Abstract

In this work we explore the boundary conditions in the Einstein-Hilbert action, by considering a displacement from the Riemannian manifold to an extended one. The latter is characterized by including spinor fields into the quantum geometric description of spacetime. These fields are defined on the background spacetime, emerging from the expectation value of the quantum structure of spacetime generated by matrices that comply with a Clifford algebra. In this framework, we demonstrate that spinor fields are candidate to describe all known interactions in physics, with gravitation included. A non-linear description of Gravitational Waves (GW) can be done with this theory.

One of the central problems in contemporary theoretical physics is the unification of quantum field theory with general relativity in a theory that contain both. The **boundary conditions in the minimum action’s principle** is a very important issue which must be taken into account to develop a physical theory. For simplicity we can consider this topic in a general EH action \[ I = \int d^4x \sqrt{-g} \left[ \frac{\kappa}{2} + \hat{\mathcal{L}} \right]. \] It is important to notice that, after variation, we obtain

\[
\delta I = \int d^4x \sqrt{-g} \left[ \delta g^{\alpha\beta} \left( G_{\alpha\beta} + \kappa T_{\alpha\beta} \right) + g^{\alpha\beta} \delta R_{\alpha\beta} \right],
\]

where \( \kappa = 8\pi G/c^4 \), \( T_{\alpha\beta} = 2 \frac{\delta^4}{\delta g_{\alpha\beta}} - g_{\alpha\beta} \hat{\mathcal{L}} \) is the stress tensor that describes matter and \( \hat{\mathcal{L}} \) is the Lagrangian density. The last term in (1) is very important because takes into account boundary conditions. When that quantity is zero, we obtain the well-known Einstein’s equations without cosmological constant. This element can be written as:

\[
g^{\alpha\beta} \delta R_{\alpha\beta} = [\delta W^\alpha]|_{\alpha} - (g^{\alpha\epsilon})|_{\epsilon} \delta \Gamma^\beta_{\alpha\beta} + (g^{\alpha\beta})|_{\epsilon} \delta \Gamma^\epsilon_{\alpha\beta},
\]

where \( g^{\alpha\beta} \delta R_{\alpha\beta} = \delta \Theta(x^\alpha) = \Lambda g^{\alpha\beta} \delta g_{\alpha\beta} \) is the flux of the 4-vector \( \delta \hat{W}^\alpha = \delta \hat{\Gamma}^\epsilon_{\beta\alpha} g^{\beta\alpha} - \delta \hat{\Gamma}^\alpha_{\beta\gamma} g^{\beta\gamma} \) that cross any 3D closed manifold defined on an arbitrary region of the background manifold, which is considered as Riemannian and is characterized by the Levi-Civita connections. The condition of integrability expresses that we can assign univocally a norm to any vector in any point, so that it must be required that \( g^{\alpha\beta} \delta R_{\alpha\beta} = \nabla_\alpha \delta W^\alpha \). Of course, this is a particular case of (3). In particular, the case \( g^{\alpha\beta} \delta R_{\alpha\beta} = 0 \), give us the standard Einstein’s equations: \( G_{\alpha\beta} + \kappa T_{\alpha\beta} = 0 \). In this work we shall relax this constraint in order to explore quantum physical consequences when the boundary terms (3) are considered. Our full connections will be defined by (1)

\[
\Gamma^\alpha_{\beta\gamma} = \left\{ \begin{array}{c} \alpha \\ \beta \\ \gamma \end{array} \right\} + \delta \Gamma^\alpha_{\beta\gamma} = \left\{ \begin{array}{c} \alpha \\ \beta \\ \gamma \end{array} \right\} + \hat{\Psi}^\alpha g_{\beta\gamma}.
\]

