SUPPORT VARIETIES FOR FINITE TENSOR CATEGORIES: COMPLEXITY AND TENSOR PRODUCTS

JULIA YAEI PLAVNIK AND SARAH WITHERSPOON

Abstract. We advance support variety theory for finite tensor categories. We prove that the dimension of the support variety of an object is equal to the rate of growth of a minimal projective resolution as measured by Frobenius-Perron dimension. We ask when the tensor product property holds, that is, when is the support variety of a tensor product of objects equal to the intersection of their support varieties? We discuss some known and some new settings in which objects do or do not possess this property as well as a weaker property involving projectivity.

1. Introduction

Tensor categories arise in many important settings such as representation theory, low dimensional topology, and quantum computing. Nonsemisimple tensor categories range from categories of representations of finite groups in positive characteristic and representations of some finite dimensional Hopf algebras to categories discovered more recently such as those appearing in logarithmic conformal field theory [10, 14], representations of dynamical quantum groups at roots of unity [19], and some new categories in characteristic two [3]. Support variety theory has been a very successful tool for examining representations of finite groups and of finite group schemes as well as of other Hopf algebras (see, e.g. [4, 5, 8, 11, 12, 22, 23, 24, 25, 26]). In this article we advance support variety theory for finite tensor categories generally, with a view toward future applications.

Our starting point is the conjecture of Etingof and Ostrik [10] that any finite tensor category $\mathcal{C}$ has finitely generated cohomology ring $\text{Ext}^\ast_{\mathcal{C}}(1, 1)$, where $1$ is the unit object. This cohomology ring is known to be graded commutative, and as a consequence, where the conjecture holds we may define the support variety $V^\ast_{\mathcal{C}}(X)$ of any object $X$ in a standard way as the variety of the annihilator of $\text{Ext}^\ast_{\mathcal{C}}(X, X)$ in the cohomology ring $\text{Ext}^\ast_{\mathcal{C}}(1, 1)$. Some properties of support varieties follow...
from this definition just as in more classical settings. See [6] for the setting of tensor triangulated categories.

We make significant contributions in a few useful directions. We define the complexity of an object $X$ as the rate of growth of a minimal projective resolution of $X$ as measured by the Frobenius-Perron dimensions of its components. We show that just as for finite dimensional Hopf algebras [11, 23], the complexity of $X$ is equal to the dimension of its support variety, $\dim V_C(X)$. We are interested in categories for which a tensor product property holds, that is the support variety of a tensor product of objects is the intersection of their support varieties. To this end, we recall a standard construction of some special modules first defined for finite groups by Carlson, and apply it to objects in tensor categories (cf. the Koszul objects in [6]). We introduce these objects $L_\zeta$ and show directly that tensoring with them always satisfies the tensor product property. We then show that the tensor product property does not always hold by generalizing a construction in [4, 25]. This construction produces examples that are not braided. It remains an open question as to whether all objects in a braided finite tensor category satisfy the tensor product property. We prove a weaker statement, that in a braided finite tensor category, an object $X$ is projective if and only if its $n$th tensor power $X^n$ is projective.

More specifically, the contents of the article are as follows. In Section 2, we recall definitions of finite tensor categories, Frobenius-Perron dimension, projective covers and minimal resolutions, and state some needed lemmas. In Section 3, we define support varieties for objects of a finite tensor category $C$ under a finiteness condition, and conclude some standard properties. In Section 4, we define complexity of an object and show that it agrees with the dimension of the support variety. As a consequence, we show that an object is projective if and only if its support variety has dimension 0. In Section 5, for each homogeneous positive degree element $\zeta$ of the cohomology ring of the finite tensor category $C$, we define an object $L_\zeta$ whose variety is the zero set of the ideal generated by $\zeta$. We obtain, as a standard consequence of the definition of $L_\zeta$, both a tensor product property and a realization result, that any conical subvariety of the support variety of the unit object $1$ can be realized as the support variety of some object. In Section 6, we consider the tensor product property for objects more generally, and show that any nonsemisimple finite tensor category for which the tensor product property holds can be embedded as a tensor subcategory in a finite tensor category for which it does not. We then prove a weaker projectivity property for objects $X$ for which $X \otimes X^* \cong X^* \otimes X$, deriving a conclusion for all braided finite tensor categories.

Acknowledgments. We thank Dave Benson, Henning Krause, Martín Mombelli, Cris Negron, and Victor Ostrik for very helpful conversations that led to improvements in this paper.
2. Preliminaries

In this section we summarize some basic facts about projective covers and resolutions in a finite tensor category $\mathcal{C}$, as well as Frobenius-Perron dimension.

We generally work over an algebraically closed field $k$ of arbitrary characteristic.

Recall that a finite tensor category $\mathcal{C}$ is a $k$-linear locally finite abelian category with finitely many simple objects (up to isomorphism) and enough projectives together with a bifunctor $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ that is associative (up to functorial isomorphisms), bilinear on morphisms, and satisfies some associativity axioms. In addition, there is a unit object $1$ in $\mathcal{C}$ (an identity with respect to $\otimes$ up to functorial isomorphism) that is simple, and every object in $\mathcal{C}$ has both left and right duals. See [1] or [9] for details. We caution that notation for left and right duals in these two sources are interchanged; we use the notation of [9]. Recall that locally finite means every object has a (finite length) Jordan-Hölder series (with simple factors), and $k$-linear means the morphism sets are $k$-vector spaces for which composition of morphisms is $k$-bilinear.

From now on, $\mathcal{C}$ will be a finite tensor category. It follows that $\mathcal{C}$ is equivalent to the category of finite dimensional modules of some finite dimensional algebra over $k$ [9, p. 9].

Some additional properties of the tensor product $\otimes$ are:

(i) The tensor product $\otimes$ is biexact [9, Proposition 4.2.1].

(ii) Whenever $X$ is an object and $P$ is a projective object of $\mathcal{C}$, the objects $P \otimes X$ and $X \otimes P$ are also projective [9, Proposition 4.2.12].

We will sometimes take $\mathcal{C}$ to be braided, meaning that there are functorial isomorphisms $X \otimes Y \cong Y \otimes X$ for all objects $X,Y$ in $\mathcal{C}$ that satisfy some hexagonal identities [9, Definition 8.1.1].

Projective covers and minimal resolutions. Let $X$ be an object in the finite tensor category $\mathcal{C}$. A projective cover of $X$ is a projective object $P(X)$ in $\mathcal{C}$ together with an epimorphism $p : P(X) \to X$ such that if $f : P \to X$ is an epimorphism from a projective object $P$ to $X$, then there is an epimorphism $g : P \to P(X)$ for which $pg = f$ [9, Definition 1.6.6]. Projective covers exist and are unique up to nonunique isomorphism [9, p. 6].

Let $X_0, \ldots, X_{r-1}$ be the simple objects in $\mathcal{C}$ (one from each isomorphism class). We will use the following equation involving vector space dimensions of morphism spaces: For any object $Y$ in $\mathcal{C}$, denote by $[Y : X_i]$ the multiplicity of the simple object $X_i$ in a Jordan-Hölder series of $Y$. By [9, Equation (1.7)],

\[(2.1) \quad [Y : X_i] = \dim_k \Hom_{\mathcal{C}}(P(X_i), Y).\]

We will need the following presentation of a projective object.

Lemma 2.2. Let $P$ be a projective object in $\mathcal{C}$. Then $P \cong \bigoplus_{i=0}^{r-1} a_i P(X_i)$ for some nonnegative integers $a_i$, where $P(X_i)$ is the projective cover of the simple object $X_i$ for each $i$. Moreover, $a_i = \dim_k \Hom_{\mathcal{C}}(P, X_i)$. 
Proof. This follows from a category equivalence with the category of modules for a finite dimensional algebra (see [8, pp. 9–10]) and standard facts about finite dimensional algebras. However, we give a more direct proof in our setting, by induction on the length $n$ of a Jordan-Hölder series for the projective object $P$.

