LINEARIZATION OF A NONAUTONOMOUS UNBOUNDED SYSTEM WITH NONUNIFORM CONTRACTION: A SPECTRAL APPROACH

I. HUERTA

ABSTRACT. For a nonautonomous linear system with nonuniform contraction, we construct a topological equivalence between this system and an unbounded nonlinear perturbation. This topological equivalence is constructed as a composition of homeomorphisms. The first one is set up by considering the fact that linear system is almost reducible to diagonal system with a small enough perturbation where the diagonal entries belong to spectrum of the nonuniform exponential dichotomy; and the second one is constructed in terms of the crossing times with respect to unit sphere of an adequate Lyapunov function associated to the linear system.

1. INTRODUCTION

The well known Hartman–Grobman’s Theorem is an essential tool for the study of the local behavior of autonomous and nonautonomous nonlinear dynamical systems. This theorem establishes the existence of a local topological conjugacy between the solutions of a nonlinear system with its linearization around an hyperbolic equilibrium, i.e., the dynamics are topologically the same in a neighborhood of the equilibrium point. The global behavior study begins in 1969, when C. Pugh [13] studied a particular case of the Hartman–Grobman’s Theorem focused to linear systems with bounded and Lipschitz perturbations allowing the construction of an explicit and global homeomorphism.

A remarkable extension of the previous work was made F. Lin [10], who considered this problem by dropping the boundedness of the nonlinear perturbations, opening new ideas and methods. The work of Lin is mainly based in three steps:

(i) The linear system

\[ \dot{x} = A(t)x \]
is supposed to be uniformly asymptotically stable, then it can be reduced to the linear system
\begin{equation}
\dot{x} = [C(t) + B(t)]x
\end{equation}
where $C(t)$ is diagonal, $B(t)$ is small enough, and the diagonal part is contained in the spectrum associated to nonautonomous hyperbolicity, a formal definition will be given later.

(ii) The system
\begin{equation}
\dot{x} = [C(t) + B(t)]x + g(t, x)
\end{equation}
is topologically equivalent to an autonomous linear system which is uniformly asymptotically stable, where $g(t, x)$ has an equilibrium point at the origin for any $t \in \mathbb{R}$ and is Lipschitz with constant dependent of the smallness of $B(t)$. The construction of this topological equivalence is made by using the concept of crossing times with respect to unit sphere. Notice that a suitable Lyapunov function is used to find this crossing times.

(iii) A chain of homeomorphisms which are involved with the topological equivalences constructed in steps (i) and (ii).

1.2. Structure and novelty of the article. The section 2 states and comments the properties of the linear system (1) and the nonlinear perturbations which will be considered in this work. Additionally, we recall the main tools that will be used along this article, namely, the property of topological equivalence, the nonuniform exponential dichotomy and its associated spectrum, the $\delta$–nonuniform kinematical similarity and the nonuniform almost reducibility.

The section 3 is devoted to characterizing the property of nonuniform contraction in terms of an adequate Lyapunov function and positive quadratic forms. We give appropriate definitions of these concepts in a nonuniform context. Moreover, we state the main Theorems of this work: (Ia): we will show that if the linear system (2) has a nonuniform contraction then is topologically equivalent to a system (3) whose nonlinearity satisfy suitable properties. (Ib): Moreover, we will prove that the Lyapunov function associated to (2) has a relation with the behavior of the solutions of the perturbed system (3). (II): We will prove that if the linear system (1) satisfies subtle conditions then is topologically equivalent to the perturbed system
\begin{equation}
\dot{x} = A(t)x + f(t, x)
\end{equation}
where $t \mapsto f(t, 0) = 0$ and $x \mapsto f(t, x)$ is Lipschitz for any $t \in \mathbb{R}_0^+$. (III): We will generalize the above result considering the boundedness of $t \mapsto f(t, 0)$ instead of the vanishing at the origin.

In the section 4 we generalize to the nonuniform context a classical result of local continuity with respect to the initial conditions.

The last sections are devoted to the proofs of our results. In the section 5 we will follow the lines of the proof of Palmer’s Lemma in [12] in order to prove (Ib). Note that the result of Palmer is immersed in a uniform context, while ours is in a nonuniform framework which entail technical difficulties. To obtain (Ia) we will use the crossing times defined by the Lyapunov functions associated to contractive linear system. Moreover, at this point, we establish the major difference with the Lin’s work: Now, it is impossible carry out the step (ii) described in Section 1.1, i.e., we can not construct a topological equivalence between a nonlinear system...
with nonuniform contractive linear part and an autonomous linear system which is uniformly stable by intrinsic nature. In the section 6 is done the proof of (II) which is immediately consequence of the (Ib). Finally, the section 7 is devoted to proof of (III).

We emphasize that only few results of topological equivalence consider the unbounded nonlinearity. To the best of our knowledge, this property of unboundedness is only considered in [10], [5] (in a differential and discrete uniform context, respectively) and [16] in an impulsive framework.

2. Preliminaries

2.1. Properties. In this article we consider the following couple of the systems

\[
\begin{align*}
(4a) & \quad \dot{x} = A(t)x \\
(4b) & \quad \dot{x} = A(t)x + f(t, x)
\end{align*}
\]

where \(A : \mathbb{R}_0^+ \rightarrow M(n, \mathbb{R})\) and \(f : \mathbb{R}_0^+ \times \mathbb{R}^n \rightarrow \mathbb{R}^n\) is continuous on \((t, x)\) and

\[
\begin{align*}
(5a) & \quad \dot{y} = [C(t) + B(t)]y \\
(5b) & \quad \dot{y} = [C(t) + B(t)]y + g(t, y)
\end{align*}
\]

where \(B, C : \mathbb{R}_0^+ \rightarrow M(n, \mathbb{R})\) and \(g : \mathbb{R}_0^+ \times \mathbb{R}^n \rightarrow \mathbb{R}^n\) is continuous on \((t, x)\). Moreover, the following properties are verified:

(P1) For \(\nu, M > 0\), \(\|A(t)\| \leq M \exp(\nu t)\) for any \(t \in \mathbb{R}_0^+\).

