VAUGHT’S CONJECTURE FOR ALMOST CHAINABLE THEORIES

Miloš S. Kurilić

Abstract

A structure \( Y \) of a relational language \( L \) is called almost chainable iff there are a finite set \( F \subset Y \) and a linear order \( < \) on the set \( Y \setminus F \) such that for each partial automorphism \( \varphi \) (i.e., local automorphism, in Fraïssé’s terminology) of the linear order \( \langle Y \setminus F, < \rangle \) the mapping \( \text{id}_F \cup \varphi \) is a partial automorphism of \( Y \). By a theorem of Fraïssé, if \( |L| < \omega \), then \( Y \) is almost chainable iff the profile of \( Y \) is bounded; namely, iff there is a positive integer \( m \) such that \( Y \) has \( \leq m \) non-isomorphic substructures of size \( n \), for each positive integer \( n \). A complete first order \( L \)-theory \( T \) having infinite models is called almost chainable iff all models of \( T \) are almost chainable and it is shown that the last condition is equivalent to the existence of one countable almost chainable model of \( T \). In addition, it is proved that an almost chainable theory has either one or continuum many non-isomorphic countable models and, thus, the Vaught conjecture is confirmed for almost chainable theories.

Key words and phrases: Vaught’s conjecture, almost chainable structure, almost chainable theory

1 Introduction

In this article we confirm Vaught’s conjecture for almost chainable theories, extending the result of [7], which concerns the smaller class of monomorphic theories. We recall that the Vaught conjecture is related to the number \( I(T, \omega) \) of non-isomorphic countable models of a countable complete first order theory \( T \). In 1959 Robert Vaught [11] asked if there is a theory \( T \) such that the equality \( I(T, \omega) = \omega_1 \) is provable without the use of the continuum hypothesis; since then, the implication \( I(T, \omega) > \omega \Rightarrow I(T, \omega) = \omega \) is known as Vaught’s conjecture.

The rich history of the investigation related to that (still unresolved) conjecture includes a long list of results confirming the conjecture in particular classes of theories (see, for example, the introduction and references of [8]) and, on the other hand, intriguing results concerning the consequences of the existence of counterexamples and the properties of (potential) counterexamples (see, e.g., [11]).

The results of this paper are built on the fundament consisting of two (groups of) results. The first one is the basic Rubin’s paper [10] from 1974 in which the

Vaught conjecture is confirmed for theories of linear orders with unary predicates; we will use the following result of Rubin (see Theorem 6.12 of [10]).

**Theorem 1.1 (Rubin)** If $\mathcal{T}$ is a complete theory of a linear order with a finite set of unary predicates, then $I(\mathcal{T}, \omega) \in \{1, c\}$.

The second group of results is a part of the fundamental work concerning combinatorial properties of relational structures collected in the book of Roland Fraïssé [2]. We will use Fraïssé’s results related to almost chainable structures, as well as a theorem of Gibson, Pouzet and Woodrow from [4], describing all linear orders which chain an almost chainable structure over a fixed finite set, which is derived from similar results obtained independently by Frasnay [3] and by Hodges, Lachlan and Shelah [5]. These results are presented in Section 2.

In Section 3 we show that a complete theory $\mathcal{T}$ with infinite models has a countable almost chainable model iff all models of $\mathcal{T}$ are almost chainable and, so, establish the notion of an almost chainable theory. In Section 4 we prove that for each complete almost chainable theory $\mathcal{T}$ having infinite models we have $I(\mathcal{T}, \omega) \in \{1, c\}$ and, thus, confirm the Vaught conjecture for such theories.

The results of this paper generalize the results of [7] about theories of monomorphic structures and we note that the arguments used in our proofs are, as in [7], more combinatorial than model-theoretical. Also we remark that some parts of this paper are (more or less) folklore or similar to the corresponding parts of [7], but, for completeness of the paper, they are included in the text.

## 2 Preliminaries. Almost chainable structures

Throughout the paper we assume that $L = \langle R_i : i \in I \rangle$ is a relational language, where $\text{ar}(R_i) = n_i \in \mathbb{N}$, for $i \in I$. If $Y$ is a non-empty set and $\mathcal{T} \subset \text{Sent}_L$ an $L$-theory, then $\text{Mod}_L(\mathcal{T}, Y)$ (resp. $\text{Mod}_L(Y)$; $\text{Mod}_L^T(Y)$) will denote the set of all models of $\mathcal{T}$ with domain $Y$ (resp. the set of all $L$-structures with domain $Y$; the class of all models of $\mathcal{T}$). Let $\mathcal{Y} = \langle Y, \langle R_i^Y : i \in I \rangle \rangle$ be an $L$-structure. For a non-empty set $H \subset Y$, $\mathcal{H} := \langle H, \langle R_i^H \upharpoonright H : i \in I \rangle \rangle$ is the corresponding substructure of $\mathcal{Y}$. If $J \subset I$, then $L_J := \langle R_i^Y : i \in J \rangle$ is the corresponding reduction of $L$ and $\mathcal{Y}|L_J := \langle Y, \langle R_i^Y : i \in J \rangle \rangle$ the corresponding reduct of $\mathcal{Y}$. By $[\mathcal{Y}]$ we will denote the class of all $L$-structures being isomorphic to $\mathcal{Y}$ (the isomorphism type of $\mathcal{Y}$).

If $X = \langle X, < \rangle$ is a linear order, then $X^*$ will denote its reverse, $\langle X, <^{-1} \rangle$. By $\text{LO}_X$ we denote the set of all linear orders on the set $X$.

---

2 A relational structure $\mathcal{Y}$ is monomorphic iff all its $n$-element substructures are isomorphic, for each positive integer $n$, while (for $|L| < \omega$, see [2], p. 297) $\mathcal{Y}$ is almost chainable iff there is a positive integer $m$ such that $\mathcal{Y}$ has $\leq m$ non-isomorphic substructures of size $n$, for each $n \in \mathbb{N}$. 

We recall the notions and concepts introduced by Fraïssé which will be used in this paper and fix a convenient notation. For \( n \in \mathbb{N} \), by \( \text{Age}_n(Y) \) we denote the collection \( \{[H] : H \in [Y]^n\} \) of isomorphism types of \( n \)-element substructures of \( Y \) (or equivalently, \( \text{Age}_n(Y) = \{H \in \text{Mod}_L(n) : H \cong Y\}/\equiv \). The age of \( Y \) is the collection \( \text{Age}(Y) := \bigcup_{n \in \mathbb{N}} \text{Age}_n(Y) \). The function \( \varphi_Y \) with the domain \( \mathbb{N} \) defined by \( \varphi_Y(n) = |\text{Age}_n(Y)| \), for all \( n \in \mathbb{N} \), is the profile of \( Y \).

By \( \text{Pa}(Y) \) we denote the set of all partial automorphisms of \( Y \) (isomorphisms between substructures of \( Y \), or, in Fraïssé’s terminology, local automorphisms). The \( L \)-structure \( Y \) is freely interpretable in an \( L' \)-structure \( X \) having the same domain iff \( \text{Pa}(X) \subset \text{Pa}(Y) \). We will say that \( Y \) is simply definable in \( X \) iff each relation \( R_i^Y \) is definable by a quantifier free \( L' \)-formula in the structure \( X \).

**Almost chainable structures** Let \( Y \in \text{Mod}_L(Y) \), \( F \in [Y]<\omega \) and \( \subset \in \text{LO}_{Y \setminus F} \).

Following Fraïssé (see [2], p. 294), the structure \( Y \) is called \((F, <)\)-chainable iff

\[
\forall \varphi \in \text{Pa}((Y \setminus F, <)) \quad \text{id}_F \cup \varphi \in \text{Pa}(Y).
\]

The structure \( Y \) is called \( F \)-chainable if it is \((F, <)\)-chainable for some linear order \( < \) on \( Y \setminus F \). \( Y \) is called \( \alpha \)-almost chainable if it is \( F \)-chainable for some \( F \in [Y]<\omega \).

The following four statements are proved in [2] for \( |L| = 1 \) and have straightforward generalizations for arbitrary relational language \( L \). So, these results of Fraïssé are cited and used in the paper in such, more general, form.

Generally, if \( Y \) is a set, \( F \in [Y]^n \), \( \subset \in \text{LO}_{Y \setminus F} \) and \( F = \{a_0, \ldots, a_{n-1}\} \) is an enumeration of the elements of the set \( F \), we introduce the auxiliary language \( L_n := \langle R, U_0, \ldots, U_{n-1} \rangle \), consisting of new relational symbols, where \( \text{ar}(R) = 2 \) and \( \text{ar}(U_j) = 1 \), for \( j < n \), and define the linear order \( \preceq \) on the set \( Y \) and the \( L_n \)-structure (in fact, the linear order with \( n \) unary predicates) \( X \) by

- (L1) \( \preceq \) \( \upharpoonright (Y \setminus F) = < \),
- (L2) \( \langle Y, \preceq \rangle = \{a_0\} + \ldots + \{a_{n-1}\} + (Y \setminus F) \),
- (L3) \( X := \langle Y, \preceq, \{a_0\}, \ldots, \{a_{n-1}\} \rangle \).

**Fact 2.1** Let \( Y \) be an \( L \)-structure, \( F = \{a_0, \ldots, a_{n-1}\} \in [Y]^n \) and \( < \in \text{LO}_{Y \setminus F} \).