If $n = 1$ then $P$ is both simple and projective, and so $P = X_i = P(X_i)$ for some $i$. Now assume that the first statement holds for all projective objects of length less than $n$. For some $i$, the vector space $\text{Hom}_C(P, X_i)$ is nonzero. Choose a nonzero morphism $f$ in $\text{Hom}_C(P, X_i)$. Since $X_i$ is simple, $f$ is an epimorphism. By definition of projective cover $p : P(X_i) \to X_i$, there exists an epimorphism $g : P \to P(X_i)$ such that $pg = f$. Since $g$ is an epimorphism and $P(X_i)$ is projective, there is a splitting morphism $h : P(X_i) \to P$, that is $gh = \text{id}_{P(X_i)}$, the identity morphism on $P(X_i)$. It follows that $P(X_i)$ is a direct summand of $P$. Write $P \cong P(X_i) \oplus Q$ for some projective object $Q$. Then $Q$ has length less than $n$, and by the induction hypothesis, it has a direct sum decomposition as in the first statement of the theorem. It follows that $P$ does as well.

Now write $P \cong \bigoplus_{j=0}^{r-1} a_j P(X_j)$. By equation (2.1), for each $i$,

$$\dim_k \text{Hom}_C(P, X_i) = \sum_{j=0}^{r-1} a_j \dim_k \text{Hom}_C(P(X_j), X_i) = \sum_{j=0}^{r-1} a_j [X_i : X_j] = a_i.$$ \hfill \Box

We will need Schanuel’s Lemma for abelian categories, and we include a proof for completeness.

Lemma 2.3 (Schanuel’s Lemma). If

$$0 \to K \to P \to X \to 0 \quad \text{and} \quad 0 \to K' \to P' \to X \to 0$$

are two short exact sequences in an abelian category $C$ with $P, P'$ projective, then $K \oplus P' \cong K' \oplus P$.

Proof. Consider the pullback of $P \xrightarrow{\phi} X$ and $P' \xrightarrow{\psi} X$, given by an object $W$ and morphisms $W \xrightarrow{\alpha} P$ and $W \xrightarrow{\beta} P'$. By definition of pullback, considering the zero morphisms from $K$ to $X$ through $P$ and $P'$, there is a morphism from $K$ to $W$ that makes the corresponding diagram commute. Similarly there is a morphism from $K'$ to $W$. By [16, Theorem 6.2], $K$ is the kernel of $\beta$ and $K'$ is the kernel of $\alpha$. Since $P \xrightarrow{\phi} X$ and $P' \xrightarrow{\psi} X$ are epimorphisms, the pullback diagram is also a pushout diagram [16, Exercise II.6.7] and it follows that $\alpha$ and $\beta$ are epimorphisms. To see this, note that if $Z$ is an object and $f, g : P \to Z$ are morphisms such that $f\alpha = ga$, then $(f - g)\alpha = 0$. Consider $f - g : P \to Z$ and the zero morphism $P' \to Z$. Since $X$ is a pushout, there is a morphism $\nu : X \to Z$ such that $\nu\phi = f - g$. If $f - g \neq 0$ then $\nu \neq 0$, but this contradicts the assumption that $0 = \nu\psi$. So $f = g$, implying that $\alpha$ is an epimorphism. Similarly we see that $\beta$...
is an epimorphism. Since $\alpha$ and $\beta$ are epimorphisms, and $P$ and $P'$ are projective, these morphisms split and we now have $W \cong K \oplus P'$ and $W \cong K' \oplus P$. □

A projective resolution $P_\ast$ of $X$ in $\mathcal{C}$ is an exact sequence
\[ \cdots \rightarrow P_2 \rightarrow P_1 \rightarrow P_0 \rightarrow X \rightarrow 0 \]
in $\mathcal{C}$ such that $P_i$ is projective for each $i$. Let $\Omega(X)$ be the kernel of the morphism $P_0 \rightarrow X$, and write $\Omega^1(X) = \Omega(X)$. Let $\Omega^n(X) = \Omega(\Omega^{n-1}(X))$ for each $n > 1$, where we view the morphism $P_{n-1} \rightarrow P_{n-2}$ as factoring through $\Omega^{n-1}(X)$. The objects $\Omega^n(X)$ are not unique up to isomorphism, however by Schanuel’s Lemma (Lemma 2.3), they are unique up to projective direct summands and isomorphism. We choose not to include the dependence of $\Omega^n(X)$ on the resolution $P$ in the notation, and it should be clear from context which resolution is involved each time the notation is used.

A projective resolution $P_\ast$ of $X$ in $\mathcal{C}$ is minimal if $P_0 = P(X)$ is a projective cover of $X$ and for each $n \geq 1$, $P_n = P(\Omega^n(X))$ is a projective cover of $\Omega^n(X)$ (see, e.g., [7, Section 7.9]).

For any two objects $X, Y$ of $\mathcal{C}$ and any nonnegative integer $n$, we define
\[ \text{Ext}^n_{\mathcal{C}}(X, Y) = H^n(\text{Hom}_{\mathcal{C}}(P_\ast, Y)) = \text{Ker} d^n_{n+1}/ \text{Im} d^n_n, \]
where $P_\ast$ is a projective resolution of $X$ with differentials $d_i : P_i \rightarrow P_{i-1}$, $d_i(f) = fd_i$ for all $i > 0$ and $f \in \text{Hom}_{\mathcal{C}}(P_{i-1}, Y)$, and $d_n^n = 0$.

**Lemma 2.4.** Let $P_\ast$ be a minimal projective resolution of an object $X$ in $\mathcal{C}$, and let $X_i$ be a simple object of $\mathcal{C}$. Then for all $n \geq 1$,
\[ \text{Ext}^n_{\mathcal{C}}(X, X_i) \cong \text{Hom}_{\mathcal{C}}(P_n, X_i) \cong \text{Hom}_{\mathcal{C}}(\Omega^n(X), X_i). \]

**Proof.** We will show that the differentials on $\text{Hom}_{\mathcal{C}}(P_\ast, X_i)$ are all zero maps. The first isomorphism will then follow immediately.

Let $f \in \text{Hom}_{\mathcal{C}}(P_n, X_i)$. If $f$ is nonzero, then it is an epimorphism since $X_i$ is simple. Let $p : P(X_i) \rightarrow X_i$ be a projective cover, so that there is an epimorphism $g : P_n \rightarrow P(X_i)$ such that $pg = f$. It follows that $P_n \cong P(X_i) \oplus Q_n$ for some projective object $Q_n$, and under this isomorphism, $g$ may be viewed as the corresponding canonical projection onto $P(X_i)$. Now if $fd_{n+1} \neq 0$, then $fd_{n+1}$ is an epimorphism, and so there is an epimorphism $h : P_{n+1} \rightarrow P(X_i)$ such that $ph = fd_{n+1}$. Again, $h$ splits and $P_{n+1} \cong P(X_i) \oplus Q_{n+1}$ for a projective object $Q_{n+1}$, and $h$ may be viewed as the corresponding canonical projection onto $P(X_i)$.