(P2) The evolution operator \(\Phi(t, s)\) of (4a) has a nonuniformly bounded growth, namely, there exist constants \(K_0 \geq 1\), \(a \geq 0\) and \(\bar{\varepsilon} \geq 0\) such that

\[
\|\Phi(t, s)\| \leq K_0 \exp(a|t - s| + \bar{\varepsilon}s), \quad t, s \in \mathbb{R}_0^+.
\]

(P3) The system (4a) is nonuniform contractible if there exist \(K > 0\), \(\alpha > 0\) and \(\mu \geq 0\) such that

\[
\|\Phi(t, s)\| \leq K \exp(-\alpha(t - s) + \mu s) \quad \text{for any } t \geq s \geq 0.
\]

(P4) The function \(f\) is continuous on \((t, x)\) and is an element of one of the following families of functions:

\[
\mathcal{A}_1 = \left\{ f : \sup_{t \in \mathbb{R}_0^+} \|f(t, 0)\| < +\infty \text{ and } \exists L_f, \beta \geq 0 \text{ s.t.} \right. \\
\left. \|f(t, u) - f(t, v)\| \leq L_f \exp(-2\beta t) \|u - v\| \quad \forall t \in \mathbb{R}_0^+ \right\},
\]

\[
\mathcal{A}_2 = \left\{ f : f \in \mathcal{A}_1 \text{ and } f(t, 0) = 0 \text{ for all } t \in \mathbb{R}_0^+ \right\}.
\]

2.2. Main Tools. The fundamental tools in our work are the concepts of topological equivalence, introduced by K.J. Palmer in [11], the nonuniform exponential dichotomy which was introduced by L. Barreira and C. Valls in [1], and the \(\delta\)-nonuniform kinematical similarity.

Definition 1. The systems (4a) and (4b) will be called topologically equivalent if there exists a map \(H : \mathbb{R}_0^+ \times \mathbb{R}^n \rightarrow \mathbb{R}^n\) with the properties

(i) For each fixed \(t \in \mathbb{R}_0^+\), the map \(\xi \mapsto H(t, \xi)\) is a bijection.

(ii) For any fixed \(t \in \mathbb{R}_0^+\), the maps \(\xi \mapsto H(t, \xi)\) and \(\xi \mapsto H^{-1}(t, \xi) = G(t, \xi)\) are continuous.
Definition 2. \((1, 6, 17)\) The system \((4a)\) has a nonuniform exponential dichotomy on \(\mathbb{R}_0^+\) if there exist an invariant projector \(P(\cdot)\), constants \(K \geq 1, \alpha > 0\) and \(\mu \geq 0\) such that

\[
\begin{array}{ll}
\|y(t)P(s)\| & \leq K \exp(-\alpha(t-s)+\mu|s|), \quad t \geq s, \quad t, s \in \mathbb{R}_0^+; \\
\|\Phi(t,s)(I-P(s))\| & \leq K \exp(\alpha(t-s)+\mu|s|), \quad t \leq s, \quad t, s \in \mathbb{R}_0^+.
\end{array}
\]

Definition 3. \((17)\) Given a \(\delta > 0\), the linear system \((4a)\) is \(\delta\)-nonuniformly kinematically similar to

\[
\dot{y} = U(t)y,
\]
if there exist a Lyapunov’s transformation \(S(\delta, t)\) and \(\nu \geq 0\), with

\[
\|S(\delta, t)\| \leq M_{\nu, \delta} \exp(\nu t) \quad \text{and} \quad \|S^{-1}(\delta, t)\| \leq M_{\nu, \delta} \exp(\nu t),
\]

such that the change of coordinates \(y(t) = S^{-1}(\delta, t)x(t)\) transforms the system \((4a)\) into \((8)\).  

Remark 1. The nonuniform kinematical similarity preserves the nonuniform contraction (see more details in \([3, \text{Lemma } 2]\)). Thus, as the systems \((4a)\) and \((5a)\) are \(\delta\)-nonuniformly kinematically similar (see Theorem 1 of \([3]\)), and as the system \((4a)\) satisfies the condition \((\text{P2})\) with \(K \geq 1, \alpha > 0, \mu \geq 0\) and if \(\alpha > \mu\), then the system \((5a)\) admits a nonuniform contraction, i.e., there exist \(K_1 \geq 1, \alpha_1 > 0\) and \(\mu_1 \geq 0\) satisfying

\[
\|\Psi(t,s)\| \leq K_1 \exp(-\alpha_1(t-s)+\mu_1 s), \quad t \geq s \geq 0,
\]

where \(\Psi(t,s)\) is the evolution operator of \((5a)\).

Remark 2. It is easy to verify that the property of \(\delta\)-nonuniform kinematical similarity is an equivalence relation and a particular case of nonuniform topological equivalence. Indeed, the properties of Definition \((17)\) are verified with \(H(t,\xi) = S^{-1}(\delta, t)\xi\).

Now we recall definition of nonuniform almost reducibility which is a generalization of the concept of almost reducibility introduced by B.F. Bylov \([2]\) in a uniform context.

Definition 4. \((3)\) The system \((4a)\) is nonuniformly almost reducible to

\[
\dot{y} = C(t)y,
\]
if for any \(\delta > 0\) and \(\varepsilon \geq 0\), there exists a constant \(K_{\delta, \varepsilon} \geq 1\) such that \((4a)\) is \(\delta\)-nonuniformly kinematically similar to

\[
\dot{y} = [C(t) + B(t)]y, \quad \text{with} \quad \|B(t)\| \leq \delta K_{\delta, \varepsilon}
\]

for any \(t \in \mathbb{R}_0^+\).

In the case when \(C(t)\) is a diagonal matrix, if \(K_{\delta, \varepsilon} = 1\) it is said that \((4a)\) is almost reducible to a diagonal system and it was proved in \([2]\) that any continuous linear system satisfies this property and the components of \(C(t)\) are real numbers. This notion of almost reducibility to a diagonal system was rediscovered and improved by F. Lin in \([9]\), who introduces the concept of contractibility. Lin showed that...
the Sacker and Sell spectrum is the minimal compact set where \( C(t) \) is contained. This minimal set which \( C(t) \) is contained is called contractible set. In a nonuniform context, in \([3]\) we proved that \( C(t) \) is contained in the spectrum associated to nonuniform exponential dichotomy.

**Definition 5.** (\([6],[17]\)) The nonuniform spectrum (also called nonuniform exponential dichotomy spectrum) of \((4a)\) is the set \( \Sigma(A) \) of \( \lambda \in \mathbb{R} \) such that the systems

\[
\dot{x} = [A(t) - \lambda I]x
\]

have not nonuniform exponential dichotomy on \( \mathbb{R}_0^+ \).

**Remark 3.** Assumptions \((P2)\) and \((P3)\) have a strong relation with the set \( \Sigma(A) \). Indeed, \((P2)\) implies that \( \Sigma(A) \) is a finite union of at most \( m \leq n \) compact intervals

\[
\Sigma(A) = \bigcup_{i=1}^{m} [a_i, b_i],
\]

with \(-\infty < a_1 \leq b_1 < \ldots < a_m \leq b_m < +\infty \) (see \([6],[15],[17]\)). On the other hand, \((P3)\) implies that \( \Sigma(A) \subset (-\infty, 0) \).

**Remark 4.** In \([3, Theorem 1]\) it was proved that if \((P1)\) and \((P2)\) are satisfied, the system \((4a)\) is \( \delta \)-nonuniformly kinematically similar via \( S^{-1}(\delta, t) \) to \((5a)\), where \( C(t) = \text{Diag}(C_1(t), \ldots, C_n(t)) \) with \( C_i(t) \in \Sigma(A) \) and \( \|B(t)\| \leq \delta K_{\delta, \varepsilon} \).