Where \( \hat{\Psi}^\alpha \) are quantum spinor fields that can represent rather bosons or fermions. In this fashion
the theory includes the effects of a quantum field in the geometry of spacetime. The background expectation value of the connection displacement with respect to the Riemann manifold will be considered to vanish: \( \langle B | \bar{\Gamma}^{\alpha}_{\beta\gamma} | B \rangle = 0 \). In this way, the averaged out classical dynamics will be General Relativity. Here \( | B \rangle \) is a quantum states that describes the Fock space in the Heisenberg representation defined on the background Riemann manifold. These states do not evolve in time, but the operators do. Therefore, the classical Einstein equations with boundary conditions included results to be

\[
\bar{G}_{\alpha\beta} = -\kappa T_{\alpha\beta},
\]

with \( \bar{G}_{\alpha\beta} = G_{\alpha\beta} - \Lambda g_{\alpha\beta} \). In the classical General Relativity theory \( \Lambda \) is an invariant on the Riemann manifold, but not on the extended manifold \( \mathcal{M} \). We promote as a quantum operator \( \hat{\Lambda} \), with expectation value

\[
\Lambda = \langle B | \hat{\Lambda} | B \rangle = -\frac{3}{4} \left[ \langle B | \nabla_{\alpha} \hat{\Psi}^{\alpha} | B \rangle + \frac{1}{2} g^{\alpha\beta} \left( 1 - \frac{\xi^2}{3} \right) \langle B | \{ \hat{\Psi}_{\alpha}, \hat{\Psi}_{\beta} \} | B \rangle \right].
\]

In order to describe the dynamics of the operators \( \hat{\Psi}_{\alpha} \) we must take into account the quantum structure of spacetime. It is expected that the background spacetime can emerge from the expectation value of a quantum structure of spacetime. To propose a description we shall consider that this spacetime is generated by a base of \( 4 \times 4 \)-matrices, \( \bar{\gamma}^{\alpha} \). The \( \bar{\gamma}_{\alpha} = E^{\mu}_{\alpha} \gamma_{\mu} \) matrices which generate the background metric are related by the vielbein \( E^{\mu}_{\alpha} \) to basis \( \gamma_{\mu} \) in the Minkowski spacetime (in cartesian coordinates). By introducing these matrices we aim to include the spinor information in the spacetime structure and construct a non-commutative basis that can describe quantum effects in a relativistic framework. The Dirac and Majorana matrices are good candidates, but in general it is possible to use any basis that describe a globally hyperbolic spacetime, which is the global geometry necessary to obtain relativistic causality. We consider the variation \( \delta \hat{X}^{\mu} \), of the quantum operator \( \hat{X}^{\mu} \), which can be represented as

\[
\hat{X}^{\alpha}(x^{\nu}) = \frac{1}{(2\pi)^2} \int d^4k \bar{\gamma}^{\alpha} \left[ b_{k} \hat{X}_{k}(x^{\nu}) + b_{k}^{\dagger} \hat{X}^{*}_{k}(x^{\nu}) \right],
\]

such that \( b_{k} \) and \( b_{k}^{\dagger} \) are the creation and annihilation operators of spacetime, with \( \langle B | \left[ b_{k}, b_{k}^{\dagger} \right] | B \rangle = \delta^{(4)}(\vec{k} - \vec{k}') \). In an analogous manner we introduce the variation \( \delta \hat{\Phi}^{\mu} \) of the

where \( \sqrt{\frac{1}{\sqrt{\eta}}} \) is the squared root of the ratio between the determinant of the Minkowski metric: \( \eta_{\mu\nu} \) and the metric that describes the background: \( g_{\mu\nu} \). This ratio describes the inverse of the relative volume of the background manifold.
quantum operator \( \hat{\Phi}^\mu \) that describes the quantum inner space related to spin

\[
\hat{\Phi}^\alpha(\phi^\nu) = \frac{1}{(2\pi)^2} \int d^4s \, \tilde{\gamma}^\alpha \left[ c_s \, \hat{\Phi}_s(\phi^\nu) + c^\dagger_s \, \hat{\Phi}^*_s(\phi^\nu) \right],
\]

where \( \langle B \left| [c_s, c^\dagger_s] \right| B \rangle = \delta^{(4)}(\vec{s} - \vec{s}') \). These operators can be applied to some background quantum state in the background curved space time and they comply with

\[
\delta \hat{X}^\mu \left| B \right\rangle = d x^\mu \left| B \right\rangle, \quad \delta \hat{\Phi}^\mu \left| B \right\rangle = d \phi^\mu \left| B \right\rangle,
\]

where \( \phi^\alpha \) are the four compact dimensions related to their canonical momentum components \( s^\alpha \) that describe the spin.

