TOWARDS A CONSTRUCTIVE SIMPLICIAL MODEL OF UNIVALENT FOUNDATIONS

NICOLA GAMBINO AND SIMON HENRY

Abstract. We provide a partial solution to the problem of defining a constructive version of Voevodsky’s simplicial model of univalent foundations. For this, we prove constructive counterparts of the necessary results of simplicial homotopy theory, building on the constructive version of the Kan-Quillen model structure established by the second-named author. In particular, we show that dependent products along fibrations with cofibrant domains preserve fibrations, establish the weak equivalence extension property for weak equivalences between fibrations with cofibrant domain and define a univalent classifying fibration for small fibrations between bifibrant objects. These results allow us to define a comprehension category supporting identity types, Σ-types, Π-types and a univalent universe, leaving only a coherence question to be addressed.

Introduction

Context and motivation. This paper investigates Voevodsky’s model of Martin-Löf type theory (ML) extended with the Univalence Axiom (UA) in the category of simplicial sets [29, 38]. This model is of fundamental importance since it informs a new approach to the development of mathematics and its computer-assisted formalisation [41]. Furthermore, in combination with the discovery of a close connection between identity types and homotopical algebra [4, 17], it provided initial inspiration for the development of Homotopy Type Theory [39].

The original definition of the simplicial model was carried out in Zermelo-Fraenkel set theory extended with the axiom of choice (ZFC) and two inaccessible cardinals [29, Theorem 3.4.3]. Given the wide gap in proof-theoretic strength between that theory and ML [18] and the fact that the former is classical while the latter is constructive, the question of whether the simplicial model could be defined working constructively (i.e. without the use of the law of excluded middle or the axiom of choice) arose immediately after its discovery around 2006 [30, 38, 40] and was one of the central issues investigated during the thematic programme on Univalent Foundations at the Institute for Advanced Study in 2012/13. In spite of significant efforts since then, the question is still open.

The aim of this paper is to provide a partial solution to this problem. In order to explain our results and the novel aspects of our work, let us recall from [29] that the main results of homotopy theory necessary to define the simplicial model of ML(UA) = ML + UA are the existence of a Quillen model structure on the category of simplicial sets whose fibrations are the Kan fibrations, the fact that dependent product along a fibration preserves fibrations, the existence of a fibration π: U → U that classifies small fibrations, the fibrancy of U and, finally, the univalence of the
fibration $\pi$. These results allow us to define a comprehension category

$$\xymatrix{ \text{Fib} \ar[r] & \text{SSet} \ar@<1ex>[l] \ar@<1ex>[r] & \text{SSet} \ar@<1ex>[l] \ar@<1ex>[r] & \text{cod} }$$

where $\text{SSet}$ is the category of simplicial sets and $\text{Fib}$ is the category of Kan fibrations, and to show that this comprehension category supports the type constructors of ML (which we take here to be $0, 1, +, \mathbb{N}, \text{Id}, \Sigma, \Pi$ and $U$), in the sense of [31], and a univalent type universe closed under the above type constructors, in the sense of [37]. Such a comprehension category is not quite a model of ML(UA) because of well-known strictness issues [24], but it gives rise to one by appropriate coherence results [12, 24, 29, 31, 37].

A fundamental obstruction to a constructive development of the simplicial model was discovered in [8], where it was shown that it is not possible to prove constructively that for a simplicial set $A$ and a Kan complex $B$, the exponential $B^A$ is again a Kan complex. Because of this, Coquand and his collaborators defined homotopy-theoretic models of type theories with the univalence axiom in categories of cubical sets [6], opening a profitable new research direction, cf. [5, 11, 34] for example. Apart from switching from simplicial sets to cubical sets, they also switched from ordinary fibrations, defined by a right lifting property, to uniform fibrations, defined as maps equipped with additional structure which provides a choice of fillers for lifting problems, as in algebraic weak factorisation systems [16, 21]. While categories of cubical sets considered in this line of work allow us to define constructively models of ML(UA) and admit a Quillen model structure [35], none of them is known to be Quillen equivalent to simplicial sets or topological spaces.

In simplicial sets, although it is possible to develop a constructive theory of uniform fibrations and prove that dependent product along a uniform fibration preserves uniform fibrations (and in particular that for a simplicial set $A$ and an algebraic Kan complex $B$, the simplicial set $B^A$ is an algebraic Kan complex), as shown in [19], the uniform fibrations are not as well-behaved as in cubical sets, since they do not admit a classifier, essentially because representables in simplicial sets are not closed under under products while they are in cubical sets [36]. In summary, to date there is no known model of ML(UA) that is definable in a constructive setting and based on a category homotopically equivalent to that of simplicial sets.

**Main results.** A breakthrough has been obtained by the second-named author in [23], where, building on his previous work on weak model structures [22], it is shown constructively that the category of simplicial sets admits a Quillen model structure in which the fibrations are the Kan fibrations. Moreover, this model structure is shown to be cartesian and proper. Crucially for our goals here, in this model structure not all monomorphisms are cofibrations, but only by those monomorphisms $i: A \to B$ that are levelwise complemented and for which the degeneracy of $n$-simplices is decidable in $B_n \setminus A_n$ for every $[n] \in \Delta$. In particular, not all simplicial sets are cofibrant, but only those with decidable degeneracies. However, this model structure coincides with the standard one as soon as the law of excluded middle is assumed. Two other proofs of the existence of this constructive model structure are obtained in [20] without relying on the results in [22].

The present paper extends this work to obtain constructive counterparts of all the other main results of homotopy theory were necessary to define the simplicial model of ML(UA). In particular, our main results are the following:

- Theorem 3.4, asserting that, for a fibration with cofibrant domain $p: A \to X$, the mapping path space gives a factorisation of the diagonal $\delta_p: A \to A \times_X A$ as a trivial cofibration followed by a fibration:
• Theorem 4.1, asserting that dependent product along fibrations with cofibrant domain preserves fibrations, which implies that, for a cofibrant simplicial set $A$ and a Kan complex $B$, the exponential $B^A$ is a Kan complex;

• Theorem 6.4, asserting the existence of a small fibration $\pi_c: \overline{U}_c \to U_c$ that classifies small fibrations between cofibrant objects;

• Theorem 7.4, asserting that the simplicial set $U_c$ is a cofibrant Kan complex;

• Theorem 7.6, asserting that the fibration $\pi_c: \overline{U}_c \to U_c$ is univalent.

These results allow us to define a comprehension category

$$
\begin{align*}
\text{Fib}_{\text{cof}} & \to \text{SSet}_{\text{cof}} \\
\text{SSet}_{\text{cof}} & \downarrow \text{cod} \\
\end{align*}
$$

where $\text{SSet}_{\text{cof}}$ is the category of cofibrant simplicial sets and $\text{Fib}_{\text{cof}}$ is the category of $\text{SSet}$ of fibrations between cofibrant simplicial sets, and to show that this comprehension category supports the type constructors of ML and a univalent type universe (Theorem 8.1). In this comprehension category, type-theoretic contexts correspond to cofibrant objects, while dependent types correspond fibrations $p: A \to X$ where $A$ and $X$ are cofibrant. This choice is informed by the fact that, for a simplicial set $X$, the slice category $\text{SSet}_{/X}$ admits a model structure in which the bifibrant objects are the fibrations $p: A \to X$ with $A$ cofibrant. Our main results above show how this comprehension category supports the type constructors of ML and a univalent type universe. For example, Theorem 3.4 shows that identity types can be interpreted as mapping path spaces.

Novel aspects. The key novelty of our approach is the use of the homotopy-theoretic notion of cofibrancy to encapsulate the logical notion of decidability of degeneracies and to work with it in a mathematically efficient way. Also, to the best of our knowledge, this paper is the first to make use of the cofibrant replacement functor in the study of models of dependent type theory.

We will use the cofibrant replacement functor to obtain $\Pi$-types and the type-theoretic universe in our comprehension category. For $\Pi$-types, given a fibration $p: A \to X$ with cofibrant domain, the result of applying the dependent product along $p$ to a fibration $q: B \to A$ with cofibrant domain produces a map $\Pi_p(q): \Pi_A(B) \to X$, which is a fibration by Theorem 4.1, but whose domain is not necessarily cofibrant. In order to remedy this, we define $\Pi$-types to be given by a cofibrant replacement of $\Pi_p(q): \Pi_A(B) \to X$, which is now a fibration with cofibrant domain. Interestingly, this definition validates a judgemental $\beta$-rule and a propositional $\eta$-rule (see Remark 4.2 for details), a combination that arises naturally when Martin-Löf type theory is presented within the Logical Framework [33, 15], as well as in the versions of the Coq assistant used for the original development of univalent foundations library [41]. Interestingly, Voevodsky’s proof that the univalence axiom implies the principle of function extensionality exploits crucially the propositional $\eta$-rule for $\Pi$-types.

For the definition of a type-theoretic universe satisfying the univalence axiom, we proceed in two steps. First, we construct a small fibration $\pi: \overline{U} \to U$ that classifies small fibrations with cofibrant fibers and prove that $U$ is fibrant. Then, we consider a cofibrant replacement $U_c$ of $U$, which comes equipped with a trivial fibration $\varepsilon: U_c \to U$, so that we obtain small fibration $\pi_c: \overline{U}_c \to U_c$ with bifibrant codomain and cofibrant domain by pullback along $\varepsilon$. Our final result, Theorem 7.6, shows that $\pi: \overline{U} \to U$ and $\pi_c: \overline{U}_c \to U_c$ are univalent fibrations.

We refrain from claiming that our work provides a complete solution to the problem of defining a constructive simplicial model of type theory since the comprehension category we construct is not split and does not satisfy strictly the stability conditions governing the interaction of substitution and type-formation rules, often referred to as the Beck-Chevalley conditions. While
there are well-known techniques to address these issues [29, 31, 37], they do not seem to apply in
our context. Thus, we only need an appropriate coherence result for the kind of comprehension
category defined in this paper, which we leave the investigation of such a coherence result to
future work (see Section 8 for details).

Let us conclude these introductory remarks by mentioning that although our main results
are inspired by the existing literature, especially those in [29], their proofs require a systematic
and careful cofibrancy considerations. In particular, in order to exhibit identity types as path
objects (Theorem 3.4) and to prove the weak equivalence extension property (Proposition 5.2)
we will need to establish the non-trivial and surprising fact that the appropriate dependent
products preserve cofibrancy (see Lemma 2.5 and Lemma 5.1 for details), a fact that does not
hold in general. Furthermore, when discussing a universe, we are not interested in defining a
small fibration that classifies small fibrations as in [29], but rather a small fibration that classifies
small fibrations between cofibrant objects.

Outline of the paper. Section 1 recalls the constructive version of the Kan-Quillen model
structure and some auxiliary results from [23]. Section 2 establishes some basic results on pull-
backs. Section 3 shows how path spaces provide factorisations as trivial cofibration followed by
fibration. Section 4 proves the restricted Frobenius property. Section 5 establishes the weak
equivalence extension property. Section 6 introduces a fibration \( \pi_c: U_c \to U_c \) that classifies
small fibrations between cofibrant Kan complexes. Section 7 proves that \( U_c \) is bifibrant and that
\( \pi_c: U_c \to U_c \) is univalent, using the weak equivalence extension property. We conclude in Sec-
tion 8 by summarising our main results in terms of the comprehension category and stating some
open problems for future research.

Remarks on constructivity. We work in Constructive Zermelo-Fraenkel set theory (CZF), a
set theory based on intuitionistic logic [2]. When discussing smallness of sets, simplicial sets and
fibrations, we assume the existence of an inaccessible set \( u \), as defined in [3, Definition 18.1.2].
We say that a set is small if it is an element of \( u \). For the closure of the type universe under
\( \Pi \)-types, we will assume a form of ‘propositional resizing’, asserting that every subset of a small
set is again small, i.e. \( \forall a, b (a \subseteq b \land b \in u \rightarrow a \in u) \). A further discussion of what can be done
without this assumption can be found in Remark 8.3. Throughout the paper, we adopt a slight
abuse of language and say that a map has a right (or left) lifting property to mean that there
exists a function mapping elements of the class of lifting problems to a chosen solution.

