THE DIRECT IMAGE OF GENERALIZED DIVISORS AND
THE NORM MAP BETWEEN COMPACTIFIED
JACOBIANS

RAFFAELE CARBONE

Abstract. Given a finite, flat morphism between embeddable noetherian schemes of pure dimension 1, we define the notion of direct and inverse image for generalized divisors and generalized line bundles. Moreover, in the case where we deal with projective curves over a field and the codomain curve is smooth, the above notions give rise to the direct and inverse image maps between Hilbert schemes and to the Norm and inverse image maps between compactified Jacobians.

Introduction

Let $\pi : X \to Y$ be a finite, flat morphism between noetherian curves. The first aim of this paper is to define and study the direct and inverse image for generalized divisors and generalized line bundles. Moreover, in the case when $X$ and $Y$ are projective curves over a field $k$, our aim is to define and study the direct and inverse image for families of generalized divisors, and the notion of Norm and inverse image for families of generalized line bundles.

Recall that the notion of Cartier divisor has been generalized by Hartshorne in his papers [Har94] and [Har07], in order to include as effective divisors any codimension-one subscheme without embedded points, defined also by more than a single equation. A generalized divisor on a curve $X$ of pure dimension 1 is a nondegenerate fractional ideal of $O_X$-modules. Moreover, recall that generalized divisors up to linear equivalence are equivalent to generalized line bundles, i.e. pure coherent sheaves which are locally free of rank 1 at each generic point.

The notions of direct and inverse image for Cartier divisors are well-known; these notions are compatible with linear equivalence, giving rise to analogous well-known maps for line bundles, called the Norm and the inverse image maps between the generalized Jacobians (see for example [Gro67, §21] and [HPT2]). To the best of our knowledge, the same notions for generalized divisors and generalized line bundles have not been discussed so far.

In the first part of this paper, we propose the definitions of the direct and inverse image for generalized divisors and generalized line bundles, and we study their properties. In the second part of the paper, restricting to the case when $X$ and $Y$ are projective curves over a field, we consider the same notions for families. On one hand, families of effective generalized divisors

2010 Mathematics Subject Classification. 14C20; 14H40, 14D20.
Key words and phrases. Generalized divisors, Generalized line bundles, Norm map, Compactified Jacobians.
on a curve $X$ are essentially families of subschemes of finite length, hence they are parametrized by the Hilbert scheme. On the other hand, families of generalized line bundles on $X$ are parametrized by the compactified Jacobian $\mathcal{J}(X)$, and in this case the direct image map is called Norm map in analogy with the Norm map defined between the generalized Jacobians of the curves. In both cases, we show that giving the definitions of the direct image and the Norm map on such moduli spaces is possible only when the curve $Y$ is smooth.

The structure of this paper is the following. In Section 4 we review in details the definition of direct and inverse image for Cartier divisors and the definition of Norm map for line bundles; we give also the definition of Norm map for families of line bundles. In Section 2 we review the theory of generalized divisors and generalized line bundles on a curve; we also introduce the geometric objects that parametrize well-behaved families of generalized divisors and generalized line bundles on a fixed curve. In Section 3 we recall briefly the notion of Fitting ideal associated to any coherent sheaf. In Section 4 we introduce and discuss in details the notion of direct and inverse image for generalized divisors and generalized line bundles. In Section 5 we study the notion of direct and inverse image for families of effective generalized divisors. Finally, in Section 6 we define the Norm map and the inverse image map between compactified Jacobians, and their relation with the generalized Abel map.

The motivation of this work comes from the Hitchin fibration for the moduli space of $G$-Higgs vector bundles on a fixed smooth and projective curve $C$, for $G$ varying among classical groups such as GL, SL, PGL, SO, Sp. When $G = GL$, the Hitchin fibres are compactified Jacobians of certain (possibly singular) covers of $C$, called spectral curves, associated to the fibre. For others $G$, a description of the generic Hitchin fibres (i.e. those for which the singular locus of the spectral curve is empty or as small as possible) is given with the help of a Prym variety, i.e. the locus in $J(X)$ of bundles whose Norm with respect to a given finite, flat morphism is zero. By studying the Norm map between compactified Jacobians, we hope to obtain a description of the remaining Hitchin fibres using “generalized” Prym varieties.

**Notation.** In the rest of the paper, by curve we refer to a noetherian scheme of pure dimension 1 which is embeddable (i.e. it can be embedded as a closed subscheme of a regular scheme). This implies that the canonical (or dualizing) sheaf $\omega_X$ of $X$ is well defined.

**Acknowledgements.** This work is part of the author’s PhD thesis under the supervision of Filippo Viviani. I would like to thank him for suggesting the problem and for his continuous guidance and proofreading. I would also like to thank Edoardo Sernesi for helpful comments and discussions. Finally, I warmly thank Fabrizio Anella for his continuous help and his patient listening during this years.
1. Review of the Norm Map

We resume now the definition and properties of the direct and inverse image for Cartier divisors and the Norm map for line bundles, associated to a finite, flat morphism between curves. For a complete treatment, the standard reference is [Gro67, §21] together with [Gro61, §6.5]. We start with the definition of the norm at the level of sheaves of algebras.

Let \( \pi : X \to Y \) be a finite, flat morphism between curves of degree \( n \). Since \( Y \) is noetherian, this is equivalent to require that \( f \) is finite and locally free, i.e. that \( \pi^* \mathcal{O}_X \) is a locally free \( \mathcal{O}_Y \)-algebra [Sta19, Tag 02K9].

**Definition 1.1.** The sheaf \( \pi^* \mathcal{O}_X \) is endowed with an homorphism of \( \mathcal{O}_Y \)-modules, called the norm and defined on local sections by:

\[
N_{Y/X} : \pi^* \mathcal{O}_X \to \mathcal{O}_Y \quad s \mapsto \det(-s)
\]

where \( \cdot s : \pi^* \mathcal{O}_X \to \pi^* \mathcal{O}_X \) is the multiplication map induced by \( s \) and \( \det(-s) \) is given locally by the determinant of the matrix with entries in \( \mathcal{O}_Y \) associated to \( \cdot s \).

By the standard properties of determinants, for local sections \( s, s' \) of \( \pi^* \mathcal{O}_X \) and any section \( \mu \) of \( \mathcal{O}_Y \), we have:

\[
N_{Y/X}(s \cdot s') = N_{Y/X}(s) \cdot N_{Y/X}(s'), \\
N_{Y/X}(\mu s) = \mu^n N_{Y/X}(s).
\]

Before giving the definitions of the present section, we need a technical lemma.

**Lemma 1.2.** Let \( \pi : X \to Y \) be a finite, flat morphism of degree \( n \) between curves and let \( \mathcal{L} \) be an invertible \( \pi^* \mathcal{O}_X \)-module. Then, \( \pi^* \mathcal{L} \) is an invertible \( \pi^* \mathcal{O}_X \)-module and there exists an open affine cover \( \{ V_i \}_{i \in I} \) of \( Y \) s.t. \( \pi^* \mathcal{O}_X \) is trivial on each \( V_i \) and \( \pi^* \mathcal{L} \) is trivial both as a \( \pi^* \mathcal{O}_X \)-module and as an \( \mathcal{O}_Y \)-module on each \( V_i \).

**Proof.** By [Sta19, Tag 02K9], \( \pi^* \mathcal{O}_X \) is a locally free \( \mathcal{O}_Y \)-module; denote with \( \{ W_\alpha \}_{\alpha \in A} \) an open affine cover such that \( \pi^* \mathcal{O}_X|_{W_\alpha} \simeq \mathcal{O}_Y^n|_{W_\alpha} \) for each \( \alpha \in A \). By [Gro61, Proposition 6.1.12], \( \pi^* \mathcal{L} \) is an invertible \( \pi^* \mathcal{O}_X \)-module; denote with \( \{ W'_\beta \}_{\beta \in B} \) an open affine cover such that \( \pi^* \mathcal{L}|_{W'_\beta} \simeq \pi^* \mathcal{O}_X|_{W'_\beta} \) for each \( \beta \in B \). Let \( \{ V_{\alpha, \beta} = W_\alpha \cap W'_\beta \}_{(\alpha, \beta) \in A \times B} \) be a common refinement. Then, for \( I = A \times B, \{ V_i \}_{i \in I} \) is an open affine cover of \( Y \) such that \( \pi^* \mathcal{O}_X \) is trivial on each open of the cover and \( \pi^* \mathcal{L} \) is trivial both as \( \pi^* \mathcal{O}_X \)-module and as \( \mathcal{O}_Y \)-module on each open. \( \square \)

We recall now the definitions of direct and inverse image for Cartier divisors. For any curve \( X \), denote with \( \mathcal{K}_X \) the sheaf of total quotient rings of the curve. Recall that the set of Cartier divisors on \( X \) is the set of global sections of the quotient sheaf of multiplicative groups \( \mathcal{K}_X^*/\mathcal{O}_X^* \):

\[
\text{CDiv}(X) = \Gamma(X, \mathcal{K}_X^*/\mathcal{O}_X^*).
\]

Although the group operation on \( \mathcal{K}_X^*/\mathcal{O}_X^* \) is multiplication, the group operation on \( \text{CDiv}(X) \) is denoted additively. The group of Cartier divisors of \( X \)
contains the subgroup $\text{Prin}(X)$ of \textit{principal divisors} defined as the image of the canonical homomorphism

$$\Gamma(X, K_X^*) \longrightarrow \Gamma(X, K_X^*/\mathcal{O}_X^*).$$

It is well known \cite{Gro67} §21.2 that the set of Cartier divisors is in one-to-one correspondence with the set of invertible fractional ideals, i.e. the set of invertible fractional ideal $I \subseteq K$. If $D \in \Gamma(X, K_X^*/\mathcal{O}_X^*)$ is represented by an open cover $\{U_i\}_{i \in I}$ and a collection of sections $f_i \in \Gamma(U_i, K_X^*)$ such that $f_i/f_j \in \Gamma(U_i \cap U_j, \mathcal{O}_X^*)$, the corresponding fractional ideal $\mathcal{L}_D$ is the sub $\mathcal{O}_X$-module of $K_X$ equal to $\mathcal{O}_X|U_i \cdot f_i$ on any $U_i$.

\textbf{Definition/Lemma 1.3.} Let $\pi : X \to Y$ be a finite, flat morphism between curves and let $\pi^\sharp : \mathcal{O}_Y \to \pi_* \mathcal{O}_X$ be the associated canonical map of sheaves of modules.

Let $D \in \text{CDiv}(X)$ be a Cartier divisor on $X$ corresponding to the invertible fractional ideal $\mathcal{L}$ and let $\{V_i\}_{i \in I}$ be an affine cover as in Lemma \ref{lemma_1.2}. Then, on each $V_i$, $\pi_* \mathcal{L}|_{V_i}$ is equal to the subsheaf $h_i \cdot (\pi_* \mathcal{O}_X)|_{V_i}$ of $(\pi_* \mathcal{O}_X)|_{V_i}$ generated by a meromorphic regular section $h_i = f_i/g_i$, with $f_i, g_i \in \Gamma(V_i, \pi_* \mathcal{O}_X^*)$. The \textit{direct image} of $D$, denoted $\pi_* (D)$, is the Cartier divisor on $Y$ corresponding to the fractional ideal generated on any $V_i$ by the meromorphic regular section $\mathcal{N}_{Y/X}^* (f_i)/\mathcal{N}_{Y/X}^* (g_i) \in \Gamma(V_i, \mathcal{O}_Y^*)$.

Let $M \in \text{CDiv}(X)$ be a Cartier divisor on $Y$ corresponding to the invertible fractional ideal $\mathcal{I} \subseteq K_Y$, and let $\{V_i\}_{i \in I}$ be an affine cover of $Y$ such that, on each $V_i$, $\mathcal{I}|_{V_i}$ is equal to the fractional ideal of $\mathcal{O}_Y|_{V_i}$-modules generated by a meromorphic regular section $u_i = s_i/t_i$ with $s_i, t_i \in \Gamma(V_i, \mathcal{O}_Y^*)$. The \textit{inverse image} of $M$, denoted $\pi^* (M)$, is the Cartier divisor on $X$ corresponding to the fractional ideal generated on any $U_i = \pi^{-1} (V_i)$ by the meromorphic regular section $\pi^\sharp (s_i)/\pi^\sharp (t_i) \in \Gamma(U_i, K_X)$.

\textbf{Proof.} The definition of direct image is a reformulation of the one given in \cite{Gro67} §21.5.5. The fact that $\mathcal{N}_{Y/X}^* (f_i)/\mathcal{N}_{Y/X}^* (g_i)$ is a regular meromorphic section follows from the discussion in \cite{Gro67} §21.5.3; the definition is independent of the choice of the $h_i$’s since the norm of sheaves is multiplicative.

The definition of inverse image is a reformulation of \cite{Gro67} Definition 21.4.2], obtained as a consequence of \cite{Gro67} §21.4.3], together with the result of \cite{Gro67} Proposition 21.4.5] that ensures that $\pi^\sharp (s_i)/\pi^\sharp (t_i)$ is regular. \hfill \Box

\textbf{Proposition 1.4.} Let $\pi : X \to Y$ be a finite, flat morphism of curves of degree $n$. The direct and inverse image for Cartier divisors induce homomorphisms of groups:

$$\pi_* : \text{CDiv}(X) \longrightarrow \text{CDiv}(Y)$$

$$\pi^* : \text{CDiv}(Y) \longrightarrow \text{CDiv}(X),$$

such that $\pi_* \circ \pi^*$ is the multiplication map by $n$.

\footnote{Differently from Grothendieck’s EGA, we pick $f_i$ instead of $f_i^{-1}$. This does not affect the other results.}
Proof. The direct image is a homomorphism thanks to [Gro67, §21.5.5.1], while the inverse image is a homomorphism as a consequence of [Gro67, Definition 21.5.5.1]. The result on $\pi_* \circ \pi^*$ is stated in [Gro67, Proposition 21.5.6]. □

We come now to the definition of the Norm map for invertible $\mathcal{O}_X$-modules.