The line elements are\(^3\)

\[
d x^2 \delta_{BB'} = \langle B \left| \delta \hat{X} \delta \hat{X} \right| B' \rangle, \quad d \phi^2 \delta_{BB'} = \langle B \left| \delta \hat{\Phi} \delta \hat{\Phi} \right| B' \rangle.
\]

The bi-vectorial squared norm of the spinor \( \hat{S} \), is

\[
\| \hat{S} \|^2 = \langle B \left| \hat{S} \hat{S}^\dagger \right| B \rangle = \frac{1}{4} \langle B \left| (\hat{S}_\mu \hat{S}_\nu) (\hat{\gamma}^\mu \hat{\gamma}^\nu) \right| B \rangle = s^2 \mathbb{I}_{4\times4},
\]

where \( \hat{S}_\mu = s \tilde{\gamma}_\mu \). We propose the universal invariance

\[
\langle B \left| \hat{S} \hat{S} \right| B \rangle = \frac{1}{4} \langle B \left| (\hat{S}_\mu \hat{\Phi}_\nu) (\hat{\gamma}^\mu \hat{\gamma}^\nu) \right| B \rangle = s \phi \mathbb{I}_{4\times4} = (2\pi n) \mathbb{I}_{4\times4},
\]

with \( n \)-integer. For this reason, gravitons (which have \( s = 2\hbar \)), will be invariant under \( \phi = n\pi \) rotations, vectorial bosons (with \( s = \hbar \)), will be invariant under \( \phi = 2n\pi \) rotations, fermions with \( s = \frac{1}{2}\hbar \) will be invariant under \( \phi = 4n\pi \) rotations, meanwhile fermions with \( s = \frac{3}{2}\hbar \) are invariant under \( \phi = \frac{4}{3}n\pi \) rotations.

We define the variation of the metric tensor on the extended manifold, with respect to the background curved (Riemannian) manifold

\[
\hat{g}_{\beta\alpha|\gamma} \delta \hat{X}^\gamma \left| B \right\rangle = \delta g_{\beta\alpha} \left| B \right\rangle.
\]

We can make the Fourier expansion of the quantum field on the space\(^9\):

\[
\hat{\Phi}_\alpha \left( x^\beta | \phi^\nu \right) = \frac{i}{\hbar(2\pi)^4} \int d^4k \int d^4s \, \hat{S}_\alpha \left[ A_{s,k} e^{ik \vec{X}} e^{\hat{\gamma}^\alpha \hat{S}^\dagger} - B^\dagger_{k,s} e^{-ik \vec{X}} e^{-\hat{\gamma}^\alpha \hat{S}^\dagger} \right],
\]

\(^3\) The squared norm of the bi-vectorial space of \( \delta \hat{\Phi} \), and the inner product of \( \delta \hat{X} \), are

\[
\delta \hat{\Phi} \delta \hat{\Phi} \equiv \frac{1}{2} (\delta \hat{\Phi}_\mu \delta \hat{\Phi}_\nu) (\hat{\gamma}^\mu \hat{\gamma}^\nu), \quad \delta \hat{X} \delta \hat{X} \equiv \frac{1}{4} \delta X_\alpha \delta X^\alpha.
\]

where \( \hat{\Phi}^\alpha = \phi \hat{\gamma}^\alpha \), \( \hat{\Phi}_\alpha = x \hat{\gamma}^\alpha \) are the components of the inner space and the coordinate space, and \( (\hat{\gamma}^\alpha \hat{\gamma}^\beta) = \frac{1}{2} \left\{ \hat{\gamma}^\alpha, \hat{\gamma}^\beta \right\} - \frac{1}{2} [\hat{\gamma}^\alpha, \hat{\gamma}^\beta] \). The matrices \( \hat{\gamma}^\mu \), comply with the Clifford algebra.
where $\hat{S}^\alpha = s \hat{\gamma}^\alpha$ is the spin operator.