In addition, under the same transformation, the system \((4b)\) is transformed in

\[
\dot{y} = (C(t) + B(t))y + S^{-1}(\delta, t)f(t, S(\delta, t)y).
\]

3. **Main Results**

3.1. **Nonuniform Contractions and Lyapunov Functions.** In this section, for the system \((4a)\), we obtain a complete characterization of nonuniform contraction in terms of a Lyapunov function which will allow us to construct a topological equivalence between systems \((4a) - (4b)\) and \((5a) - (5b)\). For this purpose, we recall the definition of strict Lyapunov function and the main results from \([7]\).

**Definition 6.** Given \( K \geq 1 \) and \( \nu \geq 0 \). We say that a continuous function \( V : [0, +\infty) \times X \rightarrow \mathbb{R}_0^+ \), where \( X \) is a Banach space, is a strict Lyapunov function for \((4a)\) if

\[
(V1) \quad \|x\|^2 \leq V(t, x) \leq K^2 \exp(2\nu t)\|x\|^2, \text{ for any } t \geq 0 \text{ and } x \in X,
\]

\[
(V2) \quad V(t, \Phi(t, s)x) \leq V(s, x), \text{ for any } t \geq s \geq 0 \text{ and } x \in X,
\]

\[
(V3) \quad \exists \gamma > 0 \text{ such that } V(t, \Phi(t, s)x) \leq \exp(-2\gamma(t-s))V(s, x), \forall t \geq s \geq 0 \text{ and } x \in X.
\]

The last definition has subtle differences with respect to Liao et al. \([7]\). In fact, we have tailored it in order to relate it with the nonuniform exponential dichotomy. Indeed, we have the following result.

**Theorem 1.** The system \((4a)\) has nonuniform contraction if and only if it admits a strict Lyapunov function.
Proof. Suppose that there exists a strict Lyapunov function for (4a). From the conditions (V1) and (V3) we have
\[
\|\Phi(t, s)x\|^2 \leq V(t, \Phi(t, s)x) \leq \exp(-2\gamma(t - s))V(s, x),
\]
which implies that
\[
\|\Phi(t, s)x\| \leq K\exp(-\gamma(t - s) + vs)\|x\|.
\]
Therefore, (4a) admits a nonuniform contraction with \(\gamma = \alpha\) and \(v = \mu\).

On the other hand, for \(t \geq 0\) and \(x \in X\) we define
\[
V(t, x) = \sup_{\tau \geq t} \left\{ \|\Phi(\tau, s)x\|^2 \exp(2\alpha(\tau - t)) \right\}.
\]
As (4a) admits nonuniform contraction, we have that \(V(t, x) \leq K^2 \exp(2\mu t)\|x\|^2\).

If we consider \(\tau = t\), then \(\|x\|^2 \leq V(t, x)\). Now, for \(t \geq s \geq 0\)
\[
V(t, \Phi(t, s)x) = \sup_{\tau \geq t} \left\{ \|\Phi(\tau, s)x\|^2 \exp(2\alpha(\tau - t)) \right\},
\]
\[
= \exp(2\alpha(s - t))\sup_{\tau \geq t} \left\{ \|\Phi(\tau, s)x\|^2 \exp(2\alpha(\tau - s)) \right\},
\]
\[
\leq \exp(2\alpha(s - t))\sup_{\tau \geq s} \left\{ \|\Phi(\tau, s)x\|^2 \exp(2\alpha(\tau - s)) \right\},
\]
\[
= \exp(-2\alpha(t - s))V(s, x).
\]
Therefore, \(V\) is a strict Lyapunov function for (4a).

Now we will focus on Lyapunov functions that are defined in terms of quadratic forms. Let \(S(t) \in \mathcal{B}(X)\) be a symmetric positive-definite operator for \(t \geq 0\), where \(\mathcal{B}(X)\) the space of bounded linear operators in a Banach space \(X\). A quadratic Lyapunov function \(V\) is given as
\[
(12) \quad V(t, x) = \langle S(t)x, x \rangle.
\]

Remark 5. Given two linear operators \(M, N\), we write \(M \leq N\) if they verify \(\langle Mx, x \rangle \leq \langle Nx, x \rangle\) for \(x \in X\).

The following result (see [7, Theorem 2.2] with \(\mu(t) = e^t\)) establishes a characterization of nonuniform contraction in terms of the existence of quadratic Lyapunov function.

Proposition 1. Assume that there exist constants \(c > 0\) and \(d \geq 1\) such that
\[
(13) \quad \|\Phi(t, s)\| \leq c, \quad \text{whenever} \quad t - s \leq \ln(d)
\]
Then (4a) admits a nonuniform contraction if and only if there exist symmetric positive definite operators \(S(t)\) and constant \(C, \mathcal{K}_1 > 0\) such that \(S(t)\) is of class \(C^1\) in \(t \geq 0\) and
\[
(14) \quad \|S(t)\| \leq C\mathcal{K}_1 \exp(2\mu t),
\]
\[
(15) \quad S'(t) + A^*(t)S(t) + S(t)A(t) \leq (-Id + \mathcal{K}_1 S(t)).
\]
3.2. Main Results. The principal results of this article are the following:

**Theorem 2.** Consider the couple of system \((5a) - (5b)\) such that \(C_i(t) \in \Sigma(A)\) for \(i = 1, \ldots, n\) and \(\|B(t)\| \leq \delta K_{\delta, \epsilon}\). If \((P1)-(P3)\) are satisfied, then

1. If \(y(t)\) is solution of \((5b)\) and \(\alpha_1 > \mu_1\), then for \(L_g < \alpha_1 - \mu_1\), we have
   \[
   \frac{dV(t, y(t))}{dt} \leq -2[\alpha_1 - \mu_1 - L_g]V(t, y(t)),
   \]
   where \(V(t, x)\) is a Lyapunov function associated to \((5a)\).

2. The systems \((5a) - (5b)\) are topologically equivalent.

**Theorem 3.** If the properties \((P1)-(P4)\) are verified with \(0 < \delta < \alpha - \mu\) and \(f \in A_2\) such that

\[
L_f \leq \frac{\delta}{M_1^2},
\]

with \(\|S(\delta, t)\| \leq M_1 \exp(\beta t)\) and \(\|S^{-1}(\delta, t)\| \leq M_1 \exp(\beta t)\), for some \(\beta > 0\), then the systems \((4a)\) and \((4b)\) are topologically equivalent.