Now let $d_{n+1} : P(X_i) \rightarrow P(X_i)$ denote the following composition of morphisms: canonical inclusion of $P(X_i)$ into $P(X_i) \oplus Q_{n+1}$, then isomorphism to $P_{n+1}$, then $d_{n+1}$, then isomorphism to $P(X_i) \oplus Q_n$, then canonical projection onto $P(X_i)$. Then $pd_{n+1} = fd_{n+1}$ by construction. Since $\dim_k(P(X_i), X_i) = 1$ by equation (2.1), $pd_{n+1} = \alpha p$ for some nonzero scalar $\alpha$. Replacing $d_{n+1}$ by $\alpha^{-1}d_{n+1}$, we may assume that $pd_{n+1} = p$. We claim that this forces $d_{n+1}$ to be an isomorphism since $\dim_k(P(X_i), X_j) = \delta_{i,j}$ by equation (2.1). To see this, note that if
were not an isomorphism, then $\text{Im}(\hat{d}_{n+1})$ would be a subobject of $P(X_i)$, and necessarily a subobject of $Y_{m-1}$ in the Jordan-Hölder series
\[ 0 = Y_0 \subseteq \cdots \subseteq Y_{m-1} \subseteq Y_m = P(X_i) \]
with $Y_m/Y_{m-1} \cong X_i$. But then $p\hat{d}_{n+1} = 0$, a contradiction. Therefore $\hat{d}_{n+1}$ is an isomorphism. However, this contradicts minimality of the projective resolution $P$ in the following way. By definition, $P_n$ is a projective cover of $\Omega^n(X)$. The image of $P(X_i)$ in $\Omega^n(X)$ under the projective cover morphism from $P_n \cong P(X_i) \oplus Q_n$ to $\Omega^n(X)$ cannot be 0, as this would contradict the definition of projective cover. To see this, map $Q_n$ to $\Omega^n(X)$ via canonical inclusion into $P_n \cong P(X_i) \oplus Q_n$ followed by the epimorphism $P_n \to \Omega^n(X)$. This composite morphism is an epimorphism since $P(X_i)$ is in the kernel of $P_n \to \Omega^n(X)$. However the length of $P_n$ is greater than that of $Q_n$, so there can be no epimorphism from $Q_n$ to $P_n$, contradicting the assumption that $P_n$ is the projective cover of $\Omega^n(X)$. On the other hand, the image of $P(X_i)$ in $\Omega^n(X)$ must be 0 since $\hat{d}_{n+1}$ is an isomorphism and $\text{Im}(d_{n+1}) \subseteq \text{Ker}(d_n)$. This is a contradiction. Therefore $f\hat{d}_{n+1} = 0$.

The second isomorphism in the statement is induced by the epimorphism $P_n \to \Omega^n(X)$, since $f\hat{d}_{n+1} = 0$. \hfill \Box

We note that for any two objects $X,Y$ of $\mathcal{C}$ and $n \geq 1$, $\text{Ext}^n_\mathcal{C}(X,Y)$ may be identified with equivalence classes of $n$-extensions of $Y$ by $X$ in $\mathcal{C}$ [21]. There are also long exact $\text{Ext}$ sequences associated to short exact sequences of objects in $\mathcal{C}$ [18]. We will use these facts about $\text{Ext}^n_\mathcal{C}(X,Y)$ in the sequel.

**Frobenius-Perron dimensions.** A very useful invariant and tool in the theory of finite tensor categories is the notion of Frobenius-Perron dimension. Here we will recall the definition and some of its properties that we will use.

As before, let $\mathcal{C}$ be a finite tensor category with (isomorphism classes of) simple objects $X_0, \ldots, X_{r-1}$. For each object $X$ in $\mathcal{C}$, let $N_X$ be the matrix of left multiplication by $X$, specifically
\[(N_X)_{ij} = ([X \otimes X_i : X_j])_{ij},\]
where $[X \otimes X_i : X_j]$ is the multiplicity of $X_j$ in a Jordan-Hölder series of the tensor product object $X \otimes X_i$ [9, Section 1.5]. The entries of this matrix are thus nonnegative integers. The **Frobenius-Perron dimension** $\text{FPdim}(X)$ of $X$ is the largest nonnegative real eigenvalue of the matrix $N_X$, which exists by the Frobenius-Perron Theorem [9, Theorem 3.2.1]. Moreover, $\text{FPdim}(X_i) \geq 1$ for all $i = 0, \ldots, r-1$ [9, Proposition 3.3.4(2)]. Positivity characterizes the Frobenius-Perron dimension in the sense that $\text{FPdim}$, extended by additivity to be a character of the Grothendieck ring of $\mathcal{C}$, is the unique such character that maps simple objects to positive real numbers [9, Proposition 3.3.6(3)]. It follows that $\text{FPdim}(X) > 0$ for each nonzero object $X$ of $\mathcal{C}$, since $\text{FPdim}(X) = \sum_{i=0}^{r-1} a_i \text{FPdim}(X_i)$ if $a_i = [X : X_i]$ for each $i$. 
3. Support varieties

Here we adapt to finite tensor categories some of the definitions and results given in [11, 22] on support varieties for modules of finite dimensional Hopf algebras. See also [6] for tensor triangulated categories. These ideas originated in the theory of support varieties for representations of finite groups (see Carlson [8], Quillen [26], or the book by Benson [2]).

Let $C$ be a finite tensor category with unit object $1$. Denote by $H^*(C)$ its cohomology ring, that is,

$$H^*(C) := \text{Ext}^*_C(1, 1).$$

This is a graded commutative ring under cup product [28], conjectured to be finitely generated [10]. The cohomology ring $H^*(C)$ acts functorially on $\text{Ext}^*_C(X, Y)$ for any two objects $X$ and $Y$ in $C$, on the left and on the right, as follows. The left and right actions will be the same up to a sign. First, at the chain level we may take a cocycle $f \in \text{Hom}_C(P_n, 1)$ where $P_n$ is a projective resolution of $1$ in $C$, and consider the morphism $f \otimes \text{id}_X \in \text{Hom}_C(P_n \otimes X, X)$, which is also a cocycle. By [9, Proposition 4.2.12], $P_n \otimes X$ is projective for all $n$, and since $\otimes$ is biexact, $P_n \otimes X$ is a projective resolution of $X$ in $C$. Consequently, $f \otimes \text{id}_X$ represents an element of $\text{Ext}^*_C(X, X)$. (Equivalently, we may take the corresponding $n$-extension of $1$ by $1$ and apply $- \otimes X$.) Next apply the action of $\text{Ext}^*_C(X, X)$ on $\text{Ext}^*_C(X, Y)$ given by first lifting $f \otimes \text{id}_X$ to a chain map given by morphisms $P_{j+n} \otimes X \to P_j \otimes X$, possible by the Comparison Theorem. Then compose with functions representing homogeneous elements of $\text{Ext}^*_C(X, Y)$. (Equivalently, this action is given by Yoneda composition of generalized extensions.) For the second action, at the chain level, we may take $f \otimes \text{id}_Y \in \text{Hom}_C(P_n \otimes Y, Y)$. (Equivalently, take the corresponding $n$-extension of $1$ by $1$ and apply $- \otimes Y$.) Then apply the action of $\text{Ext}^*_C(Y, Y)$ on $\text{Ext}^*_C(X, Y)$ given by first lifting $f \otimes \text{id}_Y$ to a chain map, then composing with chain maps representing homogeneous elements of $\text{Ext}^*_C(X, Y)$. (Equivalently, this action is given by Yoneda composition of generalized extensions.) The first action described above is a right action, the second a left action, and they agree up to a sign by a proof analogous to that of [27, Theorem 1.1]. For our purposes, the sign will not matter, and we will not need to distinguish between the left and right actions.

In order to define support varieties, we require $C$ to satisfy assumption (fg), defined next.

**Assumption (fg):**

$H^*(C)$ is finitely generated, and $\text{Ext}^*_C(X, Y)$ is a finitely generated $H^*(C)$-module for all objects $X, Y$ in $C$.