If \( \preceq \) and \( X \) are defined by (L1)–(L3), then the following conditions are equivalent:

(a) \( Y \) is \((F, <)\)-chainable,

(b) \( Y \) is freely interpretable in \( X \), (that is, \( \text{Pa}(X) \subset \text{Pa}(Y) \)),

(c) \( Y \) is simply definable in \( X \).

**Proof.** (a) \( \Rightarrow \) (b). Let (1) hold and \( f \in \text{Pa}(X) \). Then, since \( f \) preserves \( U_j \)'s, for each \( y \in \text{dom} \ f \) and each \( j < n \) we have: \( y = a_j \) iff \( f(y) = a_j \). So, if \( a_j \in \text{dom} \ f \), then \( f(a_j) = a_j \) and, hence, \( f \upharpoonright (F \cap \text{dom} \ f) = \text{id}_{F \cap \text{dom} \ f} \).
addition, if \( y \in (\text{dom } f) \setminus F \), then \( f(y) \not\in F \) and, hence, \( f[(\text{dom } f) \setminus F] \subseteq Y \setminus F \). So, by (L1), \( \varphi := f \upharpoonright ((\text{dom } f) \setminus F) \in \text{Pa}(Y \setminus F, <) \) and by (1) we have \( g := \text{id}_F \cup \varphi \in \text{Pa}(\mathcal{Y}) \). Finally, since \( f = g \upharpoonright \text{dom } f \), it follows that \( f \in \text{Pa}(\mathcal{Y}) \).

(b) \( \Rightarrow \) (c). Let \( \text{Pa}(X) \subseteq \text{Pa}(\mathcal{Y}) \) and \( i \in I \). For \( \bar{y} \in Y^m \), let \( \varepsilon_{\bar{y}}(v_0, \ldots, v_{n_i-1}) \) be the conjunction of all \( L_n \)-literals (i.e. atomic formulas and their negations) in variables \( v_0, \ldots, v_{n_i-1} \) which are satisfied in the \( L_n \)-structure \( X \) by \( \bar{y} \), that is, \( \varepsilon_{\bar{y}}(\bar{v}) := \bigwedge \{ \eta \in \text{Lit}_{L_n}(\bar{v}) : X \models \eta[\bar{y}] \} \). Since \( |L_n| < \omega \) the binary relation \( \sim \) on the set \( Y^m \) defined by \( \bar{x} \sim \bar{y} \) iff \( \varepsilon_{\bar{x}} = \varepsilon_{\bar{y}} \) is an equivalence relation with finitely many equivalence classes, say \( m \). If \( \varepsilon_1(\bar{v}), \ldots, \varepsilon_m(\bar{v}) \) is the list of the corresponding formulas and, for \( k \leq m \), \( D_{\varepsilon_k} := \{ \bar{y} \in Y^m : X \models \varepsilon_k[\bar{y}] \} \), then \( \{ D_{\varepsilon_k} : k \leq m \} \) is a partition of the set \( Y^m \). So, if we show that for each \( k \leq m \) we have

\[
D_{\varepsilon_k} \cap R_i^Y \neq \emptyset \Rightarrow D_{\varepsilon_k} \subseteq R_i^Y,
\]

then \( R_i^Y = \bigcup_{k \in J} D_{\varepsilon_k} \), where \( J := \{ k \leq m : D_{\varepsilon_k} \cap R_i^Y \neq \emptyset \} \), and the relation \( R_i^Y \) is definable in \( X \) by the quantifier-free \( L_n \)-formula \( \varphi_i(\bar{v}) := \bigvee_{k \in J} \varepsilon_k(\bar{v}) \).

So, if \( \bar{x} \in D_{\varepsilon_k} \cap R_i^Y \) and \( \bar{y} \in D_{\varepsilon_k} \), then \( X \models \varepsilon_k[\bar{x}] \) and \( X \models \varepsilon_k[\bar{y}] \) and, hence, \( p := \{ (x_r, y_r) : r < n_i \} \subseteq \text{Pa}(X) \subseteq \text{Pa}(Y) \). Thus, since \( \bar{x} \in R_i^Y \setminus \{ x_r : r < n_i \} \), we have \( \bar{y} = p\bar{x} \in R_i^Y \setminus \{ y_r : r < n_i \} \) and, hence, \( \bar{y} \in R_i^Y \). So, (2) is proved and \( R_i^Y = \{ \bar{y} \in Y^m : X \models \varphi_i[\bar{y}] \} \).

(c) \( \Rightarrow \) (a). For \( i \in I \), let \( \varphi_i(v_0, \ldots, v_{n_i-1}) \in \text{Form}_{L_n} \) be a \( \Sigma_0 \)-formula such that

\[
\forall \bar{y} \in Y^m \quad \left( \bar{y} \in R_i^Y \iff X \models \varphi_i[\bar{y}] \right).
\]

For a proof of (1) we take \( \varphi \in \text{Pa}(Y \setminus F, <) \) and show that \( f := \text{id}_F \cup \varphi \in \text{Pa}(\mathcal{Y}) \). By (L1) we have \( \varphi \in \text{Pa}(Y, <) \); by (L2), \( f \in \text{Pa}(Y, <) \) and, since \( f(a_j) = a_j \) for all \( j < n \), we obtain \( f \in \text{Pa}(X) \). So, for \( K := \text{dom } f \) and \( H := \text{ran } f \), denoting by \( K \) and \( H \) the corresponding substructures of \( X \), we have \( f \in \text{Iso}(K, H) \). Now, for \( i \in I \) and \( \bar{y} \in K^m \) we have \( \bar{y} \in R_i^Y \) iff (by (3)) \( X \models \varphi_i[\bar{y}] \) iff (since \( \varphi_i \) is a \( \Sigma_0 \)-formula) \( K \models \varphi_i[\bar{y}] \) iff (since \( f \in \text{Iso}(K, H) \)) \( H \models \varphi_i[f\bar{y}] \) iff (since \( \varphi_i \) is a \( \Sigma_0 \)-formula) \( X \models \varphi_i[f\bar{y}] \) iff (by (3)) \( f\bar{y} \in R_i^Y \). So \( f \in \text{Pa}(Y, \rho_i) \), for all \( i \in I \); thus \( f \in \text{Pa}(\mathcal{Y}) \) and (1) is true.

\[\square\]

**Fact 2.2** If \( \mathcal{Y} \) is an infinite almost chainable \( L \)-structure, then there is a minimal finite set \( F \subseteq Y \) such that \( \mathcal{Y} \) is \( F \)-chainable (the kernel of \( \mathcal{Y} \), in notation \( \text{Ker}(\mathcal{Y}) \)).

**Proof.** For \( |L| = 1 \), this is 10.9.3 of [2], p. 296. But the proof of 10.9.3 as well as the proofs of propositions (1), (2) and (3) of 10.9.2, which are used in the proof of 10.9.3 have straightforward generalizations for arbitrary relational language \( L \). We note that the Coherence lemma (2.4.1 of [2], p. 50) used in the proof of 10.9.2(2) works if, in particular, the language is finite and \( L = |X|^<\omega \) for some set \( X \). \[\square\]
Fact 2.3 If $\mathbb{Y}$ is an infinite almost chainable $L$-structure and $F \in [Y]^m$ is the kernel of $\mathbb{Y}$, then $\varphi_{\mathbb{Y}}(m) \leq 2^n$, for each positive integer $m$.

Proof. Let $\mathbb{Y}$ be $(F, \prec)$-chainable, where $\varphi \in LO_{Y \setminus F}$. For $m \in \mathbb{N}$ we prove

$$\forall K, H \in [Y]^m \ (K \cap F = H \cap F \Rightarrow K \cong H), \tag{4}$$

where $K$ and $H$ are the substructures of $\mathbb{Y}$ corresponding to $K$ and $H$ respectively. If $K, H \in [Y]^m$ and $K \cap F = H \cap F$, then, since $|K \setminus F| = |H \setminus F|$, there is $\varphi \in \text{Pa}(Y \setminus F, \prec)$ such that $\varphi[K \setminus F] = H \setminus F$ and by (1), $f := \text{id}_F \cup \varphi \in \text{Pa}(\mathbb{Y})$. Clearly we have $f[K] = H$, which implies $K \cong H$ and (4) is true. Now, by (4) we have $|(K : K \in [Y]^m)/\cong | \leq |P(F)| = 2^n$. $\square$

Fact 2.4 Let $\mathbb{Y}$ and $\mathbb{Z}$ be $L$-structures. If $\mathbb{Y}$ is almost chainable and $\text{Age}(\mathbb{Z}) \subset \text{Age}(\mathbb{Y})$, then $\mathbb{Z}$ is almost chainable and $|\text{Ker}(\mathbb{Z})| \leq |\text{Ker}(\mathbb{Y})|$.}

Proof. For $|L| = 1$, this is Lemma 10.9.6 of [2], p. 297, which has a straightforward generalization for arbitrary relational language $L$. We note that 10.1.4 of [2], p. 275, which is used in the proof 10.9.6 holds for (in the notation of [2]) $R$ and $R'$ of arbitrary signature and for $S'$ of finite signature. $\square$

If $\mathbb{Y} \in \text{Mod}_L(Y)$ is an infinite $(F, \prec)$-chainable structure, then the set

$$\mathcal{L}^F_Y := \left\{ \langle Y \setminus F, \prec \rangle : \varphi \in LO_{Y \setminus F} \text{ and } \mathbb{Y} \text{ is } (F, \prec)\text{-chainable} \right\} \tag{5}$$

is a non-empty set of linear orders and it is easy to see that $\langle Y \setminus F, \prec \rangle \in \mathcal{L}^F_Y$ iff $\langle Y \setminus F, \prec \rangle^* \in \mathcal{L}^F_Y$. Theorem 9 of [4] gives the following description of the set $\mathcal{L}^F_Y$.

