OPTIMAL REARRANGEMENT PROBLEM AND NORMALIZED OBSTACLE PROBLEM IN THE FRACTIONAL SETTING

JULIÁN FERNÁNDEZ BONDER, ZHIWEI CHENG AND HAYK MIKAYELYAN

ABSTRACT. We consider an optimal rearrangement minimization problem involving the fractional Laplace operator $(-\Delta)^s$, $0 < s < 1$, and Gagliardo-Nirenberg seminorm $|u|_s$. We prove the existence of the unique minimizer, analyze its properties as well as derive the non-local and highly non-linear PDE it satisfies

$$-(-\Delta)^s U - \chi\{U \leq 0\} \min\{-(-\Delta)^s U^+; 1\} = \chi\{U > 0\},$$

which happens to be the fractional analogue of the normalized obstacle problem $\Delta u = \chi\{u > 0\}$.

1. Introduction

One of the classical problems in rearrangement theory is the minimization of the functional

$$\Phi(f) = \int_D |\nabla u_f|^2 dx,$$

where $u_f$ is the unique solution of the Dirichlet boundary value problem

$$\begin{cases}
-\Delta u_f = f & \text{in } D, \\
u_f = 0 & \text{on } \partial D,
\end{cases}$$

and $f$ belongs to the set

$$\mathcal{R}_\beta = \left\{ f \in L^\infty(D); 0 \leq f \leq 1, \int_D f dx = \beta \right\}.$$

Recall that $\mathcal{R}_\beta$ is the closure in the weak* topology of the rearrangement class

$$\mathcal{R}_\beta := \left\{ f \in L^\infty(D); f = \chi_E, |E| = \beta \right\}.$$

This minimization problem is related to the stationary heat equation

$$\frac{\partial_t u}{0} - \Delta u = f$$

in the domain $D$, which is under the action of the external heat source modeled by the force function $f$. The Dirichlet boundary condition, $u = 0$ on $\partial D$, models the constant temperature on the boundary of $D$. Different force functions $f$ result different heat distributions $u_f$. The minimizer $\hat{f}$ of the functional $\Phi$ is the force
function from a certain rearrangement class $R$, which is resulting the most uniformly
distributed heat $u_f$.

The problem and its variations, such as the $p$–harmonic case, has been studied
by several authors (see [2, 3, 4, 8, 13]), and the results, for this particular setting,
can be formulated in the following theorem.

**Theorem 1.1.** There exists a unique solution $\hat{f} \in R_\beta$ of the minimization problem
$(1)$. For the function $\hat{u} = u_{\hat{f}}$ there exists a constant $\alpha > 0$ such that

- $0 < \hat{u} \leq \alpha$ in $D$,
- $\hat{f} = \chi\{\hat{u} < \alpha\}$,
- $\hat{u} = \alpha$ in $\{\hat{f} = 0\}$.

Moreover, the function $U = \alpha - \hat{u}$ is the minimizer of the functional

$$J(w) = \int_D |\nabla w|^2 + 2w^+ \, dx,$$

among functions $w \in H^1(D)$ with boundary values $\alpha$ on $\partial D$, and solves the obstacle
problem equation

$$(1.3) \quad \Delta U = \chi\{U > 0\} \quad \text{in } D.$$

We refrain from presenting here details about the obstacle problem $(1.1)$, which
is one of the classical free boundary problems (see [5]).

In recent years there has been a great development of nonlocal diffusion problems,
mainly due to some interesting new applications to different fields of the natural
sciences such as some physical models [7, 9, 10, 13, 18, 22], finance [1, 15, 21], fluid
dynamics [6], ecology [12, 17, 20] and image processing [11].

Among these models for nonlocal diffusion, probably the most important one
is given by the fractional laplacian $(-\Delta)^s$, ($0 < s < 1$) that is given (for smooth
functions) as

$$(-\Delta)^s u(x) := \text{p.v.} \int_{\mathbb{R}^n} \frac{u(x) - u(y)}{|x - y|^{n+2s}} \, dy$$

$$= \lim_{\epsilon \downarrow 0} \int_{\mathbb{R}^n \setminus B_\epsilon(x)} \frac{u(x) - u(y)}{|x - y|^{n+2s}} \, dy.$$

This operator is given as the gradient of the nonlocal Gagliardo energy

$$|u|^2_s := \int_{\mathbb{R}^n \times \mathbb{R}^n} \frac{|u(x) - u(y)|^2}{|x - y|^{n+2s}} \, dx\, dy,$$

that is the nonlocal analog of the Dirichlet energy $\|\nabla u\|_2^2$.

In view of the increasing interest in analyzing nonlocal diffusion models, it nat-
urally comes into attention considering problem $(1)$ where the Laplace operator is
replace by its fractional counterpart.