1. Preliminaries

We write \( \Delta \) for the simplicial category. The objects of \( \Delta \) are written as \([n]\), for \( n \geq 0 \). We
write \( SSet =_{def} [\Delta^{op}, \text{Set}] \) for the category of simplicial sets. For \( n \geq 0 \), \( \Delta[n] \in SSet \) is the
representable simplicial set associated to \([n]\) in \( \Delta \). Given a map \( f: Y \to X \) in \( SSet \), we write
\( f^*: SSet/X \to SSet/Y \) for the associated pullback functor. The functor \( f^* \) has a left adjoint,
defined by composition, which we write \( \Sigma_f: SSet/Y \to SSet/X \) and refer to as the dependent sum
along \( f \). Since \( \text{SSet} \) is locally cartesian closed, pullback along \( f \) has also a right adjoint, which we write \( \Pi_f: \text{SSet}/Y \to \text{SSet}/X \) and refer to as the dependent product along \( f \). The action of these functors on a map \( g: Z \to Y \) will be written \( \Sigma_f(g): \Sigma_Y(Z) \to X \) and \( \Pi_f(g): \Pi_Y(Z) \to X \), respectively. Since \( \Sigma_f \) is defined by composition, \( \Sigma_Y(Z) = \{Z \to X \mid g \in \text{Map}(Z, X)\} \) and \( \Sigma_f(g) = g.f \).

As a special case of a well-known result for presheaf categories for every \( [n] \in \Delta \) there is an equivalence of categories

\[
\text{SSet}/\Delta[n] \simeq [\Delta/[n]]^{\text{op}}, \text{Set}.
\]

For \( F: \Delta/[n]^{\text{op}} \to \text{Set} \), we write \( \pi_F: \int F \to \Delta[n] \) for the corresponding object of \( \text{SSet}/\Delta[n] \).

Here, \( \int F \) is the simplicial set whose \( m \)-simplices are pairs \((\theta, x)\) where \( \theta: [m] \to [n] \) is a map in \( \Delta \) and \( x \in F(\theta) \). The components of the natural transformation \( \pi_F \) are the first projections.

For \( [n] \in \Delta \), we write \( i^n: \partial \Delta[n] \to \Delta[n] \) for the boundary inclusion into the \( n \)-simplex and, for \( 1 \leq i \leq n \), \( h^n_i: \Lambda^n_i[n] \to \Delta[n] \) for the \( i \)-th horn inclusion into the \( n \)-simplex. The simplicial set \( \Delta[1] \) is an interval object in \( \text{SSet} \), with endpoint inclusions \( \delta^k: \{k\} \to \Delta[1] \) defined by \( \delta^k = \{n \} \to \Delta[1] \). Throughout this paper, we shall work with the constructive Kan-Quillen model structure \( (\text{Weq}, \text{Cof}, \text{Fib}) \) on \( \text{SSet} \) defined in [23]. For the convenience of the reader, we recall the main aspects of this model structure below. For this, let \( \text{TrivCof} = \text{def} \text{ Weq} \cap \text{Cof} \) and \( \text{TrivCof} = \text{def} \text{ Weq} \cap \text{Fib} \) be the classes of trivial cofibrations and trivial fibrations, respectively.

The weak factorisation system \( (\text{Cof}, \text{TrivFib}) \) of cofibrations and trivial fibrations is cofibrantly generated by the set \( \mathcal{I} = \{i^n: \partial \Delta[n] \to \Delta[n] \mid n \geq 0\} \) of boundary inclusions, i.e.

\[
(\text{Cof}, \text{TrivFib}) = (\text{Sat}(\mathcal{J}), \mathcal{J}^0).
\]

As shown in [22, Proposition 5.1.4] a map \( f: Y \to X \) is a cofibration if and only if it is a levelwise complemented monomorphism and the degeneracy of the simplices of \( X \setminus X_n \) is decidable for every \( [n] \in \Delta \). Thus, a simplicial set \( X \) is cofibrant if degeneracy of the simplices of \( X \) is decidable. Note that a map between cofibrant objects is a cofibration if and only if it is a levelwise complemented monomorphism. Cofibrant simplicial sets are of particular importance for our development because of their decidability property, which can be used to establish counterparts of classical results valid for all simplicial sets. An example is the Eilenberg-Zilber lemma [22, Lemma 5.1.2], asserting that in a cofibrant simplicial set \( X \), any cell \( x \in X \) can be written uniquely as \( p^n(y) \), where \( y \) is a non-degenerate cell of \( X \) and \( p \) is a degeneracy.

The weak factorisation system \( (\text{TrivCof}, \text{Fib}) \) of trivial cofibrations and fibrations is cofibrantly generated by the set \( \mathcal{J} = \{h^n_k: \Lambda^n_k[n] \to \Delta[n] \mid 0 \leq k \leq n\} \) of horn inclusions, i.e.

\[
(\text{TrivCof}, \text{Fib}) = (\text{Sat}(\mathcal{J}), \mathcal{J}^0)
\]

on \( \text{SSet} \). For a map \( f: Y \to X \), we denote the action of the pullback \( f^* \) on a fibration \( p: A \to X \) as

\[
\begin{array}{ccc}
A[f] & \to & A \\
\downarrow p[f] & \downarrow p \\
Y & \underset{f}{\to} & X.
\end{array}
\]

For \( X \in \text{SSet} \), we write \( \text{Fib}/X \) for the full subcategory of the slice category \( \text{SSet}_{/X} \) spanned by the fibrations with codomain \( X \). For \( X \in \text{SSet} \), we write \( \text{B Fib}/X \) for the full subcategory of \( \text{Fib}/X \) spanned by fibrations with cofibrant domain. For a simplicial set \( X \), we write \( \mathbb{L}(X) \) for its cofibrant replacement and \( \mathbb{R}(X) \) for its fibrant replacement. These objects come equipped with a trivial fibration \( \varepsilon_X: \mathbb{L}(X) \to X \) and a trivial cofibration \( \eta_X: X \to \mathbb{R}(X) \), respectively. An explicit definition of the cofibrant replacement is given in appendix A.

The model structure \( (\text{Weq}, \text{Cof}, \text{Fib}) \) is proper, i.e. both left and right proper [23, Propositions 2.2.9 and 3.5.2] and the weak factorization systems \( (\text{Cof}, \text{TrivFib}) \) and \( (\text{TrivCof}, \text{Fib}) \) satisfy the
so-called pushout product property [22, Proposition 5.1.5 and Corollary 5.2.3]. Recall that, given two maps \( f: Y \to X \) and \( g: B \to A \) their pushout product \( f \times g \) is defined as the unique dotted map in the diagram

\[
\begin{array}{ccc}
Y \times B & \to & X \times B \\
\downarrow & & \downarrow \\
Y \times A & \to & (Y \times A) + Y \times B (X \times B)
\end{array}
\]

The pushout-product property is the statement that if \( f \) and \( g \) are cofibrations then so is \( f \times g \) and, if additionally either \( f \) and \( g \) is a weak equivalence, then so is \( f \times g \). Note that when \( f \) and \( g \) are monomorphisms, so in particular when they are cofibrations, the pushout in the diagram above is just an union of subobjects and the pushout product of \( f \) and \( g \) is just the inclusion:

\[
f \times g: (Y \times A) \cup (X \times B) \to X \times A.
\]

Dually, using exponentials instead of products and pullbacks instead of pushouts, for maps \( f: Y \to X \) and \( p: B \to A \), the pullback exponential \( \langle f, p \rangle \) is defined as the unique dotted arrow in the diagram:

\[
\begin{array}{ccc}
B^X & \to & A^X \\
\downarrow & & \downarrow \\
B^Y \times A^Y & \to & A^Y
\end{array}
\]

By adjointness (see [27] for details), a map \( f \) has the left lifting property against \( \langle p, q \rangle \) if and only if \( f \times p \) has the left lifting property against \( q \). Therefore, the pushout-property implies its dual version, asserting that if \( f: Y \to X \) is a cofibration and \( p: B \to A \) a fibration then \( \langle f, p \rangle \) is a fibration and if, additionally, either \( p \) or \( f \) is a weak equivalence, then so so is \( \langle f, p \rangle \).

We also make use of another weak factorisation system \((L, R)\) on \( \text{SSet} \) introduced in [23, Section 3.1]. This is useful to establish decidability conditions; in particular, we will use it to prove Proposition 3.3 and Lemma 5.1 here. By definition, \((L, R)\) is the weak factorisation system cofibrantly generated by the set of degeneracy maps \( \sigma: \Delta[m] \to \Delta[n] \), i.e. the maps induced by surjections \([m] \to [n]\) in \( \Delta \). We refer to maps in \( L \) as the degeneracy quotients and the maps in \( R \) as the degeneracy-detecting maps. Since degeneracy maps are (split) epimorphisms in \( \text{SSet} \), the weak factorization system \((L, R)\) is actually a unique factorization system. Since the degeneracy-detecting maps are the maps with the (unique) right lifting property against degeneracy map, they are exactly the simplicial morphisms \( f: X \to Y \) such that for \( x \in X \), \( f(x) \) is degenerated if and only if \( x \) is degenerated. The degeneracy quotient maps are instead the pushouts of coproducts of degeneracy maps, i.e. the maps of the form \( X \to X[[x_i, \sigma_i]] \) where \( x_i \in X_{n-1} \) are a family of cells, \( \sigma: [n_i] \to [m_i] \) a family of degeneracies and \( X[[x_i, \sigma_i]] \) is obtained from \( X \) by freely making \( x_i \) in the image of \( \sigma_i \) for each \( i \). For the convenience of the reader, we recall the results about this factorization system in [23] that will be used here.
Lemma 1.1. Let \( p : A \to B \) be a degeneracy quotient between finite decidable simplicial set, \( X \) a cofibrant simplicial set and \( f : A \to X \) be any morphism. Then it is decidable whether \( f \) can be factored through \( p \) or not.

Proof. See [23, Lemma 3.1.8].

The proof of the result above can be outlined in a few words. Since \( B = A[\{a_i, \sigma_i\}] \) for a finite collection of cells \( a_i, \) \( f \) factors through \( p \) if and only if \( f(a_i) = \sigma_i^* x_i \) for each \( i, \) but when \( X \) is cofibrant one can decide for each \( i \) if this is the case or not. As there is only a finite number of such \( i, \) one can decide if it is the case for all \( i \) or not.

Proposition 1.2. The class of degeneracy quotients is stable under pullback.

Proof. See [23, Proposition 3.1.11].

By Proposition 1.2, if \( f : A \to B \) be a degeneracy quotient then \( f \times X : A \times X \to B \times X \) is again a degeneracy quotient for every \( X. \)

2. The comprehension category of cofibrant simplicial sets

The main goal of this section is to introduce the comprehension category of cofibrant simplicial sets. The results of simplicial homotopy theory that we obtain in the following sections will show how this comprehension category supports various type-theoretic constructions. We refer to [26] for the definition of a comprehension category and basic results and to [31] for the definitions categorical counterparts of the type-theoretic constructs.

Lemma 2.1.

(i) Let \( A, B \) be cofibrant simplicial sets. Then their product \( A \times B \) is cofibrant.

(ii) Let \( f : A \to X \) and \( g : B \to X \) be maps with cofibrant domain. Then their fiber product \( A \times_X B, \) fitting in the pullback diagram

\[
\begin{array}{ccc}
A \times_X B & \xrightarrow{g} & B \\
p \downarrow & & \downarrow g \\
A & \xrightarrow{f} & X,
\end{array}
\]

is cofibrant.

Proof. Part (i) follows immediately from the fact that the model structure on simplicial sets is cartesian, i.e. satisfies the pushout-product conditions.

For part (ii), \( A \times_X B \) is a sub-simplicial set of \( A \times B \) hence a cell of \( A \times_X B \) is degenerate if and only if it is degenerate as a cell of \( A \times B, \) hence degeneracy in \( A \times_X B \) is indeed decidable.