**Definition/Lemma 1.5.** Let $\pi : X \to Y$ be a finite, flat morphism between curves and let $\mathcal{L}$ be an invertible $\mathcal{O}_X$-module. Let $\{V_i\}_{i \in I}$ be an affine cover of $Y$ as in Lemma 1.2. In particular, there is for any $i \in I$ an isomorphism $\lambda_i : (\pi_* \mathcal{L})|_{V_i} \to (\pi_* \mathcal{O}_X)|_{V_i}$. For any $i, j \in I$, the isomorphism $\omega_{ij} := \lambda_i \circ \lambda_j^{-1}$ can be interpreted as a section of $\pi_* \mathcal{O}_X$ over $V_i \cap V_j$. The collection of norms $\{N_{Y/X}(\omega_{ij})\}_{i,j \in I}$ is a 1-cocycle with values in $\mathcal{O}_Y^*$. The cocycle $\{N_{Y/X}(\omega_{ij})\}_{i,j \in I}$ defines up to isomorphism an invertible $\mathcal{O}_Y$-module, which is called the Norm of $\mathcal{L}$ relative to $\pi$ and is denoted as $\text{Nm}_\pi(\mathcal{L})$ or $N_{Y/X}(\mathcal{L})$.

Proof. If $\mathcal{L}'$ is an invertible $\mathcal{O}_X$-module isomorphic to $\mathcal{L}$ through an isomorphism $h : \mathcal{L}' \to \mathcal{L}$, then a local trivialization for $\pi_* \mathcal{L}'$ over $V_i$ is given by $\lambda_i \circ (\pi_* h)$. Running over all $i \in I$, the resulting 1-cocycle $\{N_{Y/X}(\lambda_i \circ \pi_* h \circ \pi_* h^{-1} \circ \lambda_j^{-1})\}_{i,j \in I}$ is the same as for $\mathcal{L}$. □

Recall that, for any curve $X$, the Picard group of $X$ is the set $\text{Pic}(X)$ of isomorphism classes of invertible $\mathcal{O}_X$-modules, endowed with the operation of tensor product.

**Proposition 1.6.** Let $\pi : X \to Y$ be a finite, flat morphism of curves of degree $n$. The Norm and the inverse image map for line bundles induce homomorphism of groups:

$$\text{Nm}_\pi : \text{Pic}(X) \to \text{Pic}(Y)$$

$$\pi^* : \text{Pic}(Y) \to \text{Pic}(X),$$

such that $\text{Nm}_\pi \circ \pi^*$ is the $n$-th tensor power.

Proof. The inverse image for line bundles is a homomorphism since it commutes obviously with tensor products. The other results follow from [1], using the fact that tensor product of line bundles corresponds to multiplication at the level of defining cocycles. □

**Proposition 1.7.** Let $\pi : X \to Y$ be a finite, flat morphism between curves. For any invertible $\mathcal{O}_X$-modules $\mathcal{L}$, we have

$$\text{Nm}_\pi(\mathcal{L}) \simeq \det(\pi_* \mathcal{L}) \otimes \det(\pi_* \mathcal{O}_X)^{-1}.$$  

(2)

Proof. See [HP12, Corollary 3.12]. □

As we show in the next proposition, the direct image for Cartier divisors and the Norm map for line bundles are related, as well as the inverse image maps. Recall that, on any curve $X$, the Picard group is canonically isomorphic to the group of Cartier divisors modulo the subgroup $\text{Prin}(X)$ of
principal divisors. This gives rise to a canonical quotient of groups:
\[ q_X : \text{CDiv}(X) \longrightarrow \text{CDiv}(X)/\text{Prin}(X) = \text{Pic}(X) \]
\[ D \longmapsto I_D. \]

Proposition 1.8. Let \( \pi : X \rightarrow Y \) be a finite, flat morphism between curves. The direct and inverse image for Cartier divisors are compatible via the quotient maps \( q_X \) and \( q_Y \) respectively with the Norm and the inverse image map for line bundles; i.e. the following diagrams of groups are commutative:
\[
\begin{array}{ccc}
\text{CDiv}(X) & \xrightarrow{\pi_*} & \text{CDiv}(Y) \\
\downarrow{q_X} & & \downarrow{q_Y} \\
\text{Pic}(X) & \xrightarrow{\text{Nm}} & \text{Pic}(Y) \\
\end{array}
\]
\[
\begin{array}{ccc}
\text{CDiv}(Y) & \xrightarrow{\pi^*} & \text{CDiv}(X) \\
\downarrow{q_Y} & & \downarrow{q_Y} \\
\text{Pic}(Y) & \xrightarrow{\pi^*} & \text{Pic}(X) \\
\end{array}
\]

Proof. The commutativity of the first diagram follows from correspondence between \( D \) and \( I_D \) and the definitions of \( \pi_* \) and \( \text{Nm} \). The second diagram is commutative as consequence of [Gro67, Proposition 21.4.5]. □

We are finally interested in the Norm map for families of line bundles.\(^2\) To study families of line bundles, we assume that \( X \) and \( Y \) are projective curves over a base field \( k \) and that \( \pi : X \rightarrow Y \) is a finite, flat morphism of degree \( n \) defined over \( k \). Families of line bundles are parametrized by the Jacobian schemes of \( X \) and \( Y \) (denoted \( J(X) \) and \( J(Y) \)).

Definition 1.9. The Jacobian scheme of a curve \( X \) is the algebraic scheme \( J(X) \) representing the sheafification of the functor that associates to any \( k \)-scheme \( T \) the set of isomorphism classes of line bundles on \( X \times_k T \) [Kle05, Corollary 4.18.3].

Definition/Lemma 1.10. Let \( \pi : X \rightarrow Y \) be a finite, flat morphism of projective curves over a base field \( k \). For any \( k \)-scheme \( T \), the Norm map for line bundles associated to \( \pi \) is defined on the \( T \)-valued points of the Jacobian of \( X \) as:
\[ \text{Nm}_\pi(T) : J(X)(T) \longrightarrow J(Y)(T) \]
\[ \mathcal{L} \longmapsto \det (\pi_{T,*}(\mathcal{L})) \otimes \det (\pi_{T,*}\mathcal{O}_{X \times_k T})^{-1}. \]
where \( \pi_T : X \times_k T \rightarrow Y \times_k T \) is induced by pullback from \( \pi \).

Proof. We need to check that the map is well defined. Since \( \mathcal{L} \) is a line bundle on \( X \times_k T \), its pushforward \( \pi_{T,*}(\mathcal{L}) \) is a locally free sheaf of rank \( n \) on \( Y \times_k T \), as for \( \pi_{T,*}\mathcal{O}_{X \times_k T} \). Taking determinants produces line bundles, so \( \det (\pi_{T,*}(\mathcal{L})) \otimes \det (\pi_{T,*}\mathcal{O}_{X \times_k T})^{-1} \) is a well-defined line bundle on \( Y \times_k T \). The whole construction is functorial, so the above definition gives a well-defined morphism of schemes
\[ \text{Nm}_\pi : J(X) \longrightarrow J(Y). \]

\(^2\)For the sake of completeness, we note that a complete discussion regarding families of Cartier divisors and their direct and inverse images is done in [Gro67, §21.15].
2. Review of generalized divisors

The theory of generalized divisors is developed by Hartshorne in his papers [Har94] and [Har07], in order to generalize the notion of Cartier divisor on schemes satisfying condition $S_2$ of Serre.

We will review the theory of generalized divisors in the case of curves, i.e. embeddable schemes of pure dimension 1. Since we are dealing with schemes of dimension 1, the condition $S_2$ of Serre coincides with the condition $S_1$, which in turn coincides with the fact of not having embedded components (i.e. embedded points). In particular, any scheme of pure dimension 1 is also $S_1$, and hence $S_2$.

Let $X$ be a curve and let $\mathcal{K}_X$ be the sheaf of total quotient rings on $X$. Recall that a generalized divisor on $X$ is a nondegenerate fractional ideal of $\mathcal{O}_X$-modules, i.e. a subsheaf $\mathcal{I} \subseteq \mathcal{K}_X$ that is a coherent sheaf of $\mathcal{O}_X$-modules and such that $\mathcal{I}_\eta = \mathcal{K}_{X,\eta}$ for any generic point $\eta \in X$. It is effective if $\mathcal{I} \subseteq \mathcal{O}_X$. It is Cartier if $\mathcal{I}$ is an invertible $\mathcal{O}_X$-module, or equivalently locally principal. It is principal if $\mathcal{I} = \mathcal{O}_X \cdot f$ (also denoted $(f)$) for some global section $f \in \Gamma(X, \mathcal{K}_X^*)$.

The set of generalized divisors on $X$ is denoted with $\text{GDiv}(X)$, the subset of Cartier divisors with $\text{CDiv}(X)$ and the set of principal divisors with $\text{Prin}(X)$.

Using the usual notion of subscheme associated to a sheaf of ideals, the set $\text{GDiv}^+(X)$ of effective generalized divisors on $X$ is in one-to-one correspondence with the set of closed subschemes $D \subset X$ of pure codimension one (i.e. of dimension zero). With a slight abuse of notation, also for non-effective divisors, we denote with $D$ the generalized divisor and we refer to $\mathcal{I}$ (or $\mathcal{I}_D$) as the fractional ideal associated to $D$ (also called defining ideal of $D$, or ideal sheaf of $D$ if $D$ is effective).

Let $D_1, D_2$ be generalized divisors on $X$, with fractional ideals $\mathcal{I}_1, \mathcal{I}_2$. The sum $D_1 + D_2$ is the generalized divisor associated to the fractional ideal $\mathcal{I}_1 \cdot \mathcal{I}_2$. The sum is commutative, associative, with neutral element 0 defined by the trivial ideal $\mathcal{O}_X$. The inverse of a generalized divisor $D$ associated to $\mathcal{I}$ is the generalized divisor $-D$ associated to the fractional ideal $\mathcal{I}^{-1}$, i.e. the sheaf which on any open subset $U$ of $X$ is defined as $\{ f \in \Gamma(U, \mathcal{K}_X) \mid \mathcal{I}(U) \cdot f \subseteq \mathcal{O}_X(U) \}$.

The inverse operation behaves well with the sum only for Cartier divisors. For any pair of generalized divisors $D, E$ on $X$ with $E$ Cartier, $-(D + E) = (-D) + (-E)$, but $D + (-D) = 0$ if and only if $D$ is a Cartier divisor. As a consequence, the set $\text{GDiv}(X)$ of all generalized divisors over $X$ endowed with the sum operation is not a group, but the subset $\text{CDiv}(X)$ of Cartier divisors is. The set $\text{Prin}(X)$ of principal divisors is a subgroup of $\text{CDiv}(X)$ and both the groups act by addition on the set $\text{GDiv}(X)$.

Any generalized divisor is equal to the sum of an effective generalized divisor and the inverse of an effective Cartier divisor, as the following Lemma shows (inspired to [Har94, Proposition 2.11]).
Lemma 2.1. Let $X$ be a curve and let $D \in \text{GDiv}(X)$ be any generalized divisor on $X$. Then, there exist an effective generalized divisor $D'$ and an effective Cartier divisor $E$ on $X$ such that $D = D' + (−E)$.

Proof. Cover $X$ by open affines $U_i = \text{Spec}(A_i)$, $i = 1, \ldots, r$. For each $i$, denote with $I_i$ the fractional ideal of $D$ restricted to $U_i$. This is a finitely generated $A_i$-module, so there exists a nonzero-divisor $f_i \in A_i$ such that $f_i \cdot I_i \subseteq A_i$. Let $Y_i \subseteq U_i$ be the closed subscheme defined by $f_i$, which is an effective Cartier divisor of $U_i$; after the composition with $U_i \subseteq X$, $Y_i$ becomes an effective Cartier divisor of $X$. Now, the sum of divisors $D + \sum_{i=1}^{r} Y_i$ is effective since using the associative property it can be seen as sum of effective divisors on each $U_i$. Putting $E = \sum_{i=1}^{r} Y_i$ and $D' = D + E$, we get the result. □

Two generalized divisors $D_1, D_2$ over $X$ are linearly equivalent (written $D_1 \sim D_2$) if there is a divisor $(f) \in \text{Prin}(X)$ such that $D_1 + (f) = D_2$. We define the generalized Picard of $X$ to be the set of divisors on $X$ modulo linear equivalence:

$$\text{GPic}(X) = \text{GDiv}(X)/\text{Prin}(X).$$

We have the following commutative diagram of sets, where the vertical maps are quotients by $\text{Prin}(X)$:

$$\begin{array}{ccc}
\text{CDiv}(X) & \subseteq & \text{GDiv}(X) \\
\downarrow & & \downarrow \\
\text{Pic}(X) & \subseteq & \text{GPic}(X)
\end{array}$$

Taking inverse and sums preserve linear equivalence, so the two operations are well defined also on $\text{GPic}(X)$ and the subset $\text{Pic}(X) \subseteq \text{GPic}(X)$ is a group that acts on $\text{GPic}(X)$ by addition. For a curve $X$, the condition $\text{GDiv}(X) = \text{CDiv}(X)$ is also equivalent to $\text{GPic}(X) = \text{Pic}(X)$, which is also equivalent to the curve $X$ being normal.

As in the case of Cartier divisors, also the set $\text{GPic}(X)$ has an alternative description in terms of abstract sheaves. First, we need a definition.

Definition 2.2. Let $X$ be a curve. A generalized line bundle on $X$ is pure coherent sheaf of $O_X$-modules which is locally free of rank 1 at each generic point of $X$.

Let $D$ be a generalized divisor on $X$. Then, its fractional ideal $I$ is a generalized line bundle. If $D'$ is another generalized line bundle, it is linearly equivalent to $D$ if and only if its fractional ideal $I'$ is a generalized line bundle isomorphic to $I$ as an $O_X$-module. Viceversa, any generalized line bundle $F$ on $X$ is isomorphic to the fractional ideal of some generalized divisor $D$ [Har07, Proposition 2.4]. Then, $\text{GPic}(X)$ can be also defined as the set of generalized line bundles of $X$, up to isomorphism. Under this description, classes of Cartier divisors correspond to isomorphism classes of line bundles, and the operations of sum by a Cartier divisor and inverse of a divisor are replaced with tensor product and taking dual of the corresponding sheaves.
Assume now that $X$ is a curve of finite type over a base field $k$. In this case, the notion of degree of a divisor can be introduced. First, recall that for any closed point $x \in X$, the residue field of $x$ (denoted $k(x)$) is a finite extension of $k$.