Theorem 2.5 (Gibson, Pouzet and Woodrow) If $\mathbb{Y} \in \text{Mod}_L(Y)$ is an infinite $(F, \prec)$-chainable $L$-structure and $L := \langle Y \setminus F, \prec \rangle$, then one of the following holds

1. $\mathcal{L}^F_Y = LO_{Y \setminus F}$, that is, each linear order $\prec$ on $Y \setminus F$ chains $\mathbb{Y}$ over $F$,
2. $\mathcal{L}^F_Y = \bigcup_{L = F \cup I^* \cup F^*} \{F \cup I^* \cup F^*\}$,
3. There are finite subsets $K$ and $H$ of $Y \setminus F$ such that $L = K + M + H$ and

$$\mathcal{L}^F_Y = \bigcup_{K \in \text{LO}_K} \{\langle K, \prec \rangle + M + \langle H, \prec H \rangle, \langle H, \prec H \rangle^* + M^* + \langle K, \prec K \rangle^*\}.$$

3 Almost chainable theories

A complete theory $T \subset \text{Sent}_{L}$ will be called almost chainable iff each model $\mathbb{Y}$ of $T$ is almost chainable and this notion is established by the following theorem.
Theorem 3.1 If $T$ is a complete $L$-theory with infinite models, then the following conditions are equivalent:

(a) All models of $T$ are almost chainable,

(b) $T$ has an almost chainable model,

(c) $T$ has a countable almost chainable model.

If (a) is true, then there is $n \in \omega$ such that $|\text{Ker}(Y)| = n$, for each model $Y$ of $T$.

A proof of the theorem is given at the end of the section.

Claim 3.2 Let $K$ be a finite family of non-isomorphic $L$-structures of size $n \in \mathbb{N}$. Then we have

(a) For each finite set $J \subset I$ there is an $L_J$-sentence $\psi_{K,J}$ such that for each $Y \in \text{Mod}_L$ we have: $Y \models \psi_{K,J}$ iff $\{H \in [Y]^n : \exists H \in \mathbb{K} \models L_J : H \models \psi_{K,J} \}$.

(b) For the first-order theory $T_K := \{ \psi_{K,J} : J \in [I]^\omega \}$ and each $Y \in \text{Mod}_L$ we have: $Y \models T_K$ iff $\text{Age}_n(Y) = \{ \mathbb{K} : \mathbb{K} \in K \}$.

Proof. First, without loss of generality we can assume that the domain of each structure $\mathbb{K} \in K$ is the same set, say $K$. Let $K = \{x_0, \ldots, x_{n-1}\}$ be an enumeration of its elements and $\bar{x} := (x_0, \ldots, x_{n-1})$.

(a) For a structure $\mathbb{K} \in K$, let $\alpha_{\mathbb{K},J}(\bar{v}) := \bigwedge \{ \eta \in \text{Lit}_{L_J}(\bar{v}) : \mathbb{K} \models \eta[\bar{x}] \}$, where $\text{Lit}_{L_J}(\bar{v})$ is the set of all literals of $L_J$ with variables in the set $\{v_0, \ldots, v_{n-1}\}$. Then for $Y \in \text{Mod}_L$, $\bar{y} \in Y^n$ and $H := \{y_0, \ldots, y_{n-1}\}$, we have $Y \models \alpha_{\mathbb{K},J}[\bar{y}]$ iff $\{ (x_k, y_k) : k < n \}$ is an isomorphism from $\mathbb{K}|L_J$ onto $H|L_J$. If $\pi \in \text{Sym}(n)$ and $\alpha_{\mathbb{K},J}^\pi(\bar{v})$ is the formula obtained from $\alpha_{\mathbb{K},J}(\bar{v})$ by replacement of $v_k$ by $v_{\pi(k)}$, for all $k < n$, then $Y \models \alpha_{\mathbb{K},J}^\pi[\bar{y}]$ iff $Y \models \alpha_{\mathbb{K},J}[y_{\pi(0)}, \ldots, y_{\pi(n-1)}]$ iff $p_\pi := \{ (x_k, y_{\pi(k)}) : k < n \}$ is an isomorphism from $\mathbb{K}|L_J$ onto $H|L_J$. So, for the formula $\varphi_{\mathbb{K},J}(\bar{v}) := \bigvee_{\pi \in \text{Sym}(n)} \alpha_{\mathbb{K},J}^\pi(\bar{v})$ we have $Y \models \varphi_{\mathbb{K},J}[\bar{y}]$ iff $H|L_J \cong \mathbb{K}|L_J$, and the equivalence in (a) is true for the formula

$$\psi_{\mathbb{K},J} := \bigwedge_{\mathbb{K} \in K} \exists \bar{v} \varphi_{\mathbb{K},J}(\bar{v}) \land \forall \bar{v} \left( (\bigwedge_{k<l<n} v_k \neq v_l) \Rightarrow \bigvee_{\mathbb{K} \in K} \varphi_{\mathbb{K},J}(\bar{v}) \right).$$

(b) Let $Y \models T_K$. Suppose that $H = \{y_0, \ldots, y_{n-1}\} \in [Y]^n$ and that $H \not\cong \mathbb{K}$, for all $\mathbb{K} \in K$. Then for each $\mathbb{K} \in K$ and each $\pi \in \text{Sym}(n)$ we have $p_{\mathbb{K},\pi} := \{ (x_k, y_{\pi(k)}) : k < n \} \not\in \text{Iso}(\mathbb{K}, H)$ and, since $p_{\mathbb{K},\pi} : K \to H$ is a bijection, there is $\iota_{\mathbb{K},\pi} \in I$ such that $p_{\mathbb{K},\pi} \not\in \text{Iso}(\langle K, R_{i_{\mathbb{K},\pi}}^{K_0} \rangle, \langle H, R_{i_{\mathbb{K},\pi}}^{H_0} \rangle)$.

Since $J := \{ i_{\mathbb{K},\pi} : \mathbb{K} \in K \land \pi \in \text{Sym}(n) \} \in [I]^\omega$ and $Y \models \psi_{\mathbb{K},J}$, by (a) there are $\mathbb{K}_0 \in K$ and $\pi_0 \in \text{Sym}(n)$ such that $p_{\mathbb{K}_0,\pi_0} \in \text{Iso}(\mathbb{K}_0|L_J, H|L_J)$, which implies that $p_{\mathbb{K}_0,\pi_0} \in \text{Iso}(\langle K_0, R_{i_{\mathbb{K}_0,\pi_0}}^{K_0} \rangle, \langle H, R_{i_{\mathbb{K}_0,\pi_0}}^{H_0} \rangle)$ and we have a contradiction. So we have proved

$$\forall H \in [Y]^n \exists \mathbb{K} \in K \ H \cong \mathbb{K},$$

(7)
that is, $\text{Age}_n(\mathcal{Y}) \subset \{ [\mathbb{K}] : \mathbb{K} \in \mathcal{K} \}$. Concerning the inclusion "⊃", suppose that for some $\mathbb{K}_0 \in \mathcal{K}$

$$\forall H \in [Y]^n \quad \mathbb{H} \not\models \mathbb{K}_0$$

and let $\mathcal{K} = \{ \mathbb{K}_0, \ldots, \mathbb{K}_{s-1} \}$ be an enumeration. Then, for each $0 < r < s$ and $\pi \in \text{Sym}(n)$, since $\mathbb{K}_0 \not\models \mathbb{K}_r$, we have $p_\pi := \{ (x_k, x_{\pi(k)}) : k < n \} \not\models \text{Iso}(\mathbb{K}_0, \mathbb{K}_r)$ and, hence, there is $i_{r, \pi} \in I$ such that

$$p_\pi \not\models \text{Iso}(\langle K, R_{K, i_{r, \pi}} \rangle, \langle K, R_{K, i_{r, \pi}} \rangle).$$

Now $J := \{ i_{r, \pi} : 0 < r < s \land \pi \in \text{Sym}(n) \} \in [I]^{< \omega}$ and, since $\mathcal{Y} \models \psi_{K, J}$, there is $H \in [Y]^n$ such that $\mathbb{H}|L_J \cong \mathbb{K}_0|L_J$. By (7) and (8) there is $r > 0$ such that $\mathbb{H} \cong \mathbb{K}_r$, which implies $\mathbb{H}|L_J \cong \mathbb{K}_r|L_J$ and, hence, $\mathbb{K}_0|L_J \cong \mathbb{K}_r|L_J$. Thus, there is $\pi \in \text{Sym}(n)$ such that $p_\pi \in \text{Iso}(\mathbb{K}_0|L_J, \mathbb{K}_r|L_J)$, which in particular gives $p_\pi \in \text{Iso}(\langle K, R_{K, i_{s, \pi}} \rangle, \langle K, R_{K, i_{s, \pi}} \rangle)$, but this contradicts (9). So for each $\mathbb{K} \in \mathcal{K}$ there is $H \in [Y]^n$ such that $\mathbb{H} \cong \mathbb{K}$; that is, $\{ [\mathbb{K}] : \mathbb{K} \in \mathcal{K} \} \subset \text{Age}_n(\mathcal{Y})$.