In order to obtain the **dynamic equations of quantum spinor fields** on the extended manifold, we must variate the Ricci tensor using the Palatini identity\(^2\), \(\delta R^\alpha_{\beta\gamma\alpha} = \delta R_{\beta\gamma} = \left(\delta \Gamma^\alpha_{\beta\gamma}\right)_{\parallel\gamma} - \left(\delta \Gamma^\alpha_{\beta\gamma}\right)_{\parallel\alpha}\), is\(^4\)

\[
\delta \hat{R}_{\beta\gamma} = \nabla_\alpha \hat{\Psi}_\beta - 3 \left(1 - \frac{\xi^2}{3}\right) g_{\beta\gamma} \left(\hat{\Psi}^\nu \hat{\Psi}_\nu\right) - g_{\beta\gamma} \left(\nabla_\nu \hat{\Psi}^\nu\right) + \left(1 - \frac{\xi^2}{3}\right) \hat{\Psi}_\beta \hat{\Psi}_\gamma. \tag{13}
\]

Furthermore, the purely antisymmetric tensor $\hat{\Sigma}^\alpha_{\beta\gamma} \equiv \hat{\Sigma}_{\beta\gamma}$, is

\[
\hat{\Sigma}_{\beta\gamma} = \left(\nabla_\beta \hat{\Psi}_\gamma - \nabla_\gamma \hat{\Psi}_\beta\right) - \left(1 + \xi^2\right) \left[\hat{\Psi}_\beta, \hat{\Psi}_\gamma\right], \tag{14}
\]

which, once we set \((1 + \xi^2) = -i \mathbf{g}\), _is the Yang-Mills tensor_ on the curved background manifold and describes for example the gluonic (strong) interactions of quarks\(^5\). The Einstein tensor on the extended manifold can be defined using the symmetric contribution of the Ricci tensor\(^{13}\):

\[
\delta G_{\beta\gamma} = \hat{U}_{\beta\gamma} - \frac{1}{2} g_{\beta\gamma} \hat{U}, \text{ with } \hat{U} = g^{\alpha\beta} \hat{U}_{\alpha\beta}:
\]

\[
\delta G_{\beta\gamma} = \frac{1}{2} \left(\nabla_\alpha \hat{\Psi}_\gamma + \nabla_\gamma \hat{\Psi}_\beta\right) + \frac{1}{2} g_{\beta\gamma} \left[\left(1 - \frac{\xi^2}{3}\right) \left(\hat{\Psi}^\alpha \hat{\Psi}_\alpha\right) + \left(\nabla_\nu \hat{\Psi}^\nu\right)\right] + \frac{1}{2} \left(1 - \frac{\xi^2}{3}\right) \left[\hat{\Psi}_\beta, \hat{\Psi}_\gamma\right].
\]

In order to describe massless bosons and charged bosons, we define $\hat{N}_{\beta\gamma} = \frac{1}{2} \hat{V}_{\beta\gamma} - \frac{1}{4} \hat{\Sigma}_{\beta\gamma}$ and $\hat{\mathcal{M}}_{\beta\gamma} = \frac{1}{2} \hat{V}_{\beta\gamma} + \frac{1}{4} \hat{\Sigma}_{\beta\gamma}$

\[
\hat{N}_{\beta\gamma} = -\frac{1}{2} \left(\nabla_\beta \hat{\Psi}_\gamma - \nabla_\gamma \hat{\Psi}_\beta\right) + \left[\hat{\Psi}_\beta, \hat{\Psi}_\gamma\right], \tag{15}
\]

\[
\hat{\mathcal{M}}_{\beta\gamma} = \frac{1}{2} \left(1 - \xi^2\right) \left[\hat{\Psi}_\beta, \hat{\Psi}_\gamma\right]. \tag{16}
\]

The symmetric tensor $\delta G_{\beta\gamma}$, with the antisymmetric ones $\hat{\Sigma}_{\beta\gamma}$, $\hat{N}_{\beta\gamma}$ and $\hat{\mathcal{M}}_{\beta\gamma}$, describe all the possible interactions of fermions and bosons on the extended manifold. On one hand, we see that $\hat{N}_{\beta\gamma}$ corresponds to a Yang-Mills strength tensor where the coupling has been normalized to 1, and describes massless bosons like photons or gravitons with self-interactions included. On the other hand $\hat{\Sigma}_{\beta\gamma}$ describes bosons which interact with colour charge (like gluons). We can see that $\hat{N}_{\beta\gamma}$ is

