X, g) = \text{mdim}_M(X, f)$ for all $g \in B^s(f, (\delta_i)_{i \in \mathbb{Z}})$, which proves the corollary. □