Conversely, if $\text{Age}_n(\mathcal{Y}) \subset \{ [\mathbb{K}] : \mathbb{K} \in \mathcal{K} \}$ and $J \in [I]^{< \omega}$, then for each $H \in [Y]^n$ there is $\mathbb{K} \in \mathcal{K}$ such that $\mathbb{H} \cong \mathbb{K}$; so $\mathbb{H}|L_J \cong \mathbb{K}|L_J$ and, hence, $\mathbb{H}|L_J \cong \mathbb{K}|L_J$. In addition, for each $\mathbb{K} \in \mathcal{K}$ there is $H \in [Y]^n$ such that $\mathbb{H} \cong \mathbb{K}$ so $\mathbb{H}|L_J \cong \mathbb{K}|L_J$ again and, by (a), $\mathcal{Y} \models \psi_{K, J}$. Thus we have $\mathcal{Y} \models T_{\mathcal{K}}$. □

**Claim 3.3** Let $\mathcal{Y}$ be an infinite $L$-structure and $|\text{Age}_n(\mathcal{Y})| < \omega$, for each $n \in \mathbb{N}$. Then for the theory $T_{\text{Age}_n(\mathcal{Y})} := \bigcup_{n \in \mathbb{N}} T_{\text{Age}_n(\mathcal{Y})}$ and any $L$-structure $\mathcal{Z}$ we have

(a) $T_{\text{Age}_n(\mathcal{Y})} \subset \text{Th}(\mathcal{Y})$;

(b) $\mathcal{Z} \models T_{\text{Age}_n(\mathcal{Y})}$ iff $\text{Age}(\mathcal{Z}) = \text{Age}(\mathcal{Y})$;

(c) If $\mathcal{Z} \models \text{Th}(\mathcal{Y})$, then $\text{Age}(\mathcal{Z}) = \text{Age}(\mathcal{Y})$.

**Proof.** (a) By Claim 3.2(b), for $n \in \mathbb{N}$ we have $\mathcal{Y} \models T_{\text{Age}_n(\mathcal{Y})}$ so $T_{\text{Age}_n(\mathcal{Y})} \subset \text{Th}(\mathcal{Y})$.

(b) $\mathcal{Z} \models T_{\text{Age}_n(\mathcal{Y})}$ iff $\mathcal{Z} \models T_{\text{Age}_n(\mathcal{Y})}$, for all $n \in \mathbb{N}$; iff (by Claim 3.2(b)) $\text{Age}_n(\mathcal{Z}) = \text{Age}_n(\mathcal{Y})$, for all $n \in \mathbb{N}$; iff $\text{Age}(\mathcal{Z}) = \text{Age}(\mathcal{Y})$.

(c) If $\mathcal{Z} \models \text{Th}(\mathcal{Y})$, then by (a) $\mathcal{Z} \models T_{\text{Age}_n(\mathcal{Y})}$ and by (b) $\text{Age}(\mathcal{Z}) = \text{Age}(\mathcal{Y})$. □

**Claim 3.4** If $\mathcal{Y}$ is an infinite almost chainable $L$-structure and $\mathcal{Z} \models \text{Th}(\mathcal{Y})$, then $\text{Age}(\mathcal{Z}) = \text{Age}(\mathcal{Y})$, the structure $\mathcal{Z}$ is almost chainable and $|\text{Ker}(\mathcal{Z})| = |\text{Ker}(\mathcal{Y})|$.

**Proof.** By Fact 2.2 we have $\text{Ker}(\mathcal{Y}) \subset [Y]^n$, for some $n \in \mathbb{N}$, and, by Fact 2.3 $|\text{Age}_n(\mathcal{Y})| \leq 2^n$, for all $m \in \mathbb{N}$. So, by Claim 3.3(c) we have $\text{Age}(\mathcal{Z}) = \text{Age}(\mathcal{Y})$ and, by Fact 2.4 the structure $\mathcal{Z}$ is almost chainable and $|\text{Ker}(\mathcal{Z})| = |\text{Ker}(\mathcal{Y})|$. □

**Claim 3.5** If $T$ is a complete almost chainable $L$-theory with infinite models and $|I| > \omega$, then $T$ has a countable model and there are a countable language $L_J \subset L$ and a complete almost chainable $L_J$-theory $T_J$ such that

$$|\text{Mod}_L(\omega) / \cong | = |\text{Mod}_{T_J}(\omega) / \cong |.$$
Proof. Let $\mathcal{Y} = \langle Y, \langle R_i^\mathcal{Y} : i \in I \rangle \rangle \in \text{Mod}_L^T$. By Fact 2.1 there are a finite set $F = \{a_0, \ldots, a_n-1\} \subseteq Y$, a linear order $\mathcal{O}_Y$ and an $L_n$-structure $\mathcal{X}$ satisfying (L1)–(L3) and for each $i \in I$ there is a quantifier-free formula $\varphi_i(v_0, \ldots, v_{n_i-1})$ such that
\[
\forall \bar{y} \in Y^{n_i} \left( \bar{y} \in R_i^\mathcal{Y} \iff \mathcal{X} \models \varphi_i[\bar{y}] \right). \tag{11}
\]
Since there are countably many $L_n$-formulas, there is a partition $I = \bigcup_{j \in J} I_j$, where $|J| \leq \omega$, such that, picking $i_j \in I_j$, for all $j \in J$, we have $R_i^\mathcal{Y} = R_i^\mathcal{X}$, for all $i \in I_j$. So, for the $L$-sentences $\eta_{i,j} := \forall \bar{v} \left( R_i(\bar{v}) \iff R_i^\mathcal{X}(\bar{v}) \right)$, where $j \in J$ and $i \in I_j$, we have $T_\eta := \bigcup_{j \in J} \{ \eta_{i,j} : i \in I_j \} \subset \text{Th}_L(\mathcal{Y}) = \mathcal{T}$.

Now, $L_J := \langle R_i : j \in J \rangle \subset L$ and, using recursion, to each $L$-formula $\varphi$ we adjoin an $L_J$-formula $\varphi_j$ in the following way: $(v_k = v_l)_J := (v_k = v_l); (R_i(v_{k_1}, \ldots, v_{k_{n_i}-1}))_J := R_i(v_{k_1}, \ldots, v_{k_{n_i}-1})$, for all $i \in I_j; (\neg \varphi)_J := \neg \varphi_j; (\varphi \land \psi)_J := \varphi_j \land \psi_j$ and $(\forall v \varphi)_J := \forall v \varphi_j$. A simple induction proves that
\[
\forall \mathcal{Z} \in \text{Mod}_L^{T_\eta} \forall \varphi(\bar{v}) \in \text{Form}_L \forall \bar{z} \in Z \left( \mathcal{Z} \models \varphi[\bar{z}] \iff \mathcal{Z} |L_J \models \varphi_j[\bar{z}] \right). \tag{12}
\]
We prove that, in addition, for each $Z_1, Z_2 \in \text{Mod}_L^{T_\eta}$ we have
\[
Z_1 \equiv_L Z_2 \iff Z_1 |L_J \equiv_L Z_2 |L_J \quad \text{and} \quad Z_1 \equiv_L Z_2 \iff Z_1 |L_J \equiv_L Z_2 |L_J. \tag{13}
\]
The first claim is true since $\text{Iso}(Z_1, Z_2) = \text{Iso}(Z_1 |L_J, Z_2 |L_J)$. For the second, suppose that $Z_1 \equiv_L Z_2$ and $Z_1 |L_J \models \psi$, where $\psi \in \text{Sent}_{L_J}$. Then $\psi \in \text{Sent}_L$ and $Z_1 \models \psi$, which gives $Z_2 \models \psi$ so, by (12), $Z_2 |L_J \models \psi$, because $\psi \models \varphi$. Conversely, suppose that $Z_1 |L_J \equiv_L Z_2 |L_J$ and $Z_1 \models \varphi$, where $\varphi \in \text{Sent}_L$. Then, by (12), $Z_1 |L_J \models \varphi$ and, hence, $Z_2 |L_J \models \varphi$, so, by (12), $Z_2 \models \varphi$.

Let $T_\eta := \text{Th}_{L_J} (\mathcal{Y} |L_J)$. If $\mathcal{Z} \in \text{Mod}_L^{T_\eta}$, that is, $\mathcal{Z} \equiv_L \mathcal{Y}$, then by (13) we have $\mathcal{Z} |L_J \equiv_L \mathcal{Y} |L_J$, which means that $\mathcal{Z} |L_J \in \text{Mod}_{L_J}^{T_\eta}$. So we obtain the mapping $\Lambda : \text{Mod}_L^{T_\eta} \to \text{Mod}_{L_J}^{T_\eta}$, where $\mathcal{A}(\mathcal{Z}) = \mathcal{Z} |L_J$, for all $\mathcal{Z} \in \text{Mod}_L^{T_\eta}$, which is an injection, because $T_\eta \subset \mathcal{T}$.