**Definition/Lemma 2.3.** Let $D \in \text{GDiv}^+(X)$ be an effective generalized divisor on $X$ with ideal sheaf $\mathcal{I} \subseteq \mathcal{O}_X$, and let $x \in X$ be any point of $X$ in codimension 1. We define the degree of $D$ at $x$ as the non-negative integer:

$$\deg_x(D) = \ell(\mathcal{O}_{X,x}/\mathcal{I}_x)[k(x) : k].$$

The degree of any generalized divisor $D \in \text{GDiv}(X)$ at $x$ is defined as

$$\deg_x(D) = \deg_x(E) - \deg_x(F),$$

where $D = E - F$ with $E, F$ effective generalized divisors and $F$ Cartier by Lemma 2.1.

The degree of $D$ on $X$ (also denoted as $\deg(D)$ when there is no ambiguity) is equal to the sum of the degrees of $D$ at all points of $X$ in codimension 1:

$$\deg_X(D) = \sum_{x \text{ cod } 1} \deg_x(D).$$

Proof. First, note that the local ring $\mathcal{O}_{X,x}/\mathcal{I}_x$ is nonzero if and only if $x$ is in the support of $D$. In such case the local ring has Krull dimension 0, so it is Artinian and hence has finite length.

The definition of degree at a point of any generalized divisor is well-defined thanks to [Har94, Lemma 2.17], and $\deg_x(-D) = -\deg_x(D)$.

Finally, the support of $D$ contains only finitely many points, hence the degree of $D$ on $X$ is a well-defined integer. □

**Remark 2.4.** If $X$ is a quasi-projective curve in $\mathbb{P}^n_k$, then any effective generalized divisor $D$ on $X$ is also a closed subscheme of $\mathbb{P}^n_k$, of degree equal to $\deg(D)$. If the curve is also projective, linearly equivalent divisors have the same degree.

We come now to consider families of generalized divisors and related objects. First, we note that in general $\text{GDiv}(X)$ cannot be represented by a geometric object of finite type, even for fixed degrees. Also, it is not easy to give a correct definition for flat families of non-effective generalized divisors. Hence, only families of effective divisors are considered, using the Hilbert scheme.

In order to work with the theory of Hilbert schemes, we need to assume that $X$ is a projective curve over a base field $k$.

**Definition 2.5.** The Hilbert scheme of effective generalized divisors of degree $d$ on $X$ is the Hilbert scheme $\text{Hilb}_X^d$ parametrizing 0-dimensional subschemes of $X$, with Hilbert polynomial equal to a constant integer $d$. Recall that, given a $k$-scheme $T$, a $T$-valued point of $\text{Hilb}_X^d$ is a $T$-flat subscheme $D \subset X \times_k T$ such that $D$ restricted to the fibre over any $t \in T$ is a 0-dimensional subscheme of $X \times_k \{t\} \simeq X$, of degree $d$. In other words, the corresponding ideal sheaf $\mathcal{I}_D \subset \mathcal{O}_{X \times_k T}$ restricted to any fibre over $T$ defines a generalized divisor $\mathcal{D}_t$ on $X$.

The Hilbert scheme of effective Cartier divisors of degree $d$ is the open subscheme $\text{Hilb}_X^d \subseteq \text{Hilb}_X^d$ parametrizing subschemes of $X$ of degree $d$ whose ideal sheaf is locally principal.
Note that $\ell \mathrm{Hilb}^d_X = \mathrm{Hilb}^d_X$ when $X$ is smooth.

Families of effective generalized divisors can be added with families of Cartier divisors, giving rise to a morphism:

$$\mathrm{Hilb}^d_X \times \ell \mathrm{Hilb}^e_X \to \mathrm{Hilb}^{d+e}_X$$

$$(D, E) \mapsto \mathcal{Z}(I_D \cdot I_E).$$

The right object to parametrize families of generalized divisors on $X$ up to linear equivalence is the compactified Jacobian $\overline{\mathcal{J}}(X)$.

**Definition 2.6.** The compactified Jacobian of $X$ is the algebraic stack $\overline{\mathcal{J}}(X)$ such that, for any $k$-scheme $T$, $\overline{\mathcal{J}}(X)(T)$ is the groupoid of $T$-flat coherent sheaves on $X \times_k T$ whose fibres over $T$ are generalized line bundles on $X \simeq X \times_k \{t\}$. Given a family $\mathcal{L} \in \overline{\mathcal{J}}(X)(T)$, the restriction of $\mathcal{L}$ to any fibre over $T$ is an element of the generalized Picard $\mathrm{GPic}(X)$.

By Definition 1.9 the Jacobian scheme $\mathcal{J}(X)$ of $X$ is contained in $\overline{\mathcal{J}}(X)$ as an open subset. The operations of tensor products and taking inverse are well defined on $\mathcal{J}(X)$ and make $\mathcal{J}(X)$ into an algebraic group, acting on $\overline{\mathcal{J}}(X)$ via tensor product:

$$\overline{\mathcal{J}}(X) \times \mathcal{J}(X) \to \overline{\mathcal{J}}(X)$$

$$(\mathcal{L}, \mathcal{E}) \mapsto \mathcal{L} \otimes \mathcal{E}.$$

Finally, we recall the definition of the geometric Abel map. Let $\mathrm{Hilb}_X = \bigsqcup_{d \geq 0} \mathrm{Hilb}^d_X$ be the Hilbert scheme of effective generalized divisor of any degree on $X$.

**Definition 2.7.** For any line bundle $M$ on $X$, the $(M$-twisted$)$ Abel map is defined as:

$$\mathcal{A}_M : \mathrm{Hilb}_X \to \overline{\mathcal{J}}(X)$$

$$D \mapsto I_D \otimes M.$$

The restriction of $\mathcal{A}_M$ to $\ell \mathrm{Hilb}^d_X = \bigsqcup_{d \geq 1} \ell \mathrm{Hilb}^d_X$ takes values in $\mathcal{J}(X)$. Taking care of the twisting, the Abel map is equivariant with respect to the sum of effective Cartier divisors: for any pair of line bundles $M$ and $N$ on $X$ and for any $D \in \mathrm{Hilb}_X$, $E \in \ell \mathrm{Hilb}_X$,

$$\mathcal{A}_{M \otimes N}(D + E) \simeq \mathcal{A}_M(D) \otimes \mathcal{A}_N(E).$$

3. **Review of the Fitting ideal**

A fundamental tool for the definition of the direct image for generalized divisors is the Fitting ideal of a module (and of a sheaf of modules). See [Eis95, Chapter 20], [Vas04, Chapter 2.4] and [EH06, Chapter V.1.3] for a detailed treatment.

**Definition/Lemma 3.1.** Let $X$ be a scheme and let $\mathcal{F}$ be a coherent sheaf on $X$. Let

$$\begin{array}{ccc}
\mathcal{E}_1 & \xrightarrow{\psi} & \mathcal{E}_0 \\
\downarrow & & \downarrow \\
\mathcal{O} & \to & \mathcal{F} \\
\end{array}$$

be a short exact sequence of coherent sheaves. Then there is an exact sequence of sheaves of $\mathcal{O}_X$-modules:

$$0 \to Z(\mathcal{E}_0, \mathcal{E}_1) \to \mathcal{E}_1 \to \mathcal{E}_0 \to \mathcal{F} \to 0,$$

where $Z(\mathcal{E}_0, \mathcal{E}_1)$ is the kernel of the map $\mathcal{E}_1 \to \mathcal{E}_0$.

$$0 \to \mathcal{O} \to \mathcal{E}_0 \to \mathcal{F} \to 0.$$
be any finite presentation of $\mathcal{F}$, with $\mathcal{E}_0$ locally free of rank $r$. The 0-th Fitting ideal of $\mathcal{F}$, denoted $\text{Fitt}_0(\mathcal{F})$, is defined as the image of the map:

$$\bigwedge^r \mathcal{E}_1 \otimes (\bigwedge^r \mathcal{E}_0)^{-1} \xrightarrow{\psi} \mathcal{O}_X$$

induced by $\bigwedge^r \psi : \bigwedge^r \mathcal{E}_1 \to \bigwedge^r \mathcal{E}_0$ and is independent of the choice of the presentation for $\mathcal{F}$. If $\mathcal{E}_1$ is locally free, then $\psi$ can be locally represented by a matrix and the 0-th Fitting ideal is generated locally by the minors of size $r$ of such matrix, with the convention that the determinant of the $0 \times 0$ matrix is 1.

**Proof.** The definition is the sheaf-theoretic reformulation of [Eis95, Corollary-Definition 20.4].

As a consequence of the definition, the formation of Fitting ideals commutes with restrictions and with base change [Eis95, Corollary 20.5].

**Definition/Lemma 3.2.** Let $X$ be a scheme and $\mathcal{F}$ be a coherent sheaf on $X$. The 0-th Fitting scheme of $\mathcal{F}$ is the subscheme of $X$ defined as the zero locus of $\text{Fitt}_0(\mathcal{F}) \subseteq \mathcal{O}_X$ in $X$. The 0-th Fitting scheme contains the support of $\mathcal{F}$, as a closed subscheme with the same underlying topological space.

**Proof.** The result is stated in [EH06, Definition V-10].

4. THE DIRECT AND INVERSE IMAGE FOR GENERALIZED DIVISORS AND GENERALIZED LINE BUNDLES

Let $\pi : X \to Y$ be a finite, flat morphism of degree $n$ between curves. In the present section, we extend the notion of direct and inverse image from Cartier divisors to generalized divisors and generalized line bundles.

4.1. The direct image. Here, we define the notion of direct image for generalized divisors. First, we start with the case of an effective generalized divisor. Let $D \in \text{GDiv}^+(X)$ be an effective generalized divisor on $X$, associated to the ideal sheaf $\mathcal{I}$. Since $\pi$ is finite and flat, the pushforward $\pi_* (\mathcal{O}_X/\mathcal{I})$ is a coherent $\mathcal{O}_Y$-module.

**Definition/Lemma 4.1.** (Direct image of an effective generalized divisor) Let $D \in \text{GDiv}^+(X)$ be an effective generalized divisor on $X$, with ideal sheaf $\mathcal{I} \subseteq \mathcal{O}_X$. The **direct image of $D$ with respect to $\pi$**, denoted with $\pi_* (D)$, is the effective generalized divisor on $Y$ defined by the 0-th Fitting ideal of $\pi_* (\mathcal{O}_X/\mathcal{I})$.

**Proof.** Let us prove that the 0-th Fitting ideal of $\pi_* (\mathcal{O}_X/\mathcal{I})$ defines an effective generalized divisor on $Y$. First note that $\text{Fitt}_0 (\pi_* (\mathcal{O}_X/\mathcal{I}))$ is a subsheaf of $\mathcal{O}_Y$, and is a coherent $\mathcal{O}_Y$-module; hence, it is an effective fractional ideal. To prove that $\text{Fitt}_0 (\pi_* (\mathcal{O}_X/\mathcal{I}))$ is nondegenerate, consider a generic point $\eta \in Y$. Since the map $\pi$ is dominant, the preimage $\pi^{-1}(\eta) = \{\eta_i\}$ is a finite set of generic points of $X$. Then,

$$\text{Fitt}_0 (\pi_* (\mathcal{O}_X/\mathcal{I}))_\eta = \text{Fitt}_0 (\pi_* (\mathcal{O}_X/\mathcal{I})(\eta)) = \text{Fitt}_0 ((0)_\eta) = \mathcal{O}_{X,\eta} = \mathcal{K}_{X,\eta}.$$
Lemma 4.2. (Linearity w.r.t effective Cartier divisors) Let $D \in \text{GDiv}^+(X)$ be an effective generalized divisor and $E \in \text{CDiv}^+(X)$ be an effective Cartier divisor on $X$. Then, $\pi_*(E)$ is a Cartier divisor on $Y$ and $\pi_*(D+E) = \pi_*(D) + \pi_*(E)$.

Proof. Let $\mathcal{I}$ be the ideal sheaf of $E$ and let $\{V_i\}$ be an open affine cover of $Y$ such that $\pi_*\mathcal{O}_X$ and $\pi_*\mathcal{I}$ are trivial on each $V_i$ as in Lemma 1.2. The sheaf $\pi_*\mathcal{O}_X/\mathcal{I}$ is locally presented by the exact sequence:

$$(\pi_*\mathcal{O}_X)_{|V_i} \xrightarrow{h_i} (\pi_*\mathcal{O}_X/\mathcal{I})_{|V_i} \rightarrow 0$$

where $h_i \in \Gamma(\mathcal{O}_X^{-1}(V_i), \mathcal{O}_X)$ is a local generator for $\mathcal{I} \subset \mathcal{O}_X$ on $\mathcal{O}_X^{-1}(V_i)$. Since $(\pi_*\mathcal{O}_X)_{|V_i}$ is a free $(\mathcal{O}_Y)_{|V_i}$-module of rank $n$, there is a $n \times n$ matrix $H_i$ with entries in $(\mathcal{O}_Y)_{|V_i}$ representing the multiplication by $h_i$. Then, by Definition 3.1 the 0-th Fitting ideal of $\pi_*\mathcal{O}_X/\mathcal{I}$ is the principal ideal generated locally by det$(h_i)$ on $V_i$. In particular, $\pi_*(E)$ is a Cartier divisor.