Categories $C$ satisfying condition (fg) are also called *finite type* in [19]. Examples of finite tensor categories $C$ known to satisfy condition (fg) include the category
\( \mathcal{C} \) of finite dimensional modules for a finite dimensional cocommutative Hopf algebra \([13]\) as well as a number of other categories of modules of particular types of finite dimensional Hopf algebras. There are also examples not coming from Hopf algebras, such as representations of dynamical quantum groups at roots of unity \([19]\), and some new categories in characteristic two \([3]\). For those categories \( \mathcal{C} \) that do satisfy condition (fg), we will define support varieties and develop some of their properties.

Assume condition (fg) holds for a finite tensor category \( \mathcal{C} \). Let
\[
V_\mathcal{C} = \text{Max}(H^*(\mathcal{C})),
\]
the maximal ideal spectrum of the finitely generated graded commutative algebra \( H^*(\mathcal{C}) \).

Let \( X \) and \( Y \) be objects in \( \mathcal{C} \). Let \( I_\mathcal{C}(X, Y) \) be the annihilator of \( \text{Ext}^*_\mathcal{C}(X, Y) \) under the action of \( H^*(\mathcal{C}) \) described earlier in this section. Then \( I_\mathcal{C}(X, Y) \) is a homogeneous ideal of \( H^*(\mathcal{C}) \). The support variety of the pair \( X, Y \) is
\[
V_\mathcal{C}(X, Y) := \text{Max}(H^*(\mathcal{C})/I_\mathcal{C}(X, Y)),
\]
the maximal ideal spectrum of \( H^*(\mathcal{C})/I_\mathcal{C}(X, Y) \). We identify \( V_\mathcal{C}(X, Y) \) with the subset of \( V_\mathcal{C} \) consisting of ideals containing \( I_\mathcal{C}(X, Y) \). Note that by definition of localization at a maximal ideal \( m \),
\[
(3.1) \quad m \in V_\mathcal{C}(X, Y) \text{ if, and only if, } \text{Ext}^*_\mathcal{C}(X, Y)_m \neq 0.
\]
If \( X = Y \), we also write \( I_\mathcal{C}(X) = I_\mathcal{C}(X, X) \) and \( V_\mathcal{C}(X) = V_\mathcal{C}(X, X) \). In this notation, \( V_\mathcal{C}(1) = V_\mathcal{C} \).

The dimension of the affine variety \( V_\mathcal{C}(X) \), denoted \( \dim(V_\mathcal{C}(X)) \), is defined to be the Krull dimension of \( H^*(\mathcal{C})/I_\mathcal{C}(X) \) (the length of a maximal chain of prime ideals).

The following lemma is useful in extending some classical properties of support varieties in other contexts (for example, group theory) to our more general setting.

**Lemma 3.2.** (i) For all \( X, Y \) in \( \mathcal{C} \), \( I_\mathcal{C}(X) + I_\mathcal{C}(Y) \subseteq I_\mathcal{C}(X, Y) \). (ii) For all exact sequences \( 0 \to Y_1 \to Y_2 \to Y_3 \to 0 \) and all objects \( W \) in \( \mathcal{C} \), \( I_\mathcal{C}(Y_j, W) \cdot I_\mathcal{C}(Y_i, W) \subseteq I_\mathcal{C}(Y_i, W) \) and \( V_\mathcal{C}(Y_i, W) \subseteq V_\mathcal{C}(Y_j, W) \cup V_\mathcal{C}(Y_i, W) \) whenever \( \{i, j, l\} = \{1, 2, 3\} \).

**Proof.** (i) Recall from the beginning of this section that there are two equivalent definitions of the action of \( H^*(\mathcal{C}) \) on \( \text{Ext}^*_\mathcal{C}(X, Y) \), one starting with \( - \otimes X \) and the other starting with \( - \otimes Y \), both followed by Yoneda composition of generalized extensions (and these actions coincide up to a sign). By definition, the action of \( H^*(\mathcal{C}) \) on \( \text{Ext}^*_\mathcal{C}(X, Y) \) factors through the action of \( H^*(\mathcal{C}) \) on \( \text{Ext}^*_\mathcal{C}(X, X) \) (and the same is true of \( \text{Ext}^*_\mathcal{C}(Y, Y) \)). Thus \( I_\mathcal{C}(X) + I_\mathcal{C}(Y) \subseteq I_\mathcal{C}(X, Y) \).

(ii) Given an exact sequence \( 0 \to Y_1 \to Y_2 \to Y_3 \to 0 \) and object \( W \) in \( \mathcal{C} \), we see from the long exact \( \text{Ext} \) sequence \([18]\)
\[
\cdots \to \text{Ext}^n_\mathcal{C}(Y_3, W) \to \text{Ext}^n_\mathcal{C}(Y_2, W) \to \text{Ext}^n_\mathcal{C}(Y_1, W) \to \text{Ext}^{n+1}_\mathcal{C}(Y_3, W) \to \cdots
\]
that there is a containment \( I_C(Y_j, W) \cdot I_C(Y_i, W) \subseteq I_C(Y_i, W) \). Indeed, the product of two elements, one in \( I_C(Y_j, W) \) and one in \( I_C(Y_i, W) \), necessarily annihilates both \( \text{Ext}_c^*(Y_j, W) \) and \( \text{Ext}_c^*(Y_i, W) \), and so in the long exact Ext sequence, the product acts as 0 on the terms \( \text{Ext}_c^*(Y_i, W) \).

Lastly, we will show the inclusion of the varieties. If \( m \in V_C(Y_i, W) \), we now have that \( I_C(Y_j, W) \cdot I_C(Y_i, W) \subseteq I_C(Y_i, W) \subseteq m \). Since \( m \) is a maximal ideal, and therefore prime, it follows that \( I_C(Y_j, W) \subseteq m \) or \( I_C(Y_i, W) \subseteq m \). Thus \( m \in V_C(Y_j, W) \cup V_C(Y_i, W) \) as desired. \( \square \)

The following proposition holds just as in the finite group case and other more general settings. See, for example, \cite[Section 5.7]{2}. We include a proof for completeness.

**Proposition 3.3.** Let \( C \) be a finite tensor category satisfying condition \((fg)\), and let \( X, Y, Y_1, Y_2, Y_3 \) be objects in \( C \). Then

(i) \( V_C(X \oplus Y) = V_C(X) \cup V_C(Y) \).

(ii) \( V_C(X, Y) \subseteq V_C(X) \cap V_C(Y) \).

(iii) \( V_C(X) = \cup_i V_C(X, X_i) = \cup_i V_C(X_i, X) \), where \( \{X_i \mid i = 0, \ldots, r - 1\} \) is a set of simple objects of \( C \), one from each isomorphism class.

(iv) If \( 0 \to Y_1 \to Y_2 \to Y_3 \to 0 \) is a short exact sequence, then

\[
V_C(Y_i) \subseteq V_C(Y_j) \cup V_C(Y_k)
\]

whenever \( \{i, j, k\} = \{1, 2, 3\} \).

(v) \( V_C(X \otimes Y) \subseteq V_C(X) \cap V_C(Y) \).

(vi) \( V_C(\Omega X) = V_C(X) \).

**Proof.** (i) First, we want to prove that \( I_C(X \oplus Y) = I_C(X) \cap I_C(Y) \) and then show that this implies that \( V_C(X \oplus Y) = V_C(X) \cup V_C(Y) \), as desired.