Therefore, in this paper, similar to the way it has been done in [19], we will
consider an optimal rearrangement problem and derive a related free boundary
problem.
More precisely, we consider the minimization problem
\[ \Phi_s(f) \rightarrow \min, \]
where \( \Phi_s(f) = |u_f|^2_{s}, \) \( u_f \) is the unique solution to
\[ (-\Delta)^s u_f = f \quad \text{in} \; D \quad \text{and} \quad u = 0 \quad \text{in} \; D^c \]
and \( f \in \bar{R}_\beta. \)

We show existence and uniqueness of a solution to the fractional rearrangement optimization problem and show that if \( \hat{f} \) is the solution and \( \hat{u} = u_{\hat{f}}, \) then \( 0 \leq \hat{u} \leq \alpha \) for some \( \alpha > 0 \) and, moreover, \( \hat{U} = \alpha - \hat{u} \) is the unique solution to the normalized fractional obstacle problem
\[ \chi\{U > 0\} \leq -(-\Delta)^s U \leq \chi\{U \geq 0\} \quad \text{in} \; D \quad \text{and} \quad U = \alpha \quad \text{in} \; D^c. \]

Finally, we show that the solution to the fractional normalized obstacle problem is also the solution to the (highly nonlinear) equation
\[ -(-\Delta)^s U - \chi\{U \leq 0\} \min\{-(-\Delta)^s U^+; 1\} = \chi\{U > 0\}, \quad \text{in} \; D \quad \text{with} \quad U = \alpha \quad \text{in} \; D^c. \]

**Organization of the paper.** In Section 2 we give a brief introduction to fractional calculus, in Section 3 we analyze the optimal rearrangement problem in the fractional setting and show its relation with the normalized fractional obstacle problem. Finally, in Section 4, we further analyze the normalized fractional obstacle problem and derive a (highly) nonlinear equation that the solution satisfies.

2. **Preliminaries**

2.1. **A very short tour through the basics of the fractional Laplacian.** All the results in this section are either well-known or easily proved, so we just recall them for further references without any attempt of giving proofs.

The fractional order Sobolev spaces \( H^s(\mathbb{R}^n) \) (for \( 0 < s < 1 \)) is defined as
\[ H^s(\mathbb{R}^n) = \{ v \in L^2(\mathbb{R}^n) : |v|^2_s < \infty \}, \]
where \( | \cdot |_s \) is the Gagliardo energy given by [11]. This space is a Hilbert space with inner product given by
\[ (u, v)_{H^s(\mathbb{R}^n)} = \int_{\mathbb{R}^n} u(x)v(x) \, dx + \int_{\mathbb{R}^{2n}} \frac{(u(x) - u(y))(v(x) - v(y))}{|x - y|^{n+2s}} \, dx \, dy. \]

For a brief summary of the properties of fractional order Sobolev spaces \( H^s \), we refer to the survey article [7].

Further we denote by \( H^{-s}(\mathbb{R}^n) \) the topological dual space of \( H^s(\mathbb{R}^n) \) and for a domain \( D \subset \mathbb{R}^n \), we denote
\[ H^s_0(D) = \{ v \in H^s(\mathbb{R}^n) : v = 0 \text{ a.e. in } D^c \}. \]

Recall that for Lipschitz domains \( D \), the space \( H^s_0(D) \) coincides with the closure of test functions with compact support inside \( D \). We will also denote by \( H^{-s}(D) \) the topological dual space of \( H^s_0(D) \). Observe that we have
\[ H^s_0(D) \subset H^s(\mathbb{R}^n) \subset L^2(\mathbb{R}^n) \subset H^{-s}(\mathbb{R}^n) \subset H^{-s}(D), \]
with continuous inclusions. Moreover, since $\mathcal{D} \subset H^s(\mathbb{R}^n)$ with a dense inclusion, then $H^{-s}(\mathbb{R}^n) \subset \mathcal{D}'$ and, if $D$ is Lipschitz, then $H^{-s}(D) \subset \mathcal{D}'(D)$.

Recall that if $D$ is bounded, the following Poincaré type inequality holds true
\begin{equation}
\|u\|_2 \leq C|u|_s \quad \text{for all } u \in H^s_0(D).
\end{equation}

An easy fact is that the Gagliardo–Nirenberg semi-norm $|\cdot|_s^2$ is Gâteaux-differentiable in $H^s(\mathbb{R}^n)$ and
\begin{equation}
\lim_{\epsilon \to 0} \epsilon^{-1}(|u + \epsilon v|_s^2 - |u|_s^2) = \iint_{\mathbb{R}^{2n}} \frac{(u(x) - u(y))(v(x) - v(y))}{|x-y|^{n+2s}} \, dx \, dy,
\end{equation}
for every $u, v \in H^s(\mathbb{R}^n)$.