Let $\mathcal{I}$ be the ideal sheaf of $D$, so that $\mathcal{I} \cdot \mathcal{J}$ is the ideal sheaf of $D + E$. To prove the remaining part of the thesis, we show that the equality

$$\text{Fitt}_0(\pi_*\mathcal{O}_X/\mathcal{I}\mathcal{J}) = \text{Fitt}_0(\pi_*\mathcal{O}_X/\mathcal{I}) \cdot \text{Fitt}_0(\pi_*\mathcal{O}_X/\mathcal{J})$$

holds locally around any point $y \in Y$. Let $V$ be an open neighborhood of $y$ such that $(\pi_*\mathcal{O}_X)_{|V}$ is a free $\mathcal{O}_Y$-module, $\pi_*\mathcal{I}_{|V}$ is generated by sections $s_1, \ldots, s_r$ of $\Gamma(V, \pi_*\mathcal{O}_X)$ and $\pi_*\mathcal{J}_{|V}$ is a principal ideal generated by a section $h$ of $\Gamma(V, \pi_*\mathcal{O}_X)$. In terms of exact sequences:

$$(\pi_*\mathcal{O}_X)_{|V} \xrightarrow{(s_1, \ldots, s_r)} (\pi_*\mathcal{O}_X)_{|V} \rightarrow (\pi_*\mathcal{O}_X/\mathcal{I})_{|V} \rightarrow 0$$

$$(\pi_*\mathcal{O}_X)_{|V} \xrightarrow{h} (\pi_*\mathcal{O}_X)_{|V} \rightarrow (\pi_*\mathcal{O}_X/\mathcal{J})_{|V} \rightarrow 0$$

The ideal sheaf $\mathcal{I} \cdot \mathcal{J}$ is equal to $\mathcal{J} \cdot \mathcal{I}$, which is generated on $V$ by the sections $hs_1, \ldots, hs_r$. In terms of exact sequences:

$$(\pi_*\mathcal{O}_X)_{|V} \xrightarrow{(hs_1, \ldots, hs_r)} (\pi_*\mathcal{O}_X)_{|V} \rightarrow (\pi_*\mathcal{O}_X/\mathcal{I}\mathcal{J})_{|V} \rightarrow 0$$

Denote with $S_i$ and $H$ the $(\mathcal{O}_V)_{|V}$-matrices representing the multiplication by $s_i$ and $h$ respectively. The map $(hs_1, \ldots, hs_r)$ in the previous exact sequence is represented by the $n \times nr$ matrix

$$M = \left[ \begin{array}{ccc} HS_1 & \cdots & HS_r \\ H & S_1 & \cdots & S_r \end{array} \right] = H \left[ \begin{array}{ccc} S_1 & \cdots & S_r \end{array} \right]$$

The 0-th Fitting ideal of $\pi_*\mathcal{O}_X/\mathcal{I}\mathcal{J}$, restricted to $V$, is the ideal of $(\pi_*\mathcal{O}_X)_{|V}$ generated by the $n \times n$ minors of the matrix $M$. Any such minor is equal to a $n \times n$ minor of the matrix $\left[ \begin{array}{ccc} S_1 & \cdots & S_r \end{array} \right]$ multiplied by det $H$. Then, by Definition 3.1

$$\text{Fitt}_0(\pi_*\mathcal{O}_X/\mathcal{I}\mathcal{J})_{|V} = \text{Fitt}_0(\pi_*\mathcal{O}_X/\mathcal{I})_{|V} \cdot \text{Fitt}_0(\pi_*\mathcal{O}_X/\mathcal{J})_{|V}$$

Definition/Lemma 4.3. (Direct image of a generalized divisor) Let $D \in \text{GDiv}(X)$ be a generalized divisor on $X$, such that $D = D' - E$ with $D' \in \text{GDiv}^+(X)$ and $E \in \text{CDiv}^+(X)$ by Lemma 2.1. The direct image of $D$ with respect to $\pi$, denoted with $\pi_*(D)$, is the generalized divisor $\pi_*(D') - \pi_*(E)$. 

\[\square\]
Proof. To prove that it is well defined, let $D = D' - E = \tilde{D}' - \tilde{E}$, with $D', \tilde{D}'$ effective and $E, \tilde{E}$ effective Cartier. Since $E, \tilde{E}$ are Cartier, $D' + \tilde{E} = D' + E$; then, by Lemma 4.2 we have:

$$\pi_*(D') + \pi_*(\tilde{E}) = \pi_*(\tilde{D}') + \pi_*(E).$$

Since $\pi_*(E)$ and $\pi_*(\tilde{E})$ are also Cartier by Lemma 4.2, they can be subtracted from each side in order to obtain:

$$\pi_*(D') - \pi_*(E) = \pi_*(\tilde{D}') - \pi_*(\tilde{E}).$$

This shows that $\pi_*(D)$ does not depend on the choice of $D'$ and $E$. □

We study now some properties of the direct image for generalized divisors.

**Proposition 4.4.** (Properties of direct image)

1. Let $D \in \text{CDiv}(X)$ be a Cartier divisor. Then, $\pi_*(D)$ is a Cartier divisor and $\pi_*(-D) = -\pi_*(D)$. Moreover, $\pi_*(D)$ coincides with $\pi_*(D)$ of Definition 1.3.

2. Let $D, E \in \text{GDiv}(X)$ be generalized divisors, such that $E$ is Cartier. Then, $\pi_*(D + E) = \pi_*(D) + \pi_*(E)$.

3. Let $V \subset Y$ be an open subset, and denote with $\pi_U$ the restriction of $\pi$ to $U = \pi^{-1}(V) \subset X$. Let $D \in \text{GDiv}(X)$ be a generalized divisor on $X$. Then,

$$(\pi_U)_*(D|_U) = \pi_*(D)|_V$$

4. Let $D, D' \in \text{GDiv}(X)$ be generalized divisors such that $D \sim D'$. Then, $\pi_*(D) \sim \pi_*(D')$.

**Proof.** To prove (1), consider $D = E - F$ with $E, F$ effective and $F$ Cartier by Lemma 2.1. Since $D$ is Cartier and $E = D + F$, then also $E$ is Cartier. By Definition 1.3:

$$\pi_*(D) = \pi_*(E) - \pi_*(F).$$

By Lemma 4.2 it is a difference of Cartier divisors and hence it is Cartier. To compute $\pi_*(-D)$, note that since $F$ is Cartier then $-D = F - E$, and it is a difference of effective Cartier divisors; then, apply Definition 1.3 to obtain

$$\pi_*(-D) = \pi_*(F) - \pi_*(E) = -\pi_*(D).$$

To compare $\pi_*(D)$ with Definition 1.3, let $\mathcal{I}$ and $\mathcal{J}$ be the ideal sheaves of $E$ and $F$ and let $\{V_i\}_{i \in I}$ be an open cover of $Y$ such that $\pi_*\mathcal{I}|_{V_i}$ and $\pi_*\mathcal{J}|_{V_i}$ are non-degenerate principal ideals of $(\pi_*\mathcal{O}_X)|_{V_i}$-modules generated by the regular sections $f_i$ and $g_i$ of $\Gamma(V_i, \pi_*\mathcal{O}_X)$, respectively on each $i \in I$. The fractional ideal of $D$ is then generated on each $V_i$ by the meromorphic regular section $h_i = f_i/g_i$ of $\Gamma(V_i, \pi_*\mathcal{K}_X^*)$. By the proof of Lemma 4.2, the ideal sheaves of $\pi_*(E)$ and $\pi_*(F)$ are generated on each $V_i$ by $\det(f_i)$ and $\det(g_i)$, so the fractional ideal of $\pi_*(D)$ is generated on each $V_i$ by the meromorphic regular section $\det(f_i)/\det(g_i)$ of $\Gamma(V_i, \mathcal{K}_X^*)$. Using the same cover in Definition 1.3 and applying Definition 1.3 the sheaf $\pi_*(D)$ defined above and the sheaf $\pi_*(D)$ defined in Section 1 have the same local generators, hence they are equal.
To prove (2), consider $D = D_1 - D_2$ and $E = E_1 - E_2$, with $D_1, D_2, E_1, E_2$ effective and $D_2, E_2$ Cartier. Note that $D + E = (D_1 + E_1) - (D_2 + E_2)$, and it is a difference of effective divisors with $D_2 + E_2$ Cartier. Note that $D + E = (D_1 + E_1) - (D_2 + E_2)$, and it is a difference of effective divisors with $D_2 + E_2$ Cartier. Then, applying Definition 4.3 and Lemma 4.2, we obtain:

$$\pi^*(D + E) = \pi^*( (D_1 + E_1) - (D_2 + E_2)) =$$

$$= \pi^*(D_1 + E_1) - \pi^*(D_2 + E_2) =$$

$$= \pi^*(D_1) + \pi^*(E_1) - \pi^*(D_2) - \pi^*(E_2) =$$

$$= (\pi^*(D_1) - \pi^*(D_2)) - (\pi^*(E_1) - \pi^*(E_2)) =$$

$$= \pi^*(D) + \pi^*(E).$$

To prove (3), if $D$ is effective, the result follows from Definition 3.1. Then, observe that the operations of product and inverse of fractional ideals commute with restrictions.

To prove (4), let $f \in \Gamma(X, K_X)$ be a global section that generates a principal divisor $E = (f) \in \text{Prin}(X)$. By linearity, it is sufficient to prove that $\pi^*(E)$ is again principal. Let $\{V_i\}$ be an affine open cover of $Y$, such that locally

$$f|_{\pi^{-1}(V_i)} = g_i/h_i, \quad g_i, h_i \in \Gamma(\pi^{-1}(V_i), \mathcal{O}_X)$$

In terms of divisors, this means that $(f)|_{\pi^{-1}(V_i)} = (g_i) - (h_i)$, and it is a difference of effective Cartier divisors on $\pi^{-1}(V_i)$. Then, applying Part (3) and reasoning similarly to Part (1), we obtain:

$$\pi^*((f))|_V = (\pi^*)((g_i)) - (\pi^*)((h_i)) =$$

$$= (\det[g_i]) - (\det[h_i]) =$$

$$= (\det[g_i]/\det[h_i]).$$

Since taking determinants is multiplicative, the local sections $\det[g_i]/\det[h_i]$ glue together to give a global section $\tilde{f}$ of $K_Y$, such that $\pi^*(E) = (\tilde{f})$. □

We are now ready to define the direct image for generalized line bundles.

**Definition/Lemma 4.5. (Direct image for generalized line bundles)**

The direct image for generalized divisors induce a direct image map between the sets of generalized line bundles, defined as:

$$[\pi_*] : \text{GPic}(X) \rightarrow \text{GPic}(Y)$$

$$[D] \mapsto [\pi_*(D)].$$

**Proof.** Recall that for any curve $X$, the set $\text{GPic}(X)$ can be seen equivalently as the set of generalized line bundles or as the set of generalized divisors modulo linear equivalence. Here, $[\pi_*]$ is defined in terms of generalized divisors modulo linear equivalence. By Proposition 4.4, the direct images of linearly equivalent divisors are linearly equivalent, hence $[\pi_*]$ is well defined. □

In the remaining part of this subsection, we study an alternative formula for $[\pi_*]$ in terms of generalized line bundles. First, we need a technical lemma.
Lemma 4.6. Let $\mathcal{F}$ be a coherent sheaf on a curve $X$ which is locally free of rank 1 at any generic point and let $\omega = \omega_X$ be the canonical, or dualizing sheaf of $X$. Let $T(\mathcal{F})$ be the torsion subsheaf of $\mathcal{F}$ and $\mathcal{F}^{\omega} = \text{Hom}(\text{Hom}(\mathcal{F}, \omega), \omega)$ be the double $\omega$-dual. There, there is a canonical isomorphism

$$\mathcal{F}^{tf} = \mathcal{F}/T(\mathcal{F}) \xrightarrow{\sim} \mathcal{F}^{\omega}.$$ 

Proof. The sheaf $\mathcal{F}^{tf}$ is endowed with a quotient map $q : \mathcal{F} \twoheadrightarrow \mathcal{F}^{tf}$, which is universal among all arrows from $\mathcal{F}$ to torsion-free sheaves (i.e. pure of dimension 1). Note that, since $\mathcal{F}$ is locally free of rank 1 at any generic point of $X$, then $q$ is generically an isomorphism. Let $\alpha(\mathcal{F}) : \mathcal{F} \to \mathcal{F}^{\omega}$ be the canonical map from $\mathcal{F}$ to its double $\omega$-dual. Since taking double $\omega$-duals is functorial, there is a commutative diagram of homomorphism of sheaves:

$$\begin{array}{ccc}
\mathcal{F} & \xrightarrow{q} & \mathcal{F}^{tf} \\
\downarrow{\alpha(\mathcal{F})} & & \downarrow{\alpha(\mathcal{F}^{tf})} \\
\mathcal{F}^{\omega} & \xrightarrow{\omega} & (\mathcal{F}^{tf})^{\omega}.
\end{array}$$

Using [Har07, Proposition 1.5] and recalling that $S_1 = S_2$ for sheaves on curves, we note that a sheaf on $X$ is $\omega$-reflexive if and only if it is $S_1$. In particular, $\mathcal{F}^{\omega}$ is $\omega$-reflexive by [Har07, Proposition 1.6] and hence it is $S_1$. Then, by the universal property of $q$, there is a unique map $\psi : \mathcal{F}^{tf} \to \mathcal{F}^{\omega}$ such that $\psi \circ q = \alpha(\mathcal{F})$. Note that $q^{\omega} \circ \psi \circ q = q^{\omega} \circ \alpha(\mathcal{F}) = \alpha(\mathcal{F}^{tf}) \circ q$, so by surjectivity of $q$ we conclude that $q^{\omega} \circ \psi = \alpha(\mathcal{F}^{tf})$.

We show moreover that $\psi$ is an isomorphism. By construction $\mathcal{F}^{tf}$ is pure, hence it is $\omega$-reflexive and $\alpha(\mathcal{F}^{tf})$ is an isomorphism. Moreover, $q^{\omega}$ is surjective and generically an isomorphism since $q$ is surjective and generically an isomorphism. Then, the kernel $K$ of $q^{\omega}$ is a subsheaf of $\mathcal{F}^{\omega}$ which is generically zero. Since $\mathcal{F}^{\omega}$ is pure, we conclude that $K$ is everywhere zero and then $q^{\omega}$ is an isomorphism. This shows that $\psi = (q^{\omega})^{-1} \circ \alpha(\mathcal{F}^{tf})$ is an isomorphism. \hfill $\square$

In order to study a formula for $[\pi_*]$, we study a preliminary formula for $\pi_*$ in the case of effective generalized divisors.