**Theorem 4.** If the properties \((P1)-(P4)\) are verified with \(0 < \delta < \alpha - \mu\) and \(f \in A_1\) such that

\[
L_f \leq \min \left\{ \frac{\delta}{M_1^2}, \frac{\alpha}{K} \right\},
\]

then the systems \((4a)\) and \((4b)\) are topologically equivalent.

4. SOME CLASSICAL RESULTS

The following proposition is a classical result of local continuity with respect to the initial conditions for differential equations.

**Proposition 2.** Let us consider the differential equation

\[
\dot{x} = F(t, x)
\]

where \(F \in A_2\), then for the solution \(X(t, s, u)\) of \((19)\) with \(X(s, s, u) = u\), we have that

\[
\|u - v\| \exp(-L_F|t - s|) \leq \|X(t, s, u) - X(t, s, v)\| \leq \|u - v\| \exp(L_F|t - s|).
\]

**Proof.** See [10], Proposition 2. \(\square\)

The following result is an extension to the nonuniform context of [10, Proposition 5].

**Proposition 3.** Assume that the system \((1a)\) has a nonuniform exponential dichotomy on \(\mathbb{R}_0^+\) with \(K \geq 1\), constants \(\alpha > 0\), \(\mu \geq 0\) and \(P(t) = I\) for any \(t \in \mathbb{R}_0^+\). Let us consider the nonlinear perturbation

\[
\dot{x} = A(t)x + F(t, x(t), \kappa)
\]

where \(F : \mathbb{R}_0^+ \times \mathbb{R}^n \times B \to \mathbb{R}^n\) and \(B\) is a Banach space. Moreover, \(F\) satisfies the following conditions:
(i) $F(t, x, \kappa)$ is bounded with respect to $t$, for all $x \in \mathbb{R}^n$ and $\kappa \in B$ fixed with the norm

$$\|F(x, \kappa)\|_A = \sup_{t \in \mathbb{R}_0^+} \exp(-\mu t) \|F(t, x, \kappa)\|.$$ 

(ii) There exist $L_F > 0$ such that

$$\|F(t, x_1, \kappa) - F(t, x_2, \kappa)\| \leq L_F \exp(-2\mu t) \|x_1 - x_2\|$$

for any $t \in \mathbb{R}_0^+$ and $\kappa \in B$.

(iii) $K_0 = \sup_{t \in \mathbb{R}_0^+, \kappa \in B} \|F(t, 0, \kappa)\| < +\infty$

If $KL_F < \alpha$ then for any fixed $\kappa \in B$ the system (20) has a unique bounded solution $Z(t, \kappa)$, with the norm $\|\cdot\|_A$, described by

$$Z(t, \kappa) = \int_0^t \Phi(t, \tau)F(\tau, Z(\tau, \kappa), \kappa) d\tau.$$ 

such that $\sup_{t \in \mathbb{R}_0^+, \kappa \in B} \|Z(t, \kappa)\| < +\infty$.

Proof. Let us consider a fixed $\kappa \in B$ and construct the sequence $\{\varphi_j\}_j$ recursively defined by

$$\varphi_j+1(t, \kappa) = \int_0^t \Phi(t, \tau)F(\tau, \varphi_j(\tau, \kappa), \kappa) d\tau$$

and

$$\varphi_0(t, \kappa) = \int_0^t \Phi(t, \tau)F(\tau, 0, \kappa) d\tau,$$

where $\varphi_0(t, \kappa) \in C$, where $C$ is defined by

$$C = \left\{ U : \mathbb{R}_0^+ \times B \to \mathbb{R}^n : \text{for any } \kappa \in B \text{ fixed,} \right\}$$

with $\|U(\kappa)\|_A = \sup_{t \in \mathbb{R}_0^+} \exp(-\mu t) \|U(t, \kappa)\|$.

In the first place we will proof that $(C, \|\cdot\|_A)$ is a Banach space. Indeed, let $\{U_n\}_{n \in \mathbb{N}}$ be a Cauchy sequence in $C$, then for any $\varepsilon > 0$ and for $\tau \in \mathbb{R}_0^+$ fixed, there exists $N \in \mathbb{N}$ such that for all $n, m \in \mathbb{N}$

$$\|U_n(\kappa) - U_m(\kappa)\|_A = \sup_{t \in \mathbb{R}_0^+} \exp(-\mu t) \|U_n(t, \kappa) - U_m(t, \kappa)\| < \varepsilon,$$

but the expression $\exp(-\mu \tau) \|U_n(\tau, \kappa) - U_m(\tau, \kappa)\| \leq \|U_n - U_m\|_A$ implies that

$$\|U_n(\tau, \kappa) - U_m(\tau, \kappa)\| \leq \exp(\mu \tau) \varepsilon,$$

then $\{U_n(\tau, \kappa)\}_{n \in \mathbb{N}}$ is a Cauchy sequence in $\mathbb{R}^n$, so we obtain a well-defined function $U : \mathbb{R}_0^+ \times B \to \mathbb{R}^n$ that satisfies $U(\tau, \kappa) = \lim_{n \to +\infty} U_n(\tau, \kappa)$ for $\tau, \kappa$ fixed. Therefore we have

$$\|U(\tau, \kappa) - U_n(\tau, \kappa)\| = \lim_{m \to +\infty} \|U_m(\tau, \kappa) - U_n(\tau, \kappa)\| \leq \lim_{m \to +\infty} \exp(\mu \tau) \varepsilon = \exp(\mu \tau) \varepsilon,$$

then

$$\exp(-\mu \tau) \|U(\tau, \kappa) - U_n(\tau, \kappa)\| < \varepsilon,$$

so

$$\sup_{\tau \in \mathbb{R}_0^+} \exp(-\mu \tau) \|U(\tau, \kappa) - U_n(\tau, \kappa)\| \leq \varepsilon.$$
Thus, \( \|U(\kappa)\|_A \leq \|U(\kappa) - U_n(\kappa)\|_A + \|U_n(\kappa)\|_A < \infty \) for big \( n \in \mathbb{N} \) and \( U \) is continuous due to the continuity of \( U_k \), then \( U \in C \), so \( (C, \| \cdot \|_A) \) is a Banach space.