Furthermore, for a function $u \in H^s(\mathbb{R}^n)$ we can also define the fractional Laplace operator as
\begin{equation}
(-\Delta)^s u(x) = \text{p.v.} \int_{\mathbb{R}^n} \frac{u(x) - u(y)}{|x-y|^{n+2s}} \, dy = \lim_{\epsilon \to 0} (-\Delta)^\epsilon u(x),
\end{equation}
where
\begin{equation}
(-\Delta)^\epsilon u(x) = \int_{\mathbb{R}^n \setminus B_\epsilon(x)} \frac{u(x) - u(y)}{|x-y|^{n+2s}} \, dy
\end{equation}
and the limit is understood in $H^{-s}(\mathbb{R}^n)$.

Moreover, it holds that
\begin{equation}
(\langle -\Delta \rangle^s u, v) = \iint_{\mathbb{R}^{2n}} \frac{(u(x) - u(y))(v(x) - v(y))}{|x-y|^{n+2s}} \, dx \, dy \leq |u|_s|v|_s
\end{equation}
for any $u, v \in H^s(\mathbb{R}^n)$.

For any $f \in H^{-s}(D)$ we say $u_f \in H^s_0(D)$ solves the fractional boundary value problem in $D$ with homogeneous Dirichlet boundary condition
\begin{equation}
\begin{cases}
(-\Delta)^s u_f = f & \text{in } D, \\
u_f = 0 & \text{in } D^c,
\end{cases}
\end{equation}
if the equation is satisfied in the sense of distributions. Equivalently, if
\begin{equation}
\frac{1}{2} \iint_{\mathbb{R}^{2n}} \frac{(u_f(x) - u_f(y))(v(x) - v(y))}{|x-y|^{n+2s}} \, dx \, dy = \int_D fv \, dx
\end{equation}
for any $v \in H^s_0(D)$. It is easily seen from Riesz representation Theorem, using Poincaré inequality (2.4), that for any $f \in H^{-s}(D)$ there exists a unique $u_f \in H^s_0(D)$ satisfying (2.1).

To finish these preliminaries, let us recall that for $f \in L^\infty$ it is a well known fact that the weak solution of (2.1), $u_f$, is in $C^s_{\text{loc}}(D)$ for some $\delta > 0$. Moreover, $u_f$ is a strong solution to (2.1), namely the limit in (2.1) exists pointwise a.e. and the equation (2.1) is also satisfied pointwise a.e.

3. The optimal fractional rearrangement problem

Let us now introduce the fractional analogue of the optimal rearrangement problem given in Theorem 1.1. Given $f \in L^2(D)$, let $u_f$ be the solution of (2.1) and let us define the functional
\begin{equation}
\Phi_s(f) = |u_f|_s^2.
\end{equation}
We are going to consider the minimization of the functional $\Phi_s$ on the closed, convex set $\bar{R}_\beta$, for $0 < \beta < |D|$. The main result of this section is the following theorem.

**Theorem 3.1.** There exists a unique minimizer $\hat{f} \in \bar{R}_\beta \setminus R_\beta$ such that

$$\Phi_s(\hat{f}) \leq \Phi_s(f)$$

for any $f \in \bar{R}_\beta$. Moreover, for some $\alpha > 0$ the function $\hat{u} = u_{\hat{f}}$ satisfies the following conditions

$$\{\hat{f} < 1\} \subset \{\hat{u} = \alpha\}, \quad \{\hat{u} < \alpha\} \subset \{\hat{f} = 1\}, \quad \hat{f} > 0 \quad \text{and} \quad 0 \leq \hat{u} \leq \alpha \text{ in } D.$$

**Remark 3.2.** Observe that this result shows a remarkable difference with the local optimal rearrangement problem, since the optimal configuration $\hat{f}$ for the fractional case is not a characteristic function. c.f. Theorem 1.1.

For the proof of Theorem 3.1 we need a couple of lemmas.

**Lemma 3.3.** The set $\bar{R}_\beta \subset L^\infty(D)$ is convex and

$$\text{ext}(\bar{R}_\beta) = R_\beta,$$

where for a convex set $C$, $\text{ext}(C)$ denotes the extreme points of $C$.

**Proof.** The proof is standard and is omitted. □

**Lemma 3.4.** Let $\Phi_s$ be the functional defined in (3). Then $\Phi_s : \bar{R}_\beta \to \mathbb{R}$ is strictly convex and sequentially lower semi-continuous with respect to the weak* topology. Moreover, there exists a unique minimizer $\hat{f}$ of the functional $\Phi_s$ in $\bar{R}_\beta$.