If $\mathcal{A} \in \text{Mod}_{L_J}^{T_\eta}$, then $\mathcal{Z} = \langle A, \langle R_i^Z : i \in I \rangle \rangle \in \text{Mod}_L^{T_\eta}$, where $R_i^Z = R_i^\mathcal{A}$, for $j \in J$ and $i \in I_j$. Now $\mathcal{Z} |L_J = \mathcal{A} \equiv_L \mathcal{Y} |L_J$ and, by (13), $\mathcal{Z} \equiv_L \mathcal{Y}$, that is, $\mathcal{Z} \in \text{Mod}_L^{T_\eta}$ and $\mathcal{A}$ is a surjection. Since the mapping $\Lambda$ preserves cardinalities of structures, we have $\Lambda(\text{Mod}_L^{T_\eta}(\omega)) = \text{Mod}_{L_J}^{T_\eta}(\omega)$. By the Löwenheim-Skolem theorem there is $\mathcal{A} \in \text{Mod}_{L_J}^{T_\eta}(\omega)$ and $\Lambda^{-1}(\mathcal{A})$ is a countable model of $\mathcal{T}$.

By (13), the mapping $\Lambda$ preserves the isomorphism relation and (10) is true. By (11) the reduct $\mathcal{Y} |L_J$ is simply definable in $\mathcal{X}$ and, by Fact 2.1, it is almost chainable. By Claim 3.4 the theory $\mathcal{T}_J = \text{Th}_{L_J}(\mathcal{Y} |L_J)$ is almost chainable. □

Proof of Theorem 3.1. The implication (a) $\Rightarrow$ (c) follows from Claim 3.5, the implication (c) $\Rightarrow$ (b) is trivial and (b) $\Rightarrow$ (a) follows from Claim 3.4 □
4 Vaught’s Conjecture

In this section we confirm Vaught’s Conjecture for almost chainable theories. More precisely, the whole section is devoted to a proof of the following statement.

**Theorem 4.1** If \( \mathcal{T} \) is a complete almost chainable theory having infinite models, then \( I(\mathcal{T}, \omega) \in \{1, \epsilon\} \). In addition, the theory \( \mathcal{T} \) is \( \omega \)-categorical iff it has a countable model which is chained by an \( \omega \)-categorical linear order over its kernel.

So, let \( \mathcal{T} \) be a complete almost chainable \( L \)-theory having infinite models. By Theorem 3.1 there is \( n \in \omega \) such that each model of \( \mathcal{T} \) has the kernel of size \( n \) and, by Claim 3.3 w.l.o.g. we suppose that \( |L| \leq \omega \), which gives \( \text{Mod}_L^0(\omega) \neq \emptyset \). As above, let \( L_n \) denote the language \( \langle R, U_0, \ldots, U_{n-1} \rangle \), where \( R \) is a binary and \( U_j \)'s are unary symbols. In the sequel, for \( \mathcal{Y} \in \text{Mod}_L(\omega) \), by \([\mathcal{Y}]\) we denote the set \( \{ \mathcal{Y}' \in \text{Mod}_L(\omega) : \mathcal{Y}' \cong \mathcal{Y} \} \) and similarly for the structures from \( \text{Mod}_{L_n}(\omega) \).

Following the architecture of the proof of the corresponding statement from \([7]\) we divide the proof into two subsections. In “Preliminaries” we take an arbitrary countable model \( \mathcal{Y}_0 \) of \( \mathcal{T} \) and a linear order with \( n \) unary predicates \( \mathcal{X}_0 \) such that \( \text{Pa}(\mathcal{X}_0) \subset \text{Pa}(\mathcal{Y}_0) \) (see Figure 1) and describe the cardinal argument which will be used in our proof. In “Proof”, distinguishing some cases, taking convenient structures \( \mathcal{Y}_0 \) and \( \mathcal{X}_0 \) and using that cardinal argument, we prove Theorem 4.1.

4.1 Preliminaries

For convenience, let \( \Delta_n := \{ \langle x_0, \ldots, x_{n-1} \rangle \in \omega^n : \bigvee_{k<i<n} x_k = x_i \} \) and, for an \( n \)-tuple \( \bar{a} := \langle a_0, \ldots, a_{n-1} \rangle \in \omega^n \), let us define \( F_{\bar{a}} := \{ a_0, \ldots, a_{n-1} \} \).

We fix a model \( \mathcal{Y}_0 = \langle \omega, \langle R_i^{\mathcal{Y}_0} : i \in I \rangle \rangle \in \text{Mod}_L(\omega) \) and an enumeration of its kernel, \( \text{Ker}(\mathcal{Y}_0) = \{ a_0, \ldots, a_{n-1} \} \). By Fact 2.1 there is a linear order \( \prec \in LO_\omega \) such that, defining \( \bar{a} = \langle a_0, \ldots, a_{n-1} \rangle \) and \( \mathcal{X}_0 := \langle \omega, \prec, \{ a_0 \}, \ldots, \{ a_{n-1} \} \rangle \),

\[
\langle \omega, \prec \rangle = \{ a_0 \} + \ldots + \{ a_{n-1} \} + (\omega \setminus F_{\bar{a}}) \quad \text{and} \quad \text{Pa}(\mathcal{X}_0) \subset \text{Pa}(\mathcal{Y}_0).
\]

Thus, the structure \( \mathcal{Y}_0 \) is \( (F_{\bar{a}}, \prec \restriction (\omega \setminus F_{\bar{a}})) \)-chainable. Let \( \mathcal{T}_{\mathcal{X}_0} \) denote the complete theory of \( \mathcal{X}_0 \), \( \text{Th}_{L_n}(\mathcal{X}_0) \). The structure \( \mathcal{X}_0 \) has the following properties expressible by first order sentences of the language \( L_n \):

(i) The interpretation of \( R \) is a linear order,

(ii) The interpretations of the relations \( U_k \), \( k < n \), are different singletons,

(iii) These singletons are ordered as the indices of \( U_k \)'s (that is, the \( L_n \)-sentence \( \bigwedge_{k<i<n} \forall u, v \ (U_k(u) \land U_i(v) \Rightarrow R(u, v)) \) is true in \( \mathcal{X}_0 \)),

(iv) The union of these singletons is an initial segment of the linear order; that is \( \mathcal{X}_0 \models \forall u, v \ ((U_{n-1}(u) \land \bigwedge_{k<n} -U_k(v)) \Rightarrow R(u, v)) \).
So, if $T^*$ is the set of the $L_n$-sentences expressing (i)–(iv), then $T^* \subset T_{\bar{X}_0}$ and

$$X_0 \in M_{Y_0} := \\{ \langle \omega, <, \{a_0\}, \ldots, \{a_{n-1}\} \rangle \in \text{Mod}_{L^*_n}(\omega) : \ Y_0 \text{ is } (F_0, <\upharpoonright (\omega \setminus F_0))\text{-chainable} \}.$$  

By Fact 2.1, the structure $Y_0$ is simply definable in the $L_n$-structure $X_0$. Thus, for each $i \in I$ there is a quantifier free $L_n$-formula $\varphi_i(v_0, \ldots, v_{n-1})$ such that

$$\forall \bar{x} \in \omega^n_i \left( \bar{x} \in R^Y_{i_0} \iff X_0 \models \varphi_i[\bar{x}] \right), \quad (14)$$

Generally speaking, using the $L_n$-formulas $\varphi_i$, $i \in I$, to each $L_n$-structure $X \in \text{Mod}_{L_n}(\omega)$ we can adjoin the $L$-structure $Y_X := \langle \omega, \langle R^X_i : i \in I \rangle \rangle \in \text{Mod}_L(\omega)$, where, for each $i \in I$, the relation $R^X_i$ is defined in the structure $X$ by the formula $\varphi_i$, that is,

$$\forall \bar{x} \in \omega^n_i \left( \bar{x} \in R^Y_{i_0} \iff X \models \varphi_i[\bar{x}] \right). \quad (15)$$
Claim 4.2 For each structure $\forall_0 \in \text{Mod}_L^{\bar{T}}(\omega)$, each enumeration $\text{Ker}(\forall_0) = \{a_0, \ldots, a_{n-1}\}$ each structure $\forall_0 \in \text{Mod}_L^{\bar{T}}(\omega)$, and each choice of formulas $\varphi_i$, $i \in I$, satisfying (14), defining $\forall_0$ by (15), for $\forall_0 \in \text{Mod}_L(\omega)$, we have

(a) The mapping $\Phi : \text{Mod}_L(\omega) \rightarrow \text{Mod}_L(\omega)$, defined by $\Phi(\forall_0) = \forall_0$, for each $\forall_0 \in \text{Mod}_L(\omega)$, preserves elementary equivalence and isomorphism; moreover, $\text{Iso}(\forall_0, \forall_0) \subset \text{Iso}(\forall_0, \forall_0)$, for all $\forall_0, \forall_0 \in \text{Mod}_L(\omega)$;

(b) The mapping $\Psi : \text{Mod}_0^{T_0}(\omega) / \cong \rightarrow \text{Mod}_L^{\bar{T}_0}(\omega) / \cong$, given by $\Psi([\forall_0]) = [\forall_0]$, for all $[\forall_0] \in \text{Mod}_0^{T_0}(\omega) / \cong$, is well defined.