The next proposition introduces the comprehension category cofibrant simplicial sets. Recall that we write \( \text{SSet}_{\text{cof}} \) for the full subcategory of \( \text{SSet} \) spanned by cofibrant simplicial sets.

Proposition 2.2. The category \( \text{SSet}_{\text{cof}} \) is the base of a comprehension category of the form

\[
\begin{array}{ccc}
\text{Fib}_{\text{cof}} & \xrightarrow{x} & \text{SSet}_{\text{cof}} \\
p \downarrow & & \downarrow \text{cod} \\
\text{SSet}_{\text{cof}},
\end{array}
\]

where \( \text{Fib}_{\text{cof}} \) is the full subcategory of \( \text{SSet}_{\text{cof}}^{\text{cof}} \) spanned by fibrations.
Proof. Recall that the category $\text{SSet}_{\text{cof}}^\rightarrow$ is the arrow category of $\text{SSet}_{\text{cof}}$, whose objects are maps $p: A \to X$ between cofibrant objects. Then, the codomain functor

$$\text{cod} : \text{SSet}_{\text{cof}}^\rightarrow \to \text{SSet}_{\text{cof}}$$

is a Grothendieck fibration by part (ii) of Lemma 2.1. Since $\text{Fib}_{\text{cof}}$ is the full subcategory of $\text{SSet}_{\text{cof}}^\rightarrow$ spanned by fibrations and the comprehension functor $\chi$ is the inclusion, $p = \text{cod} \circ \chi$ and $\chi$ preserves pullbacks. $\square$

Remark 2.3. It is immediate to see that the comprehension category of cofibrant simplicial sets supports $\Sigma$-types. since for a fibration $p: A \to X$ between cofibrant objects, dependent sum along $p$ functor $\Sigma_p : \text{SSet}/A \to \text{SSet}/X$, which is defined by composition with $p$, maps fibrations to fibrations.

We conclude this section with some auxiliary results on cofibrant objects and cofibrations that will be useful in the following.

Proposition 2.4. Let $p: A \to X$ be a map with cofibrant domain. Then pullback along $p$,

$$p^* : \text{SSet}/X \to \text{SSet}/A,$$

preserves cofibrations.

Proof. Let $f : Y \to X$ be a cofibration and consider the pullback

$$\begin{array}{ccc}
A[f] & \to & A \\
\downarrow & \searrow & \downarrow p \\
Y & \to & X.
\end{array}$$

We need to show that the monomorphism $A[f] \hookrightarrow A$ is a cofibration. Since $A$ is cofibrant, it suffices to show that it is a levelwise complemented. For $a \in A_n$, we have that $a \in A[f]_n$ if and only if $p(a) \in Y_n$. Since $f : Y \hookrightarrow X$ is a levelwise complemented monomorphism, this is decidable. $\square$

Lemma 2.5.

(i) Let $X$ be cofibrant and $K$ finite and decidable. Then $X^K$ is cofibrant.

(ii) Let $f : A \to B$ be a degeneracy quotient of finite decidable simplicial sets and $X$ cofibrant. Then $X^f : X^B \to X^A$ is a cofibration between cofibrant objects.

Proof. For part (i), recall that an $n$-cell $\Delta[n] \to X^K$ is a morphism $\Delta[n] \times K \to X$. Now let $\sigma : \Delta[n] \to \Delta[m]$ be a degeneracy map. Then the map $\sigma \times K : \Delta[n] \times K \to \Delta[m] \times K$ is again degeneracy quotient. Since it is a map between finite decidable simplicial sets, the question of whether a map $\Delta[n] \times K \to X$ factor through $\Delta[n] \times K \to \Delta[m] \times K$ is decidable by Lemma 1.1. But this is exactly the question of degeneracy of cells in $X^K$. Similarly, for part (ii), since an $n$-cell of $X^A$ is a morphism $\Delta[n] \times A \to X$, it belongs to $X^B$ if and only it can be factored as $\Delta[n] \times A \to \Delta[n] \times B \to X$. This is decidable by Lemma 1.1 because $\Delta[n] \times A \to \Delta[n] \times B$ is a degeneracy quotient between finite decidable simplicial sets by part (i). $\square$

3. Identity types as path spaces

In this section we begin to show how the the comprehension category of cofibrant simplicial sets introduced in Proposition 2.2 supports various type-theoretic constructs by considering identity types. Following the fundamental insight in [4], in order to equip the comprehension category
with identity types it suffices to show that for every fibration \( p: A \to X \) with cofibrant domain, there is a fibration with cofibrant domain \( \delta: \text{id}_A \to A \times_X A \) and a trivial cofibration \( \text{refl}_A: A \to \text{id}_A \) that provide a factorisation of the diagonal map \( \delta_p: A \to A \times_X A \) [31]. While such a factorisation is guaranteed to exist by the model structure on \( \text{SSet} \), here we show that it can be obtained by letting \( \text{id}_A \) be a mapping path space. This is useful in order to support the intuition of elements of identity types as paths, a central idea in Homotopy Type Theory [39].

**Lemma 3.1.**

(i) Let \( X \) be cofibrant and \( A \) be fibrant. Then \( A^X \) is fibrant.

(ii) Let \( f: Y \to X \) be a cofibration and \( A \) be fibrant. Then \( A^f: A^X \to A^Y \) is a fibration.

(iii) Let \( f: Y \to X \) be a trivial cofibration and \( A \) be fibrant. Then \( A^f: A^X \to A^Y \) is a trivial fibration.

(iv) Let \( X \) be cofibrant and \( p: B \to A \) be a (trivial) fibration. Then \( p^X: B^X \to A^X \) is also a (trivial) fibration.

**Proof.** The claims follow easily from the pushout product property of the model structure. □

Interestingly, the cofibrancy assumptions of part (i) of Lemma 3.1 allows us also to prove the claim constructively following the combinatorial proof in [32], exploiting the decidability of degeneracy in \( X \) instead of appealing to the law of excluded middle.

For a simplicial set \( A \), we define its path object by letting \( \text{Path}(A) = \text{def} A^\Delta[1] \). There are evident boundary map \( \partial: \text{Path}(A) \to A \times A \), giving the endpoints of a path. We write \( \partial_0, \partial_1: \text{Path}(A) \to A \) for the compositions of \( \partial \) with the two projections and \( r: A \to \text{Path}(A) \) for the ‘constant path’ map.

**Proposition 3.2.** Assume that \( A \) is fibrant. Then,

(i) \( \text{Path}(A) \) is fibrant,

(ii) the boundary map \( \partial: \text{Path}(A) \to A \times A \) is a fibration,

(iii) the composite of \( \partial: \text{Path}(A) \to A \times A \) with either projection is a trivial fibration,

(iv) the map \( r: A \to \text{Path}(A) \) induced by the unique map \( \Delta[1] \to \Delta[0] \) is a weak equivalence.

**Proof.** Part (i) is just a special case of part (i) of Lemma 3.1. For part (ii), apply part (ii) of Lemma 3.1 to the cofibration \( i^1: \partial \Delta[1] \hookrightarrow \Delta[1] \). For part (iii), apply part (iii) of Lemma 3.1 to the horn inclusions \( h^k_\lambda: \Lambda^k[1] \to \Delta[1] \). Part (iv) follows from the 3-for-2 property for weak equivalences applied to \( A \to A^{\Delta[1]} \to A \). Indeed, the composite is the identity and the second factor has just been proved to be a trivial fibration. □

In order to interpret identity types, we need \( \text{Path}(A) \) to be cofibrant and the map \( r: A \to \text{Path}(A) \) to be a trivial cofibration. This is achieved by the following proposition.

**Proposition 3.3.** Let \( A \) be cofibrant. Then \( \text{Path}(A) \) is cofibrant and the map \( r: A \to \text{Path}(A) \) is a cofibration.

**Proof.** This follows from part (iii) of Lemma 2.5, applied to the cofibrant simplicial set \( X \), and the degeneracy map between finite simplicial sets \( \Delta[1] \to \Delta[0] \). □

We now define mapping path spaces and extend Proposition 3.2 and Proposition 3.3. Given a map \( p: A \to X \), we define \( \text{Path}(p) \) via the pullback diagram

\[
\begin{array}{ccc}
\text{Path}(p) & \longrightarrow & \text{Path}(A) \\
\downarrow & & \downarrow \\
X & \underset{r_X}{\longrightarrow} & \text{Path}(X)
\end{array}
\]
The structural maps $r_p: A \to \text{Path}(p)$ and $\partial: \text{Path}(p) \to A \times X$ are produced by the diagram:

\[
\begin{array}{c}
A \\
\downarrow \quad r \\
\text{Path}(p) \\
\quad \downarrow \quad \partial \\
A \times X \\
\end{array}
\quad A \\
\downarrow \\
\text{Path}(A) \\
\quad \downarrow \\
A \times A
\]

where the three square in the vertical/diagonal direction are pullbacks. As before, the maps $\partial_0, \partial_1: \text{Path}(A) \to A$ are defined as the composites of $\partial$ with the two projections.

**Theorem 3.4.** Assume that $p: A \to X$ is a fibration between cofibrant objects. Then,

(i) $\text{Path}(p)$ is cofibrant,

(ii) the map $\text{Path}(p) \to X$ is a fibration,

(iii) the map $\partial: \text{Path}(p) \to A \times X$ is a fibration,

(iv) $\partial_k: \text{Path}(p) \to A \times X$ is a trivial fibration, for $k \in \{0, 1\}$,

(v) the map $r_p: A \to \text{Path}(p)$ is a trivial cofibration.

**Proof.** The map $\text{Path}(p) \to X$ is a pullback of the maps $\text{Path}(A) \to \text{Path}(X)$ along $X \to \text{Path}(X)$. Hence, since $\text{Path}(A) \to \text{Path}(X)$ is a fibration (by part (iv) of Lemma 3.1), the map $\text{Path}(p) \to X$ is a fibration. Since $X$ is cofibrant by assumption and $\text{Path}(A)$ is cofibrant by Proposition 3.3, we have that $\text{Path}(p)$ is also cofibrant by Lemma 2.1.

By the dual of the pushout-product property, the map $\langle \partial \Delta[n] \hookrightarrow \Delta[n], A \to X \rangle$ is a trivial fibration. This map is

\[
\text{Path}(A) \to (A \times A) \times_X \text{Path}(X)
\]

Moreover, in the diagram

\[
\begin{array}{c}
\text{Path}(p) \\
\downarrow \\
\text{Path}(A)
\end{array}
\quad \begin{array}{c}
\downarrow \\
\downarrow
\end{array}
\quad \begin{array}{c}
A \times X \\
\downarrow \\
A \\
\downarrow \\
X
\end{array}
\quad \begin{array}{c}
\downarrow \\
\downarrow
\end{array}
\quad \begin{array}{c}
\text{Path}(X) \\
\downarrow \\
\text{Path}(X)
\end{array}
\]

the right hand square is easily seen to be a pullback and the total rectangle is the pullback defining $\text{Path}(p)$, hence the left hand square is also a pullback. Since the bottom left map is a fibration, $\text{Path}(p) \to A \times X$ is a fibration as well.