Since \( \text{Ext}_c^*(X, X) \oplus \text{Ext}_c^*(Y, Y) \subseteq \text{Ext}_c^*(X \otimes Y, X \otimes Y) \), there is a containment of ideals, \( I_C(X \otimes Y) \subseteq I_C(X) \cap I_C(Y) \). For the other inclusion, recall also that \( I_C(X) \cap I_C(Y) \subseteq I_C(X) \cap I_C(Y) \subseteq I_C(X, Y) \), by Lemma \cite[3.2(i)]{2}. Then, since

\[
\text{Ext}_c^*(X \otimes Y, X \otimes Y) = \text{Ext}_c^*(X, X) \oplus \text{Ext}_c^*(X, Y) \oplus \text{Ext}_c^*(Y, X) \oplus \text{Ext}_c^*(Y, Y),
\]

it follows that \( I_C(X) \cap I_C(Y) \subseteq I_C(X, Y) \).

We will check next that the equality \( I_C(X \oplus Y) = I_C(X) \cap I_C(Y) \) implies that \( V_C(X \oplus Y) = V_C(X) \cup V_C(Y) \). If \( m \in V_C(X \oplus Y) \), we can identify it with an ideal in \( V_C \) that contains \( I_C(X \oplus Y) \), and by abuse of notation we will write \( I_C(X \oplus Y) \subseteq m \). Then \( I_C(X) \cap I_C(Y) \subseteq m \). It is enough to show that if \( I_C(X) \nsubseteq m \) then \( I_C(Y) \nsubseteq m \). If \( I_C(X) \nsubseteq m \), there exists \( x \in I_C(X) \) for which \( x \notin m \) and the ideal generated by \( x \) and \( m \) generate the cohomology ring. Then \( 1 = ax + s \), with \( a \in H^*(C) \), and \( s \in m \). Now, if \( y \in I_C(Y) \), then \( y = yax + ys \). Since \( I_C(Y) \) and \( I_C(X) \) are ideals, \( yax \in I_C(X) \cap I_C(Y) \subseteq m \) and \( ys \in m \). So \( I_C(Y) \subseteq m \).

Consider \( m \in V_C(X) \cup V_C(Y) \). Then \( m \in V_C(X) \) or \( m \in V_C(Y) \), that is \( I_C(X) \subseteq m \) or \( I_C(Y) \subseteq m \). Since \( I_C(X \oplus Y) = I_C(X) \cap I_C(Y) \subseteq m \), it follows that \( m \in V_C(X \oplus Y) \).
(ii) This is an immediate consequence of Lemma 3.2(i). In fact, if \( m \in V_C(X,Y) \), it follows that \( I_C(X) + I_C(Y) \subseteq I_C(X,Y) \subseteq m \). Then \( m \in V_C(X) \cap V_C(Y) \).

(iii) This follows from item (ii) in this proposition and Lemma 3.2(ii). We will prove only one equality of the statement; the other can be shown in a similar way.

By (ii), there is a containment \( V_C(X_i,X) \subseteq V_C(X_i) \cap V_C(X) \subseteq V_C(X) \), for all \( i = 0, \ldots, r - 1 \). Then \( \cup_i V_C(X_i,X) \subseteq V_C(X) \).

For the other inclusion, recall that since our category \( C \) is a finite tensor category, there exists a simple subobject \( X_j \) of \( X \). Then, we have an associated exact sequence and \( V_C(X) \subseteq V_C(X_j,X) \subseteq \cup_i V_C(X_i,X) \), by Lemma 3.2(ii).

(iv) By Lemma 3.2(ii), \( V_C(Y_i) \subseteq V_C(Y_j,Y_i) \cup V_C(Y_i,Y_i) \), and by part (ii) of this proposition, that union is contained in \( V_C(Y_j) \cup V_C(Y_i) \).

(v) By the definition of the action, we apply \( - \otimes X \) and \( - \otimes X \otimes Y \), respectively, followed in both cases by Yoneda composition of generalized extensions, which implies that \( I_C(X) \subseteq I_C(X \otimes Y) \). Consequently, \( V_C(X \otimes Y) \subseteq V_C(X) \). Moreover, if \( X \otimes Y \cong Y \otimes X \) (for example, when \( C \) is braided), we also conclude that \( V_C(X \otimes Y) \subseteq V_C(Y) \) via the same argument. Then, \( V_C(X \otimes Y) \subseteq V_C(X) \cap V_C(Y) \) when \( C \) is braided.

(vi) This follows from (iii) and a long exact Ext sequence for each \( X_i \) corresponding to the short exact sequence \( 0 \to \Omega(X) \to P(X) \to X \to 0 \), where \( P(X) \) is a projective cover of \( X \) and \( \Omega(X) \) is the kernel of the epimorphism \( P(X) \to X \). \( \square \)

4. Complexity

In this section, we define complexity of an object \( X \) as the rate of growth, defined next, of a minimal projective resolution, and show that it is equal to the dimension of the support variety \( V_C(X) \).

Let \( a_* = (a_0, a_1, a_2, \ldots) \) be a sequence of nonnegative real numbers \( a_i \). The rate of growth \( \gamma(a_*) \) is defined to be the smallest nonnegative integer \( c \) for which there exists a real number \( b \) such that \( a_n \leq bn^{c-1} \) for all positive integers \( n \). If no such \( c \) exists, we define \( \gamma(a_*) \) to be \( \infty \). We will be interested in the rates of growth of sequences \( \dim_k W_i \) and \( \FPdim P_i \), where \( W_i \) is an \( \mathbb{N} \)-graded vector space over \( k \) and \( P_i \) is an \( \mathbb{N} \)-graded object of \( C \).

Let \( X \) be an object in \( C \). The complexity of \( X \) is defined to be the rate of growth of a minimal projective resolution \( P \) of \( X \) as measured by Frobenius-Perron dimension:

\[
\text{cxc}_C(X) := \gamma(\FPdim(P)).
\]

It follows from the proof of Theorem 4.1 below that our definition of complexity is equivalent to [6] Definition 4.1. It also follows from the proof that all objects in a finite tensor category satisfying condition (fg) have finite complexity, since the dimensions of the support varieties are necessarily finite. The proof of the theorem is in the same spirit as that for modules for finite group algebras [2] Proposition 5.7.2]. However, we use Frobenius-Perron dimensions of objects in
place of vector space dimensions, and exploit a connection with vector space dimension of Hom spaces.

**Theorem 4.1.** Let $\mathcal{C}$ be a finite tensor category satisfying condition (fg). For every object $X$ of $\mathcal{C}$,

$$cx_{\mathcal{C}}(X) = \dim V_{\mathcal{C}}(X).$$

**Proof.** By assumption (fg), $\text{Ext}^*_\mathcal{C}(X, X)$ is a finitely generated module over $H^*(\mathcal{C})$, and since the annihilator of this action is $I_\mathcal{C}(X)$ by definition, $\text{Ext}^*_\mathcal{C}(X, X)$ is a finitely generated module over $H^*(\mathcal{C})/I_\mathcal{C}(X)$. By definition, $\dim V_{\mathcal{C}}(X)$ is the Krull dimension of $H^*(\mathcal{C})/I_\mathcal{C}(X)$, which in turn is equal to its rate of growth as a graded vector space (see [17, Section 14] or [2, Theorem 5.4.6]), so that we have

$$\dim V_{\mathcal{C}}(X) = \dim (H^*(\mathcal{C})/I_\mathcal{C}(X)) = \gamma(\dim_k (H^*(\mathcal{C})/I_\mathcal{C}(X))).$$

The latter is equal to $\gamma(\dim_k (\text{Ext}^*_\mathcal{C}(X, X)))$ since $\text{Ext}^*_\mathcal{C}(X, X)$ is finitely generated as a module over the quotient $H^*(\mathcal{C})/I_\mathcal{C}(X)$. Thus we must show that $cx_{\mathcal{C}}(X) = \gamma(\dim_k (\text{Ext}^*_\mathcal{C}(X, X)))$, that is, we must show that

$$\gamma(\text{FPdim}(P)) = \gamma(\dim_k (\text{Ext}^*_\mathcal{C}(X, X))),$$

where $P$ is a minimal projective resolution of $X$ in $\mathcal{C}$. We will do this by proving that each quantity above is less than or equal to the other.