**Proof.** The strict convexity is a direct consequence of the linearity $u_{f_1} + u_{f_2} = u_{f_1} + u_{f_2}$ and the strict convexity of $t \mapsto t^2$. Moreover, from (2.1), Hölder’s inequality and (2.1), we obtain

$$|u_{f}|_{s} \leq C\|f\|_2.$$ 

Therefore, $f \mapsto u_f$ is strongly continuous from $L^2(D)$ into $H^s_0(D)$ and hence, $\Phi_s$ is strongly continuous from $L^2(D)$ into $\mathbb{R}$. Since $\Phi_s$ is convex, it follows that is sequentially weakly lower semicontinuous.

Finally, observe that if $f_n \in \bar{R}_\beta$ is such that $f_n \rightharpoonup f$ weakly* in $L^\infty(D)$, then $f_n \rightharpoonup f$ weakly in $L^2(D)$, and so

$$\Phi_s(f) \leq \liminf \Phi_s(f_n).$$

To finish the proof just notice that the existence of a minimizer follows from Banach-Alaoglu’s theorem and the uniqueness of the minimizer from the strict convexity of $\Phi_s$ and the convexity of $\bar{R}_\beta$. □

Now we are ready to prove Theorem 3.1.

**Proof of Theorem 3.1.** The proof will be divided into a series of claims.

**Claim 1.**

$$\int_D \hat{u}\hat{f} \, dx \leq \int_D \hat{u}f \, dx \quad \text{for any } f \in \bar{R}_\beta.$$

Let us take $\Psi : L^2(D) \to \mathbb{R}$ defined as

$$\Psi(f) = \Phi_s(f) + \xi_{\bar{R}_\beta}(f),$$

where $\xi_{\bar{R}_\beta}(f) = \inf_{g \in \bar{R}_\beta} \Phi_s(g)$. By the definition of $\xi_{\bar{R}_\beta}(f)$, we have $\Phi_s(f) = \Phi_s(\hat{f}) + \xi_{\bar{R}_\beta}(f)$ and

$$\int_D \hat{u}\hat{f} \, dx \leq \int_D \hat{u}f \, dx.$$ 

Therefore, $\hat{u} \leq f$ weakly in $L^2(D)$, and so

$$\Phi_s(f) \leq \liminf \Phi_s(f_n).$$

Finally, observe that if $f_n \in \bar{R}_\beta$ is such that $f_n \rightharpoonup f$ weakly* in $L^\infty(D)$, then $f_n \rightharpoonup f$ weakly in $L^2(D)$, and so

$$\Phi_s(f) \leq \liminf \Phi_s(f_n).$$

To finish the proof just notice that the existence of a minimizer follows from Banach-Alaoglu’s theorem and the uniqueness of the minimizer from the strict convexity of $\Phi_s$ and the convexity of $\bar{R}_\beta$. □
where $\xi_{\mathcal{R}_\beta}(f)$ is the indicator function, i.e.

$$
\xi_{\mathcal{R}_\beta}(f) = \begin{cases} 
0, & \text{if } f \in \mathcal{R}_\beta, \\
\infty, & \text{if } f \notin \mathcal{R}_\beta.
\end{cases}
$$

Observe that $\Psi$ is strictly convex there. Moreover, it is easy to see that $\hat{f}$ minimizes $\Psi$ in $L^2(D)$. Thus

$$
0 \in \partial \Psi(\hat{f}),
$$

where

$$
\partial \Psi(\hat{f}) = \left\{ g \in L^2(D): \Psi(f) - \Psi(\hat{f}) \geq \int_D g(f - \hat{f}) \, dx, \text{ for any } f \in L^2(D) \right\}
$$

is the sub-differential of $\Psi$ at $\hat{f}$.

From (2.1) and (2.1) we get that

$$
\partial \Phi_s(\hat{f}) = \{2\hat{u}\}.
$$

Moreover

$$
\partial \xi_{\mathcal{R}_\beta}(\hat{f}) = \left\{ g \in L^2(D): \xi_{\mathcal{R}_\beta}(f) - \xi_{\mathcal{R}_\beta}(\hat{f}) \geq \int_D g(f - \hat{f}) \, dx, \text{ for any } f \in L^2(D) \right\}
$$

$$
= \left\{ g \in L^2(D): 0 \geq \int_D g(f - \hat{f}) \, dx, \text{ for any } f \in \mathcal{R}_\beta \right\}.
$$

Therefore the equation

$$
0 \in \partial \Psi(\hat{f}) = \partial \Phi_s(\hat{f}) + \partial \xi_{\mathcal{R}_\beta}(\hat{f}),
$$

implies that

$$
-\hat{u} \in \partial \xi_{\mathcal{R}_\beta}(\hat{f})
$$

and thus the claim.