By a similar argument, for $k \in \{0, 1\}$, the map $\langle \Lambda^k[n] \hookrightarrow \Delta[n], A \to X \rangle$ is a trivial fibration. Indeed, this is the map $\text{Path}(A) \to A \times X \text{Path}(X)$ which fits into the pullback diagrams

\[
\begin{array}{c}
\text{Path}(p) \\
\downarrow \\
\text{Path}(A)
\end{array}
\quad \begin{array}{c}
\downarrow \\
\downarrow
\end{array}
\quad \begin{array}{c}
A \times X \\
\downarrow \\
A \\
\downarrow \\
X
\end{array}
\quad \begin{array}{c}
\downarrow \\
\downarrow
\end{array}
\quad \begin{array}{c}
\text{Path}(X) \\
\downarrow \\
\text{Path}(X)
\end{array}
\]

which shows that the canonical maps $\partial_k: \text{Path}(p) \to A$ are trivial fibrations.
We conclude by showing that the map $A \rightarrow \text{Path}(p)$ is levelwise complemented. Indeed, it fits into a factorization

$$A \rightarrow \text{Path}(p) \rightarrow \text{Path}(A)$$

of a map which has been proved to be a levelwise complemented inclusion in Proposition 3.3 and therefore for any cell of $\text{Path}(p)$ one can decide if it is in $A$ or not by considering it as a cell of $\text{Path}(A)$. Since $A$ and $\text{Path}(A)$ are cofibrant, this shows that $A \rightarrow \text{Path}(p)$ is a cofibration. The 3-for-2 property for weak equivalences applied to $A \rightarrow \text{Path}(p) \rightarrow A$ show that $A \rightarrow \text{Path}(p)$ is moreover a weak equivalence, hence a trivial cofibration. □

4. Π-types via cofibrant replacements

The aim of this section is to prove the results of simplicial homotopy theory necessary to show that the comprehension category of cofibrant simplicial sets supports Π-types. In order to do this, we should consider a fibration with cofibrant domain $p: A \rightarrow X$ and define an operation mapping a fibration with cofibrant domain $q: B \rightarrow A$ to a new fibration with cofibrant domain $\tilde{\Pi}_p(q): \tilde{\Pi}_A(B) \rightarrow X$ together with additional data [31]. Given such a map $q: B \rightarrow A$, we proceed in two steps. First, we apply the dependent product along $p$,

$$\Pi_p: \text{SSet}_{/A} \rightarrow \text{SSet}_{/X},$$

to $q: B \rightarrow A$ and obtain a map $\Pi_p(q): \Pi_A(B) \rightarrow X$, which we will show to be again a fibration. Since this fibration does not seem to have cofibrant domain in general, we then apply a cofibrant replacement in $\text{SSet}_{/X}$ to $\Pi_p(q): \Pi_A(B) \rightarrow X$ so as to obtain a map with all the desired properties. Remarkably, the result will support a categorical counterpart of the propositional η-rule.

Below, we show that, for a fibration $p: A \rightarrow X$ with cofibrant domain, the dependent product along $p$ preserves fibrations. By adjointness, this is equivalent to showing that its left adjoint, i.e. pullback along $f$, preserves trivial cofibrations. This amounts to proving a restricted version of the Frobenius property [9], obtained by considering pullbacks along fibrations with cofibrant domain rather than general fibrations. By the results in [8] these cofibrancy assumptions are essential in our constructive setting.

**Theorem 4.1.** Let $p: A \rightarrow X$ be a fibration with cofibrant domain,

(i) The pullback functor $p^*: \text{SSet}_{/X} \rightarrow \text{SSet}_{/A}$ preserves fibrations.

(ii) The dependent product $\Pi_p: \text{SSet}_{/A} \rightarrow \text{SSet}_{/X}$ preserves fibrations.

**Proof.** Part (i) follows from Proposition 2.4 which show that it preserves cofibrations, together with the right properness of the simplicial model structure which shows that it preserve weak equivalences. Part (ii) follows from part (i) as $\Pi_p$ is right adjoint to $p^*$. □

Another proof of Theorem 4.1 is given in [20] modifying appropriately the arguments in [19].

**Remark 4.2.** We define explicitly how the Π-types of the comprehension category of cofibrant simplicial sets are defined. For this, let us recall that, for maps $p: A \rightarrow X$ and $q: B \rightarrow A$, the dependent product $\Pi_p(q): \Pi_A(B) \rightarrow X$ is equipped with a map

$$\text{app}: \Pi_A(B) \times_A A \rightarrow B$$

in $\text{SSet}_{/A}$ which is universal in the sense that, for every $Y \rightarrow X$, the function

$$\text{SSet}_{/X}[Y, \Pi_A(B)] \quad \rightarrow \quad \text{SSet}_{/A}[Y \times_A A, B]$$

$$f \quad \mapsto \quad \text{app}(f \times_A 1_A)$$
is a bijection. This means that we have a function $\lambda$ in the opposite direction such that
\[
\text{app}(\lambda(b) \times_A 1_A) = b, \quad \lambda(\text{app}(f \times_A 1_A)) = f,
\] (4.1)
for every $b: Y \times_A A \to B$ and $f: Y \to \Pi_A(B)$. These equations correspond to the well-known judgemental $\beta$-rule and $\eta$-rule for $\Pi$-types, respectively.

When $p$ and $q$ are fibrations and $A$ is cofibrant, the map $\Pi_p(q): \Pi_A(B) \to X$ is a fibration by Theorem 4.1 but $\Pi_A(B)$ is not cofibrant in general. Thus, we interpret $\Pi$-types as the cofibrant replacement of $\Pi_A(B)$, which is given by a cofibrant simplicial set $L(\Pi_A(B))$ equipped with a trivial fibration $\varepsilon: L(\Pi_A(B)) \to \Pi_A(B)$. We then define $\tilde{\text{app}}: L(\Pi_A(B)) \times A \to B$ by letting
\[
\tilde{\text{app}} = \text{app} \circ (\varepsilon \times_A 1_A).
\]
For a bifibrant simplicial set $Y$ and maps $Y \to X$, $b: Y \times_A A \to B$, we define $\tilde{\lambda}(b): Y \to L(B^A)$ to be the diagonal filler
\[
\begin{array}{ccc}
0 & \longrightarrow & L(\Pi_A(B)) \\
\downarrow & & \downarrow \varepsilon \\
Y & \xrightarrow{\lambda(b)} & \Pi_A(B),
\end{array}
\]
which exists since $Y$ is cofibrant and $\varepsilon$ is a trivial fibration. It follows immediately that
\[
\tilde{\text{app}}(\tilde{\lambda}(b) \times_A 1_A) = b,
\]
so the $\beta$-rule holds as an equality. Instead, for $f: X \to L(\Pi_A(B))$, we have a homotopy
\[
\eta_f: \tilde{\lambda}(\tilde{\text{app}}(f \times_A 1_A)) \sim f,
\]
which is constructed as the diagonal filler in the following diagram
\[
\begin{array}{ccc}
\partial \Delta[1] \times Y & \xrightarrow{[f, \tilde{\lambda}(f \times_A 1_A)]} & L(\Pi_A(B)) \\
\downarrow & & \downarrow \varepsilon \\
\Delta[1] \times Y & \longrightarrow & \Pi_A(B),
\end{array}
\]
where the bottom map is the constant homotopy given by the equality in the $\eta$-rule in (4.1).

5. The weak equivalence extension property

The main goal of this section is to prove the so-called weak equivalence extension property, which will be the key to prove the univalence of the classifying fibrations considered in Sections 6 and 7. For this, we follow closely the approach in [29], but exploiting crucially the cofibrancy requirements that are part of our set-up.

**Lemma 5.1.** Let $f: Y \to X$ be a cofibration between cofibrant objects.

(i) The dependent product along $f$, $\Pi_f: \text{SSet}/Y \to \text{SSet}/X$, preserves trivial fibrations.
(ii) The counit of the adjunction $f^* \dashv \Pi_f$ is a natural isomorphism.
(iii) If $q: B \to Y$ is a map with cofibrant domain, then $\Pi_f(q): \Pi_Y(B) \to X$ is so.
(iv) Trivial fibrations extend along \( f \), i.e. given a trivial fibration \( q: B \rightarrow Y \) as in the solid diagram

\[
\begin{array}{ccc}
B & \xrightarrow{f} & A \\
\downarrow{q} & & \downarrow{p} \\
Y & \xrightarrow{f} & X,
\end{array}
\]

then there exists a trivial fibration \( p: A \rightarrow X \) which fits in the dotted pullback square above. Moreover if \( B \) is cofibrant then \( A \) can be chosen to be cofibrant as well.

**Proof.** We prove the different parts separately.

For part (i), since the dependent product functor \( \Pi_f \) is right adjoint to the pullback functor \( f^* \) and trivial fibrations are the maps with the the right lifting property with respect to cofibrations, \( \Pi_f \) preserves trivial fibrations if and only if \( f^* \) preserves cofibrations. But this follows by Proposition 2.4.

For part (ii), since \( f \) is a monomorphism, \( \Sigma_f: \text{SSet}/X \rightarrow \text{SSet}/Y \) is fully faithful and hence the unit \( \eta: 1 \rightarrow f^*\Sigma_f \) is an isomorphism. By adjointness, the counit \( \varepsilon: f^*\Pi_f \rightarrow 1 \) is also an isomorphism.

For part (iii), Let \( y: \Delta[n] \rightarrow \Pi_Y(B) \) be a \( k \)-cell, we will show that for a given degeneracy \( \sigma: [n] \rightarrow [k] \) it is decidable if \( y \) is “\( \sigma \)-degenerated”, i.e. if \( y \) factors through \( \Delta[n] \rightarrow \Delta[k] \). As degeneracy is decidable in \( Y \), one can freely assume that the image of \( y \) in \( Y \) is \( \sigma \)-degenerated (as if it is not the case, \( y \) is not \( \sigma \)-degenerated) hence one has a solid diagram:

\[
\begin{array}{ccc}
\Delta[n] & \xrightarrow{\sigma} & \Pi_Y(B) \\
\downarrow{\sigma} & & \downarrow{?} \\
\Delta[k] & \rightarrow & X.
\end{array}
\]

Because of the adjunction between dependent product and the pullback along \( f \), the existence of a lift as above is equivalent to the existence of a lift in:

\[
\begin{array}{ccc}
f^*\Delta[n] & \xrightarrow{x} & B \\
f^*\sigma & \downarrow & \downarrow \\
f^*\Delta[k] & \rightarrow & Y.
\end{array}
\]

The objects \( f^*\Delta[n] \) and \( f^*\Delta[k] \) are decidable simplicial subset of \( \Delta[n] \) and \( \Delta[k] \) because \( f \) is itself a levelwise complemented monomorphism, hence they are both finite decidable simplicial sets. The map \( f^*\sigma \) is degeneracy quotient by Proposition 1.2), hence Lemma 1.1 shows that the existence of such a lift is decidable (as degeneracy quotients are epimorphisms, the existence of lift making the upper triangle commutes is equivalent to the existence of lift making the square commutes).

For part (iv), given a trivial fibration \( q: B \rightarrow Y \), define \( p: A \rightarrow X \) to be \( \Pi_f(q): \Pi_Y(B) \rightarrow Y \). This map is a trivial fibration by part (i) and the square is a pullback by part (ii). The final remark about the cofibrancy of \( A \) follows from part (iii). □
Proposition 5.2 (Weak equivalence extension property). Let

\[
\begin{array}{ccc}
B & \xrightarrow{q} & A \\
\downarrow{f} & & \downarrow{p} \\
Y & \xrightarrow{Y} & X,
\end{array}
\]

be a commutative diagram with \( p: A \to X \) and \( q: B \to Y \) be fibrations with cofibrant domains, \( f: Y \to X \) a cofibration and such that the map \( u: B \to A[f] \) defined by \( u \overset{\text{def}}{=} (q, g) \), fitting the diagram of solid maps

\[
\begin{array}{ccc}
B & \xrightarrow{u} & B \\
\downarrow{q} & & \downarrow{q} \\
A[f] & \xrightarrow{v} & A \\
\downarrow{f} & & \downarrow{p} \\
Y & \xrightarrow{f} & X,
\end{array}
\]

is a weak equivalence in \( \text{SSet}_{/Y} \). Then there exist a fibration \( \bar{q}: \bar{B} \to X \), a weak equivalence \( v: \bar{B} \to A \) in \( \text{SSet}_{/X} \) and a map \( B \to \bar{B} \) such that both squares in the diagram above are pullbacks.