By Lemma [2.2], the multiplicity of the projective cover $P(X_i)$ of a simple object $X_i$ in $\mathcal{C}$, as a direct summand of $P_n$, is $\dim_k \text{Hom}_\mathcal{C}(P_n, X_i)$. By Lemma [2.4] since $P$ is a minimal resolution,

$$\dim_k \text{Hom}_\mathcal{C}(P_n, X_i) = \dim_k \text{Ext}^n_\mathcal{C}(X, X_i).$$

We thus have

$$\text{FPdim}(P_n) = \sum_i \text{FPdim}(P(X_i)) \cdot \dim_k (\text{Ext}^n_\mathcal{C}(X, X_i)).$$

It follows that

$$(4.2) \quad \gamma(\text{FPdim}(P)) \leq \max \{\gamma(\dim_k (\text{Ext}^*_\mathcal{C}(X, X_i)))\}.$$

Now condition (fg) implies that each $\text{Ext}^*_\mathcal{C}(X, X_i)$ is a finitely generated $H^*(\mathcal{C})$-module, and since this action factors through $\text{Ext}^*_\mathcal{C}(X, X)$ by the definition of the action, each $\text{Ext}^*_\mathcal{C}(X, X_i)$ is finitely generated as a module over $\text{Ext}^*_\mathcal{C}(X, X)$. Thus

$$\gamma(\dim_k (\text{Ext}^*_\mathcal{C}(X, X_i))) \leq \gamma(\dim_k (\text{Ext}^*_\mathcal{C}(X, X)))$$

for each simple object $X_i$ in $\mathcal{C}$. It now follows from inequality (1.2) that

$$\gamma(\text{FPdim}(P)) \leq \gamma(\dim_k (\text{Ext}^*_\mathcal{C}(X, X))).$$

It remains to prove the other inequality. Since $\text{Ext}^*_\mathcal{C}(X, X)$ is a subquotient of the vector space $\text{Hom}_\mathcal{C}(P_n, X)$, we have $\dim_k (\text{Ext}^*_\mathcal{C}(X, X)) \leq \dim_k \text{Hom}_\mathcal{C}(P_n, X)$, and so

$$\gamma(\dim_k (\text{Ext}^*_\mathcal{C}(X, X))) \leq \gamma(\dim_k (\text{Hom}_\mathcal{C}(P_n, X))).$$
In turn, we claim that $\gamma(\dim_k \text{Hom}_C(P, X)) \leq \gamma(\text{FPdim}(P))$. To see this, by Lemma 2.2, we may write each $P_n = \oplus a_{n,i} P(X_i)$ for some nonnegative integers $a_{n,i}$, where the $X_i$ are the simple objects. By additivity of Hom and equation (2.1),

$$\dim_k \text{Hom}_C(P_n, X) = \sum_i a_{n,i} \dim_k(\text{Hom}_C(P(X_i), X)) = \sum_i a_{n,i} [X : X_i],$$

where $[X : X_i]$ is the multiplicity of $X_i$ as a composition factor of $X$. In addition,

$$\text{FPdim}(P_n) = \sum_i a_{n,i} \text{FPdim}(P(X_i)).$$

Comparing rates of growth, we now must show that

$$(4.3) \quad \gamma(\sum_i a_{n,i} [X : X_i]) \leq \gamma(\sum_i a_{n,i} \text{FPdim}(P(X_i))).$$

To see that this is indeed the case, note that for each $i$, the quantities $[X : X_i]$ and $\text{FPdim}(P(X_i))$ are fixed real numbers. Moreover, $\text{FPdim}(P(X_i))$ is positive for all $i$ as explained in Section 2. In each expression, the rate of growth depends on the integers $a_{n,i}$. The expression on the left side only depends on those $a_{n,i}$ for which $[X : X_i]$ is nonzero, and the expression on the right side depends on all $a_{n,i}$ (since $\text{FPdim}(P(X_i))$ is nonzero for all $i$). So the inequality (4.3) holds. It follows that $\gamma(\dim_k \text{Hom}_C(P, X)) \leq \gamma(\text{FPdim}(P))$ as claimed, and therefore $\gamma(\dim_k \text{Ext}^*_C(X, X)) \leq \gamma(\text{FPdim}(P))$. Consequently

$$\gamma(\text{FPdim}(P)) = \gamma(\dim_k(\text{Ext}^*_C(X, X))),$$

as required. $\square$

As a consequence of the theorem, we obtain an expected result on the variety of a projective object.

**Corollary 4.4.** An object $X$ of $\mathcal{C}$ is projective if and only if $\dim V_C(X) = 0$.

**Proof.** If $X$ is projective, then $\text{cx}_C(X) = 0$ and so $\dim(V_C(X)) = 0$ by Theorem 4.1. Conversely, if $\dim(V_C(X)) = 0$, then $X$ has a projective resolution of finite length, say $0 \to P_n \to \cdots \to P_0 \to X \to 0$. By [9, Proposition 6.1.3], projective objects are also injective, and so the morphism $P_n \to P_{n-1}$ splits, and similarly for the other morphisms in the resolution. This implies that $X$ is a direct summand of $P_0$, and so is projective. $\square$

We illustrate the notion of complexity and the theorem with an example of Benson and Etingof [3].

**Example 4.5.** Let $\mathcal{C} = \mathcal{C}_3$, the category defined in [3, Section 5.3]. In [3], it is shown that $\mathcal{C}_3$ has two simple objects, $1$ and $V$, with $\text{FPdim}(1) = 1$ and $\text{FPdim}(V) = \sqrt{2}$. Their projective covers $P(1)$ and $P(V)$ have Frobenius-Perron
dimensions FPdim(P(1)) = 3 + \sqrt{2} and FPdim(P(V)) = 2 + 2\sqrt{2}. It is also shown in [8] that
\[ \text{Ext}_{C_3}^*(1, 1) \cong k[x, y, z]/(y^2 + xz) \text{ and } \text{Ext}_{C_3}^*(V, V) \cong k[u, v]/(u^2) \]
where \(|x| = 1, |y| = |u| = 2, |z| = |v| = 3\), and the minimal projective resolution of \(V\) is
\[ \cdots \to P(V) \to P(1) \to P(V) \to P(V) \to P(1) \to P(V) \to V \to 0. \]
It follows that \(c_{x_C}(V) = 1\) and \(c_{x_C}(1) = 2\). See [8] for more details on the structure of \(C_3\).

5. Carlson’s \(L_\zeta\) objects

In this section, to each homogeneous element \(\zeta\) of the cohomology ring \(H^*(C)\) of the finite tensor category \(C\), we associate an object \(L_\zeta\) of \(C\). These objects are defined analogously to Carlson’s \(L_\zeta\) modules for finite groups and to Koszul objects in triangulated categories (see, e.g. [6]), and have similar useful properties. We give a somewhat different approach to that in [6], and include proofs for completeness.

Let \(n > 0\). By Lemma 2.4, since the unit object \(1\) is simple,
\[ H^n(C) = \text{Ext}_C^n(1, 1) \cong \text{Hom}_C(\Omega^n(1), 1). \]
Let \(\zeta \in H^n(C)\) and identify \(\zeta\) with a morphism \(\hat{\zeta}\) from \(\Omega^n(1)\) to \(1\) under the above isomorphism. Let \(L_\zeta\) be its kernel, so that \(L_\zeta\) is defined by a short exact sequence:
\[ 0 \to L_\zeta \to \Omega^n(1) \xrightarrow{\hat{\zeta}} 1 \to 0. \]

The following theorem generalizes [23, Proposition 3] and [11, Theorem 2.5], and parallels [6, Proposition 3.6]. Our proof is essentially that in [23]. For any ideal \(I\) of \(H^*(C)\), let \(Z(I)\) be the set of all maximal ideals of \(H^*(C)\) containing \(I\).