Proof. (a) By recursion on the construction of $L$-formulas to each $L$-formula $\varphi(v)$ we adjoin an $L_0$-formula $\varphi^*(v)$ in the following way: $(v_k = v_l)^* := v_k = v_l$, $R_i(v_{k_0}, \ldots, v_{k_{n_i}})^* := \varphi_i(v_{k_0}, \ldots, v_{k_{n_i}})$ (replacement of $v_j$ by $v_{k_j}$ in $\varphi_i$), $(\neg \varphi)^* := \neg \varphi^*$, $(\varphi \land \psi)^* := \varphi^* \land \psi^*$ and $(\exists v_k \varphi)^* := \exists v_k \varphi^*$. A routine induction shows that, writing $\bar{v}$ instead of $v_0, \ldots, v_{n-1}$, we have (see [6], p. 216)

$$\forall \forall \in \text{Mod}_L(\omega) \forall \varphi(\bar{v}) \in \text{Form}_L \forall x \in \omega^n \left( \forall \forall \models [\varphi(\bar{x})] \iff \forall \forall \models [\varphi(\bar{x})] \right).$$

(16)

Let $\forall_1, \forall_2 \in \text{Mod}_L(\omega)$. If $\forall_1 \equiv \forall_2$, then for an $L$-sentence $\varphi$ we have: $\forall \forall_1 \models \varphi$ iff $\forall \forall_2 \models \varphi$ (by (16)) iff $\forall \forall_2 \models \varphi$ (since $\forall_1 \equiv \forall_2$) iff $\forall \forall_2 \models \varphi$ (by (16) again). So, $\forall \forall_1 \equiv \forall \forall_2$ and the mapping $\Phi$ preserves elementary equivalence.

If $f : \forall_1 \rightarrow \forall_2$ is an isomorphism, then by (15) and since isomorphisms preserve all formulas in both directions, for each $i \in I$ and $\bar{x} \in \omega^n$ we have: $\bar{x} \in R_i^{\forall_1}$ iff $\forall \forall_1 \models \varphi_i(\bar{x})$ iff $\forall \forall_2 \models \varphi_i(\bar{x})$ iff $f \bar{x} \in R_i^{\forall_2}$. Thus $f \in \text{Iso}(\forall_1, \forall_2)$.

(b) For $\forall_0 \in \text{Mod}_0^{T_0}(\omega)$ we have $\forall_0 \equiv \forall_0$, which, by (a), (14) and (15), implies that $\Phi(\forall_0) = \forall_0 \equiv \forall_0 = \forall_0$. So, since $\forall_0 \models T$, we have $\Phi(\forall_0) \in \text{Mod}_L^{\bar{T}}(\omega)$ and, thus,

$$\Phi[\text{Mod}_0^{T_0}(\omega)] \subset \text{Mod}_L^{\bar{T}}(\omega).$$

(17)

Assuming that $\forall_1, \forall_2 \in \text{Mod}_0^{T_0}(\omega)$ and $\forall_1 \equiv \forall_2$, by (a) we have $\forall \forall_1 \equiv \forall \forall_2$, that is $[\forall \forall_1] = [\forall \forall_2]$. So, the mapping $\Psi$ is well defined.

Thus, by Claim 4.2(b), if $I(\forall_0, \omega) = c$, then for a proof that $I(\forall_0, \omega) = c$ it is sufficient to show that the mapping $\Psi$ is at-most-countable-to-one, which will be true if for each $\forall_0 \in \text{Mod}_0^{T_0}(\omega)$ we have $|\Psi^{-1}([\forall_0])| \leq \omega$. We note that, by Example 4.2 of (17), it is possible that $|\Psi^{-1}([\forall_0])| = \omega$.

Now, let $\forall_0 \in \text{Mod}_0^{T_0}(\omega)$. Then we have $\forall_0 \models T^*$ and, hence, there is $\bar{b} := (b_0, \ldots, b_{n-1}) \in \omega^n \setminus \Delta_n$ such that $\forall_0 = \langle \omega, \forall_0, \{b_0, \ldots, b_{n-1}\} \rangle$ and $\forall_0$ is
definable in \( \mathcal{X} \) by (15). So, by Fact 2.1 the structure \( \mathcal{Y}_X \) is \((F_b, \prec_X \restriction (\omega \setminus F_b))\)-

chainable and (see (5))

\[
\mathcal{L}_{X} := (\omega \setminus F_b, \prec_X \restriction (\omega \setminus F_b)) \in \mathcal{L}_{Y_X}^{T_b}.
\]

(18)

For an \( n \)-tuple \( \bar{c} := \langle c_0, \ldots, c_{n-1} \rangle \in \omega^n \setminus \Delta_n \) let us define

\[
\mathcal{M}_{Y_X}^{\bar{c}} := \left\{ (\omega, \prec, \{c_0\}, \ldots, \{c_{n-1}\}) \in \text{Mod}_{L_n}^{\mathcal{T}_u}(\omega) : \mathcal{Y}_X \text{ is } (F_{\bar{c}}, \prec \restriction (\omega \setminus F_{\bar{c}}))\text{-chainable} \right\},
\]

(19)

\[
\mathcal{M}_{Y_X} := \bigcup_{\bar{c} \in \omega^n \setminus \Delta_n} \mathcal{M}_{Y_X}^{\bar{c}}.
\]

(20)

Thus, \( \mathcal{X} \in \mathcal{M}_{Y_X}^{\bar{c}} \subset \mathcal{M}_{Y_X} \). For \( \mathcal{M} \subset \text{Mod}_{L_n}^{\mathcal{T}_u}(\omega) \), let \( \mathcal{M}^{\equiv} := \{ [A] : A \in \mathcal{M} \} \).

**Claim 4.3** For each structure \( \mathcal{X} \in \text{Mod}_{L_n}^{\mathcal{T}_{\mathcal{L}^0}}(\omega) \) we have

\[
\Psi^{-1}[[[\mathcal{Y}_X]]] \subset \mathcal{M}_{Y_X}^{\equiv} \cap \text{Mod}_{L_n}^{\mathcal{T}_{\mathcal{L}^0}}(\omega)/ \equiv.
\]

**Proof.** Let \( \mathcal{X} \in \text{Mod}_{L_n}^{\mathcal{T}_{\mathcal{L}^0}}(\omega) \). Then, by (17) we have \( \mathcal{Y}_X \in \text{Mod}_I^{\mathcal{T}}(\omega) \); so \( \Psi([[\mathcal{X}]] = [[\mathcal{Y}_X]] \in \text{Mod}_I^{\mathcal{T}}(\omega)/ \equiv \) and \( \Psi^{-1}[[[\mathcal{Y}_X]]] \subset \text{dom}(\Psi) = \text{Mod}_{L_n}^{\mathcal{T}_{\mathcal{L}^0}}(\omega)/ \equiv \).

Let \( [X_1] \in \Psi^{-1}[[[\mathcal{Y}_X]]] \). Then \( [X_1] \in \text{Mod}_{L_n}^{\mathcal{T}_{\mathcal{L}^0}}(\omega)/ \equiv \) and, since the set \( \text{Mod}_{L_n}^{\mathcal{T}_{\mathcal{L}^0}}(\omega) \) is closed under \( \equiv \), we have \( X_1 \in \text{Mod}_{L_n}^{\mathcal{T}_{\mathcal{L}^0}}(\omega) \). This implies that \( X_1 \models \mathcal{T}^s \) and, hence, \( X_1 = (\omega, \prec, \{c_0\}, \ldots, \{c_{n-1}\}) \), for some \( \bar{c} := \langle c_0, \ldots, c_{n-1} \rangle \in \omega^n \setminus \Delta_n \). Since \( X_1 \in \text{Mod}_{L_n}^{\mathcal{T}_{\mathcal{L}^0}}(\omega) \), by (15) for \( i \in I \) we have

\[
\forall \bar{x} \in \omega^{n_i} \ (\bar{x} \in R_i^X \iff X_1 \models \varphi_i[\bar{x}]).
\]

(21)

Also we have \( [Y_{X_1}] = \Psi([X_1]) = [Y_X] \), so there is \( f \in \text{Iso}(\mathcal{Y}_X, X_{X_1}) \) and we prove that \( X_1 \in \mathcal{M}_{Y_X}^{\equiv} \).

Clearly, \( X_2 := (\omega, f^{-1}[\prec_{X_1}], \{f^{-1}(c_0)\}, \ldots, \{f^{-1}(c_{n-1})\}) \equiv X_1 \) and \( f \in \text{Iso}(X_2, X_1) \). For \( i \in I \) and \( \bar{x} \in \omega^{n_i} \) we have \( \bar{x} \in R_i^X \iff f\bar{x} \in R_i^{Y_{X_1}} \) (since \( f \in \text{Iso}(Y_{X_1}, X_{X_1}) \)), if \( X_1 \models \varphi_i[\bar{x}] \) (by 2.1), if \( X_2 \models \varphi_i[f\bar{x}] \) (since \( f \in \text{Iso}(X_2, X_1) \)). Thus \( \bar{x} \in R_i^X \iff \bar{x} \models \varphi_i[f\bar{x}] \), for all \( \bar{x} \in \omega^{n_i} \), so, by Fact 2.1 the structure \( \mathcal{Y}_X \) is \((F_{f^{-1}\bar{c}}, f^{-1}[\prec_{X_1}] \restriction (\omega \setminus F_{f^{-1}\bar{c}}))\)-chainable. Now, \( X_2 \in \mathcal{M}_{Y_X}^{f^{-1}\bar{c}} \) and, hence, \( [X_1] = [X_2] \in (\mathcal{M}_{Y_X}^{f^{-1}\bar{c}})^{\equiv} \subset \mathcal{M}_{Y_X}^{\equiv} \). Thus \( \Psi^{-1}[[[\mathcal{Y}_X]]] \subset \mathcal{M}_{Y_X}^{\equiv} \). \( \square \)

The following folklore statement will be used in our case analysis as well.