---

\(^4\) This tensor has both, symmetric $\hat{U}_{\beta\gamma}$ and antisymmetric $\hat{V}_{\beta\gamma}$ contributions:

\[
\hat{U}_{\beta\gamma} = \frac{1}{2} \left(\nabla_\beta \hat{\Psi}_\gamma + \nabla_\gamma \hat{\Psi}_\beta\right) - g_{\beta\gamma} \left(\nabla_\nu \hat{\Psi}^\nu\right) - 3 \left(1 - \frac{\xi^2}{3}\right) g_{\beta\gamma} \left(\hat{\Psi}^\alpha \hat{\Psi}_\alpha\right) + 3 \left(1 - \frac{\xi^2}{3}\right) \left[\hat{\Psi}_\beta, \hat{\Psi}_\gamma\right],
\]

\[
\hat{V}_{\beta\gamma} = \frac{1}{2} \left(\nabla_\beta \hat{\Psi}_\gamma - \nabla_\gamma \hat{\Psi}_\beta\right) + \frac{3}{2} \left(1 - \frac{\xi^2}{3}\right) \left[\hat{\Psi}_\beta, \hat{\Psi}_\gamma\right].
\]

\(^5\) Notice that $\hat{U}_{\beta\gamma}$ can describe the gluon field strength tensor related to the gluon field components: $\hat{\Psi}^\mu = \lambda^\mu_{\alpha} A^\alpha_{\mu}$, such that $\lambda^\alpha_{\beta\gamma}$ are the eight $(3 \times 3)$ Gell-Mann matrices in the $SU(3)$ group representation and $\xi^2 = -(1 + i \mathbf{g})$, such that $\mathbf{g} = \sqrt{4\pi\alpha_s}$, $\alpha_s$ being the coupling constant of the strong force. The experimental value is $\alpha_s \approx 0.11823$, that corresponds to $\xi = \pm(0.5369 - 1.135 i)$. 

---
independent of the coupling and all the coupling-related information is on the tensor \( \hat{M}_{\beta \gamma} \). Also, \( \hat{M}_{\beta \gamma} \) does not contain a free-like term, so that can describe massive and charged bosons (may be \( X^\pm \) and \( Y \) mediators predicted by GUT theories) which will result in a non-wave-like propagating field dynamics. If the four fundamental tensors are conserved on the extended manifold, then they must comply

\[
\left( \hat{\delta G}^{\beta \gamma} \right)_{\parallel \gamma} = 0, \quad \left( \hat{N}^{\beta \gamma} \right)_{\parallel \gamma} = 0, \quad \left( \hat{\Sigma}^{\beta \gamma} \right)_{\parallel \gamma} = 0, \quad \left( \hat{M}^{\beta \gamma} \right)_{\parallel \gamma} = 0. \quad (17)
\]

To finalize, we can obtain a description of non-perturbative gravitational waves (GW) by introducing a 2-rank quantum operator \( \hat{h}_{\mu \nu} \)

\[
\frac{1}{2} \square \hat{h}_{\mu \nu} = -\delta U_{\mu \nu}. \quad (18)
\]

The d’Alambertian in the left side of (18) ensures the wave nature of \( \hat{h}_{\mu \nu} \), and the right side is the quantum source of these waves given by (13). The TT (Transverse-Traceless) components of these waves: \( \hat{h}_{ij} = \delta h_{ij} - \frac{1}{2} g_{ij} \delta h \), have a dynamics governed by the equations

\[
\square \left\langle B \right| \hat{\delta h}_{ij} \left| B \right\rangle = -2\kappa \left\langle B \right| \hat{S}_{ij} \left| B \right\rangle, \quad (19)
\]

where \( \kappa \hat{S}_{\alpha \beta} = \delta U_{\alpha \beta} - \frac{1}{2} g_{\alpha \beta} \delta U \).

To explore the model we can consider the production of GW during inflation. This is an important issue that should be tested in the next years and would give relevant information about the early stages of the inflationary expansion of the universe. We consider a de Sitter (inflationary) expansion, where the background spacetime is described by the line element

\[
dS^2 = a^2(\tau) \left[ d\tau^2 - \delta_{ij} dx^i dx^j \right], \quad (20)
\]

where \( \tau \), that runs from \(-\infty \) to zero, is the conformal time of the universe, which is considered as spatially flat, isotropic and homogeneous. The \( ij \)-components of \( \left\langle B \right| \hat{\delta h}_{ij} \left| B \right\rangle \equiv \bar{h}_{ij} \), can be expanded as