Lemma 4.7. Let $D \in \text{GDiv}^+(X)$ be an effective generalized divisors with ideal sheaf $\mathcal{I} \subset \mathcal{O}_X$. Then, there is an injection:

$$(\bigwedge^n (\pi_* \mathcal{I}))^{\omega} \otimes \det(\pi_* \mathcal{O}_X)^{-1} \to \det(\pi_* \mathcal{O}_X) \otimes \det(\pi_* \mathcal{O}_X)^{-1} \xrightarrow{\sim} \mathcal{O}_Y$$

whose image in $\mathcal{O}_Y$ is the 0-th Fitting ideal of $\pi_* \mathcal{O}_X / \mathcal{I}$.

Proof. Consider the short exact sequence:

$$0 \to \mathcal{I} \to \mathcal{O}_X \to \mathcal{O}_D \to 0.$$ 

Since $\pi$ is finite and flat, the pushforward induces a a short exact sequence:

$$0 \to \pi_* \mathcal{I} \xrightarrow{\pi_*} \pi_* \mathcal{O}_X \to \pi_* (\mathcal{O}_X / \mathcal{I}) \to 0.$$
In particular, the last exact sequence is a finite presentation of $\pi_* (\mathcal{O}_X / \mathcal{I})$ whose middle term is locally free. Hence, by Definition 3.1, the 0-th Fitting ideal of $\pi_* (\mathcal{O}_X / \mathcal{I})$ is equal to the image of the morphism:

$$\wedge^n (\pi_* \mathcal{I}) \otimes (\pi_* \mathcal{O}_X)^{-1} \xrightarrow{\det \varphi \otimes 1} \det (\pi_* \mathcal{O}_X) \otimes (\pi_* \mathcal{O}_X)^{-1} \sim \mathcal{O}_Y.$$ 

Consider now the determinant map $\det \varphi$. Since $\det (\pi_* \mathcal{O}_X)$ is also a pure sheaf, applying the universal property of the torsion-free quotient together with Lemma 4.6 we obtain the following commutative diagram:

$$\begin{array}{ccc}
\wedge^n (\pi_* \mathcal{I}) & \xrightarrow{\det \varphi} & \det (\pi_* \mathcal{O}_X) \\
\downarrow \alpha & & \downarrow \beta \\
(\wedge^n (\pi_* \mathcal{I}))^\omega & \xrightarrow{\beta \otimes 1} & (\wedge^n (\pi_* \mathcal{I}))^\omega \otimes (\pi_* \mathcal{O}_X)^{-1}
\end{array}$$

The canonical map $\alpha$ is surjective by Lemma 4.6. Since $\mathcal{I}$ is locally free of rank 1 at the generic points of $X$, both $\det \varphi$ and $\alpha$ are generically isomorphisms; hence, the map $\beta$ is generically an isomorphism. We have then factorized $\det \varphi$ as the composition of a surjective map $\alpha$ followed by an injective map $\beta$.

Tensoring by $(\pi_* \mathcal{O}_X)^{-1}$, we obtain then the following commutative diagram:

$$\begin{array}{ccc}
\wedge^n (\pi_* \mathcal{I}) & \xrightarrow{\det \varphi \otimes 1} & \det (\pi_* \mathcal{O}_X) \otimes (\pi_* \mathcal{O}_X)^{-1} \\
\downarrow \alpha \otimes 1 & & \downarrow \beta \otimes 1 \\
(\wedge^n (\pi_* \mathcal{I}))^\omega \otimes (\pi_* \mathcal{O}_X)^{-1}
\end{array}$$

The map $\alpha \otimes 1$ is surjective, so the composition $\eta \circ (\beta \otimes 1)$ is an injective map whose image in $\mathcal{O}_Y$ is equal to the image of the map $\eta \circ (\det \varphi \otimes 1)$. By the previous remark, such image coincides with the 0-th Fitting ideal of $\pi_* (\mathcal{O}_X / \mathcal{I})$, proving the lemma. \hfill $\square$

We are now ready to give a sheaf-theoretic formula for $[\pi_*]$. Recall that, for any curve $X$, the set $\text{GPic}(X)$ can be seen as the set of isomorphism classes of generalized line bundles on on $X$.

**Proposition 4.8.** (Formula for the direct image of generalized line bundles)

*Let $\mathcal{L}$ be a generalized line bundle on $X$. Then,

$$[\pi_*]\mathcal{L} \simeq (\wedge^n (\pi_* \mathcal{L}))^\omega \otimes (\pi_* \mathcal{O}_X)^{-1}.$$*

**Proof.** By the surjectivity of $\text{GDiv}(X) \rightarrow \text{GPic}(X)$, we can pick a generalized divisor $D \in \text{GDiv}(X)$ with fractional ideal $\mathcal{I}$ isomorphic to $\mathcal{L}$; then,

$$[\pi_*]\mathcal{L} = [\pi_*][[D]] = [\pi_* (D)]$$

by Definition 4.5. By Lemma 2.1 there are effective generalized divisors $E, F$ on $X$ such that $D = E - F$ and $F$ Cartier. Denote with $\mathcal{I}'$ the ideal sheaf of $E$ and with $\mathcal{J}$ the ideal sheaf of $F$. Since $F$ is Cartier, the condition $D = E - F$ can be rewritten as $E = D + F$, or in terms of sheaves:

$$\mathcal{I}' = \mathcal{I} : \mathcal{J}.$$
Consider the direct images of $E$ and $F$. By Lemma 4.7, the ideal sheaf of $\pi_*(E)$ is isomorphic to

$$(\Lambda^n(\pi_*\mathcal{I}'))^{\omega_\omega} \otimes \det(\pi_*\mathcal{O}_X)^{-1},$$

while the ideal sheaf of $\pi_*(F)$ is isomorphic to

$$(\Lambda^n(\pi_*\mathcal{J}))^{\omega_\omega} \otimes \det(\pi_*\mathcal{O}_X)^{-1} \simeq (\Lambda^n(\pi_*\mathcal{J}) \otimes \det(\pi_*\mathcal{O}_X)^{-1}.$$

By Definition 4.3, $\pi_*(D) = \pi_*(E) - \pi_*(F)$. Then, the fractional ideal of $\pi_*(D)$ is isomorphic to:

$$(\Lambda^n(\pi_*\mathcal{I}'))^{\omega_\omega} \otimes \det(\pi_*\mathcal{O}_X)^{-1} \otimes (\Lambda^n(\pi_*\mathcal{J}))^{-1} \otimes \det(\pi_*\mathcal{O}_X),$$

which in turn is isomorphic to:

$$(\Lambda^n(\pi_*\mathcal{I}'))^{\omega_\omega} \otimes (\Lambda^n(\pi_*\mathcal{J}))^{-1}.$$

Then, we are left to prove that:

$$(\Lambda^n(\pi_*\mathcal{I}'))^{\omega_\omega} \otimes (\Lambda^n(\pi_*\mathcal{J}))^{-1} \simeq (\Lambda^n(\pi_*\mathcal{I}))^{\omega_\omega} \otimes \det(\pi_*\mathcal{O}_X)^{-1},$$

or, equivalently, that:

$$(\Lambda^n(\pi_*\mathcal{I}))^{\omega_\omega} \otimes \det(\pi_*\mathcal{O}_X) \simeq (\Lambda^n(\pi_*\mathcal{I}))^{\omega_\omega} \otimes (\Lambda^n(\pi_*\mathcal{J})),$$

under the assumptions $\mathcal{I}' = \mathcal{I} \cdot \mathcal{J}$ and $\mathcal{J}$ locally principal. Consider an open cover $\{V_i\}_{i \in I}$ of $Y$ such that $\mathcal{J}$ is trivial on each $U_i = \pi^{-1}(V_i)$, i.e. there is an isomorphism $\lambda_i : \mathcal{J}_{|U_i} = (f_i) \cong \mathcal{O}_{X|U_i}$ for each $i \in I$. On the intersections $U_i \cap U_j$, the collection $\{\lambda_i \circ \lambda_j^{-1}\}$ of automorphisms $\mathcal{O}_{X|U_i \cap U_j}$ is a cochain that measures the obstruction for the $\lambda_i$'s to glue to a global isomorphism. We define now an isomorphism

$$\alpha : (\Lambda^n(\pi_*\mathcal{I}))^{\omega_\omega} \otimes \det(\pi_*\mathcal{O}_X) \longrightarrow (\Lambda^n(\pi_*\mathcal{I}))^{\omega_\omega} \otimes (\Lambda^n(\pi_*\mathcal{J}))$$

by gluing a collection of isomorphisms $\alpha_i$ defined on each $V_i$. To do so, we define each $\alpha_i$ as the following composition of arrows:

$$\begin{array}{ccc}
((\Lambda^n(\pi_*\mathcal{I}))^{\omega_\omega})_{|V_i} & \longrightarrow & ((\Lambda^n(\pi_*\mathcal{I}))^{\omega_\omega} \otimes \Lambda^n(\pi_*\mathcal{J}))_{|V_i} \\
\| & & \uparrow \quad i \\
(\Lambda^n(\pi_*\mathcal{I}_{|U_i}))^{\omega_\omega} \otimes \det(\pi_*\mathcal{O}_{X|U_i}) & \longrightarrow & (\Lambda^n(\pi_*\mathcal{J}_{|U_i}))^{\omega_\omega} \otimes (\Lambda^n(\pi_*\mathcal{J}_{|U_i}))^{\omega_\omega} \\
\alpha_i & \downarrow \quad \text{id} & \quad \uparrow \quad \text{id} \otimes (\Lambda^n(\pi_*\mathcal{J}_{|U_i}))^{\omega_\omega} \\
(\Lambda^n(\pi_*\mathcal{I}_{|U_i}))^{\omega_\omega} \otimes \det(\pi_*\mathcal{O}_{X|U_i}) & \simeq & (\Lambda^n(\pi_*\mathcal{I}_{|U_i}))^{\omega_\omega} \otimes (\Lambda^n(\pi_*\mathcal{O}_{X|U_i}))^{\omega_\omega}
\end{array}$$

i.e. $\alpha_i := (\Lambda^n(\pi_*\mathcal{I}_i))^{\omega_\omega} \otimes (\Lambda^n(\pi_*\mathcal{J}_i))^{\omega_\omega}$. Since $\Lambda^n(\pi_*\mathcal{I})$ and $(\_)^{\omega_\omega}$ are functorial, the obstruction $\alpha_i \circ \alpha_j^{-1}$ is trivial on any $V_i \cap V_j$, whence the $\alpha_i$'s glue together to a global isomorphism $\alpha$.

**Corollary 4.9.** Let $\mathcal{L}$ be a line bundle on $X$. Then,

$$\text{Nm}_\pi(\mathcal{L}) = [\pi_*](\mathcal{L}).$$
Proof. By Lemma 1.7
\[ \Nm_\pi(L) \simeq \det(\pi_*L) \otimes \det(\pi_*O_X)^{-1}. \]
On the other side, by Proposition 4.8,
\[ [\pi_*](L) \simeq (\det(\pi_*L))^{\omega \omega} \otimes \det(\pi_*O_X)^{-1}. \]
Since \( L \) is locally free, \( \det(\pi_*L) \) is a line bundle and in particular is a pure coherent sheaf. Then, \( \det(\pi_*L) \simeq (\det(\pi_*L))^{\omega \omega} \), proving the thesis. \( \square \)

Corollary 4.10. Let \( L \) be a generalized line bundle on \( X \). Suppose that \( Y \) is smooth. Then:
\[ [\pi_*](L) \simeq \Lambda^n(\pi_*L) \otimes \det(\pi_*O_X)^{-1}. \]

Proof. First note that, by Proposition 4.8,
\[ [\pi_*](L) \simeq (\Lambda^n(\pi_*L))^{\omega \omega} \otimes \det(\pi_*O_X)^{-1}. \]
Second, observe that the pure sheaf \( \pi_*L \) is locally free of rank \( n \) since \( Y \) is smooth (see [HL10, Example 1.1.16]), and \( \Lambda^n(\pi_*L) \) is a line bundle. Then,
\[ (\Lambda^n(\pi_*L))^{\omega \omega} \simeq \Lambda^n(\pi_*L). \]
Combining these two facts, we have proved the thesis. \( \square \)

4.2. Relation with the degree. In this subsection, assuming that \( X \) and \( Y \) are curves of finite type over a base field \( k \), we show that \( \pi_* \) preserves the degree of divisors under the condition that \( Y \) is smooth over \( k \). In general, however, the direct image of a generalized divisor \( D \) may not have the same degree of \( D \), as the following example shows.

Example 4.11. Fix \( k \) an algebraically closed field. Let \( A = k[x, y]/(y^2 - x^4) \) be the affine coordinate ring of a curve \( X = \text{Spec} A \) with a tacnode at the point \( P \) corresponding to the maximal ideal \( p = (x, y) \). The involution \( \sigma \) on \( A \) defined by \( x \mapsto -x, y \mapsto y \) induces an involution \( \sigma_X \) on the curve \( X \). The geometric quotient \( Y = X/\sigma_X \) is an affine curve with coordinate ring equal to the ring of invariants \( A^\sigma = k[x^2, y]/(y^2 - x^4) \), that is isomorphic to \( B = k[s, t]/(t^2 - s^2) \) putting \( s \mapsto x^2 \) and \( t \mapsto y \). The quotient curve \( Y \) has a simple node at the point \( Q \) corresponding to the maximal ideal \( q = (s, t) \).

The inclusion map \( A^\sigma \subset A \) gives to \( A \) the structure of free \( B \)-module, with basis \( \{1, x\} \); so, the corresponding morphism of curve \( \pi : X \to Y = X/\sigma_X \) is a finite, locally free map of degree 2 sending \( P \) to \( Q \).

Let \( D \) be the generalized divisor on \( X \) defined by the ideal \( I = (x^2, y) \subset A \); note that \( D \) is supported only on the tacnode \( P \). Since we want to compare \( \deg(D) = \deg_P(D) \) with \( \deg(\pi_*(D)) = \deg_Q(\pi_*(D)) \), we can restrict to work locally around \( P \) and \( Q \). Let \( B_q \) be the local ring of \( Y \) at \( Q \). The induced map \( B_q \to A_p \) makes \( A_p \) a free \( B_q \)-module of rank 2.