Now we will prove by induction that \( \phi_j \in C \) for any \( j \in \mathbb{N} \cup \{0\} \). Indeed, if \( \phi_j \in C \), we estimate \( \|\phi_{j+1}(\kappa)\|_A \)
\[
\|\phi_{j+1}(t, \kappa)\| \leq \int_0^t K \exp(-\alpha(t - \tau) + \mu\tau)(L_F \exp(-2\mu\tau) \|\phi_j(\tau, \kappa)\| + K_0),
\]
from which it follows that if \( K_j = \|\phi_j(\kappa)\|_A \), then
\[
\exp(-\mu t) \|\phi_{j+1}(t, \kappa)\| \leq \int_0^t K \exp(-\alpha(t - \tau))(L_F K_j + \exp(\mu\tau)K_0) d\tau,
\]
and we obtain
\[
\|\phi_{j+1}(\kappa)\|_A = \sup_{t \in \mathbb{R}_+^+} \exp(-\mu t) \|\phi_{j+1}(t, \kappa)\| \leq \frac{KK_j L_F}{\alpha} + \frac{KK_0}{\mu} < +\infty.
\]

From the above, we can consider a map \( T : C \to C \) given by
\[
T(Z(t, \kappa)) = \int_0^t \Phi(t, \tau) F(\tau, Z(\tau, \kappa), \kappa) d\tau,
\]
which is well defined. Since we have that \( KL_F < \alpha \), we have that \( T \) is a contraction, indeed
\[
\|T(Z_1(t, \kappa)) - T(Z_2(t, \kappa))\| \leq \int_0^t KL_F \exp(-\alpha(t - \tau) + \mu\tau - 2\mu\tau) \|Z_1(\tau, \kappa) - Z_2(\tau, \kappa)\| d\tau,
\]
\[
\|T(Z_1(\kappa)) - T(Z_2(\kappa))\|_A \leq \frac{KL_F}{\alpha} \|Z_1(\kappa) - Z_2(\kappa)\|_A,
\]
which implies that \( \{\phi_j\} \) is the unique sequences in \( C \) satisfying the recursivity stated above.

Now we will prove that \( \{\phi_j\} \) is a Cauchy sequence in the Banach space \( (C, \| \cdot \|_A) \).
We proceed inductively. We observe that, firstly
\[
\|\phi_1(t, \kappa) - \phi_0(t, \kappa)\| \leq \int_0^t K \exp(-\alpha(t - \tau) + \mu\tau)L_F \exp(-2\mu\tau) \|\phi_0(\tau, \kappa)\| d\tau,
\]
\[
\leq KL_F \frac{KK_0}{\alpha} \int_0^t \exp(-\alpha(t - \tau)) d\tau \leq \bar{K} KL_F \frac{KK_0}{\alpha},
\]
which implies that
\[
\|\phi_1(\kappa) - \phi_0(\kappa)\|_A \leq \bar{K} KL_F \frac{KK_0}{\alpha}
\]
with \( \bar{K} = \frac{KK_0}{\alpha} \).
As inductive hypothesis, we have that \( \|\varphi_j(\kappa) - \varphi_{j-1}(\kappa)\|_A \leq \bar{K} \left( \frac{KL_F}{\alpha} \right)^j \), and therefore
\[
\|\varphi_{j+1}(t, \kappa) - \varphi_j(t, \kappa)\| \leq \int_0^t K \exp(-\alpha(t-\tau) + \mu \tau) L_F \exp(-2\mu \tau) \|\varphi_j(\tau, \kappa) - \varphi_{j-1}(\tau, \kappa)\| d\tau,
\]
\[
\leq \bar{K} KL_F \left( \frac{KL_F}{\alpha} \right)^j \int_0^t \exp(-\alpha(t-\tau)) d\tau \leq \bar{K} \left( \frac{KL_F}{\alpha} \right)^{j+1},
\]
\[
\|\varphi_{j+1}(\kappa) - \varphi_j(\kappa)\|_A \leq \bar{K} \left( \frac{KL_F}{\alpha} \right)^j.
\]
Finally, for all \( \varepsilon > 0 \) there exists \( N(\varepsilon) \in \mathbb{N} \) such that for any \( n, m \geq N \) we have
\[
\|\varphi_n(\kappa) - \varphi_m(\kappa)\|_A \leq \bar{K} \left( \frac{KL_F}{\alpha} \right)^N \left( 1 + \frac{KL_F}{\alpha} + \cdots + \left( \frac{KL_F}{\alpha} \right)^{n-m} - \frac{KL_F}{\alpha} \right),
\]
\[
\leq \bar{K} \left( \frac{KL_F}{\alpha} \right)^N \left( 1 \frac{1 - \left( \frac{KL_F}{\alpha} \right)^{n-m}}{1 - \frac{KL_F}{\alpha}} \right) < \varepsilon.
\]
which proves that \( \{\varphi_j\} \) is a Cauchy sequence in the Banach space \( C \) convergent to the fixed point \( Z(t, \kappa) \) defined by (21).

Considering a fixed \( \kappa \in B \) we have that \( \|Z(\kappa)\|_A < C(\kappa) \). That is, \( Z(\cdot, \kappa) \in C \) but its bound \( C(\kappa) \) could be dependent of \( \kappa \). However, we will prove that \( C(\kappa) \) has an upper bounded independent of \( \kappa \). Indeed, combining the properties (ii), (iii) with the nonuniform exponential dichotomy of (4a), we have that
\[
\|Z(t, \kappa)\| \leq KL_F \int_0^t \exp(-\alpha(t-\tau) + \mu \tau) \exp(-2\mu \tau) \|Z(\tau, \kappa)\| d\tau
\]
\[
+ KK_0 \int_0^t \exp(-\alpha(t-\tau) + \mu \tau) d\tau,
\]
which implies that
\[
\exp(-\mu t) \|Z(t, \kappa)\| \leq KL_F \int_0^t \exp(-\alpha(t-\tau)) \exp(-\mu \tau) \|Z(\kappa)\|_A d\tau
\]
\[
+ KK_0 \int_0^t \exp(-\alpha(t-\tau)) d\tau.
\]
Thus,
\[
\exp(-\mu t) \|Z(t, \kappa)\| \leq \frac{KL_F C(\kappa)}{\alpha} + \frac{KK_0}{\alpha},
\]
and taking supremum over \( t \in \mathbb{R}_0^+ \), we obtain
\[
C(\kappa) \leq \frac{KK_0}{\alpha} \left( 1 - \frac{KL_F}{\alpha} \right)^{-1}
\]
\( \square \)
5. Proof of Theorem 2

We will follow the lines of proof of the Lemma of the Palmer’s article \[12\] p. 11 in order to obtain (1) and (2) of our Theorem. We point out that in the calculations of the derivative of \(V\) with respect \(t\) evaluated at the origin, we are considering only the right side derivative.

Let \(x(t) = X(t, \tau, \xi)\) be the solution of (5a) such that \(x(\tau) = \xi \neq 0\) and \(y(t) = Y(t, s, \omega)\) be the solution of (5b) such that \(y(s) = \omega \neq 0\).