**Proof.** We define the required object \( \bar{B} \) as the following pullback:

\[
\begin{array}{ccc}
\bar{B} & \xrightarrow{\eta_A} & \Pi_{Y}(B) \\
\downarrow & & \downarrow \\
A & \xrightarrow{\eta_A} & \Pi_{Y}(A[f]),
\end{array}
\]

where \( \eta_A \) is a component of the unit of adjunction \( f^* \dashv \Pi_f \). An application of the pullback \( f^*: \text{SSet}_{/X} \to \text{SSet}_{/Y} \) to this square gives the commutative square

\[
\begin{array}{ccc}
B[f] & \xrightarrow{\eta_A} & B \\
\downarrow & & \downarrow \\
A[f] & \xrightarrow{\eta_A} & A[f],
\end{array}
\]

which is a pullback since \( f^* \Pi_f \cong 1 \) by part (ii) Lemma 5.1. Hence \( B \cong B[f] \), as required.

Since \( B \) is cofibrant, we have that \( \Pi_{Y}(B) \) is cofibrant by part (iii) of Lemma 5.1. Hence, the simplicial set \( \bar{B} \) is also cofibrant by Lemma 2.1. Furthermore, the maps \( B \to \bar{B} \) and \( A[f] \to A \) are cofibrations by Proposition 2.4, as they are pullback of the cofibration \( f: Y \to X \).

It remains to prove that \( v: \bar{B} \to A \) is a weak equivalence and that \( q: \bar{B} \to X \) is a fibration. The map \( u \) can be factored into a trivial cofibration followed by a trivial fibration, and it is sufficient to prove these claims for each half of the factorization separately, i.e. when \( u \) is a trivial fibration and when it is a trivial cofibration.

If \( u \) is a trivial fibration, then its image under \( \Pi_f \) is a trivial fibration by part (i) of Lemma 5.1. Since the map \( \bar{B} \to A \) is a pullback of this map, it is also a trivial fibration. This also implies that the composite \( \bar{B} \to A \to X \) is a fibration.

We now assume that \( u: B \to A[f] \) is a trivial cofibration. Using that the maps from \( B \) and \( A[f] \) to \( Y \) are fibrations, we can show that \( u \) is a strong deformation retract over \( Y \), i.e. there is
a retraction $r: A[f] \to B$ of $u$ in $\textbf{SSet}_{/Y}$ and a homotopy
between $u \circ r$ and $1_{A[f]}$, whose composite with $A[f] \to Y$ is the trivial homotopy. Indeed, $r$ and $H$ are respectively constructed as the dotted diagonal liftings in the squares:

\[
\begin{array}{ccc}
B & \rightarrow & A[f] +_B (B \times \Delta[1]) +_B A[f] \\
\downarrow r & \downarrow & \downarrow H \\
\end{array}
\]

We want to show that $\bar{B} \to A$ is also a deformation retract by constructing a similar homotopy $H': \Delta[1] \times A \to A$.

This homotopy will be constructed so that it is $H$ on $\Delta[1] \times A[f]$, it is the map $\Delta[1] \times B \to \Delta[0] \times B \cong B \to A$ on $\Delta[0] \times B$ (indeed they agree on $\Delta[1] \times B$) and it is the identity on $\Delta[0] \times A$. This is achieved by taking a diagonal filling in the square:

\[
\begin{array}{ccc}
(\Delta[1] \times (B \cup A[f])) \cup (\Delta[0] \times A) & \rightarrow & A \\
\downarrow & \downarrow & \downarrow w' \\
\Delta[1] \times A & \rightarrow & X
\end{array}
\]

Such a diagonal filler exists since the map on the left-hand side is a trivial cofibration, being the pushout-product of $Y_0: \Delta[0] \to \Delta[1]$, and the cofibration $\bar{B} \cup A[f] \to A$, and the map on the right-hand side is a fibration by assumption.

It remains to see that the map $H_1: A \to A$ is indeed a retraction of $\bar{B} \to A$. We already know that the restriction of $H_1$ to $\bar{B}$ is the inclusion of $\bar{B}$ in $A$, so it is enough to show that $H_1$ has values in $\bar{B}$. We also know that $H_1$ restricted to $A[f]$ takes values in $B \subseteq B$. By definition of $\bar{B}$, the map $H_1$ factor into $\bar{B}$ if and only if it takes values in $\Pi_Y(B)$ when seen as a map to $\Pi_Y(A[f])$, and by adjunction this is the case if and only if the map corresponding to $H_1$, $A[f] = f^*(A) \to A[f]$ takes values in $B$, but already mentioned above that this was indeed the case.

Since $\bar{B} \to A$ is a deformation retract, it is invertible in the homotopy category and so it is a weak equivalence. The construction above also shows that $B$ is retract of $A$ in $\textbf{SSet}_{/X}$ and hence $q: \bar{B} \to X$ is a fibration because $p: A \to X$ is.

Another proof of Theorem 4.1 is given in [20] modifying appropriately the arguments in [35].

6. A classifying small fibration between bifibrant objects

The aim of this section is to begin establishing the results necessary to have a pseudo Tarski universe satisfying the univalence axiom in the comprehension category of cofibrant simplicial sets. For this, we need to define a cofibrant Kan complex $U_c$ and a Kan fibration with cofibrant domain $\pi_c: \overline{U}_c \to U_c$. The closure of the type-theoretic universe under various type-formation operations corresponds to the closure of the class of maps arising as pullbacks of $\pi_c$ under the operations necessary to interpret the corresponding types. For this, it is convenient to consider $\pi_c$ to be a fibration that classifies small fibrations between cofibrant simplicial sets, i.e. such that
for every such fibration \( p: A \to X \) there exists a map \( a: X \to \mathcal{U}_c \) fitting in a pullback diagram of the form

\[
\begin{array}{ccc}
A & \to & \mathcal{U}_c \\
\downarrow p & & \downarrow \pi_c \\
X & \to & \mathcal{U}_c.
\end{array}
\]

Here, note that we make no requirement for the map \( a \) to be unique, in contrast for example with the situation of the subobject classifier in an elementary topos. Indeed, the map \( a \) is not unique, but only unique up to a contractible space of choices, a fact that will be expressed by showing that \( \pi_c \) is univalent.

In this section, we limit ourselves to define \( \pi_c: \mathcal{U}_c \to \mathcal{U}_c \) and prove that it classifies small fibrations between cofibrant simplicial sets. We will then show that \( \mathcal{U}_c \) is bifibrant, that \( \mathcal{U}_c \) is cofibrant and that \( \pi_c \) is univalent in Section 7. For the goal of this section, we proceed in two steps. First, we modify the construction of the weak classifier for small fibrations in [29] to obtain a small fibration \( \pi: \mathcal{U} \to \mathcal{U} \) which classifies small fibrations with cofibrant fibers. Since the base of this fibration does not appear to be cofibrant, we then consider a suitable cofibrant replacement of \( \mathcal{U} \) and obtain the required fibration \( \pi_c: \mathcal{U}_c \to \mathcal{U}_c \) via a pullback.

As a preliminary step, let us recall that a simplicial set \( A \) is small if \( A_n \) is a small set for every \( [n] \in \Delta \) and that a map \( p: A \to X \) of simplicial sets is small if for every \( x: \Delta[n] \to X \) the simplicial set \( A[x] \) given by the pullback square

\[
\begin{array}{ccc}
A[x] & \to & A \\
\downarrow & & \downarrow p \\
\Delta[n] & \to & \Delta[n] \\
\end{array}
\]

is small. Let us also recall the construction of a map of simplicial sets \( \rho: \mathcal{V} \to \mathcal{V} \) that classifies small maps of simplicial sets, which is a special case of the results in [25] for arbitrary presheaf categories. For this, we use the equivalence in (1.1) and the notation associated to it. The simplicial set \( \mathcal{V} \) is defined by letting

\[
\mathcal{V}_n = \{ F: \Delta/[n]^\text{op} \to \text{Set} \mid \pi_F: \int F \to \Delta[n] \text{ is a small map} \}
\]

for \( [n] \in \Delta \). The object \( \mathcal{V} \) and the map \( \rho: \mathcal{V} \to \mathcal{V} \) are then defined in an evident way.

We now come to our first step, in which we define a small fibration \( \pi: \mathcal{U} \to \mathcal{U} \) which classifies the class of small fibrations with cofibrant fibers.

**Definition 6.1.** We say that a map \( p: A \to X \) has cofibrant fibers if for every \( x: \Delta[n] \to X \) the simplicial set \( A[x] \) given by the pullback square

\[
\begin{array}{ccc}
A[x] & \to & A \\
\downarrow & & \downarrow p \\
\Delta[n] & \to & \Delta[n] \\
\end{array}
\]

is cofibrant.

**Lemma 6.2.**

(i) If a map \( p: A \to X \) has cofibrant domain then it has cofibrant fibers.
(ii) If \( X \) is cofibrant and \( p: A \to X \) has cofibrant fibers then \( A \) is cofibrant.

**Proof.** Part (i) follows from Lemma 2.1. For part (ii), let \([n] \in \Delta, a \in A_n\). Since \( X \) is cofibrant, by the constructive version of the Eilenberg-Zilber lemma we can write \( p(a) \in X \) in a unique way as \( p(a) = s^*(x) \), where \( s: [n] \to [k] \) is a degeneracy and \( x \in X_k \) is a non-degenerate cell. Let \( x: \Delta[k] \to X \) be the corresponding map. We now form the pullback

\[
\begin{array}{ccc}
A[x] & \xrightarrow{w} & A \\
\downarrow & & \downarrow \rho \\
\Delta[k] & \xrightarrow{x} & X.
\end{array}
\]

By the universal property of the pullback, there is a unique cell \( e \in A[x] \) such that \( w(e) = a \), and the image of \( e \) in \( \Delta[k] \) is the cell \( s: [n] \to [k] \), whose image in \( X \) are both equal to \( p(a) = s^*(x) \).

Indeed as \( a = w(e) \) then if \( e \) is degenerate so \( a \) is. Conversely, assume that \( a = \sigma^*(y_1) \) for a non-trivial degeneracy \( \sigma \). Then \( p(a) = \sigma^*(x_1) \), hence by the uniqueness part of the Eilenberg-Zilber lemma for \( X \) one has that \( s = s_1 \circ \sigma \) for some degeneracy \( s_1 \), and \( x_1 = s_1^*(x') \). In particular, we get a unique cell \( e_1 \) of \( A[x] \) whose image in \( \Delta[n] \) and \( X \) are both equal as \( x_1 = s_1^*(x') \). Finally, the image of \( p^*(e_1) \) in \( \Delta[n] \) and \( A \) are also equal to \( x_1 = s_1^*(x') \). Hence \( p^*(e_1) = e \), which proves that \( e \) is degenerate as soon as \( a \) is. \( \square \)

Define a subobject \( U \subseteq V \) by letting, for \([n] \in \Delta\),

\[
U_n = \{ F \in V_n \mid \pi_F: \int F \to \Delta[n] \text{ is a small fibration and } \int F \text{ is cofibrant} \}.
\]

We then define the map \( \pi: U \to V \) via the pullback

\[
\begin{array}{ccc}
\mathbb{U} & \xrightarrow{\pi} & V \\
\downarrow & & \downarrow \rho \\
U & \longrightarrow & V.
\end{array}
\]

**Proposition 6.3.**

(i) The map \( \pi: \mathbb{U} \to U \) is a small fibration with cofibrant fibers.

(ii) The map \( \pi: \mathbb{U} \to U \) classifies small fibrations with cofibrant fibers, i.e. a map \( p: A \to X \) is a small fibrations with cofibrant fibers if and only if there is a map \( a: X \to U \) and a pullback of the form

\[
\begin{array}{ccc}
A & \xrightarrow{p} & \mathbb{U} \\
\downarrow & & \downarrow \pi \\
X & \xrightarrow{a} & U.
\end{array}
\]
Proof. We prove the two claims separately. For part (i), consider a map \( a: \Delta[n] \to U \) and the pullbacks

\[
\begin{array}{ccc}
A & \to & \overline{U} \\
p \downarrow & & \downarrow \pi \\
\Delta[n] & \to & U \\
\end{array}
\]

This shows that \( p: A \to \Delta[n] \) is isomorphic to \( \pi_F: \int F \to \Delta[n] \) in \( \mathbf{SSet}/\Delta[n] \), where \( F \) corresponds under the equivalence in (1.1) to \( a: \Delta[n] \to V \). Therefore, by definition of \( U \), \( A \) is cofibrant and \( p: A \to \Delta[n] \) is a small fibration. This implies that \( \pi: \overline{U} \to U \) is has cofibrant fibers. To show it is a fibration, we rewrite a general lifting problem against a horn inclusion \( h^k_n: \Lambda^k[n] \to \Delta[n] \) as follows:

\[
\begin{array}{ccc}
\Lambda^k[n] & \to & A \\
\downarrow & & \downarrow \pi \\
\Delta[n] & \to & \Delta[n] \\
\end{array}
\]

and then use that \( p: A \to \Delta[n] \) is a fibration.