**Claim 4.4** If some structure \( \mathcal{Y} \in \text{Mod}_I^{\mathcal{T}}(\omega) \) is simply definable in an \( \omega \)-categorical structure \( \mathcal{X} \) with domain \( \omega \), then \( \mathcal{Y} \) is an \( \omega \)-categorical structure and \( I(\mathcal{T}, \omega) = 1 \).
Vaught’s conjecture for almost chainable theories

Proof. By the theorem of Engeler, Ryll-Nardzewski and Svenonius (see [6], p. 341), the automorphism group of \( \mathcal{X} \) is oligomorphic; that is, for each \( n \in \mathbb{N} \) we have \( |\omega^n / \sim_{\mathcal{X},n}| < \omega \), where \( \bar{x} \sim_{\mathcal{X},n} \bar{y} \) iff \( f \bar{x} = \bar{y} \), for some \( f \in \text{Aut}(\mathcal{X}) \).

As in Claim 4.4(a) we prove that \( \text{Aut}(\mathcal{X}) \subseteq \text{Aut}(\mathcal{Y}) \), which implies that for \( n \in \mathbb{N} \) and each \( \bar{x}, \bar{y} \in \omega^n \) we have \( \bar{x} \sim_{\mathcal{X},n} \bar{y} \Rightarrow \bar{x} \sim_{\mathcal{Y},n} \bar{y} \). Thus \( |\omega^n / \sim_{\mathcal{Y},n}| \leq |\omega^n / \sim_{\mathcal{X},n}| < \omega \), for all \( n \in \mathbb{N} \), and, since \( |L| \leq \omega \), using the same theorem we conclude that \( \mathcal{Y} \) is an \( \omega \)-categorical \( L \)-structure.

4.2 Proof

First we prove that \( |\text{Mod}_{L}^{T}(\omega)| \cong | \in \{1, \text{c} \} \), using definitions and notation from “Preliminaries” and distinguishing the following cases.

Case A: There exist a structure \( \mathcal{Y}_0 \in \text{Mod}_{L}^{T}(\omega) \), an enumeration of its kernel, \( \text{Ker}(\mathcal{Y}_0) = \{a_0, \ldots, a_{n-1}\} \), and a structure \( \mathcal{X}_0 \in \mathcal{M}_{\mathcal{Y}_0}^{\theta} \) such that the theory \( \mathcal{T}_{\mathcal{X}_0} \) is \( \omega \)-categorical. Then by Fact 2.1 the structure \( \mathcal{Y}_0 \) is simply definable in \( \mathcal{X}_0 \) and by Claim 4.4 we have \( I(\mathcal{T}, \omega) = 1 \).

In particular, Case A appears if there is a structure \( \mathcal{Y} \in \text{Mod}_{L}^{T}(\omega) \) satisfying condition (1) of Theorem 2.5 \( \mathcal{Y} \) is \( F \)-chainable and \( L_{\mathcal{Y}} = LO_{\omega \setminus F} \). Then, taking an enumeration \( F = \{a_0, \ldots, a_{n-1}\} \), the relations \( R_{\mathcal{Y}}^{i} \) of the structure \( \mathcal{Y} \) are definable in the structure \( \mathcal{X} := \langle \omega, \{a_0\}, \ldots, \{a_{n-1}\} \rangle \) of the unary language \( L' := \langle U_0, \ldots, U_{n-1} \rangle \) by quantifier free \( L' \)-formulas and, since the structure \( \mathcal{X} \) is \( \omega \)-categorical, \( \mathcal{Y} \) is \( \omega \)-categorical as well; so, \( I(\mathcal{T}, \omega) = 1 \) again. We note that such structures are called \textit{finist} by Fraïssé, see [2], p. 292.

Case B: For each structure \( \mathcal{Y}_0 \in \text{Mod}_{L}^{T}(\omega) \), each enumeration of its kernel \( \text{Ker}(\mathcal{Y}_0) = \{a_0, \ldots, a_{n-1}\} \) and each structure \( \mathcal{X}_0 \in \mathcal{M}_{\mathcal{Y}_0}^{\theta} \), the theory \( \mathcal{T}_{\mathcal{X}_0} \) is not \( \omega \)-categorical; so, by Theorem 2.7 \( |\text{Mod}_{L}^{T_{\mathcal{Y}_0}}(\omega)| \cong | \in \{1, \text{c} \} \), for all \( \mathcal{X}_0 \in \mathcal{M}_{\mathcal{Y}_0}^{\theta} \). Then, by the remark from Case A concerning condition (1) of Theorem 2.5 we have

\[
\forall \mathcal{Y} \in \text{Mod}_{L}^{T}(\omega) \quad L_{\mathcal{Y}}^{\text{Ker}(\mathcal{Y})} \neq LO_{\omega \setminus \text{Ker}(\mathcal{Y})},
\]

and we prove that \( |\text{Mod}_{L}^{T}(\omega)| \cong | \ = \text{c} \), distinguishing the following two subcases.

Subcase B1: There exist a structure \( \mathcal{Y}_0 \in \text{Mod}_{L}^{T}(\omega) \), an enumeration of its kernel, \( \text{Ker}(\mathcal{Y}_0) = \{a_0, \ldots, a_{n-1}\} \), and a structure \( \mathcal{X}_0 \in \mathcal{M}_{\mathcal{Y}_0}^{\theta} \) such that the linear order \( L_{\mathcal{X}_0} := \langle \omega, \forall \bar{a}, \langle \omega \setminus F_{\bar{a}}, \prec_{\mathcal{X}_0} \rangle \rangle \in \mathcal{L}_{\mathcal{X}_0}^{F_{\bar{a}}} \) has at least one end-point.

Then we take such \( \mathcal{Y}_0, \bar{a} \) and \( \mathcal{X}_0 \) and notice that \( \mathcal{X}_0 \models \mathcal{T}^* \) and that the mentioned property of \( L_{\mathcal{X}_0} \) gives a first order property of \( \mathcal{X}_0 \). Namely, \( \mathcal{X}_0 \models \theta_0 \land \theta_1 \), where

\[
\theta_0 := \exists v \forall u \left( U_{n-1}(u) \Rightarrow R(u, v) \land \neg \exists w \left( R(u, w) \land R(w, v) \right) \right),
\]

(23)
\[
\theta_1 := \exists v \forall u \left( \neg u = v \Rightarrow R(u, v) \right).
\] (24)

Now we have \(|\text{Mod}^{T_{n_0}}(\omega)| / \cong | = \varepsilon\) and, by Claim 4.2(b), for a proof that \(|\text{Mod}^F(\omega)| / \cong | = \varepsilon\) it is sufficient to show that the mapping \(\Psi\) is at-most-countable-to-one. This will follow from the following claim and Claim 4.3.

**Claim 4.5** \(|\mathcal{M}^\cong_{\mathcal{Y}_X} \cap \text{Mod}^{T_{n_0}}(\omega)| / \cong | \leq \omega\), for all \(\mathcal{X} \in \text{Mod}^{T_{n_0}}(\omega)\).

**Proof.** Let \(\mathcal{X} \in \text{Mod}^{T_{n_0}}(\omega)\). By (20) it is sufficient to show that for each \(\bar{c} \in \omega^n \setminus \Delta_n\) we have

\[
\left| \langle \mathcal{M}^\cong_{\mathcal{Y}_X} \rangle / \cong \cap \text{Mod}^{T_{n_0}}(\omega) / \cong \right| \leq \omega.
\] (25)

Let \(\mathcal{X}_1 = \langle \omega, \prec_{\mathcal{X}_1}, \{c_0\}, \ldots, \{c_{n-1}\} \rangle \in \mathcal{M}^\cong_{\mathcal{Y}_X}\). Then by (19) and (5) we have

\[
\mathbb{L}_{\mathcal{X}_1} := \langle \omega \setminus F_c, \prec_{\mathcal{X}_1} \upharpoonright (\omega \setminus F_c) \rangle \in \mathcal{L}^F_{\mathcal{Y}_X}.
\]

First, if the set \(\mathcal{L}^F_{\mathcal{Y}_X}\) satisfies condition (iii) of Theorem 2.5 then we have \(\langle \mathcal{M}^\cong_{\mathcal{Y}_X} \rangle / \cong \cap \text{Mod}^{T_{n_0}}(\omega) / \cong \leq 2\) and (25) is true.

Otherwise, by (22) and Theorem 2.5 \(\mathcal{L}^F_{\mathcal{Y}_X} = \bigcup_{\mathcal{L}_{\mathcal{X}_1} = \mathbb{I} + \mathbb{F}} \{\mathbb{F} + \mathbb{I}, \mathbb{I}^* + \mathbb{F}^*\}\).