As the system (5a) has nonuniform contraction (by Remark 1), we have that its evolution operator satisfies (13), we can use Proposition 1 to obtain a symmetric positive definite operator \(S(t)\) which define a strict Lyapunov function \(V(t)\) associated to the system (5a). Thus, by using the construction of \(V(t)\), \[12\], Remark 1 and the Lipschitz constant \(L_g\) of function \(g\), we obtain that:

\[
\begin{align*}
\frac{dV(t, y(t))}{dt} &= \langle S'(t)y(t), y(t) \rangle + \langle S(t)[A(t)y(t) + g(t, y(t))], y(t) \rangle \\
&\quad + \langle S(t)y(t), A(t)y(t) + g(t, y(t)) \rangle,
\end{align*}
\]

\[
\begin{align*}
&= \langle S(t)y(t) + S(t)A(t)y(t) + A^*(t)S(t)y(t), y(t) \rangle \\
&\quad + \langle S(t)g(t, y(t)), y(t) \rangle + \langle S(t)y(t), g(t, y(t)) \rangle,
\end{align*}
\]

\[
\leq \langle -[Id + 2(\alpha_1 - \mu_1)S(t)y(t), y(t)] \rangle + 2 \langle S(t)g(t, y(t)), y(t) \rangle,
\]

\[
\leq \langle -2(\alpha_1 - \mu_1)S(t)y(t), y(t) \rangle + 2 \langle S(t)L_gy(t), y(t) \rangle,
\]

\[
= -2(\alpha_1 - \mu_1)V(t, y(t)) + 2L_gV(t, y(t)),
\]

\[
\leq -2[\alpha_1 - \mu_1 - L_g]V(t, y(t)),
\]

and the part (1) of our result follows.

Notice that if we consider \(x(t)\), then in the previous inequality we have

\[
(22) \quad \frac{dV(t, x(t))}{dt} \leq -2[\alpha_1 - \mu_1]V(t, x(t)) \leq -2[\alpha_1 - \mu_1 - L_g]V(t, x(t)).
\]

Now we will prove that second statement our result. From \[7\] Lemma 2.4 with \(\mu(\cdot) = \exp(\cdot)\) and considering \(\gamma = \alpha_1 - \mu_1 - L_g > 0\), we have that

\[V(t, x(t)) \leq V(s, x(s)) \exp(-\gamma (t - s)), \quad t \geq s\]

with \(\gamma = 2\gamma\), then \(V(t, x(t))\) is strictly decreasing and converges to 0 as \(t\) tends to infinity. Now given \(\varepsilon > 0\), let \(\ell = \ell(\varepsilon) > 0\) such that there exists a unique \(T = T(\tau, \xi)\) that satisfies

\[V(T, x(T)) = \ell/2.\]

It is easy to see that \(T(\tau, \varepsilon)\) is a continuous function of \((\tau, \xi)\) for \(\xi \neq 0\). Now we define
(23) \[ H(\tau, \xi) = \begin{cases} Y(\tau, T(\tau, \xi), X(T(\tau, \xi), \tau, \xi)) & \text{if } \xi \neq 0, \\ 0 & \text{if } \xi = 0. \end{cases} \]

Clearly, \( H(\tau, \xi) \) is continuous for \( \xi \neq 0 \). With the purpose to discuss its continuity at \( \xi = 0 \), we analyze the behaviour of \( |T(\tau, \xi) - \tau| \) as \( \xi \) tends to 0. By (V1) and Proposition 2 we have

\[ \frac{\ell}{2} = V(T(\tau, \xi), X(T(\tau, \xi), \tau, \xi)), \]

\[ \leq \kappa^2 \exp(2\nu T(\tau, \xi)) \|X(T(\tau, \xi), \tau, \xi)\|^2, \]

\[ = \kappa^2 \exp(2\nu T(\tau, \xi)) \exp(2L_F |T(\tau, \xi) - \tau|) \|\xi\|^2. \]

Then

(24) \[ \exp(-|T(\tau, \xi) - \tau|) \leq \left( \frac{2\kappa \exp(2\nu T(\tau, \xi)) \|\xi\|^2}{\ell} \right)^{\frac{1}{2\nu F}}, \]

where \( L_F = |\bar{a}_1| + \delta K_{\delta, \varepsilon} \). Notice that the system \([\text{III}]\) has nonuniform contraction with its evolution operator with nonuniformly bounded growth (see [3, Remark 1]) which imply that the spectrum \( \Sigma(C(t) + B(t)) = \bigcup_{i=1}^{m} [\bar{a}_i, \bar{b}_i] \subset (-\infty, 0) \).

Now by [7, Lemma 2.3], there exists \( \eta > 0 \) such that

\[ \eta \|H(\tau, \xi)\|^2 \leq V(\tau, H(\tau, \xi)), \]

\[ \leq V(\tau, Y(\tau, T, X(T, \tau, \xi))). \]

However, we have

\[ \|\xi\| \leq \left( \frac{\ell \exp(-2\nu \tau)}{2\kappa^2} \right)^{\frac{1}{2}} \Rightarrow V(\tau, \xi) \leq \kappa^2 \exp(2\nu \tau) \|\xi\|^2 \leq \frac{\ell}{2} \Rightarrow T(\tau, \xi) \leq \tau. \]

It follows by [7, Lemma 2.4] and (24) that

\[ \|H(\tau, \xi)\|^2 \leq \eta^{-1} \exp(-\bar{\gamma}(\tau - T)) V(T, Y(T, T, X(T, \tau, \xi))), \]

\[ = \frac{\eta^{-1} \ell \exp(-\bar{\gamma}(\tau - T))}{2}, \]

\[ \leq \left( \frac{\eta^{-1} \ell}{2} \right) \left( \frac{2\kappa \exp(2\nu T(\tau, \xi)) \|\xi\|^2}{\ell} \right)^{\frac{1}{2\nu F}}. \]

Hence, if \( \|\xi\| \leq \left( \frac{\ell \exp(-2\nu \tau)}{2\kappa^2} \right)^{\frac{1}{2}} \), we obtain

\[ \|H(\tau, \xi)\| \leq \left( \frac{\eta^{-1} \ell}{2} \right)^{\frac{1}{2}} \left( \frac{2\kappa \exp(2\nu T(\tau, \xi)) \|\xi\|^2}{\ell} \right)^{\frac{1}{2\nu F}}. \]