For part (ii), if a map \( p: A \to X \) fits in a diagram as in the statement, then it is clearly a small fibration with cofibrant fibers. Conversely, let \( p: A \to X \) be a small fibration with cofibrant fibers. Being a small map, \( p \) fits into a pullback of the form

\[
\begin{array}{ccc}
A & \to & \overline{V} \\
p \downarrow & & \downarrow \rho \\
X & \to & V \\
\end{array}
\]

For each cell of \( X, x: \Delta[n] \to X \) the pullback \( A[x] \to \Delta[n] \) is a small fibration with cofibrant domain by the assumptions on \( p \), which means, by the definition of \( U \) that the image of the cell \( x \) in \( V \) belongs to \( U \). Hence \( X \to V \) factors in \( U \), and hence \( A \to X \) is actually the pullback of \( \overline{U} \to U \).

We now construct a fibration \( \pi_c: \overline{U} \to U_c \) that classifies small fibrations between cofibrant objects. In particular, the base \( U_c \) of this fibration will be cofibrant. In order to do this, let \( U_c \) be a cofibrant replacement of \( U \), which comes with a trivial fibration

\[
\tau: U_c \to U.
\]

We then define \( \overline{U}_c \) via the pullback

\[
\begin{array}{ccc}
\overline{U}_c & \to & \overline{U} \\
\pi \downarrow & & \downarrow \pi \\
U_c & \to & U \\
\end{array}
\]

We now prove that \( \pi_c: \overline{U}_c \to U_c \) has the required properties.

Theorem 6.4.

(i) \( \pi_c: \overline{U}_c \to U_c \) is a small fibration with cofibrant fibers and cofibrant codomain.
(ii) The map $\pi_c: U_c \to U_c$ classifies small fibrations between cofibrant objects, i.e. if a map $p: A \to X$, with $X$ cofibrant, is a small fibration between cofibrant objects if and only there exists a pullback diagram of the form

$$
\begin{array}{ccc}
A & \xrightarrow{j} & U_c \\
\downarrow{p} & & \downarrow{\pi_c} \\
X & \xrightarrow{a} & U_c \\
\end{array}
$$

**Proof.** For part (i), $U_c$ is cofibrant by construction and the rest of the claim follows from part (ii) of Proposition 6.3.

For part (ii), let $p: A \to X$ be a small fibration between cofibrant objects, by part (i) of Lemma 6.2, it has cofibrant fibers and hence by part (ii) of Proposition 6.3 there is a pullback diagram of the form

$$
\begin{array}{ccc}
A & \xrightarrow{j} & U \\
\downarrow{p} & & \downarrow{\pi} \\
X & \xrightarrow{a} & U \\
\end{array}
$$

Since $X$ is cofibrant, we have a diagonal filler in the diagram

$$
\begin{array}{ccc}
0 & \xrightarrow{n_c} & U_c \\
\downarrow{n_c} & & \downarrow{\tau} \\
X & \xrightarrow{a} & U \\
\end{array}
$$

We then obtain the diagram

$$
\begin{array}{ccc}
A & \xrightarrow{j} & U_c & \xrightarrow{\pi_c} & U \\
\downarrow{p} & & \downarrow{\pi_c} & & \downarrow{\pi} \\
X & \xrightarrow{a} & U_c & \xrightarrow{a} & U \\
\end{array}
$$

Here, the right-hand side square and the rectangle are pullbacks and therefore the left-hand side square is also a pullback. Hence $p$ is indeed a pullback of $U_c \to U_c$. Conversely, any pullback $p: A \to X$ of $U_c \to U_c$ is a small fibrations with cofibrant fibers, hence by part (ii) of 6.2, if $X$ is cofibrant, $p$ is small fibration between cofibrant objects. \(\square\)

7. Fibrancy and univalence of the universe

The aim of this section is to show that $U_c$ is a cofibrant Kan complex and that $\pi_c: U_c \to U_c$ is univalent. For this, let us first return to consider the fibration $\pi: \overline{U} \to U$ defined via the pullback in (6.1). Let $U^*$ be the simplicial set whose $n$-simplices are triples of the form $(F_0, F_1, \phi)$, where $F_0$ and $F_1$ are $n$-simplices of $U$, i.e. functors

$$
F_0, F_1: \Delta/_{[n]}^{op} \to \text{Set}
$$
Lemma 7.2. and trivial fibrations, hence also preserves weak equivalences between fibrant objects (either equivalence. This is the case because the pullback
\[\Delta[n],\]

where \(p_1\) and \(p_2\) are fibrations with cofibrant domain.

**Lemma 7.1.** \(U^+ \to U \times U\) is a fibration

**Proof.** Observe that \(U^+\) is exactly \(\Pi_p(\overline{U} \times \overline{U})\), where \(p: \overline{U} \times U \to U \times U\) is the evident map. It follows from Theorem 4.1 that \(U^+ \to U \times U\) is a fibration. More precisely, Theorem 4.1 implies that any pullback of \(U^+ \to U \times U\) to a cofibrant \(X \to U \times U\) is a fibration (due to the cofibrancy assumption of Theorem 4.1), but this is sufficient to prove that \(U^+ \to U \times U\) is a fibration, as in the argument for part (i) of Proposition 6.3. \(\square\)

We define \(\text{Weq}(U)\) as the simplicial subset of \(U^+\) whose \(n\)-simplices are the \(n\)-simplices \((F_1, F_2, \phi)\) of \(U^+\) such that the corresponding map \(f\) in (7.1) is a weak equivalence.

In order for \(\text{Weq}(U)\) to actually be a simplicial subset of \(U^+\), one needs to check that given two fibrations with cofibrant domain \(F_1: X_1 \to \Delta[n]\) and \(F_2: X_2 \to \Delta[n]\) and a weak equivalence \(\phi : F_1 \to F_2\) over \(\Delta[n]\), the pullback of \(\phi\) along any morphisms \(\Delta[m] \to \Delta[n]\) is again an equivalence. This is the case because the pullback \(\text{SSet}_{/\Delta[n]} \to \text{SSet}_{/\Delta[m]}\) preserves fibrations and trivial fibrations, hence also preserves weak equivalences between fibrant objects (either by Ken Brown’s lemma or because it is a right Quillen functor).

**Lemma 7.2.** For any cofibrant object \(X\), a map \(a : X \to U^+\) factors via \(\text{Weq}(U)\) if and only the map in \(\text{BFib}_{/X}\) classified by \(a\),

\[
\begin{array}{ccc}
A_1 & \xrightarrow{w} & A_2 \\
p_1 & \swarrow & \searrow p_2 \\
X & & \Delta[n],
\end{array}
\]

is a weak equivalence.

**Proof.** By definition of \(\text{Weq}(U)\), a factors via \(\text{Weq}(U)\) if and only if the pullback of \(w: A_1 \to A_2\) along any simplex \(x: \Delta[n] \to X\) is a weak equivalence. As observed above, pullbacks preserves equivalences between fibrations so this is indeed the case if \(w\) is an equivalence.

Conversely, we let \(w: A_1 \to A_2\) be a map between bifibrant objects of \(\text{SSet}_{/X}\), assume that the pullback of \(w\) along every \(x: \Delta[n] \to X\) is a weak equivalence and show that \(w\) is also a weak equivalence. One factors \(w = pj\) as a trivial cofibration \(j\) followed by a fibration \(p\) and we will show that \(p\) is a trivial fibration. For any \(x: \Delta[n] \to X\), the pullback of \(x^*w\) is an equivalence by assumption and the pullback of \(x^*j\) is an equivalence by the first part of the proof, hence by the 3-for-2 property for weak equivalences, the pullback of \(x^*p\) is also an equivalence, and hence a trivial fibration.

To conclude, let \(p : Y_1 \to Y_2\) be a fibration in \(\text{SSet}_{/X}\) such that for all cell \(x : \Delta[n] \to X\) the morphism \(x^*p: \Delta[n] \times_X Y_1 \to \Delta[n] \times_X Y_2\) is a trivial fibration, we show that \(p\) is a trivial fibration. Indeed, given any lifting problem of \(\partial \Delta[n] \to \Delta[n]\) against \(p\), one can consider the composite of \(x : \Delta[n] \to Y_2 \to X\), take the pullback \(x^*p\) of \(p\) along this map, using that this pullback is a trivial fibration one obtains the lift:
Lemma 7.3. The map $\text{Weq}(U) \to U^\rightarrow$ is a fibration.

Proof. Let $f: Y \to X$ be a trivial cofibration between cofibrant objects and consider the diagram

$$
\begin{array}{c}
Y \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
\text{Weq}(U) \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
X
\end{array}
$$

Such a lifting exists if and only if the map $\overline{a}: A_1 \to A_2$ in $\text{SSet}_{/X}$ classified by $a$ is a weak equivalence. Its pullback $f^*(\overline{a})$, fitting in the diagram:

$$
\begin{array}{c}
f^*(A_1) \\
\downarrow \quad \downarrow \\
A_1
\end{array}
\begin{array}{c}
f^*(A_2) \\
\downarrow \quad \downarrow \\
A_2
\end{array}
\begin{array}{c}
Y \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
\text{Weq}(U) \\
\downarrow \quad \downarrow \\
X
\end{array}
$$

is a weak equivalence, because the map $Y \to U^\rightarrow$ corresponding to it factors into $\text{Weq}(U)$.

Since the maps $p_i: A_i \to X$ (for $i = 1, 2$) are fibrations with cofibrant domain, Theorem 4.1 implies that pullbacks of trivial cofibrations between cofibrant objects along such a map are trivial cofibrations. This implies that all the horizontal maps of the diagram above are weak equivalence, and so $\overline{a}$ as well. This shows that $\text{Weq}(U) \to U^\rightarrow$ is a fibration.

Theorem 7.4.

(i) The simplicial set $U$ is fibrant.

(ii) The simplicial set $U_c$ is bifibrant.

Proof. We prove part (i). Since $(s,t): \text{Weq}(U) \to U \times U$ is a fibration, for any cofibrant simplicial set $X$, maps $a_1, a_2: X \to U$ and homotopy $h: \Delta[1] \times X \to U$ from $a_1$ to $a_2$, there is a weak equivalence in $\text{SSet}_{/X}$ between the objects classified by $a_1$ and $a_2$, constructed as follows. For this, we first consider a diagonal filler in the diagram

$$
\begin{array}{c}
X \\
\downarrow \quad \downarrow \\
\text{Weq}(U)
\end{array}
\begin{array}{c}
\Delta[1] \times X \\
\downarrow \quad \downarrow (a_1,h) \\
U \times U
\end{array}
$$
Here, \( i_1 \) denotes a map classifying the identify of the object classified by \( a_1 \). By \( a_1 \) in the first component of the bottom arrow we mean the composite \( \Delta[1] \times X \to X \to U \). Composing the dotted arrow with \( \delta^1 \) gives us a map \( X \to \text{Weq}(U) \) whose projection to \( U \times U \) if \( (a_1, a_2) \), i.e. it classifies a weak equivalence between the objects classified by \( a_1 \) and \( a_2 \). One can do the same thing with \( \delta^0 \) and \( \delta^1 \) exchanged to get a weak equivalence in the other direction.