**Claim 2.** There exists a function $\tilde{f} = \chi_E \in \mathcal{R}_\beta$ such that

$$
\int_D \tilde{u} \tilde{f} \, dx \leq \int_D \hat{u} \tilde{f} \, dx
$$

for any $f \in \mathcal{R}_\beta$.

This follows from Claim 1, Lemma 3.3 and the fact that the minimum of the linear functional $L(f) = \int_D \tilde{u} f \, dx$ on a bounded closed convex set $\mathcal{R}_\beta$ is attained in an extreme point $\hat{f} = \chi_E \in \mathcal{R}_\beta$.

**Claim 3.** There exists $\alpha > 0$ such that

$$
\{\hat{u} < \alpha\} \subset E \subset \{\hat{u} \leq \alpha\}.
$$

The proof is an immediate consequence of the bathtub principle for $\hat{f}$. See [16, Theorem 1.14].

**Claim 4.**

$$
\hat{f} = 1 \text{ in } \{\hat{u} < \alpha\}.
$$

The proof is again an immediate consequence of the bathtub principle for $\hat{f}$.

**Claim 5.**

$$
\{\hat{u} > \alpha\} \subset \{\hat{f} = 0\}.
$$
Since $\hat{f}, \tilde{f} \in \mathcal{R}_\beta$, we have that

$$
\beta = \int_D \hat{f} \, dx = \int_{\{\hat{u} < \alpha\}} \hat{f} \, dx + \int_{\{\hat{u} = \alpha\}} \hat{f} \, dx + \int_{\{\hat{u} > \alpha\}} \hat{f} \, dx \\
= \int_D \tilde{f} \, dx = \int_{\{\tilde{u} < \alpha\}} \tilde{f} \, dx + \int_{\{\tilde{u} = \alpha\}} \tilde{f} \, dx + \int_{\{\tilde{u} > \alpha\}} \tilde{f} \, dx
$$

Therefore, by Claims 3 and 4, we obtain that

$$
(3.2) \quad \int_{\{\hat{u} < \alpha\}} \hat{f} \, dx + \int_{\{\hat{u} = \alpha\}} \hat{f} \, dx = \int_{\{\tilde{u} = \alpha\}} \tilde{f} \, dx.
$$

On the other hand, by Claims 1 and 2, we get

$$
\int_D \hat{u} \hat{f} \, dx = \int_D \tilde{u} \tilde{f} \, dx
$$

that together with (3) give us

$$
\alpha \int_{\{\tilde{u} = \alpha\}} \hat{f} \, dx = \alpha \int_{\{\tilde{u} = \alpha\}} \hat{f} \, dx + \alpha \int_{\{\tilde{u} > \alpha\}} \hat{f} \, dx \\
\leq \int_{\{\tilde{u} = \alpha\}} \hat{u} \hat{f} \, dx + \int_{\{\tilde{u} > \alpha\}} \hat{u} \hat{f} \, dx \\
= \int_{\{\tilde{u} = \alpha\}} \hat{u} \hat{f} \, dx \\
= \alpha \int_{\{\tilde{u} = \alpha\}} \hat{f} \, dx,
$$

which implies

$$
\alpha \int_{\{\tilde{u} > \alpha\}} \hat{f} \, dx = \int_{\{\tilde{u} > \alpha\}} \hat{u} \hat{f} \, dx,
$$

and thus the claim.

**Claim 6.**

$$\{\tilde{u} > \alpha\} = \emptyset.$$
For $\beta > \alpha$ let us take $\phi(x) = (\hat{u}(x) - \beta)^+$. Since $\text{supp} \phi = \omega \subset \{\hat{u} > \alpha\}$, claim 5 implies that

$$0 = 2(\Delta)^s \hat{u}, \phi = \iint_{\mathbb{R}^n} \frac{(\hat{u}(x) - \hat{u}(y))(\phi(x) - \phi(y))}{|x-y|^{n+2s}} \, dx dy$$

$$= \iint_{\mathbb{R}^n} \frac{(\hat{u}(x) - \hat{u}(y))^2}{|x-y|^{n+2s}} \, dx dy$$

$$+ \iint_{\mathbb{R}^n} \frac{(\hat{u}(x) - \hat{u}(y))((\hat{u}(x) - \beta))}{|x-y|^{n+2s}} \, dx$$

$$+ \iint_{\mathbb{R}^n} \frac{(\hat{u}(x) - \hat{u}(y))((\beta - \hat{u}(y)))}{|x-y|^{n+2s}} \, dx$$

Thus, $|\omega| = |\{\hat{u} > \beta\}| = 0$ for any $\beta > \alpha$. Moreover, since $\hat{u} \in C^{1,\delta}_{\text{loc}}(D)$ for some $\delta > 0$, it is easy to see that the claim follows.