On the other hand, by [7, Lemma 2.3] and Proposition 2 we have that
\[
\ell = V(T(\tau, \xi), X(T(\tau, \xi), \tau, \xi)),
\]
\[
\geq \eta \|X(T(\tau, \xi), \tau, \xi)\|^2,
\]
\[
\geq \eta \|\xi\|^2 \exp(-2L_F|T(\tau, \xi) - \tau|).
\]
Thus,
\[
\exp(|T(\tau, \xi) - \tau|) \geq \left(\frac{2\eta \|\xi\|^2}{\ell}\right)^{\frac{1}{\tau F}}.
\]
Notice that
\[
\|\xi\| \geq \left(\frac{\ell}{2\eta}\right) = \frac{\ell}{2} \leq \eta \|\xi\|^2 \leq V(\tau, \xi) \Rightarrow T(\tau, \xi) \geq \tau.
\]
Then if \( \|\xi\| \geq \left(\frac{\ell}{2\eta}\right)^{\frac{1}{2}} \), by \(25\) and \(V3\), we have
\[
\|H(\tau, \xi)\|^2 \geq \frac{\exp(-2\nu T)}{K^2} V(\tau, H(\tau, \xi)),
\]
\[
= \frac{\exp(-2\nu T)}{K^2} V(\tau, Y(\tau, T, X(T, \tau, \xi))),
\]
\[
\geq \frac{\exp(-2\nu T + \bar{\gamma}(T - \tau))}{K^2} V(T, Y(T, T, X(T, \tau, \xi))),
\]
\[
= \frac{\ell \exp(-2\nu T)}{2K^2} \exp(\bar{\gamma}(T - \tau)),
\]
\[
\geq \frac{\ell \exp(-2\nu T)}{2K^2} \left(\frac{2\eta \|\xi\|^2}{\ell}\right)^{\frac{1}{\tau F}}.
\]
Therefore
\[
\|H(\tau, \xi)\| \geq \left(\frac{\ell \exp(-2\nu T)}{2K^2}\right)^{\frac{1}{2}} \left(\frac{2\eta \|\xi\|^2}{\ell}\right)^{\frac{1}{\tau F}}.
\]
Now we prove that if \( x(t) \) is a solution of \(5a\), \( H(t, x(t)) \) is a solution of \(5b\). If \( \xi = 0 \), \( H(t, X(t, \tau, \xi)) = H(t, 0) = 0 \).
In the case when \( \xi \neq 0 \), we have that
\[
H(t, X(t, \tau, \xi)) = Y(t, T(t, X(t, \tau, \xi))), X(T(t, X(t, \tau, \xi)), t, X(t, \tau, \xi))),
\]
\[
= Y(t, T(t, X(t, \tau, \xi))), X(T(t, X(t, \tau, \xi)), \tau, \xi)).
\]
On the one hand we have
\[
\ell = H(T(\tau, \xi), X(T(\tau, \xi), \tau, \xi)) = H(T(\tau, \xi), X(T(\tau, \xi), t, X(t, \tau, \xi))),
\]
and on the other hand
\[
\ell = H(T(t, X(t, \tau, \xi)), X(T(t, X(t, \tau, \xi))), t, X(t, \tau, \xi))),
\]
and by the equations (26) and (27), we deduce that $T(t, X(t, \tau, \xi)) = T(\tau, \xi)$. Hence, for all $t, \tau \geq 0$, and $\xi \neq 0$, 

\[(28)\quad H(t, X(t, \tau, \xi)) = Y(t, T(\tau, \xi), X(T(\tau, \xi), \tau, \xi)),\]

which is a solution of (5b).

Similarly, we define a mapping

\[(29)\quad G(\tau, \xi) = \begin{cases} 
X(\tau, S(\tau, \xi), Y(S(\tau, \xi), \tau, \xi)) & \text{if } \xi \neq 0, \\
0 & \text{if } \xi = 0,
\end{cases}\]

where $S = S(\tau, \xi)$ is the unique time $s$ such that

\[V(s, y(s)) = \frac{\ell}{2}.\]

We can deduce similar properties to those of the function $H$ for $G$ and, moreover we have

\[G(t, Y(t, \tau, \xi)) = X(t, S(\tau, \xi), Y(S(\tau, \xi), \tau, \xi)), \quad \xi \neq 0,\]

which is obtained in a similar way to (28).

To prove that $H(\tau, G(\tau, \xi)) = \xi$, if $S = S(\tau, y)$ we note that $\frac{\ell}{2}$ can be written as

\[(30)\quad \frac{\ell}{2} = V(T(S, Y(S, \tau, y)), X(T(S, Y(S, \tau, y)), S, Y(S, \tau, y))));\]

and as

\[(31)\quad \frac{\ell}{2} = V(S, Y(S, \tau, y)) = V(S, X(S, S, Y(S, \tau, y)))).\]

From the equations (30) and (31) we can assure that

\[(32)\quad T(S(\tau, y), Y(S(\tau, y), \tau, y)) = S(\tau, y).\]

Therefore we have

\[H(\tau, G(\tau, \xi)) = H(\tau, X(\tau, S(\tau, \xi), Y(S(\tau, \xi), \tau, \xi)));
= Y(\tau, T(S, Y(S, \tau, \xi)), X(T(S, Y(S, \tau, \xi)), S, Y(S, \tau, \xi))),\]

and from (32), then we obtain

\[H(\tau, G(\tau, \xi)) = Y(\tau, S, X(S, S, Y(S, \tau, \xi))),
= Y(\tau, S, Y(S, \tau, \xi)) = \xi.\]

In a similar way, we can obtain that

\[G(\tau, H(\tau, \xi)) = \xi,\]

for all $\tau \in \mathbb{R}^+_0$, $\xi \in \mathbb{R}^n$. 
6. Proof Theorem 3

This result is a consequence of the Theorem 2. Indeed, we have that (4a) and (5b) are topologically equivalent through of the matrix $S(\delta, t)$. Then the systems (4a) and (11) are topologically equivalent through of the matrix $S(\delta, t)$ also. If we denote $g(t, y) = S^{-1}(\delta, t)f(t, S(\delta, t)y)$, then $g \in \mathcal{A}_2$ with $L_g = M_f^2 L_f$. In fact,

$$
\|g(t, y_1) - g(t, y_2)\| = \|S^{-1}(\delta, t)f(t, S(\delta, t)y_1) - S^{-1}(\delta, t)f(t, S(\delta, t)y_2)\|,
$$

$$
\leq M_1 \exp(\beta t) \|f(t, S(\delta, t)y_1) - f(t, S(\delta, t)y_2)\|,
$$

$$
\leq M_1 L_f \exp(\beta t) \|S(\delta, t)y_1 - S(\delta, t)y_2\|,
$$

$$
\leq M_1^2 L_f \|y_1 - y_2\|.
$$

Since $L_g \leq \delta < \alpha - \mu$, by combining Theorem 2 and the fact that topological equivalence is a equivalence relation, the systems (4a) and (4b) are topologically equivalent.