Let \( E = A_p/I_p \simeq k[x]/(x^2) \) be the local ring of \( D \) at the \( P \). We have:
\[ \deg_P(D) = \ell(E) = 2. \]
Observe that \( E \) has the following free presentation as \( A_p \)-module:
\[ A_p^\otimes 2 \xrightarrow{(x^2, y)} A_p \to E \to 0. \]
Since $A_p$ is a free $B_q$-module of rank 2, $E$ has also a presentation as $B_q$-module:

$$B_q^2 \xrightarrow{\varphi} E \rightarrow 0$$

where

$$\varphi = \begin{bmatrix} s & 0 \\ 0 & s \end{bmatrix}.$$

Then, the 0-th Fitting ideal of $E$ as $B_q$-module is $F_0(E) = (s^2, t^2, st) \subset B_q$. We have:

$$\deg_Q(\pi_\ast(D)) = \ell(B_q/F_0(E)) = 3.$$ 

Note that there are divisors of degree 2 on $X$, supported at $P$, whose direct image has degree 2 on $Y$. For example, take $D' = (x)$.

**Remark 4.12.** The previous example shows, in particular, that Proposition 2.33 in [Vas04] is false.

We now prove that the degree is preserved if the direct image is Cartier. We show first a proposition that computes the degree at any point where the direct image is locally principal.

**Proposition 4.13.** (Degree of the direct image of a generalized divisor)

Let $D \in G\text{Div}(X)$ be a generalized divisor on $X$ and let $y \in Y$ be a point in codimension 1 of the support of $\pi_\ast(D)$. Suppose that $\pi_\ast(D)$ is locally principal at $y$. Then,

$$\deg_y(\pi_\ast(D)) = \sum_{\pi(x) = y} \deg_x(D).$$

**Proof.** First, suppose that $D$ is effective. Let $V = \text{Spec}(B)$ be an affine open neighborhood of $y$ with affine pre-image $U = \pi^{-1}(V) = \text{Spec}(A)$, and let $I \subset A$ denote the ideal of $D$ restricted to $U$. The coordinate ring of $D$ on $U$ is the Artin ring $A/I$ whose spectrum is equal to $\text{Spec}(A) \cap \text{Supp}(D) = \{p_1, \ldots, p_s\}$; hence we have:

$$A/I = \prod_{i=1}^s (A/I)_{p_i}.$$ 

Let $q \subset B$ denote the maximal ideal corresponding to $y$ in $\text{Spec}(B)$ and let $B_q$ be the associated local ring of dimension 1. Then, the localization of $A/I$ at $q$, denoted $E$, is the coordinate ring of $D$ restricted to the fibre of $y$:

$$E = (A/I)_q = \prod_{\pi^{-1}(p_i) = q} (A/I)_{p_i}.$$ 

Since $\pi_\ast(D)$ is effective, the degree of $\pi_\ast(D)$ at $y$ is:

$$\deg_y(\pi_\ast(D)) = \ell(O_{Y,y}/F_0(\pi_\ast(O_D))_y)[k(y) : k] = \ell(B_q/F_0(E))[k(y) : k].$$
By hypothesis $F_0(E)$ is an invertible module, so by [Vas04 Proposition 2.32], we have $\ell \left( B_q / F_0(E) \right) = \ell(E)$. On the other hand, thanks to [Sta19, Tag 02M0], note that:

\[
\ell(E) = \ell \left( \prod_{\pi^{-1}(p_i) = q} \left( A / I_{p_i} \right) \right) = \\
\sum_{\pi^{-1}(p_i) = q} \ell(A_{p_i} / I_{p_i}) \cdot \left[ k(p_i) : k(q) \right] = \\
\sum_{\pi(x) = y} \ell \left( \mathcal{O}_{X,x} / I_x \right) \cdot \left[ k(x) : k(y) \right] = \\
\sum_{\pi(x) = y} \deg_x(D) \cdot \left[ k(x) : k(y) \right].
\]

Putting everything together we have:

\[
\deg_Y(\pi_*(D)) = \ell(E) \cdot \left[ k(y) : k \right] = \\
\left( \sum_{\pi(x) = y} \deg_x(D) \cdot \left[ k(x) : k(y) \right] \right) \cdot \left[ k(y) : k \right] = \\
\sum_{\pi(x) = y} \deg_x(D) \cdot \left[ k(x) : k \right] = \\
\sum_{\pi(x) = y} \deg_x(D)
\]

for $D$ effective generalized divisor on $X$.

Let now $D = E - F$ be a generalized divisor, written as a difference of effective generalized divisors with $F$ Cartier by Lemma 2.1. Since $\pi_*(F)$ is Cartier, using the result for effective divisors established before, we have:

\[
\deg_Y(\pi_*(D)) = \deg_Y(\pi_*(E) - \pi_*(F)) = \\
\deg_Y(\pi_*(E)) - \deg_Y(\pi_*(F)) = \\
\sum_{\pi(x) = y} [\deg_x(E) - \deg_x(F)] = \\
\sum_{\pi(x) = y} \deg_x(D).
\]

\[
\square
\]

**Corollary 4.14.** Let $D \in \text{GDiv}(X)$ be a generalized divisor on $X$ such that $\pi_*(D)$ is Cartier. Then,

\[
\deg_Y(\pi_*(D)) = \deg_X(D).
\]
Proof. Applying Definition 2.3 and Proposition 4.13 we get:
\[
\deg_Y(\pi_*(D)) = \sum_{y \text{ cod 1}} \deg_y(\pi_*(D)) = \\
= \sum_{y \text{ cod 1}} \sum_{\pi(x) = y} \deg_x(D).
\]
By the properties of the Fitting image, \(\pi_*(D)\) is supported on the set-theoretic image of the support of \(D\); hence, the \(x\) appearing in the last sum are all the \(x\) for which \(\deg_x(D)\) is not zero. Then, the previous sum gives:
\[
\deg_Y(\pi_*(D)) = \sum_{x \text{ cod 1}} \deg_x(D) = \deg_X(D).
\]
\[\square\]

**Corollary 4.15.** Suppose that \(Y\) is smooth. Then, for any generalized divisor \(D\) on \(X\),
\[
\deg_Y(\pi_*(D)) = \deg_X(D).
\]
*Proof.* Let \(D\) be a generalized divisor on \(X\). The direct image \(\pi_*(D)\) is a generalized divisor on \(Y\) smooth, hence Cartier. Then, apply Corollary 4.14. \(\square\)

### 4.3. The inverse image

In this subsection, we define the inverse image for generalized divisors and generalized line bundles and we study the relation of the inverse image with the direct image. We start from the case of effective divisors.

**Definition/Lemma 4.16.** (Inverse image of an effective generalized divisor) Let \(D \in \mathbb{GDiv}^+(Y)\) be an effective generalized divisor with ideal sheaf \(I \subseteq \mathcal{O}_Y\). The **inverse image of \(D\) relative to \(\pi\)**, denoted \(\pi^{-1}(D)\), is the effective generalized divisor with ideal sheaf \(\pi^{-1}(I) \cdot \mathcal{O}_X\).

*Proof.* The inverse image ideal \(\pi^{-1}(I)\) is an ideal sheaf of \(\pi^{-1}(\mathcal{O}_Y)\)-modules and can be extended to \(\mathcal{O}_X\)-modules via the canonical map of sheaves of rings \(\pi^\sharp : \pi^{-1}(\mathcal{O}_Y) \to \mathcal{O}_X\). It is coherent since \(\mathcal{I}\) is coherent. If \(\eta\) is a generic point of \(X\), then \(\pi(\eta)\) is a generic point of \(Y\), hence
\[
(\pi^{-1}(\mathcal{I}) \cdot \mathcal{O}_X)_{\eta} = \mathcal{I}_{\pi(\eta)} \cdot \mathcal{O}_{X,\eta} = \mathcal{O}_{X,\eta}.
\]
since \(\mathcal{I}_{\pi(\eta)} = \mathcal{O}_{Y,\pi(\eta)}\). \(\square\)

**Remark 4.17.** In the setting of Definition 4.16 consider the short exact sequence:
\[
0 \to \mathcal{I} \to \mathcal{O}_Y \to \mathcal{O}_D \to 0.
\]
Since \(\pi\) is flat and surjective, the pullback functor \(- \otimes_{\mathcal{O}_X} \mathcal{O}_Y\) is exact as well as the inverse image functor \(\pi^{-1}\). Then, the previous exact sequence induces the following exact sequence:
\[
0 \to \pi^*\mathcal{I} \to \pi^*\mathcal{O}_Y \to \pi^*\mathcal{O}_D \to 0.
\]
Since \(\pi^*\mathcal{O}_Y = \mathcal{O}_X\), the pullback sheaf \(\pi^*(\mathcal{I})\) has a canonical injection in \(\mathcal{O}_X\), whose image is exactly the inverse image ideal \(\pi^{-1}(\mathcal{I}) \cdot \mathcal{O}_X\).
Lemma 4.18. Let $D \in \text{GDiv}^+(Y)$ be a generalized effective divisor and $E \in \text{CDiv}^+(Y)$ be an effective Cartier divisor on $Y$. Then, the inverse image divisor $\pi^*(E)$ is Cartier and $\pi^*(D+E) = \pi^*(D) + \pi^*(E)$.

Proof. Let $\mathcal{I}$ and $\mathcal{J}$ be the ideal sheaves of $D$ and $E$ respectively. The ideal sheaf $\mathcal{J}$ is locally principal, hence its inverse image $\pi^{-1}(\mathcal{J}) \cdot \mathcal{O}_X$ is again locally principal; then, $\pi^*(E)$ is Cartier. The generalized divisor $D + E$ is defined by the ideal sheaf $\mathcal{I} \cdot \mathcal{J}$, whose inverse image is:

$$\pi^{-1}(\mathcal{I} \cdot \mathcal{J}) \cdot \mathcal{O}_X = (\pi^{-1}(\mathcal{I}) \cdot \pi^{-1}(\mathcal{J})) \cdot \mathcal{O}_X = (\pi^{-1}(\mathcal{I}) \cdot \mathcal{O}_X) \cdot (\pi^{-1}(\mathcal{J}) \cdot \mathcal{O}_X),$$

which is the defining ideal of $\pi^*(D) + \pi^*(E)$. $\square$

Now, we can extend the definition of inverse image to any generalized divisor and study its properties.

Definition/Lemma 4.19. (Inverse image of a generalized divisor)

Let $D \in \text{GDiv}(Y)$ be any generalized divisor and let $D = E - F$ with $E, F$ effective generalized divisors and $F$ Cartier by Lemma 2.14. The inverse image of $D$ relative to $\pi$, denoted $\pi^*(D)$, is the generalized divisor $\pi^*(E) - \pi^*(F)$.

Proof. To prove that it is well defined, let $D = D' - E = \tilde{D}' - \tilde{E}$, with $D', \tilde{D}'$ effective and $E, \tilde{E}$ effective Cartier. Since $E, \tilde{E}$ are Cartier, $D' + \tilde{E} = \tilde{D}' + E$; then, by Lemma 4.18 we have:

$$\pi^*(D') + \pi^*(\tilde{E}) = \pi^*(\tilde{D}') + \pi^*(E).$$

Again by Lemma 4.18 $\pi^*(E)$ and $\pi^*(\tilde{E})$ are Cartier, so they can be subtracted from each side in order to obtain:

$$\pi^*(D') - \pi^*(E) = \pi^*(\tilde{D}') - \pi^*(\tilde{E}),$$

so $\pi^*(D)$ does not depend on the choice of $D'$ and $E$. $\square$

Proposition 4.20. (Properties of inverse image)

1. Let $D \in \text{CDiv}(Y)$ be a Cartier divisor on $Y$. Then, $\pi^*(D)$ is a Cartier divisor and $\pi^*(-D) = -\pi^*(D)$. Moreover, $\pi^*(D)$ coincides with $\pi^*(D)$ of Definition 1.13.

2. Let $D, E \in \text{GDiv}(Y)$ be generalized divisors, such that $E$ is Cartier. Then, $\pi^*(D + E) = \pi^*(D) + \pi^*(E)$.

3. Let $V \subset Y$ be an open subset, and denote with $\pi|_U$ the restriction of $\pi$ to $U = \pi^{-1}(V) \subset X$. Let $D \in \text{GDiv}(Y)$ be a generalized divisor on $Y$. Then,

$$(\pi|_U)^*(D|_V) = \pi^*(D)|_U$$

4. Let $D, D' \in \text{GDiv}(Y)$ be generalized divisors such that $D \sim D'$. Then, $\pi^*(D) \sim \pi^*(D')$.

Proof. To prove (1), consider $D = E - F$ with $E, F$ effective and $F$ Cartier by Lemma 2.14 on $Y$. Since $D$ is Cartier and $E = D + F$, then also $E$ is Cartier. By Definition 4.19

$$\pi^*(D) = \pi^*(E) - \pi^*(F).$$
By Lemma 4.18 it is a difference of Cartier divisors and hence it is Cartier.
To compute \( \pi^*(-D) \), note that since \( F \) is Cartier then \( -D = F - E \), and it is a difference of effective Cartier divisors; then, apply Definition 4.19 to obtain

\[
\pi^*(-D) = \pi^*(F) - \pi^*(E) = -\pi^*(D).
\]

To compare \( \pi^*(D) \) with Definition 4.18, let \( \mathcal{I} \) and \( \mathcal{J} \) be the ideal sheaves of \( E \) and \( F \) and let \( \{V_i\}_{i \in I} \) be an open cover of \( Y \) such that \( \mathcal{I}|_{V_i} \) and \( \mathcal{J}|_{V_i} \) are principal ideals of \( \mathcal{O}_{V_i} \)-modules generated by regular sections \( s_i \) and \( t_i \) of \( \Gamma(V_i, \mathcal{O}_Y) \), respectively on each \( i \in I \). The fractional ideal of \( D \) is generated on each \( V_i \) by the meromorphic regular section \( u_i = s_i/t_i \) of \( \Gamma(V_i, \mathcal{K}_Y) \). By Definition 4.19, the ideal sheaves of \( \pi^*(E) \) and \( \pi^*(F) \) are generated on each \( U_i = \pi^{-1}(V_i) \) by \( \pi^+_i(s_i) \) and \( \pi^+_i(t_i) \) respectively. Then, by Definition 4.19 the fractional ideal of \( \pi^*(D) \) is generated on each \( U_i \) by the meromorphic regular section \( \pi^+_i(s_i)/\pi^+_i(t_i) \) of \( \Gamma(U_i, \mathcal{K}_Y) \). These are exactly the local generators for \( \pi^*(D) \) as defined in Definition 4.18.