Let \(\mathcal{X}_2 = \langle \omega, \prec_{\mathcal{X}_2}, \{c_0\}, \ldots, \{c_{n-1}\} \rangle \in \mathcal{M}^\cong_{\mathcal{Y}_X} \cap \text{Mod}^{T_{n_0}}(\omega)\). Then \(\mathbb{L}_{\mathcal{X}_2} := \langle \omega \setminus F_c, \prec_{\mathcal{X}_2} \upharpoonright (\omega \setminus F_c) \rangle \in \mathcal{L}^F_{\mathcal{Y}_X}\) and, hence, there is a cut \(\{\mathbb{I}, \mathbb{F}\}\) in \(\mathbb{L}_{\mathcal{X}_1}\) (i.e. a decomposition \(\mathbb{L}_{\mathcal{X}_1} = \mathbb{I} + \mathbb{F}\)) such that \(\mathbb{L}_{\mathcal{X}_2} = \mathbb{F} + \mathbb{I}\) or \(\mathbb{L}_{\mathcal{X}_2} = \mathbb{I}^* + \mathbb{F}^*\). Suppose that \(\mathbb{I}, \mathbb{F} \neq \emptyset\), that \(\mathbb{I}\) does not have a largest element and that \(\mathbb{F}\) does not have a smallest element. Then \(\mathbb{F} + \mathbb{I}\) and \(\mathbb{I}^* + \mathbb{F}^*\) are linear orders without end points. But, since \(\mathcal{X}_2 \in \text{Mod}^{T_{n_0}}(\omega)\) we have \(\mathcal{X}_2 \models \theta_0 \lor \theta_1\) and, hence, the linear order \(\mathbb{L}_{\mathcal{X}_2}\) must have at least one end-point, which gives a contradiction.

So, for each \(\mathcal{X}_2 \in \mathcal{M}^\cong_{\mathcal{Y}_X} \cap \text{Mod}^{T_{n_0}}(\omega)\) we have \(\mathbb{L}_{\mathcal{X}_2} = \mathbb{F} + \mathbb{I}\) or \(\mathbb{L}_{\mathcal{X}_2} = \mathbb{I}^* + \mathbb{F}^*\), where \(\mathbb{I}\) has a largest element or \(\mathbb{F}\) has a smallest element. Since such cuts \(\{\mathbb{I}, \mathbb{F}\}\) in \(\mathbb{L}_{\mathcal{X}_1}\) are defined by the elements of the set \(\omega \setminus F_c\), there are countably many of them. Thus \(|\mathcal{M}^\cong_{\mathcal{Y}_X} \cap \text{Mod}^{T_{n_0}}(\omega)| = \omega\), which implies (25), since each class from the set \(\langle \mathcal{M}^\cong_{\mathcal{Y}_X} \rangle / \cong \cap \text{Mod}^{T_{n_0}}(\omega) / \cong\) has a representative in \(\mathcal{M}^\cong_{\mathcal{Y}_X} \cap \text{Mod}^{T_{n_0}}(\omega)\). □

**Subcase B2:** For each structure \(\mathcal{Y}_0 \in \text{Mod}^{T_{L}}(\omega)\), each enumeration of its kernel, \(\text{Ker}(\mathcal{Y}_0) = \{a_0, \ldots, a_{n-1}\}\), and each structure \(\mathcal{X}_0 \in \mathcal{M}^\cong_{\mathcal{Y}_0}\), the linear order \(\mathbb{L}_{\mathcal{X}_0} := \langle \omega \setminus F_a, \prec_{\mathcal{X}_0} \upharpoonright (\omega \setminus F_a) \rangle \in \mathcal{L}^F_{\mathcal{Y}_0}\) is a linear order without end points.
Then we fix arbitrary $\forall 0 \in \text{Mod}^{T_{\Lambda_0}}(\omega)$ and $X_0 \in \mathcal{M}^b_{\forall 0}$, where $\text{Ker}(\forall 0) = F_{\forall 0}$.

Again we have $|\text{Mod}^{T_{\Lambda_0}}(\omega)/\cong| = \omega$ and, as in Subcase B1, the equality $|\text{Mod}^{T_{\Lambda_0}}(\omega)/\cong| = \omega$ will follow from Claims 4.2(b), 4.3 and the next claim.

Claim 4.6 $|\mathcal{M}^c_{\forall X} \cap \text{Mod}^{T_{\Lambda_0}}(\omega)/\cong| \leq \omega$, for all $X \in \text{Mod}^{T_{\Lambda_0}}(\omega)$.

**Proof.** Let $X \in \text{Mod}^{T_{\Lambda_0}}(\omega)$. By (20) it is sufficient to show that for each $\bar{c} \in \omega^n \setminus \Delta_n$ we have $|\mathcal{M}^c_{\forall X}| \leq 2$.

Let $X_1 = \langle \omega, \prec_{X_1}, \{c_0\}, \ldots, \{c_{n-1}\} \rangle \in \mathcal{M}^c_{\forall X}$. Then, by our assumption, $\mathbb{L}_{X_1} = \langle \omega \setminus F_{\bar{c}}, \prec_{X_1} \setminus (\omega \setminus F_{\bar{c}}) \rangle$ is a linear order without end points and $\mathbb{L}_{X_1} \in \mathcal{L}^c_{\bar{X}}$.

Suppose that the set $\mathcal{L}^c_{\bar{X}}$ satisfies condition (11) of Theorem 2.5 that is, $\mathcal{L}^c_{\bar{X}} = \bigcup_{L_{X_1} \in \mathbb{L}} \{F + \bar{I}, \bar{I}^* + \bar{I}^*\}$. Then, taking an arbitrary $x \in \omega \setminus F_{\bar{c}}$ we have $L_{X_1} = (-\infty, x]_{L_{X_1}} + [x, \infty]_{L_{X_1}} =: \bar{I} + \bar{F}$ and, since $L_{X_1}$ is a linear order without end points, $\bar{I}, \bar{F} \neq \emptyset$. Let $X_2 = \langle \omega, \prec_{X_2}, \{c_0\}, \ldots, \{c_{n-1}\} \rangle$, where $\prec_{X_2}$ is the linear order on $\omega$ such that $\langle \omega, \prec_{X_2}, \{c_0\} + \ldots + \{c_{n-1}\} + \bar{F} + \bar{I} \rangle$ and then $X_2$ is a linear order without end points $L_{X_2}$ which implies $\mathbb{L}_{X_2} \in \mathcal{M}^c_{\forall X}$.

Thus there are finite sets $K, H \subset \omega \setminus F_{\bar{c}}$ such that $L_{X_1} = K + \bar{I} + \bar{F}$ and $L_{X_2} = \mathbb{L}_{X_1} = \mathbb{L}_{X_2}$.

In addition, since each element of $\mathcal{L}^c_{\bar{X}}$ is a linear order without end points, we have $K = H = \emptyset$ and, hence, $\mathbb{M} = L_{X_1}$ and $\mathcal{L}^c_{\bar{X}} = \langle \omega \setminus F_{\bar{c}}, \prec_{X_1} \setminus (\omega \setminus F_{\bar{c}}) \rangle$ is an $\omega$-categorical linear order. Since $\text{Aut}(\mathbb{X}_0) = \{\text{id}_{\mathbb{X}_0} \cup f : f \in \text{Aut}(\mathbb{L}_{\mathbb{X}_0})\}$, for $n \in \mathbb{N}$ and $x, y \in (\omega \setminus F_{\bar{c}})^n$ we have $x \sim L_{\mathbb{X}_0} y \iff \bar{x} \sim x \sim \mathbb{X}_0 y$, which implies that $|\omega \setminus F_{\bar{c}}|^n / \sim L_{\mathbb{X}_0} \leq |\omega|^n / \sim \mathbb{X}_0|$. So, if $\mathbb{X}_0$ is $\omega$-categorical, then $L_{\mathbb{X}_0}$ is $\omega$-categorical (by the theorem of Engeler, Ryll-Nardzewski and Svenonius).

Finally we prove the second part of Theorem 4.1. By our analysis, the theory $T$ is $\omega$-categorical iff Case A appears; so, we have to prove that the $L_n$-structure $\mathbb{X}_0 = \langle \omega, \prec, \{a_0\}, \ldots, \{a_{n-1}\} \rangle$ is $\omega$-categorical iff $L_{\mathbb{X}_0} := \langle \omega \setminus F_{\bar{c}}, \prec \setminus (\omega \setminus F_{\bar{c}}) \rangle$ is an $\omega$-categorical linear order. Since $\text{Aut}(\mathbb{X}_0) = \{\text{id}_{\mathbb{X}_0} \cup f : f \in \text{Aut}(\mathbb{L}_{\mathbb{X}_0})\}$, for $n \in \mathbb{N}$ and $x, y \in (\omega \setminus F_{\bar{c}})^n$ we have $x \sim L_{\mathbb{X}_0} y \iff \bar{x} \sim x \sim \mathbb{X}_0 y$, which implies that $|\omega \setminus F_{\bar{c}}|^n / \sim L_{\mathbb{X}_0} \leq |\omega|^n / \sim L_{\mathbb{X}_0}$. So, if $\mathbb{X}_0$ is $\omega$-categorical, then $L_{\mathbb{X}_0}$ is $\omega$-categorical (by the theorem of Engeler, Ryll-Nardzewski and Svenonius).

On the other hand, if $L_{\mathbb{X}_0}$ is $\omega$-categorical, then the linear order $\langle \omega, \prec \rangle \cong n$, $L_{\mathbb{X}_0}$ is $\omega$-categorical (see Rosenstein’s theorem, [9], p. 299) and, since $\text{Aut}(\mathbb{X}_0) = \text{Aut}(\langle \omega, \prec \rangle)$, $\mathbb{X}_0$ is $\omega$-categorical too.