Using this fact, we can now prove that \( U \) is fibrant. A map \( h^k_n : \Lambda^k[n] \to U \) classifies a fibration \( q : B \to \Lambda^k[n] \) with cofibrant domain. The horn inclusions \( h^k_n : \Lambda^k[n] \to \Delta[n] \) fits into solid diagram of the form

\[
\begin{array}{cccccc}
\Lambda^k[n] & \rightarrow & (\Delta[1] \times \Lambda^k[n]) \cup \Delta[n] & \rightarrow & \Lambda^k[n] \\
\downarrow & & \downarrow & & \downarrow \\
\Delta[n] & \rightarrow & \Delta[1] \times \Delta[n] & \rightarrow & \Delta[n].
\end{array}
\]

Where the map \( \Delta[0] \to \Delta[1] \) can be either \( \delta^0 \) or \( \delta^1 \) depending on whether \( 0 < k \) or \( k < n \). See for example the last part of the proof of theorem 3.2.3 in [28].

By the observation above, the composite map \((\Delta[1] \times \Lambda^k[n]) \cup \Delta[n] \to \Lambda^k[n] \to U \) gives a solid diagram of the form

\[
\begin{array}{ccc}
B & \rightarrow & \Lambda^k[n] \\
\downarrow & & \downarrow h^k_n \\
\Lambda^k[n] & \rightarrow & \Delta[n]
\end{array}
\]

So we can construct a fibration \( \bar{q} : \bar{B} \to \Delta[n] \) with cofibrant domain whose pullback along \( h^k_n \) is isomorphic to \( q : B \to \Lambda^k[n] \). The map \( b : \Delta[n] \to U \) classifying \( \bar{q} \) gives the lift we are looking for. More precisely, we can use \( q : B \to \Delta[n] \) to construct a map \( b : \Delta[n] \to U \) which extend the one we started from and classifies an object isomorphic to \( \bar{B} \).

Part (ii) follows immediately from part (i) since \( \tau : U_c \to U \) is a trivial fibration.

We now wish to define what it means for a small fibration with cofibrant fibers, and in particular for a small fibration between cofibrant objects, to be univalent. For this, we fix such a fibration \( p : A \to X \) and construct an object \( \text{Weq}(p) \to X \times X \) that represents weak equivalences between fibers of \( p \), in the sense that maps \( Y \to \text{Weq}(p) \) in \( \text{SSet}_{/X \times X} \) are in bijective correspondence with triples \((x_1, x_2, w)\) consisting of two map \( x_1, x_2 : Y \to X \) and a weak equivalence \( w : A[x_1] \to A[x_2] \) in \( \text{SSet}_{/Y} \). The required object \( \text{Weq}(p) \) can be constructed as the pullback

\[
\begin{array}{ccc}
\text{Weq}(p) & \rightarrow & \text{Weq}(U) \\
\downarrow & & \downarrow (s, t) \\
X \times X & \rightarrow & U \times U,
\end{array}
\]

where \( a : X \to U \) is a classifying map for the small fibration \( p : A \to X \), which exists by our assumption that \( A \) and \( X \) are cofibrant and part (iii) of Proposition 6.3. The verification that \( \text{Weq}(p) \) has the required universal property is an easy calculation, which we leave to the readers.

There is an evident map \( i : X \to \text{Weq}(p) \) corresponding via the universal property of \( \text{Weq}(p) \) to the triple of identity maps \((1_X, 1_X, 1_A)\).
Definition 7.5. Let \( p: A \to X \) be a small fibration with cofibrant fibers. We say that \( p \) is \textit{univalent} if the map \( i: X \to \text{Weq}(p) \) is a weak equivalence.

For a small fibration with cofibrant fibers \( p: A \to X \), being univalent is equivalent to either \( s: \text{Weq}(p) \to X \) or \( t: \text{Weq}(p) \to X \) being a trivial fibration. Also note that, when \( X \) is cofibrant, we have a map \( j: \text{Path}(X) \to \text{Weq}(p) \) fitting in the diagram

\[
\begin{array}{ccc}
X & \xrightarrow{i} & \text{Weq}(p) \\
\downarrow{r} & & \downarrow{(s,t)} \\
\text{Path}(X) & \xrightarrow{j} & X \times X \\
\end{array}
\]

In this case, \( p \) is univalent if and only if \( j \) is a weak equivalence, mirroring the type-theoretic definition of univalence. This will be the case for \( \pi_c: \overline{U}_c \to U_c \), for example.

Theorem 7.6.

(i) The fibration \( \pi: \overline{U} \to U \) is univalent.

(ii) The fibration \( \pi_c: U_c \to U_c \) is univalent.

Proof. For part (i), we prove that \( t: \text{Weq}(U) \to U \) has the right lifting property with respect to all cofibrations. So let \( f: Y \to X \) be a cofibration and consider the diagonal filling problem

\[
\begin{array}{ccc}
Y & \xrightarrow{f} & \text{Weq}(U) \\
\downarrow{Y} & & \downarrow{U} \\
X & \xrightarrow{i} & U \\
\end{array}
\]

By Lemma 7.2, this corresponds exactly to a diagram as in the equivalence extension property as in Proposition 5.2. Indeed, the map \( X \to U \) gives us \( p: A \to X \), the composite of \( Y \to \text{Weq}(U) \) with the first projection gives us \( q: B \to Y \), while the rest of the data and the commutativity of the square gives us a weak equivalence \( u \) between \( B \) and \( A[f] \) over \( X \). The completion of this diagram given by Proposition 5.2 is exactly what one needs to produce the required diagonal filler.

For part (ii), we prove that \( t: \text{Weq}(\pi_c) \to U_c \) is a trivial fibration. For this, let us observe that we have a diagram

\[
\begin{array}{ccc}
\text{Weq}(U_c) & \xrightarrow{\sigma} & \text{Weq}(U) \\
\downarrow{(s,t)} & & \downarrow{(s,t)} \\
U_c \times U_c & \xrightarrow{\tau \times \tau} & U \times U \\
\downarrow{\pi_2} & & \downarrow{\pi_2} \\
U_c & \xrightarrow{\tau} & U \\
\end{array}
\]

The composite on the left-hand side is the map \( t \) that we wish to show to be a trivial cofibration. First, using part (i), observe that it is a fibration since it is the composite of two fibrations. Secondly, observe that the top square is a pullback and so \( \sigma \) is a trivial fibration since \( \tau \times \tau \) is so. Thus, applying 3-for-2 to the outer square, we obtain that \( t \) is a weak equivalence and hence a trivial fibration, as required. \( \square \)
8. Conclusions and future work

We can now summarize our results using the comprehension category of cofibrant simplicial sets introduced in Proposition 2.2,

\[ \xymatrix{ \text{Fib}_{\text{cof}} \ar[r]^-{\chi} & \text{SSet}_{\text{cof}} \ar[l]_-{\text{cod}} \ar[d]^-{\text{P}} \ar[l]_-{\text{cof}} } \]

For this, we use the terminology of [31] regarding the stability conditions and that of [37, Appendix A] regarding the type-theoretic universe. When we say that the universe is closed under some constructions, we simply mean that the fibrations classified by the universe are closed under these constructions.

**Theorem 8.1.** The comprehension category of cofibrant simplicial sets has:

- a pseudo-stable empty type 0, unit type 1 and natural numbers type \( \mathbb{N} \),
- pseudo-stable + -types,
- partially pseudo-stable \( \text{id} \)-types,
- pseudo-stable \( \Sigma \)-types,
- weakly stable \( \Pi \)-types,
- a pseudo Tarski universe \( \pi_c : \overline{\mathbb{U}_c} \to \mathbb{U}_c \), containing 0, 1, \( \mathbb{N} \) and closed under the \( \Sigma \)-types, \( \text{id} \)-types, \( \Pi \)-types and + -types constructions.

Furthermore, the fibration \( \pi_c : \overline{\mathbb{U}_c} \to \mathbb{U}_c \) is univalent.

**Proof.** We have checked that this is indeed a comprehension category in Proposition 2.2. For 0, 1, and \( \mathbb{N} \), these are simply given by the discrete simplicial sets, which are cofibrant (as every cell of dimension \( > 0 \) is degenerated) and fibrant. For + types, we use coproducts observing that \( A + B \) is fibrant and cofibrant if \( A \) and \( B \) are so.

Identity types are constructed in Section 3. In particular, see Theorem 3.4. The construction of \( \text{id} \)-types themselves involves only categorical dependents products and pullbacks, which are all pseudo-stable, but the construction of the J-eliminator involves a lifting properties which is not pseudo-stable in general. Thus, we have partially pseudo-stable identity types, as in [31, Definition 2.3.4]. The \( \Sigma \)-types have been constructed in Remark 2.3 and are clearly stable under pullback up to isomorphism. The \( \Pi \)-types have been constructed in Section 4 as cofibrant replacement \( L\Pi AB \) of the categorical dependent products \( \Pi AB \). The categorical dependant products are pseudo-stable, so given such a \( \Pi \)-type \( L\Pi AB \), in context \( \Gamma \) its pullback \( f^*(L\Pi AB) \) along a context morphism \( f : \Gamma' \to \Gamma \) might be different from \( L\Pi f^*Af^*B \) but is also a cofibrant replacement of \( \Pi f^*Af^*B \) hence also has the property of being a \( \Pi \)-type.

Finally, in Section 6 we constructed the universe \( \overline{\mathbb{U}_c} \to \mathbb{U}_c \) as a classifier for all small fibrations between cofibrant objects. As small fibrations are stable under all the constructor above, this gives the stability of the universe. It has been shown in Theorem 7.6 in that this fibration is indeed univalent. Regarding the closure of the universe, the only delicate point concerns \( \Pi \)-types because of the use of the cofibrant replacement. The explicit definition of the cofibrant replacement functor in appendix A shows that the trivial fibration \( \varepsilon_X : L\mathbb{X} \to X \) is a small fibration for every \( X \), independently of whether \( X \) is small or not (see part (i) of Corollary A.9 for details). Hence the construction of \( \Pi \)-types preserves small fibrations, even between non-small objects. \( \square \)
Remark 8.2. The Π-types constructed in the present paper have stronger properties than being weakly stable Π-types as stated above. First, as explained in Remark 4.2, they satisfy a propositional \( \eta \)-rule, while [31] require no \( \eta \)-rule. Secondly, given our Π-type \( \mathbb{L}(\Pi_A B) \) over \( X \) in the sense of Theorem 8.1, and \( f : X' \to X \), then both \( f^*(\mathbb{L}(\Pi_A B)) \) and Π-type \( \mathbb{L}(\Pi f^*A f^*B) \) are both cofibrant replacements of \( f^*(\Pi A B) \cong \Pi f^*A f^*B \). Hence, they are homotopy equivalent.

Remark 8.3. Our proof that the universe is closed under Π-types relies on the assumption that the inaccessible set \( u \) satisfies a form of propositional resizing, as observed in Corollary A.9. If one wishes to avoid this additional assumption, there are at least two alternatives. The first alternative arises if one does not make the assumption that subsets of small sets are small and keeps all the definitions the same. Then, we still have a comprehension category with all the structure mentioned in Theorem 8.1, but do not have anymore that the universe is closed under the construction of arbitrary Π-types. Instead, one has (in type-theoretic notation) that if \( \Gamma, a : A \vdash B(a) : U_c \) then \( \Gamma \vdash \Pi_A B : U_c \) if \( \Gamma \) is a context involving only small types. The second alternative arises if one works instead in CZF without assuming any inaccessible sets, and changes to an interpretation where contexts are “simplicial classes” (where classes are formulas), general types are given by Kan fibrations between simplicial classes and a small fibrations is one whose fibers are sets. In this case, part (ii) of Corollary A.9 provides the smallness property that ensures that the cofibrant replacement preserves small type even in non-small context. We then have that the universe is closed under Π-type, but we cannot form general Π-types, but only those of the form \( \Pi A B \) where \( A \) is a small type.

Remark 8.4. A lack of strict stability for Π-types is also present in the semisimplicial model defined in [7]. This is of interest since cofibrant simplicial sets are closely connected to semisimplicial sets [23].