To prove (2), consider \( D = D_1 - D_2 \) and \( E = E_1 - E_2 \), with \( D_1, D_2, E_1, E_2 \) effective and \( D_2, E_2 \) Cartier. Note that \( D + E = (D_1 + E_1) - (D_2 + E_2) \), and it is a difference of effective divisors with \( D_2 + E_2 \) Cartier. Then, applying Definition 4.19 and Lemma 4.18 we obtain:

\[
\pi^*(D + E) = \pi^*((D_1 + E_1) - (D_2 + E_2)) = \\
= \pi^*(D_1 + E_1) - \pi^*(D_2 + E_2) = \\
= \pi^*(D_1) + \pi^*(E_1) - \pi^*(D_2) - \pi^*(E_2) = \\
= (\pi^*(D_1) - \pi^*(D_2)) - (\pi^*(E_1) - \pi^*(E_2)) = \\
= \pi^*(D) + \pi^*(E).
\]

To prove (3), if \( D \) is effective, the result follows the fact that the inverse image functor \( \pi^{-1} \) commutes with restrictions. Then, observe that the operations of product and inverse of fractional ideals also commute with restrictions.

To prove (4), let \( f \in \Gamma(Y, \mathcal{K}_Y) \) be a global section that generates a principal divisor \( E = (f) \in \text{Prin}(Y) \) such that \( D = D' + E \). The inverse image \( \pi^*(E) \) is the principal divisor \( (\pi^*(f)) \in \text{Prin}(X) \). Then, by Lemma 4.18 \( \pi^*(D) = \pi^*(D') + (\pi^*(f)) \); so \( \pi^*(D) \) and \( \pi^*(D') \) are linearly equivalent. \( \square \)

We are now ready to define the inverse image for generalized line bundles.

**Definition/Lemma 4.21.** (Inverse image for generalized line bundles) The inverse image for generalized divisors induce a inverse image map between the sets of generalized line bundles, defined as:

\[
[\pi^*] : \text{GPic}(Y) \longrightarrow \text{GPic}(X) \\
[D] \mapsto [\pi^*(D)].
\]

**Proof.** Recall that for any curve \( X \), the set \( \text{GPic}(X) \) can be seen equivalently as the set of generalized line bundles or as the set of generalized divisors modulo linear equivalence. Here, \([\pi^*]\) is defined in terms of generalized divisors modulo linear equivalence. By Proposition 4.20 the direct images of
linearly equivalent divisors are linearly equivalent, hence \([\pi^*]\) is well defined.

\[\square\]

**Remark 4.22.** If \(L\) is a generalized line bundle on \(Y\) and \(D\) is a generalized divisor with fractional ideal \(I\) isomorphic to \(L\), then the inverse image divisor \(\pi^*(D)\) has fractional ideal isomorphic to the pullback sheaf \(\pi^*(I)\) by Remark 4.17. Since \(\pi^*(I)\) is isomorphic to \(\pi^*(L)\) as abstract \(O_X\)-modules, we conclude that the inverse image \([\pi^*](L)\) of the generalized line bundle \(L\) is equal to the pullback sheaf \(\pi^*(L)\).

We prove now a result on the composition of the direct image with the inverse image of generalized divisors.

**Proposition 4.23.** (Composition of the direct image with the inverse image) Let \(D \in G\text{Div}(Y)\) be a generalized divisor on \(Y\). Then,

\[\pi_*(\pi^*(D)) = n \cdot D\]

**Proof.** Since both of the terms are linear with respect to the sum of Cartier divisor, we can suppose that \(D\) is effective with ideal sheaf \(I \subseteq O_Y\). First note that, from the exact sequence:

\[0 \to \pi^*\mathcal{I} \to \pi^*\mathcal{O}_Y \to \pi^*\mathcal{O}_D \to 0\]

together with Remark 4.17, we obtain \(\mathcal{O}_X/(\pi^{-1}\mathcal{I} \cdot \mathcal{O}_X) = \mathcal{O}_X/\pi^*\mathcal{I} = \pi^*(\mathcal{O}_Y/\mathcal{I})\). To prove the thesis, we show that the equality

\[\text{Fitt}_0(\pi_*(\mathcal{O}_X/\pi^*\mathcal{I})) = \mathcal{I}^n\]

holds locally around any point \(y \in Y\). Let \(V \subseteq Y\) be an open neighborhood of \(y\) such that \((\pi_*\mathcal{O}_X)|_V \simeq (\mathcal{O}_Y|_V)^{\oplus n}\) and \(\mathcal{I}|_V\) is generated by sections \(s_1, \ldots, s_r\) of \(\Gamma(V, \mathcal{I})\). Then, consider the following presentation:

\[\mathcal{O}^{\oplus r}_{Y|V} \xrightarrow{(s_1, \ldots, s_r)} \mathcal{O}_Y|_V \to (\mathcal{O}_Y/\mathcal{I})|_V \to 0.\]

Pulling back with \(\pi^*\), we obtain the following exact sequence on \(U = \pi^{-1}(V)\):

\[\mathcal{O}^{\oplus r}_{X|U} \xrightarrow{(s_1, \ldots, s_r)} \mathcal{O}_X|_U \to (\mathcal{O}_X/\pi^*\mathcal{I})|_U \to 0.\]

In order to compute \(\text{Fitt}_0(\pi_*(\mathcal{O}_X/\pi^*\mathcal{I}))|_V\), we consider then the pushforward sequence:

\[(\pi_*\mathcal{O}^{\oplus r}_X)|_V \xrightarrow{(s_1, \ldots, s_r)} (\pi_*\mathcal{O}_X)|_V \to \pi_*(\mathcal{O}_X/\pi^*\mathcal{I})|_V \to 0.\]

Since \(\pi_*(\mathcal{O}_X/\pi^*\mathcal{I})|_V \simeq (\mathcal{O}^{\oplus n}_Y)|_V\), the map on the left is represented by the following \(n \times nr\) matrix with entries in \(\Gamma(V, \mathcal{O}_Y)\):

\[M = \begin{bmatrix} s_1 & \cdots & s_n \\ \vdots & \ddots & \vdots \\ s_1 & \cdots & s_n \end{bmatrix}.\]

Now, \(\text{Fitt}_0(\pi_*(\mathcal{O}_X/\pi^*\mathcal{I}))|_V\) is generated by the \(n \times n\) minors of \(M\), i.e. all the possible products of \(n\) generators of \(\mathcal{I}\) on \(V\), with repetitions. This shows that \(\text{Fitt}_0(\pi_*(\mathcal{O}_X/\pi^*\mathcal{I}))|_V = \mathcal{I}^n|_V.\)
5. The direct and inverse image for families of generalized divisors

Let $\pi : X \to Y$ be a finite, flat map of degree $n$ between projective curves over a field $k$. In the present section, we discuss the definition of direct and inverse image for families of effective generalized divisors. Under suitable conditions, recalling Definition 2.5, we aim to define a pair of geometric morphisms:

$$
\pi_* : \text{Hilb}_X \to \text{Hilb}_Y
$$

$$
\pi^* : \text{Hilb}_Y \to \text{Hilb}_X
$$

that, on $k$-valued points, coincide with the direct and inverse image between $\text{GDiv}^+(X)$ and $\text{GDiv}^+(Y)$.

First, notice that defining the direct image for families of effective generalized divisors is not possible when the curve $Y$ is not smooth over $k$. Consider, for example, the setting of Example 4.11; since $X$ and $Y$ are reduced curves with planar singularities, their Hilbert schemes of generalized divisors of given degree are connected (see [AIK77], [BeGS81]). The effective divisors $D_1$ and $D_2$ on $X$ defined by $\langle x^2, y \rangle$ and $\langle x \rangle$ on $X$ have both degree 2, but their direct images on the quotient node $Y$ have degree respectively equal to 3 and 2. Then, their $k$-points $D_1, D_2$ in the connected component $\text{Hilb}_2^X$ of $\text{Hilb}_X$ are sent to different connected components of $\text{Hilb}_Y$. This shows that the direct image of divisors in general is not defined as a geometric map.

In the rest of the section, consider $\pi : X \to Y$ a finite, flat map of degree $n$ between projective curves over $k$, and suppose that $Y$ is smooth over $k$. Recall that, in such case, $\text{Hilb}_Y = \ell \text{Hilb}_Y$.

**Definition/Lemma 5.1. (Direct image for families of effective generalized divisors)** Let $T$ be any $k$-scheme. The direct image map for the Hilbert scheme of effective generalized divisors is defined on the $T$-valued points as:

$$
\pi_*(T) : \text{Hilb}_X(T) \longrightarrow \ell \text{Hilb}_Y(T)
$$

$$
D \subseteq X \times_k T \longrightarrow \mathcal{Z} \left( \text{Fitt}_0(\pi_{T,*}(\mathcal{O}_D)) \right)
$$

where $\pi_T : X \times_k T \to Y \times_k T$ is the morphism induced by base change of $\pi$.

**Proof.** Let $D \subseteq X \times_k T$ be a $T$-flat family of effective divisors of $X$, defined by an ideal sheaf $\mathcal{I} \subseteq \mathcal{O}_{X \times_k T}$ such that $\mathcal{O}_D = \mathcal{O}_{X \times_k T}/\mathcal{I}$ is flat over $S$. From the exact sequence

$$
0 \to \mathcal{I} \to \mathcal{O}_{X \times_k T} \to \mathcal{O}_D \to 0
$$

we deduce that also $\mathcal{I}$ is flat over $T$. Since $\pi$ is finite and flat, $\pi_{T,*}(\mathcal{I})$ is also flat over $T$, fibrewise locally free since $Y$ is smooth and hence locally free on $Y \times_k T$ by [HL10, Lemma 2.1.7]. Moreover, it fits the exact sequence

$$
0 \to \pi_{T,*}(\mathcal{I}) \xrightarrow{\phi} \pi_{T,*}(\mathcal{O}_{X \times_k T}) \to \pi_{T,*}(\mathcal{O}_D) \to 0.
$$
Then, by Definition 3.1 the 0-th Fitting ideal of $\pi_{T,*}(\mathcal{O}_D)$ is the image of the canonical injection
\[
\det (\pi_{T,*}(\mathcal{I})) \otimes \det (\pi_{T,*}\mathcal{O}_{X \times_k T})^{-1} \xrightarrow{\det(\varphi)} \mathcal{O}_{Y \times_k T}
\]
and this is locally free over $Y \times_k T$, hence flat over $T$. Then, it defines a $T$-flat family of effective divisors of $Y$. 

□

Remark 5.2. For any $T$-family of effective generalized divisors $D \subseteq X \times_k T$ and for any point $t \in T$, the fibre $\pi_t(D)(t)$ is equal to the direct image $\pi_t(D_t)$ defined for the effective divisor $D_t$ on $X$. Moreover, since $Y$ is smooth, by Corollary 4.15 we have:
\[
\deg_Y(\pi_t(D_t)) = \deg_X(D_t).
\]
Then, for any $d \geq 0$, $\pi_t$ restricts to a map:
\[
\pi^d_t : \Hilb_Y^d \longrightarrow \ell \Hilb_Y^d.
\]

Definition/Lemma 5.3. (Inverse image for families of effective generalized divisors) Let $T$ be any $k$-scheme. The inverse image map for the Hilbert scheme of effective Cartier divisors is defined on the $T$-valued points as:
\[
\pi^*(T) : \ell \Hilb_Y(T) \longrightarrow \ell \Hilb_X(T)
\]
\[
D \subseteq Y \times_k T \longmapsto \mathcal{Z}(\pi^{-1}_T(\mathcal{I}) \cdot \mathcal{O}_{X \times_k T})
\]
where $\pi_T : X \times_k T \rightarrow Y \times_k T$ is the morphism induced by base change of $\pi$ and $\mathcal{I} \subseteq \mathcal{O}_{Y \times_k T}$ is the ideal sheaf of $D$.

Proof. Since $\mathcal{I}$ is locally principal, $\pi^{-1}_T(\mathcal{I}) \cdot \mathcal{O}_{X \times_k T} \subseteq \mathcal{O}_{X \times_k T}$ is locally principal. The restriction of $\pi^*(T)(D)$ to the fibre over any $t \in T$ has ideal sheaf $\pi^{-1}_t(\mathcal{I}_t) \cdot \mathcal{O}_{X \times_k T}$, which is equal to the defining ideal of $\pi_t^*(D_t)$ by Definition 4.19. Hence, $\pi^*(T)(D)$ is a locally principal subscheme of $X \times_k T$, such that all fibres over $T$ are effective Cartier divisors by Lemma 4.18. Then, $\pi^*(T)(D)$ is $T$-flat by [Sta19, Tag 062Y], hence it is a $T$-family of Cartier divisors.

We study now some properties of the direct and inverse image for families of effective generalized divisors. With a slight abuse of notation, we will write $\pi_*$ and $\pi^*$ instead of $\pi_*(T)$ and $\pi^*(T)$, when it is clear that we are working on $T$-points.

Proposition 5.4. (Properties of the direct and inverse image for families of effective generalized divisors) Let $T$ be any $k$-scheme. Then, the following fact holds.

1. Let $D, E$ be $T$-families of effective divisors over $X$ such that $E$ is a family of Cartier divisors. Then, $\pi_*(D + E) = \pi_*(D) + \pi_*(E)$.
2. Let $F, G$ be $T$-families of effective divisors over $Y$. Then, $\pi^*(F + G) = \pi^*(F) + \pi^*(G)$.
3. If $F$ is a $T$-family of effective divisors over $Y$, then $\pi_*(\pi^*(F)) = n F$.

Proof. The proof of parts (1) and (2) follows the proofs of the second part of Lemma 4.2 and 4.18 respectively. The proof of part (3) follows the proof of Proposition 4.23. □
Let $\pi : X \to Y$ be a finite, flat map of degree $n$ between projective curves over a field $k$. In the present section, we provide the definition for the Norm and the inverse image maps between the compactified Jacobians of $X$ and $Y$, induced by $\pi$.