\[
\bar{h}_{ij} = \frac{1}{(2\pi)^8} \int d^4s \int d^4k \sum_{n=+,-,\times}^{(n)} \epsilon_{ij} \left[ \left[ C_{k,s}^{(n)} \right] \theta_k(\tau) e^{ik_j x^i} e^{i\epsilon_{\alpha \beta} \phi^\alpha} + \left[ C_{k,s}^{(n)} \right]^\dagger \bar{\theta}^*_k(\tau) e^{-ik_j x^i} e^{-i\epsilon_{\alpha \beta} \phi^\alpha} \right], \quad (21)
\]

where \( +, \times \) denote the polarisation states in the Transverse-Traceless (TT) gauge, defined by

\[
\hat{h}_{0j} = 0, \quad \bar{h} = 0. \quad (22)
\]

For \( (n) \epsilon_{00} = 0 \), the polarization tensor is transverse: \( k^i (n) \epsilon_{ji} = 0 \) to the propagation of the wave characterized by the wavenumber components \( k^i \). Accounting for \( h = 0 \) and \( (n) \epsilon_{ij} = (n) \epsilon_{ji} \), we can
define
\[(n)\epsilon_{11} = \frac{1}{2} \{\bar{\gamma}_1, \bar{\gamma}_1\}, \quad (n)\epsilon_{22} = -(n)\epsilon_{11}, \quad (n)\epsilon_{12} = \frac{1}{2} \{\bar{\gamma}_1, \bar{\gamma}_2\}, \quad (n)\epsilon_{21} = \frac{1}{2} \{\bar{\gamma}_2, \bar{\gamma}_1\}.\] (23)

The creation and destruction operators satisfy:
\[
\left\langle B \left| C_{k,s}^{(n)} \right| C_{k',s'}^{(n')} \right| \right. B = m^2 \delta_{nn'} \delta^{(4)}(\vec{k} - \vec{k}') \delta^{(4)}(\vec{s} - \vec{s}'),
\] (24)

where \(m\) is the mass of the fermion fields which are the source of GW during inflation. The modes are described by the dynamics
\[
\theta_k''(\tau) - \frac{2}{\tau} \theta_k'(\tau) + k^2 \theta_k(\tau) = -\frac{6}{\tau^2} \frac{s^2}{\hbar^2} (\xi^2 - 3) \theta_k(\tau),
\] (25)

which, after normalization result to be
\[
\theta_k(\tau) = \frac{i\pi}{3} \tau^{3/2} \mathcal{H}^{(2)}_\nu[\zeta(\tau)],
\] (26)

where \(\mathcal{H}^{(2)}_\nu[\eta(\tau)]\) is the second kind Hankel function with argument \(\eta(\tau) = k \tau\), and parameter \(\nu = \frac{1}{2} \sqrt{9 + 24 \frac{s^2}{\hbar^2} (3 - \xi^2)}\), such that, due to the fact that the tensor index is given by \(n_T = 3 - 2\nu\),

we obtain \(n_T = 3 - \sqrt{9 + 24 \frac{s^2}{\hbar^2} (3 - \xi^2)}\). Evidence from Planck 2018\cite{Planck2018} estimates the tensor index \(n_T = 1 - n_s\), in the range \(0.0283 < n_T < 0.0407\), for a spectral index: \(n_s = 0.9655 \pm 0.0062\). An estimation of \(\Omega_{GW} = \frac{\rho_{GW}}{\rho_c}\), such that \(\rho_c = 3 H^2/(8\pi G)\) is the critical energy density, and

\[
\rho_{GW} = \int d^4x \sqrt{-g} \int d^4\phi \left\langle B \left| T_0^0 \right| B \right\rangle = \frac{5 m^2}{24 \kappa} (\xi^2 - 3),
\] (27)

that situates \(\Omega_{GW} = \frac{\rho_{GW}}{\rho_c}\) in the range
\[
1.25 \times 10^{-4} \left(\frac{m}{H} \right)^2 < \Omega_{GW} < 1.75 \times 10^{-4} \left(\frac{m}{H} \right)^2.
\] (28)

This result is consistent with \((h_0\) is the dimensionless Hubble parameter): \(\Omega_{GW} \lesssim 1.6 \times h_0^2 \times 10^{-15}\)\cite{Planck2018}, for very lightly primordial fermions with mass of the order of \(\left(\frac{m}{H} \right)^2 \lesssim 1.1 h_0^2 \times 10^{-11}\).