**Claim 7.**

$$|\{\hat{f} = 0\}| = 0.$$  

Since $(-\Delta)^s \hat{u} = \hat{f} \in L^\infty(D)$ and $\hat{f} \geq 0$ it is enough to check $\hat{f} > 0$ point-wise.

By standard regularity theory, $\hat{u} \in C^{1,\delta}_{\text{loc}}(D)$ for some $\delta > 0$, and so is a strong solution of $(-\Delta)^s \hat{u} = \hat{f}$ in $D$. Taken Claim 4 we need to check this only in the set $\{\hat{u} = \alpha\}$. But

$$\hat{f}(x) = \text{p.v.} \int_{\mathbb{R}^n} \frac{\hat{u}(x) - \hat{u}(y)}{|x-y|^{n+2s}} \, dy > \int_{\mathbb{R}^n \setminus D} \frac{\alpha}{|x-y|^{n+2s}} \, dy > 0.$$  

This proves the claim.

The proof of the Theorem is complete. \qed

### 4. The Normalized Fractional Obstacle Problem

This section is devoted to the study of the connection between the solutions to the optimal fractional rearrangement problem considered in Section 3 with solutions of the normalized fractional obstacle problem.

The fractional analogue of the classical obstacle problem has been well known in the literature, however its so called normalized version, i.e., the equation

$$\Delta u = \chi_{\{u > 0\}}$$

has not been considered. Here we find the corresponding fractional analog of (4) and prove that the solution of the fractional rearrangement problem is a solution of the fractional normalized obstacle problem.
Our first result is the following.

**Theorem 4.1.** Let \( \hat{f} \in \bar{R}_\beta \) be the solution to the optimal fractional rearrangement problem and \( \hat{u} := u\hat{f} \in H^\alpha_0(D) \) be given by (2.1). Let \( \alpha > 0 \) be the constant given in Theorem 3.1. Then the function \( \hat{U} := \alpha - \hat{u} \) minimizes the functional

\[
J(v) = |v|_s^2 + \int_D v^+ \, dx
\]

over the set

\[
H_{\alpha} = \{ v \in H^s_{\text{loc}}(\mathbb{R}^n) : v - \alpha \in H^\alpha_0(D) \}.
\]

Moreover, \( \hat{U} \) verifies the inequalities

\[
\chi_{\{U > 0\}} \leq -(-\Delta)^s U \leq \chi_{\{U \geq 0\}} \quad \text{in } D
\]

in the sense of distributions.

Finally, the minimizer of \( J \) in \( H_{\alpha} \) is unique and is the unique solution to the inequality (4.1).

**Proof.** Let

\[
I(v) = |v|_s^2 + \int_D \hat{f} \, dx
\]

and observe that, since \( 0 \leq \hat{f} \leq 1 \), for any \( v \in H_{\alpha} \) it follows that \( J(v) \geq I(v) \).

Next, observe that \( I(\hat{U}) = J(\hat{U}) \) and so the set of inequalities

\[
J(v) \geq I(v) \geq I(\hat{U}) = J(\hat{U}), \quad \text{for any } v \in H_{\alpha}
\]

imply the desired result.

Next, observe that the inequalities

\[
\chi_{\{U > 0\}} \leq -(-\Delta)^s \hat{U} \leq \chi_{\{U \geq 0\}};
\]

are the Euler-Lagrange equation for the functional \( J \) based on the variation \( u_\epsilon(x) = u(x) + \epsilon \phi(x) \), with \( \phi \in C^\infty_c(D) \).

Now, the uniqueness of minimizer for \( J \) is an immediate consequence of the strict convexity of \( J \).

Assume that the function \( U \) satisfies the inequalities (4.1), but the unique minimizer of the convex functional \( J \) is the function \( V \neq U \).

Since \( J \) is strictly convex and \( J(V) < J(U) \) by taking \( U_\epsilon = U + \epsilon(V - U) \) we will obtain

\[
\lim_{\epsilon \to 0^+} \frac{J(U_\epsilon) - J(U)}{\epsilon} < 0.
\]
Thus for $\psi = V - U$

$$0 > \lim_{\varepsilon \to 0^+} \frac{J(U_{\varepsilon}) - J(U)}{\varepsilon} = \iint_{\mathbb{R}^2} \frac{(u(x) - u(y))(\psi(x) - \psi(y))}{|x - y|^{n+2s}} dxdy + \int_D \chi\{U > 0\} \psi + \chi\{U = 0\} \psi^+ dx$$

$$= \iint_{\mathbb{R}^2} \frac{(u(x) - u(y))(\psi^+(x) - \psi^+(y))}{|x - y|^{n+2s}} dxdy + \int_D \chi\{U > 0\} \psi^+ dx$$

$$- \left( \iint_{\mathbb{R}^2} \frac{(u(x) - u(y))(\psi^-(x) - \psi^-(y))}{|x - y|^{n+2s}} dxdy + \int_D \chi\{U > 0\} \psi^- dx \right) \geq 0,$$

where the last inequality follows from (4.1). This is a contradiction and the result follows.