**Theorem 5.2.** Let \(C\) be a finite tensor category satisfying condition (fg). Let \(X\) be an object in \(C\) and let \(\zeta \in H^n(C), \zeta \neq 0\). Then
\[ V_C(X \otimes L_\zeta) = V_C(X) \cap Z(\langle \zeta \rangle). \]
In particular, \(V_C(L_\zeta) = Z(\langle \zeta \rangle)\).

**Proof.** First we note that the second statement follows from the first, by setting \(X = 1\).

We will first show that \(V_C(X \otimes L_\zeta) \subseteq V_C(X) \cap Z(\langle \zeta \rangle)\). By Proposition 3.3(v), we need only show that \(V_C(L_\zeta) \subseteq Z(\langle \zeta \rangle)\). By Proposition 3.3(iii), it suffices to show that \(V_C(L_\zeta, X_i) \subseteq Z(\langle \zeta \rangle)\) for each simple object \(X_i\). Due to the observation (3.1), we must show that if \(m\) is a maximal ideal in \(H^*(C)\) for which \(\text{Ext}_C^*(L_\zeta, X_i)_m \neq 0\), then \(\zeta \in m\).

Suppose \(\zeta \notin m\). Then \(\zeta\) is invertible in \(H^*(C)_m\) and so \(\zeta\) induces an isomorphism,
\[ \tilde{\zeta} : \text{Ext}_C^j(1, X_i)_m \xrightarrow{\sim} \text{Ext}_C^{j+n}(1, X_i)_m \cong \text{Ext}_C^n(\Omega^n(1), X_i)_m, \]
the latter isomorphism holding by Lemma 2.4. Consider the long exact sequence obtained by applying $\text{Ext}^j_C(-, X_i)$ to the short exact sequence \([5.1]\) and localizing at \(m\) for each \(i:\)

\[
\cdots \rightarrow \text{Ext}^j_C(1, X_i)_m \rightarrow \text{Ext}^j_C(\Omega^n(1), X_i)_m \rightarrow \text{Ext}^j_C(L_\zeta, X_i)_m \rightarrow \cdots,
\]

where \(\tilde{\zeta}\) is the isomorphism described above. (The long exact Ext sequence is one of \(H^*(C)\)-modules, and since localization is an exact functor, the above sequence is also exact.) Since \(\text{Ext}^j_C(-, X_i)_m = 0\). Therefore if \(\text{Ext}^j_C(L_\zeta, X_i)_m \neq 0\), then \(\zeta \in m\). It follows that \(V_C(L_\zeta, X_i) \subseteq Z(\langle \zeta \rangle)\), as explained above.

Next we will show that \(V_C(X) \cap Z(\langle \zeta \rangle) \subseteq V_C(X \otimes L_\zeta)\). By Proposition 3.3(iii),

\[
V_C(X) = \cup_i V_C(X, X_i) \quad \text{and} \quad V_C(X \otimes L_\zeta) = \cup_i V_C(X \otimes L_\zeta, X_i),
\]

so it suffices to show that

\[
V_C(X, X_i) \cap Z(\langle \zeta \rangle) \subseteq V_C(X \otimes L_\zeta, X_i)
\]

for every simple object \(X_i\). Let \(m\) be a maximal ideal in \(V_C(X, X_i) \cap Z(\langle \zeta \rangle)\), that is, \(I_C(X, X_i) \subseteq m\) and \(\langle \zeta \rangle \subseteq m\). We must show that \(I_C(X \otimes L_\zeta, X_i) \subseteq m\). Suppose that \(I_C(X \otimes L_\zeta, X_i) \not\subseteq m\). By observation \([3.1]\), \(\text{Ext}^j_C(X \otimes L_\zeta, X_i)_m = 0\). Apply \(X \otimes -\) and \(\text{Ext}^j_C(-, X_i)\) to the short exact sequence \([5.1]\). Note that \(\Omega^n(X)\) is isomorphic to \(X \otimes \Omega^n(1)\) up to projective direct summands since \(X \otimes P\) is a projective resolution of \(X\) whenever \(P\) is a projective resolution of \(1\). Thus

\[
\text{Ext}^j_C(X \otimes \Omega^n(1), X_i) \cong \text{Ext}^j_C(\Omega^n(X), X_i) \cong \text{Ext}^{j+n}_C(X, X_i)
\]

by Lemma 2.4. So there is a long exact sequence of \(H^*(C)\)-modules:

\[
\cdots \rightarrow \text{Ext}^j_C(X \otimes \Omega^n(X), X_i) \rightarrow \text{Ext}^j_C(\Omega^n(X), X_i) \rightarrow \text{Ext}^j_C(X \otimes L_\zeta, X_i) \rightarrow \cdots
\]

where \(\hat{\zeta}\) denotes the action of \(\zeta\) on \(\text{Ext}^j_C(X, X_i)\). Now localize at \(m\), and note that since \(\text{Ext}^j_C(X \otimes L_\zeta, X_i)_m = 0\), the map \(\hat{\zeta}\) must induce isomorphisms

\[
\text{Ext}^j_C(X, X_i)_m \cong \text{Ext}^{j+n}_C(X, X_i)_m.
\]

Then \(\zeta\) could not be an element of \(m\), contradicting our assumption. Therefore \(I_C(X \otimes L_\zeta, X_i) \subseteq m\), and so \(V_C(X, X_i) \cap Z(\langle \zeta \rangle) \subseteq V_C(X \otimes L_\zeta, X_i)\).

We obtain as a consequence the following realization result. Recall that a conical variety is by definition the zero set of an ideal generated by homogeneous elements.

**Corollary 5.3.** Let \(C\) be a finite tensor category satisfying condition (fg). Let \(V\) be any conical subvariety of \(V_C\). Then \(V = V_C(X)\) for some object \(X\) of \(C\).

**Proof.** Let \(V\) be a conical subvariety of \(V_C\), that is \(V = Z(I)\) for \(I\) a homogeneous ideal in \(H^*(C)\). By definition, \(I = \langle \zeta_1, \ldots, \zeta_t \rangle\) for some homogeneous elements \(\zeta_1, \ldots, \zeta_t\). Let \(X = L_{\zeta_1} \otimes \cdots \otimes L_{\zeta_t}\). By Theorem 5.2 \(V_C(X) = Z(I) = V\). \(\square\)
6. Tensor product property and projective objects

Let \( \mathcal{C} \) be a finite tensor category that satisfies condition (fg). We say that \( \mathcal{C} \) has the tensor product property if

\[
V_\mathcal{C}(X \otimes Y) = V_\mathcal{C}(X) \cap V_\mathcal{C}(Y)
\]

for all objects \( X \) and \( Y \) in \( \mathcal{C} \). The tensor product property holds for the categories of finite dimensional modules of finite dimensional cocommutative Hopf algebras \([12, \text{Proposition 3.2}]\) as well as some other types of Hopf algebras (see, e.g., \([5, 24]\)). When the tensor product property holds, it yields useful representation theoretic information. For example, it can be used to detect projectivity of algebras \([12, \text{Proposition 3.2}]\) as well as some other types of Hopf algebras (see, e.g., \([5, 24]\)).