Our definition of the Norm map on the compactified Jacobians will be inspired by the sheaf-theoretic formula of Proposition 1.7. By Proposition 4.8 and its corollaries, the generalization of such formula to generalized divisors involves taking the double $\omega$-dual of the exterior power of the pushforward of generalized line bundles. In general, this operation does not behave well in families if $Y$ is not smooth. 

Then, in accordance with the previous section, we suppose that $Y$ is smooth over $k$.

Recall that, for any line bundle $M$ on $X$, the compactified Jacobian of $X$ is related to the Hilbert scheme of effective generalized divisors via the twisted Abel map $A_M$. We will show that the direct image map and the Norm map are compatible as well as the inverse image maps, meaning that there are commutative diagrams of $k$-schemes:

$$
\begin{array}{c c c}
\text{Hilb}_X & \xrightarrow{\pi^*} & \text{Hilb}_Y \\
\downarrow A_M & & \downarrow A_{\text{Nm}(M)} \\
\mathcal{J}(X) & \xrightarrow{\text{Nm}} & J(Y)
\end{array}
\quad
\begin{array}{c c c}
\text{Hilb}_Y & \xrightarrow{\pi^*} & \text{Hilb}_X \\
\downarrow A_N & & \downarrow A_{\pi^*(N)} \\
J(Y) & \xrightarrow{\pi^*} & J(X)
\end{array}
$$

We give first the definition of the Norm map and the inverse image map for compactified Jacobians.

**Definition/Lemma 6.1. (Norm map for families of generalized line bundles)** Let $T$ be any $k$-scheme. The Norm map between compactified Jacobians associated to $\pi$ is defined on the $T$-valued points as:

$$
\text{Nm}_\pi(T) : \mathcal{J}(X)(T) \to J(Y)(T)
$$

$$
\mathcal{L} \mapsto \det (\pi_{T,*}(\mathcal{L})) \otimes \det (\pi_{T,*}\mathcal{O}_{X \times_k T})^{-1}.
$$

*Proof.* Let $\mathcal{L}$ be a $T$-family of generalized line bundles on $X$, i.e. a $T$-flat coherent sheaf on $X \times_k T$, whose fibres over $T$ are generalized line bundles. The push-forward $\pi_{T,*}(\mathcal{L})$ is a $T$-flat coherent sheaf on $Y \times_k T$ such that, for any $t \in T$, the fibre $(\pi_{T,*}\mathcal{L})_t$ equals $\pi_*(\mathcal{L}_t)$ on $Y \simeq Y \times_k t$. Since $Y$ is smooth, $\pi_*(\mathcal{L}_t)$ is a locally free sheaf of rank $n$ for any $t \in T$. Then, by [HL10, Lemma 2.1.7], $\pi_{T,*}(\mathcal{L})$ is a locally sheaf of rank $n$ on $Y \times_k T$. Its determinant bundle is a line bundle on $Y \times_k T$, hence flat over $T$. \qed

**Definition/Lemma 6.2. (Inverse image for families of generalized line bundles)** Let $T$ be any $k$-scheme. The inverse image map between
compactified Jacobians associated to $\pi$ is defined on the $T$-valued points as:

$$
\pi^*(T) : J(Y)(T) \longrightarrow J(X) \subseteq \mathcal{I}(X)(T)
$$

$N \mapsto \pi^*TN$.

**Proof.** By hypothesis, $N$ is a $T$-flat coherent sheaf on $Y \times_k T$ that is a line bundle on any fibre over $T$; then, by [HL10, Lemma 2.1.7], it is a line bundle on $Y \times_k T$. We conclude that $\pi^*N$ is a line bundle on $X \times_k T$ and hence a $T$-flat family of line bundles over $T$. □

**Remark 6.3.** When there is no ambiguity, we will write $Nm_\pi$ and $\pi^*$ instead of $Nm_\pi(T)$ and $\pi^*(T)$. The Norm and the inverse image for generalized line bundles define morphisms of algebraic stacks

$$
Nm_\pi : \mathcal{I}(X) \longrightarrow J(Y)
$$

$$
\pi^* : J(Y) \longrightarrow J(X).
$$

The Norm for generalized line bundles, restricted to the locus of line bundles $J(X) \subseteq \mathcal{I}(X)$, coincides with the classical Norm map from $J(X)$ to $J(Y)$ (Definition [1.10]).

We study now some properties of the Norm and the inverse image map between compactified Jacobians. First, we need a technical lemma.

**Lemma 6.4.** Let $T$ be a fixed $k$-scheme. For any $T$-flat family of generalized line bundles $L$ on $X \times_k T$ and any line bundle $M$ on $X \times_k T$, there is an isomorphism:

$$
\det (\pi_T^*(L \otimes M)) \otimes \det (\pi_T^*O_{X \times_k T}) \simeq \det (\pi_T^*(L)) \otimes \det (\pi_T^*(M)).
$$

**Proof.** The proof is similar to the second part of the proof of Proposition [4.3].

Since $\pi_T : X \times_k T \rightarrow Y \times_k T$ is finite and flat, $\pi_T^*(L)$ is a $T$-flat coherent sheaf on $Y \times_k T$, that is locally free on any fibre over $T$ since $Y$ is smooth; then, $\pi_T^*(L)$ is locally free or rank $n$ by [HL10, Lemma 2.1.7]. The same holds for $\pi_T^*(L \otimes M)$. On the other hand, by [Gro61, Proposition 6.1.12], $\pi_T^*M$ is a locally free $\pi_T^*O_X$-module of rank 1. In particular, there is an open cover $\{V_i\}_I$ of $Y$ such that $M$ is a trivial $O_{X|U_i}$-module on each $U_i = \pi_T^{-1}(V_i)$, i.e. there are isomorphisms $\lambda_i : M|_{U_i} \xrightarrow{\sim} O_{X|U_i}$ for each $i \in I$.

On the intersections $U_i \cap U_j$, the collection $\{\lambda_i \circ \lambda_j^{-1}\}$ of automorphisms of $O_{X	imes_k T|U_i \cap U_j}$ is a cochain that measures the obstruction for the $\lambda_i$’s to glue to a global isomorphism. We define now an isomorphism

$$
\alpha : \det (\pi_T^*(L \otimes M)) \otimes \det (\pi_T^*O_{X \times_k T}) \longrightarrow \det (\pi_T^*(L)) \otimes \det (\pi_T^*(M))
$$

by glueing a collection of isomorphisms $\alpha_i$ defined on each $V_i$. To do so, we define each $\alpha_i$ as the following composition of arrows:
To prove (3), compute by Definitions 6.1 and 6.2:

\[
\frac{\det(\pi_{T,*}(L \otimes M)) \otimes \det(\pi_{T,*}O_X))}{\det(\pi_{T,*}(\mathcal{L}) \otimes \det(\pi_{T,*}M))}
\]

Part (2) follows from the associative properties of the tensor product.

\[
\det(\pi_{T,*}(\mathcal{L} \otimes \mathcal{M}))_U \otimes \det(\pi_{T,*}O_X|_U) = \det(\pi_{T,*}\mathcal{L}|_U) \otimes \det(\pi_{T,*}\mathcal{M}|_U)
\]

\[
\det(\pi_{T,*}(\lambda_i) \otimes \id) \Rightarrow \id \otimes \det(\pi_{T,*}\lambda_i^{-1})
\]

\[
\det(\pi_{T,*}\mathcal{L}|_{U_i}) \otimes \det(\pi_{T,*}O_X|_{U_i}) = \det(\pi_{T,*}\mathcal{L}|_{U_i}) \otimes \det(\pi_{T,*}O_X|_{U_i})
\]

\(i.e. \alpha_i := \det(\pi_{T,*}\lambda_i) \otimes \det(\pi_{T,*}\lambda_i^{-1})\). Since \(\det(\pi_{T,*})\) is functorial, the obstruction \(\alpha_i \circ \alpha_j^{-1}\) is trivial on any \(V_i \cap V_j\), whence the \(\alpha_i\)'s glue together to a global isomorphism \(\alpha\).

**Proposition 6.5.** (Properties of the Norm and inverse image for families of generalized line bundles) Let \(T\) be any \(k\)-scheme. Then, the following facts hold.

1. Let \(\mathcal{L}, \mathcal{M} \in \mathbb{F}(X)(T)\) such that \(\mathcal{M}\) is a \(T\)-flat family of line bundles. Then, \(\text{Nm}_\pi(\mathcal{L} \otimes \mathcal{M}) \simeq \text{Nm}_\pi(\mathcal{L}) \otimes \text{Nm}_\pi(\mathcal{M})\).
2. Let \(\mathcal{N}, \mathcal{N}' \in J(Y)(T)\). Then, \(\pi^*(\mathcal{N} \otimes \mathcal{N}') \simeq \pi^*(\mathcal{N}) \otimes \pi^*(\mathcal{N}')\).
3. Let \(\mathcal{N} \in J(Y)(T)\). Then, \(\pi^*(\mathcal{N})\) is a \(T\)-flat family of line bundles over \(X\) and \(\text{Nm}_\pi(\pi^*(\mathcal{N})) \simeq \mathcal{N}^\otimes n\).

**Proof.** To prove (1), note that \(\mathcal{M}\) is a \(T\)-flat coherent sheaf on \(X \times_k T\) that is a line bundle on any fibre over \(T\); hence it is a line bundle on \(X \times_k T\) by [HL10] Lemma 2.1.7. Then, applying Definition 6.1 and Lemma 6.4 we have:

\[
\text{Nm}_\pi(\mathcal{L} \otimes \mathcal{M}) = \det(\pi_{T,*}(\mathcal{L} \otimes \mathcal{M})) \otimes \det(\pi_{T,*}O_{X \times_k T})^{-1} \simeq \det(\pi_{T,*}(\mathcal{L})) \otimes \det(\pi_{T,*}(\mathcal{M})) \otimes \det(\pi_{T,*}O_{X \times_k T})^{-2} \simeq \text{Nm}_\pi(\mathcal{L}) \otimes \text{Nm}_\pi(\mathcal{M}).
\]

Part (2) follows from the associative properties of the tensor product.

To prove (3), compute by Definitions 6.1 and 6.2.

\[
\text{Nm}_\pi(\pi^*(\mathcal{N})) = \det(\pi_{T,*}(\pi^T(\mathcal{N}))) \otimes \det(\pi_{T,*}O_{X \times_k T})^{-1}.
\]

By the projection formula [Sta19] Tag 01E8 and the standard properties of determinants, we have:

\[
\text{Nm}_\pi(\pi^*(\mathcal{N})) = \det(\mathcal{N} \otimes \pi_{T,*}O_{X \times_k T}) \otimes \det(\pi_{T,*}O_{X \times_k T})^{-1} \simeq \mathcal{N}^n \otimes \det(\pi_{T,*}O_{X \times_k T}) \otimes \det(\pi_{T,*}O_{X \times_k T})^{-1} \simeq \mathcal{N}^n.
\]

We compare now the Norm and the inverse image maps between the compactified Jacobians with the direct and inverse image maps between the Hilbert schemes of divisors, respectively.

**Proposition 6.6.** (Comparison of the direct image and the Norm map via the Abel map) For any line bundle \(M\) on \(X\), there is a commutative diagram
of algebraic stacks over $k$:

$$
\begin{array}{ccc}
\text{Hilb}_X & \xrightarrow{\pi^*} & \text{Hilb}_Y \\
\downarrow^\text{AM} & & \downarrow^\text{Nm}_x(M) \\
\mathcal{J}(X) & \xrightarrow{\text{Nm}_x} & J(Y)
\end{array}
$$

Proof. Let $T$ be any $k$-scheme, let $D$ be a $T$-flat family of effective divisors on $X$ with ideal sheaf $\mathcal{I}$, and denote with $\mathcal{M}$ the pullback of $M$ to $X \times_k T$. Following the bottom-left side of the square, combining Definitions 2.7 and 6.1 we get:

$$\text{Nm}_x(A_M(D)) = \det (\pi_{T,*}(\mathcal{I} \otimes \mathcal{M})) \otimes \det (\pi_{T,*}(\mathcal{O}_{X \times_k T}))^{-1}.$$ 

Following the top-right side of the square, combining definitions 5.1, 6.1 and 2.7 we get:

$$A_{\text{Nm}_x(M)}(\mathcal{I}) = \det (\pi_{T,*}(\mathcal{I})) \otimes \det (\pi_{T,*}(\mathcal{M})) \otimes \det (\pi_{T,*}(\mathcal{O}_{X \times_k T}))^{-2}.$$ 

We are left to prove that:

$$\det (\pi_{T,*}(\mathcal{I} \otimes \mathcal{M})) \otimes \det (\pi_{T,*}(\mathcal{O}_{X \times_k T})) \simeq \det (\pi_{T,*}(\mathcal{I})) \otimes \det (\pi_{T,*}(\mathcal{M})).$$

Now, $\mathcal{I}$ is a $T$-flat family of generalized line bundles by hypothesis and $\mathcal{M}$ is a line bundle on $X \times_k T$ since it is the pull-back of a line bundle on $X$. Then, the assertion is true by Lemma 6.4. □

**Proposition 6.7.** (Comparison of the inverse image maps via the Abel map) For any line bundle $\mathcal{N}$ on $Y$, there is a commutative diagram of algebraic stacks over $k$:

$$
\begin{array}{ccc}
\mathcal{J}(Y) & \xrightarrow{\pi^*} & \mathcal{J}(X) \\
\downarrow^\text{AM} & & \downarrow^\text{AM} \\
\mathcal{J}(Y) & \xrightarrow{\pi^*} & \mathcal{J}(X)
\end{array}
$$

Proof. Let $T$ be any $k$-scheme, let $D$ be a $T$-flat family of divisors on $Y$ with ideal sheaf $\mathcal{I} \subseteq Y \times_k T$, and denote with $\mathcal{N}$ the pullback of $\mathcal{N}$ to $Y \times_k T$. By Definition 2.7, Proposition 6.5(2) and Remark 4.22 we have:

$$\pi^*(A_N(D)) = \pi^*_{T}(\mathcal{I} \otimes \mathcal{N}) \simeq \pi^*_{T}(\mathcal{I}) \otimes \pi^*_{T}(\mathcal{N}) \simeq \mathcal{A}_{\pi^*(\mathcal{N})}(\pi^*(\mathcal{N})).$$