**Remark 4.2.** This result again shows an interesting difference between the classical obstacle problem and the fractional normalized version. Observe that in the positivity set, we still have $-(\Delta)^s U = 1$, but in the zero set the function $\hat{U}$ is not $s$-harmonic (even if it is identically zero!). The free boundary condition on $\partial\{\hat{U} > 0\}$ is given by the fact that $-(\Delta)^s \hat{U}$ is a function bounded by 0 and 1 across the free boundary.

The results in Theorem 4.1 are not completely satisfactory, since we don’t obtain an equation satisfied by $\hat{U}$ but the inequalities (4.1). Our last result shows that in fact $\hat{U}$ is the solution to a fully nonlinear equation.

**Theorem 4.3.** Let $\hat{U}$ be solution of the normalized fractional obstacle problem given by Theorem 4.1. Then $\hat{U}$ is a solution to

$$(4.3) \begin{cases}
-(\Delta)^s U - \chi\{U \leq 0\} \min\{-(\Delta)^s U^+; 1\} = \chi\{U > 0\}, & \text{in } D, \\
U = \alpha & \text{in } D^c.
\end{cases}$$

Moreover, problem (4.3) is equivalent to (4.1). Finally, $U$ verifies (4.1) if and only if it is a minimizer of $J$ in $H_\alpha$, where $J$ and $H_\alpha$ are given in Theorem 4.1.

Before we start with the proof, let us observe that for $u \in H^s(\mathbb{R}^n)$,

$$|u^\pm|_s \leq |u|_s$$

and hence $-(\Delta)^s u^\pm \in H^{-s}(\mathbb{R}^n)$. On the other hand $-(\Delta)^s u^\pm$ is a distribution and the expression

$$\min\{-(\Delta)^s u^+; 1\} = -\max\{-(\Delta)^s u^+, -1\} = 1 - (-(\Delta)^s u^+ + 1)^+$$

makes in general no sense, unless $-(\Delta)^s u^+$ is a signed measure in $D$. Let us further observe that since

$$\chi\{u \leq 0\}(-(\Delta)^s u^+) \leq 0,$$

we need to search for solutions of (4.3) only among functions $u$, such that $-(\Delta)^s u \leq 0$ in $D$. This leads us to the introduction of fractional subharmonic functions in $D$. 

which form a convex subset of $H^s(D)$

$$H^s_{sub}(D) = \{ u \in H^s_{loc}(\mathbb{R}^n) : (-\Delta)^s u \leq 0 \text{ in } D \}.$$ 

Here the inequality $(-\Delta)^s u \leq 0$ should be understood in the sense of distributions.

The following lemma is essential for the equation (4.3) to make sense.

**Lemma 4.4.** Let $u \in H^s_{sub}(D)$. Then $u^+ \in H^s_{sub}(D)$.

**Proof.** If $u$ is smooth, then the fractional laplacian has pointwise values. In this case, we simply compute:

- For $x \in \{ u \leq 0 \}$,

$$(-\Delta)^s u^+(x) = \text{p.v.} \int_{\mathbb{R}^n} \frac{-u^+(y)}{|x - y|^{n+2s}} \, dy \leq 0.$$

- For $x \in \{ u > 0 \}$,

$$(-\Delta)^s u^+(x) = \text{p.v.} \int_{\mathbb{R}^n} \frac{u(x) - u^+(y)}{|x - y|^{n+2s}} \, dy = \text{p.v.} \int_{\mathbb{R}^n} \frac{u^-(y)}{|x - y|^{n+2s}} \, dy - \text{p.v.} \int_{\mathbb{R}^n} \frac{-u(y)}{|x - y|^{n+2s}} \, dy \leq 0.$$

For a general $u \in H^s(\mathbb{R}^n)$, we take $\{ \rho_\varepsilon \}_{\varepsilon > 0}$ a smooth family of approximations of the identity such that $\rho_\varepsilon(z) = \rho_\varepsilon(-z)$ and define $u_\varepsilon = u * \rho_\varepsilon$.

The result of the lemma will follow from the identity

$$((-\Delta)^s u_\varepsilon, \phi) = ((-\Delta)^s u, \phi_\varepsilon),$$

for every $\phi \in C^\infty_c(\mathbb{R}^n)$.

Indeed, assuming (4.4), if $(-\Delta)^s u \leq 0$, then $(-\Delta)^s u_\varepsilon \leq 0$ for every $\varepsilon > 0$. Hence, from the smooth case we conclude that $(-\Delta)^s u^+_\varepsilon \leq 0$ and since $u^+_\varepsilon \to u^+$ in $H^s$ the result is proved.