Let \( \mathcal{C} \) be a finite tensor category on which a finite group \( G \) acts by autoequivalences. For each object \( X \) in \( \mathcal{C} \) and element \( g \) in \( G \), denote by \( {}^gX \) the object of \( \mathcal{C} \) that is the image of the action of \( g \) on \( X \). The crossed product category \( \mathcal{C} \rtimes G \) is the category \( \oplus_{g \in G} \mathcal{C} \) with objects \( \oplus_{g \in G} (X, g) \) in which \( X_g \) is an object of \( \mathcal{C} \) for each \( g \in G \). Tensor products are given by \( (X, g) \otimes (Y, h) = (X \otimes {}^gY, gh) \). For more on crossed product categories, see for example \([9, \text{Definition 1.11.1}]\) or \([15, 20, 29]\).

For finite tensor categories \( \mathcal{C} \) and \( \mathcal{D} \), the Deligne tensor product category \( \mathcal{C} \boxtimes \mathcal{D} \) is an abelian \( k \)-linear category that is universal with respect to bifunctors from \( \mathcal{C} \times \mathcal{D} \) to \( k \)-linear abelian categories that are right exact in both arguments \([9, \text{Definition 1.11.1}]\). By \([9, \text{Proposition 4.6.1}]\), it is again a finite tensor category. Note that the crossed product category \( \mathcal{C} \rtimes G \) is equivalent to \( \mathcal{C} \boxtimes \text{Vec}^G \) as an abelian category, where \( \text{Vec}^G \) is the category of \( k^G \)-modules (the Hopf algebra \( k^G \) is dual to the group algebra \( kG \)). Also note that \( \mathcal{C} \) is a tensor subcategory of \( \mathcal{C} \rtimes G \) by sending an object \( X \) of \( \mathcal{C} \) to \( (X, 1) \). Using \([9, \text{Proposition 1.11.2(iv)}]\), it can be shown that \( H^*(\mathcal{C} \boxtimes \mathcal{D}) \cong H^*(\mathcal{C}) \otimes_k H^*(\mathcal{D}) \), where this is interpreted as a graded tensor product of algebras over \( k \). For example, \( H^*(\mathcal{C} \rtimes G) \cong H^*(\mathcal{C}) \) since \( k^G \) is semisimple.

We will next construct crossed product categories for which the tensor product property does not hold.

**Theorem 6.2.** Let \( \mathcal{C} \) be a nonsemisimple finite tensor category satisfying condition (fg) and the tensor product property \([6, 7]\). Let \( \mathcal{D} = (\mathcal{C} \boxtimes \mathcal{C}) \rtimes \mathbb{Z}_2 \), where \( \mathbb{Z}_2 \) acts on \( \mathcal{C} \boxtimes \mathcal{C} \) by interchanging factors. Then \( \mathcal{D} \) does not have the tensor product property.

**Proof.** As stated above, \( H^*(\mathcal{C} \boxtimes \mathcal{C}) \cong H^*(\mathcal{C}) \otimes_k H^*(\mathcal{C}) \). We find that \( \mathcal{C} \boxtimes \mathcal{C} \) satisfies condition (fg) since \( \mathcal{C} \) does. Now \( H^*(\mathcal{D}) \cong H^*(\mathcal{C}) \otimes_k H^*(\mathcal{C}) \) as well. The unit object in \( (\mathcal{C} \boxtimes \mathcal{C}) \rtimes \mathbb{Z}_2 \) is \( ((1 \boxtimes 1), 1) \) and \( V_{(\mathcal{C} \boxtimes \mathcal{C}) \rtimes \mathbb{Z}_2}((1 \boxtimes 1), 1) = V_\mathcal{C}(1) \times V_\mathcal{C}(1) \) where \( V_\mathcal{C}(1) \)
denotes the variety of \( 1 \) in \( C \). Let \( P \) be a projective object in \( C \). Let \( g \) be the nonidentity element in \( \mathbb{Z}_2 \). We consider the object \( X = (1 \boxtimes P, g) \) of \( D \), and note that its support variety is \( (V_C(1), 0) \), and so it is not projective. Also note that \( g(1 \boxtimes P) = P \boxtimes 1 \). Therefore

\[
X \otimes X = (1 \boxtimes P, g) \otimes (1 \boxtimes P, g) \cong ((1 \boxtimes P) \otimes g(1 \boxtimes P), 1) \cong (P \boxtimes P, 1),
\]

which is projective. Therefore its variety has dimension 0 by Corollary \[4.4\] that is, \( \dim_k(V_C(X \otimes X)) = 0 \). On the other hand, since \( X \) is not projective,

\[
\dim_k(V_C(X) \cap V_C(X)) \neq 0.
\]

Therefore the tensor product property does not hold. \( \square \)

Note that in general, \( C \) can be embedded as a tensor subcategory of any tensor product category \( C \boxtimes D \), by sending each object \( X \) to \( X \boxtimes 1 \), and similarly for morphisms. Specifically in the theorem, \( C \) can be embedded as a tensor subcategory of \( (C \boxtimes C) \rtimes \mathbb{Z}_2 \), by sending an object \( X \) of \( C \) to \( (X \boxtimes 1, 1) \) and we immediately obtain the following corollary.

**Corollary 6.3.** Let \( C \) be a nonsemisimple finite tensor category satisfying condition \((fg)\) and the tensor product property \((6.1)\). Then \( C \) can be embedded as a tensor subcategory of a finite tensor category that does not have the tensor product property.

We finally show that under some hypotheses, a weaker condition than the tensor product property does hold. A finite tensor category \( C \) is rigid by assumption, that is, for every object \( X \in C \), the composition of morphisms

\[
(6.4) \quad X \xrightarrow{\text{coev}_X \otimes \text{id}_X} X \otimes X^* \otimes X \xrightarrow{\text{id}_X \otimes \text{ev}_X} X
\]

is the identity map on \( X \), where \( \text{ev}_X \) and \( \text{coev}_X \) denote the canonical evaluation and coevaluation maps. Details are given in [9, Section 2.10] or [1, Section 2.1].

**Theorem 6.5.** Let \( C \) be a finite tensor category, and let \( n \) be a positive integer. Let \( X \) be an object in \( C \) for which \( X \otimes X^* \cong X^* \otimes X \). Then \( X \) is projective if and only if its \( n \)th tensor power \( X^n \) is projective.

*Proof.* The proof is the same as in the Hopf algebra case, see [25, Theorem 5.2]. The tensor product of a projective object with another object in a finite tensor category \( C \) is projective [9, Proposition 4.2.12], so if \( X \) is a projective object, then \( X^n \) is projective.

For the converse, we use induction on \( n \). The case \( n = 1 \) is a tautology. Assume that for some \( n \geq 2 \), if \( X^n \) is projective, then \( X \) is projective. Apply the functor \( X^{(n-1)} \otimes - \) to sequence \((6.4)\). Since the composition is the identity map, we see in this way that \( X^n \) is a direct summand of \( X^n \otimes X^* \otimes X \). By hypothesis, since \( X \otimes X^* \cong X^* \otimes X \), the object \( X^n \otimes X^* \otimes X \) is isomorphic to \( X^{(n+1)} \otimes X^* \). Therefore if \( X^{(n+1)} \) is projective, then \( X^n \otimes X^* \otimes X \) is projective. Since \( X^n \) is a
direct summand of $X^n \otimes X^* \otimes X$, it follows that $X^n$ is projective. By the induction hypothesis, $X$ is projective. □

The following corollary is immediate.

**Corollary 6.6.** Let $\mathcal{C}$ be a braided finite tensor category, let $n$ be a positive integer, and let $X$ be an object in $\mathcal{C}$. Then $X$ is projective if and only if its $n$th tensor power $X^n$ is projective.