Remark 8.5. The main result of [31] assert that if a contextual category \( C \), satisfying the additional condition (LF) of [31, Definition 3.1.3]) has weakly stable type constructors, then left adjoint splitting \( C \) has the same constructors, but now strictly stable, thus solving the coherence problem. Unfortunately, condition (LF) is not satisfied in our constructive setting, essentially because cofibrant objects are generally not closed under dependent products.

We leave as an open problem the question of whether a comprehension category as in Theorem 8.1 can be split so as obtain a model of ML(UA) and so, in particular, obtain a constructive version of the simplicial model of ML(UA). It should be noted that this question is now completely independent from simplicial homotopy theory, as our results in this paper have obtained all the necessary results to produce the structure in Theorem 8.1. We also leave as open problem the question of whether our comprehension category supports other inductive types [10] and higher-inductive types in the sense of [39]. We expect these to work without the need to perform cofibrant replacements.

Finally, we mention as a potential area of further research the idea of designing a dependent type theory with explicit substitutions [1] with rules matching the structure of the comprehension category of Theorem 8.1, extending the idea of substitution up to isomorphism of [14] to that of substitution up to weak equivalence. A conservativity result of such a system over ML(UA) would then be essentially equivalent to a solution to the coherence problem, cf. [13].

Appendix A. The cofibrant replacement functor

The goal of this appendix is to give an explicit description of the cofibrant replacement functor on simplicial sets (Proposition A.7) and to use it to discuss the size of this cofibrant replacement.
Definition A.1.
(i) If \( x \in X_n \) is an \( n \)-cell in a simplicial set \( X \), the degeneracy type of \( x \) is the set of face maps \( \delta : [i] \to [n] \) such that \( \delta^*x \) is a degenerate cell.
(ii) By a degeneracy type or degeneracy n-type we mean a subset of faces of \( \Delta[n] \) that can appear as the degeneracy type of an \( n \)-cell of a simplicial sets.

Note that given any \( n \)-cell \( x \in X_n \), the factorization of \( x : \Delta[n] \to X \) as a degeneracy quotient followed by a degeneracy detecting morphism constructs a degeneracy quotient \( y : \Delta[n] \to K \) such that \( y \) has the same degeneracy type as \( x \). This induces a correspondence between degeneracy n-types and (isomorphism classes of) degeneracy quotients \( \Delta[n] \to K \).

Lemma A.2. A degeneracy n-type is the degeneracy type of a cell in a cofibrant object if and only if it is decidable as a subset of faces of \( \Delta[n] \).

Proof. Given an \( n \)-cell \( x \) in a cofibrant simplicial set \( X \), given any face \( \delta : [m] \to [n] \) it is decidable if \( \delta^*x \) is degenerated or not, hence the degeneracy type of \( x \) is decidable. Conversely, given any degeneracy type \( p \), it is the degeneracy type of a degeneracy quotient \( \Delta[n] \to K \). Any cell of \( K \) is the image of a cell of \( \Delta[n] \), and it is degenerated in \( K \) if and only if it is the image of a degenerated cell, or the image of a cell in \( p \). Hence if \( p \) is decidable \( K \) is cofibrant.

We will now construct a “simplicial set of decidable degeneracy type \( D^\circ \)”. Note that the construction would work exactly the same without the assumption “decidable”, with the exception that CZF do not has power set, this might not be a simplicial set, but rather a simplicial class.

We start with a simplicial set \( D_0 \) whose \( n \)-cells are all the decidable subset of the faces of \( \Delta[n] \), i.e. decidable subsets of the set of finite subsets of \([n]\). As decidable subsets are justs functions to \( \{0,1\} \) this is indeed a set. If \( f : [m] \to [n] \) and \( P \in D_0([n]) \) one defines \( f^*P \) as the set of faces \( [i] \to [m] \) such that the composite
\[
[i] \to [m] \xrightarrow{f} [n]
\]
is either in \( P \) or non-injective, which is indeed a decidable set of faces.

Lemma A.3. \( D_0 \) is a cofibrant simplicial set, and for any cofibrant simplicial set \( X \), the map \( X \to D_0 \) sending each \( n \) cell to its degeneracy type is a simplicial and degeneracy detecting map.

Proof. It is immediate to check that \( D_0 \) is a simplicial set. Moreover as if has decidable equality one can decide whether a cell \( x \) is degenerated by testing if it is equal to \( s^*d^*x \) for some non trivial face \( d \) and degeneracy \( s \), hence \( D_0 \) is cofibrant. Let \( x \in X_n \) and \( f : [m] \to [n] \), in order to check that the maps \( X \to D_0 \) sending each cell to its degeneracy type is simplicial, one need to check that the degeneracy type of \( f^*x \) is indeed described from the degeneracy type of \( x \) using the formula for the functoriality of \( D_0 \). For face maps \( [i] \to [m] \) the cell \( i^*f^*x \) is degenerated as soon as \( f \circ i \) is non injective, and if \( f \circ i \) is injective, then it depends on whether \( f \circ i \) is in the degeneracy type of \( x \) or not.

If \( f : [n] \to [m] \) is non-injective then for any \( s \in (D_0)_m \) the identity map \( [n] \to [n] \) is in \( f^*s \). So a degenerate cell of \( D_0 \) always contains the maximal face. In particular the map \( X \to D_0 \) constructed above send non-degenerate cell of \( X \) to non-degenerate cells of \( D_0 \).

Lemma A.3 constructs a map \( P : D_0 \to D_0 \) sending any cell to its degeneracy type. As \( P \) preserves and detects degeneracy, it preserves the degeneracy type and hence \( P \circ P = P \).

Definition A.4. The simplicial set \( D \) is the set of fix point of the idempotent \( P \) acting on \( D_0 \).
Note that for any simplicial set $X$, the map $f : X \to D_0$ sending each cell to its degeneracy type preserves the degeneracy type, hence $P f = f$. In particular a cell of $D_0$ is in $D$ if and only if it is a degeneracy type. This leads to the following fact.

**Lemma A.5.** $n$-cells of $D$ are in bijection with decidable degeneracy $n$-type. Each cofibrant simplicial set $X$ has a unique map detecting degeneracy to $D$, which is the map sending a cell to its degeneracy type. □

**Lemma A.6.** Given a map $\partial \Delta[n] \to D$ there is a unique way to extend it into map $\Delta[n] \to D$ such that the non-degenerate $n$-cell of $\Delta[n]$ is sent to a non-degenerate cell.

**Proof.** If such an extension exists the $n$-cell $x$ corresponding to $\Delta[n] \to D$ has to be as follows: $x$ does not contain the face $[n] \to [n]$, and for all other face $\delta : [i] \to [n]$ it is in $x$ is and only if the composite $[i] \to \partial \Delta[n] \to D$ is a degenerate cell. So the uniqueness is clear. We only need to show that this set is indeed a degeneracy type. But if one form $D \coprod_{\partial \Delta[n]} \Delta[n]$ then the new added $n$-cell has exactly this degeneracy type so this conclude the proof. □

Let $\varepsilon_X : \mathbb{L}X \to X$ be the cofibrant replacement of a simplicial set $X$ constructed using Richard Garner’s version of the small object argument [16].

**Proposition A.7.** The map $\mathbb{L}X \to D \times X$ sending an $n$-cell to its degeneracy type $s \in D$ and its image is $X$ induces a bijection between $\mathbb{L}X([n])$ and the set of pairs of a decidable degeneracy type $s$ and a cell of $x$ of degeneracy type larger than $s$.

**Proof.** Because of the stratified nature of the simplicial generating cofibration, $\mathbb{L}X$ can be written as the colimit of a sequence: $$\mathbb{L}^{(0)}X \hookrightarrow \mathbb{L}^{(1)}X \hookrightarrow \cdots \hookrightarrow \mathbb{L}^{(n)}X \hookrightarrow \cdots$$ where $\mathbb{L}^{(0)}X$ is just the set of 0-cell of $X$ and the map $\mathbb{L}^{(n-1)}X \to \mathbb{L}^{(n)}X$ is constructed as the pushout of the coproduct of one copy of $\partial \Delta[n] \to \Delta[n]$ for each square of the form:

\[
\begin{array}{ccc}
\partial \Delta[n] & \to & \mathbb{L}^{(n-1)}X \\
\downarrow & & \downarrow \\
\Delta[n] & \to & X
\end{array}
\]

Indeed, the pushout constructing $\mathbb{L}^{(n)}X$ from $\mathbb{L}^{(n-1)}X$ do not change the $k$-skeleton for $k < n$ and the set of maps $\partial \Delta[k] \to \mathbb{L}^{(n-1)}X$ only depends on the $k$-skeleton of $X$, so one can always do all the necessary pushout by $\partial \Delta[k] \hookrightarrow \Delta[k]$ by for $k < n$ before those by $\partial \Delta[n] \hookrightarrow \Delta[n]$.

We will prove by induction on $n$ that $\mathbb{L}^{(n)}X$ identifies with $n$-skeleton of the simplicial set mentioned in the proposition, i.e. the sub-simplicial set $Y^n$ of $D \times X$ of pairs $(s, x)$ such $s$ is decidable, the degeneracy type of $x$ is at least $s$ and $(s, x)$ is of dimension at most $n$, or a degeneracy of a cell of dimension at most $n$.

Note that as the degeneracy type of $x$ is larger than $s$, $s$ is the degeneracy type of the pair $(s, x)$, so the condition on $(s, x)$ being a degeneracy is equivalent to the same condition on $s$.

In the case $n = 0$, there is only one degeneracy type in dimension 0, so both $\mathbb{L}^{(0)}X$ and $Y^0$ are the simplicial set of cells of $X$ that are degeneracy of 0-cells.

Assuming $Y^{n-1}$ and $\mathbb{L}^{(n-1)}X$ are isomorphic as claimed. One only needs to check that the new non-degenerate $n$-cell that appears in $Y^n$ and $\mathbb{L}^{(n)}X$ are in bijection compatible to their boundary and their image in $X$. In $\mathbb{L}^{(n)}X$ there is exactly one such cell for each square as above. In $Y^n$, any non-degenerate $n$-cells does produce such a square, and conversely given a square:
Lemma A.6 above gives a unique map to extend \( \partial \Delta[n] \to D \) to a non-degenerate \( n \)-cell of \( D \), and the image of \( \Delta[n] \) in \( X \) automatically has a larger degeneracy type that this extension so this gives a non-degenerate cell of \( Y^n \) generating this square. This is the unique way to get such a cell in \( Y^n \) to be non-degenerate: indeed a cell in \( Y^n \) is non-degenerate if and only if its image in \( D \) is non-degenerate. \( \square \)

**Corollary A.8.** The simplicial set \( D \) of decidable degeneracy type is the cofibrant replacement \( \mathbb{L}1 \) of \( 1 \).

**Corollary A.9.**

(i) Under the assumption that “subsets of small sets are small sets”, the map \( \mathbb{L}X \to X \) is a small fibration for any simplicial set \( X \).

(ii) In CZF, given a simplicial class \( X \), the cofibrant replacement \( \mathbb{L}X \to X \) exists as a simplicial class, is cofibrant, and the class map \( \mathbb{L}X \to X \) is a trivial fibrations whose fibers are sets.

**Proof.** For part (i), the cells of \( \mathbb{L}X \) over a given cell \( x \in X([n]) \) are the decidable degeneracy \( n \)-types \( s \) smaller than the degeneracy type of \( x \). In particular this identifies with a subset of the set of all degeneracy \( n \)-types and hence form a small set by assumption.

For part (ii), the explicit description of \( \mathbb{L}X \) given by Proposition A.7 immediatly allows to make sense of it as a simplicial class. Indeed the class of \( (s, x) \) where \( x \in X_n, s \) is a decidable degeneracy type smaller than the degeneracy type of \( x \) is clearly a type. Such a pair \( (s, x) \) is degenerated if and only if \( s \) is, hence this is decidable, and using Lemma A.6 one can immediately see that the projection \( \varepsilon_X : \mathbb{L}X \to X \) is a trivial fibrations. Finally, the fiber over an \( n \)-cell \( x \in X \), is isomorphic to a subsets of the set of decidable degeneracy \( n \)-types defined by Restricted Separation, hence it is a set. \( \square \)