It remains to prove (4.4). For that purpose, it is useful to introduce the notation

$$D^s u(x, y) = \frac{u(x) - u(y)}{|x - y|^{\frac{n}{2} + s}}.$$
the Hölder quotient of order \(s\) of \(u\). Then, using that \(\rho(z, -z) = \rho(z, z)\), we observe that

\[
\langle (-\Delta)^s u, \phi \rangle = \int_{\mathbb{R}^n} D^s u(x, y) D^s \phi(x, y) \, dx dy
\]

\[
= \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} D^s u(x - z, y - z) \rho(z) D^s \phi(x, y) \, dz \, dx dy
\]

\[
= \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} D^s u(x, y) \rho(z) D^s \phi(x + z, y + z) \, dz \, dx dy
\]

\[
= \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} D^s u(x, y) \rho(z) D^s \phi(x - z, y - z) \, dz \, dx dy
\]

\[
= \int_{\mathbb{R}^n} D^s u(x, y) D^s \phi(x, y) \, dx dy
\]

\[
= \langle (-\Delta)^s u, \phi \rangle.
\]

The proof is now complete.

\[\square\]

**Corollary 4.5.** If \(u \in H^s_{\text{sub}}(D)\) then \(\min\{-(-\Delta)^s u^+; 1\} \in L^\infty(D)\).

Corollary 4.5 allows us to formulate the following normalized fractional obstacle problem:

For \(\alpha > 0\) solve

\[
\text{For convenience let us break down the proof into several claims.}
\]

**Claim 1.** Assume that \(U \in H^s_{\text{loc}}(\mathbb{R}^n)\) is a solution of (4). Then \(U \geq 0\).

Observe first the following general fact:

\[
(U(x) - U(y))(\phi(x) - \phi(y)) = (U^+(x) - U^+(y))(U^-(x) - U^-(y)) - (U^-(x) - U^-(y))^2.
\]

This simple identity implies that

\[
\langle (-\Delta)^s U, U^- \rangle = \langle (-\Delta)^s U^+, U^- \rangle - |U^-|^2.
\]
Now, let us take $\phi = U^-$ as a test function in the weak formulation of (4). Then we obtain
\begin{align}
\langle (-\Delta)^s U, U^- \rangle &= -\int_D \chi_{\{U \leq 0\}} \min(-(-\Delta)^s U^+; 1) + \chi_{\{U > 0\}} U^- \, dx \\
&= -\int_D \min\{-(-\Delta)^s U^+; 1\} U^- \, dx \\
&= \int_D \max\{-(-\Delta)^2 U^-; -1\} U^- \, dx
\end{align}
(4.7)

But
\begin{align}
\int_D \max\{-(-\Delta)^s U^+; -1\} U^- \, dx &\geq \langle (-\Delta)^s U^+, U^- \rangle.
\end{align}
(4.8)

Therefore, combining (4.1), (4.1) and (4.1), we arrive at
\begin{align}
|U^-|^2_s &\leq 0,
\end{align}
and so the claim is proved.

Claim 2. (4.1) implies (4.1).
It is immediate from Claim 1.

Claim 3. (4.1) implies $U \geq 0$.
The argument is similar to the one of Claim 6 in Theorem 3.1. Let $U \in H^s_{loc}(\mathbb{R}^n)$ be a solution to (4.1). Take $\beta < 0$ and $\phi = (U - \beta^-)$, so $\omega = \text{supp } \phi \subset \{U < 0\}$.

\begin{align}
0 &= 2\langle (-\Delta)^s U, \phi \rangle = \iint_{\mathbb{R}^n} \frac{(U(x) - U(y))(\phi(x) - \phi(y))}{|x - y|^{n+2s}} \, dx \, dy \\
&= \int_{\omega} \int_{\omega} \frac{U(x) - U(y)(U(y) - U(x))}{|x - y|^{n+2s}} \, dx \, dy + \int_{\omega} \int_{\mathbb{R}^n \setminus \omega} \frac{(U(x) - U(y))(\beta - U(x))}{|x - y|^{n+2s}} \, dx \, dy \\
&\quad + \int_{\mathbb{R}^n \setminus \omega} \int_{\omega} \frac{(U(x) - U(y))(U(y) - \beta)}{|x - y|^{n+2s}} \, dx \, dy + \int_{\mathbb{R}^n \setminus \omega} \int_{\mathbb{R}^n \setminus \omega} \frac{(U(x) - U(y))(0 - 0)}{|x - y|^{n+2s}} \, dx \, dy \\
&\leq 0.
\end{align}
Thus, $|\omega| = |\{U < \beta\}| = 0$ for any $\beta < 0$.

Claim 4. (4.1) implies (4).
Can be verified directly.