7. Proof Theorem 4

We take the function $f_0(t, x) = f(t, x) - f(t, 0)$, then $f \in \mathcal{A}_1$ implies $f_0 \in \mathcal{A}_2$. Indeed, $f_0(t, 0) = 0$ and

$$
\|f_0(t, x_1) - f_0(t, x_2)\| = \|f(t, x_1) - f(t, x_2)\| \leq L_f \exp(-2\beta t) \|x_1 - x_2\|,
$$

for any $t \in \mathbb{R}^+_0$, $x_1, x_2 \in \mathbb{R}^n$ and some $\beta \geq 0$. As $f$ and $f_0$ have the same Lipschitz constant, by Theorem 3 and inequality (18) it is sufficient to prove that the systems (11) and

$$
\dot{x} = A(t)x + f_0(t, x)
$$

are topologically equivalent. By the condition (P3) there exist constants $K \geq 1$, $\alpha > 0$ and $\mu \geq 0$ satisfying (9). For the unique solution $X(t, \tau, \xi)$ of (13) passing through $\xi$ at $t = \tau$, we define the function $F : \mathbb{R}^+_0 \times \mathbb{R}^n \times \mathcal{B} \to \mathbb{R}^n$, with $\mathcal{B} = \mathbb{R}^+_0 \times \mathbb{R}^n$, as

$$
F(t, y, (\tau, \xi)) = f(t, y + X(t, \tau, \xi)) - f_0(t, X(t, \tau, \xi)),
$$

$$
= f(t, y + X(t, \tau, \xi)) - f(t, X(t, \tau, \xi)) + f(t, 0).
$$

If $K_0 = \sup \{t \in \mathbb{R}^+_0 : \|f_0(t, 0)\|\}$ then

$$
\begin{cases}
\|F(t, y, (\tau, \xi))\| \leq L_f \exp(-2\beta t) \|y\| + K_0, \\
\|F(t, y_1, (\tau, \xi)) - F(t, y_2, (\tau, \xi))\| \leq L_f \exp(-2\beta t) \|y_1 - y_2\|.
\end{cases}
$$

We note that $F$ verifies the hypothesis of Proposition 3 which implies that the system

$$
\dot{z} = A(t)z + F(t, z, (\tau, \xi))
$$

has a unique bounded and continues solution $Z(t, (\tau, \xi))$ defined by

$$
Z(t, (\tau, \xi)) = \int_0^t \Phi(t, s)[f(s, Z(s, (\tau, \xi))) + X(s, \tau, \xi)) - f_0(s, X(s, \tau, \xi)))]ds
$$
with the norm

$$\|Z\| = \sup_{t \in \mathbb{R}_0^+ \times \mathbb{R}^n} \exp(-\beta t) \|Z(t, (\tau, \xi))\| = M_0 < +\infty.$$ 

Now, let us construct the map $H : \mathbb{R}_0^+ \times \mathbb{R}^n \to \mathbb{R}^n$ as

(35) \hspace{1cm} H(\tau, \xi) = \xi + Z(\tau, (\tau, \xi)).

**Lemma 1.** For any $(r, t) \in \mathbb{R}_0^+ \times \mathbb{R}_0^+ \times (\tau, \xi) \in \mathbb{R}_0^+ \times \mathbb{R}^n$ we have that

(36) \hspace{1cm} Z(r, (t, X(t, \tau, \xi))) = Z(r, (\tau, \xi)).

**Proof.** Firstly, we note that

$$Z(r, (t, X(t, \tau, \xi))) = \int_0^r \Phi(r, s)[f(s, Z(s, (t, X(t, \tau, \xi)))) + X(s, t, X(t, \tau, \xi)) - f_0(s, X(s, t, X(t, \tau, \xi)))]ds,$$

and

$$Z(r, (\tau, \xi)) = \int_0^r \Phi(r, s)[f(s, Z(s, (\tau, \xi))) + X(s, \tau, \xi)) - f_0(s, X(s, \tau, \xi))]ds$$

and the Lemma follows. \(\square\)

**Lemma 2.** If $t \mapsto X(t, \tau, \xi)$ is solution of (33) such that $X(\tau, \tau, \xi) = \xi$, then $t \mapsto H(t, X(t, \tau, \xi))$ is solution of (4b).

**Proof.** Combining the equations (35) and (36), we have that

$$H(t, X(t, \tau, \xi)) = X(t, \tau, \xi) + Z(t, (\tau, \xi)),$$

and a simple computation allows us to verify the statement. \(\square\)

**Lemma 3.** The map $\xi \mapsto H(\tau, \xi)$ is continuous for any fixed $\tau \in \mathbb{R}_0^+$. 

Proof. By (35), the only thing that we should prove is that the map \( \xi \mapsto Z(\tau, (\tau_0, \xi)) \) is continuous for any fixed \( \tau \). Indeed, let us recall \( \tau \mapsto Z(\tau, (\tau, \xi)) \) is the unique bounded solution in \( C \) of (34), which was constructed by successive approximations in Proposition 3. That is

\[
\lim_{j \to +\infty} Z_j(\tau, (\tau_0, \xi)) = Z(\tau, (\tau_0, \xi)),
\]

where

\[
Z_{j+1}(\tau, (\tau_0, \xi)) = \int_0^\tau \Phi(\tau, s) F(s, Z_j(s, (\tau_0, \xi)), (\tau_0, \xi)) ds.
\]

Moreover we know that for any \( \varepsilon > 0 \), there exists \( J = J(\varepsilon) > 0 \) such that for any \( j > J \) it follows that

\[
\|Z(\tau, (\tau_0, \xi)) - Z(\tau, (\tau_0, \xi'))\| \leq \|Z(\tau, (\tau_0, \xi)) - Z_j(\tau, (\tau_0, \xi))\|
\]

\[
+ \|Z_j(\tau, (\tau_0, \xi)) - Z_j(\tau, (\tau_0, \xi'))\|
\]

\[
+ \|Z_j(\tau, (\tau_0, \xi')) - Z(\tau, (\tau_0, \xi'))\|
\]

\[
< \frac{2}{3} \varepsilon + \|Z_j(\tau, (\tau_0, \xi)) - Z_j(\tau, (\tau_0, \xi'))\|.
\]

We will prove by induction that for any \( j \in \mathbb{N} \), there exists \( \delta_j > 0 \) such that

(37) \[\|Z_j(\tau, (\tau_0, \xi)) - Z_j(\tau, (\tau_0, \xi'))\| < \frac{\varepsilon}{3} \text{ if } \|\xi - \xi'\| < \delta_j.\]

Indeed, we consider an initial term

\[
Z_0(\tau, (\tau, \xi)) = Z_0(\tau, (\tau, \xi')) = \phi_0 \in C
\]

and suppose that (37) is verified for some \( j \) as inductive hypothesis. Now, we have that

\[
\|Z_{j+1}(\tau, (\tau_0, \xi)) - Z_{j+1}(\tau, (\tau_0, \xi'))\| \leq \Delta
\]

where

\[
\Delta = \left\| \int_0^\tau \Phi(\tau, s)[F(s, Z_j(s, (\tau_0, \xi)), (\tau_0, \xi)) - F(s, Z_j(s, (\tau_0, \xi')), (\tau_0, \xi'))] ds \right\|
\]
From the definition and properties of $F$, by Gronwall’s Lemma and inductive hypothesis, we have that

$$
\Delta \leq \left\| \int_0^\tau \Phi(\tau, s)[f(s, Z_j(s, (\tau_0, \xi))) + X(s, \tau_0, \xi)] - f(s, Z_j(s, (\tau_0, \xi'))) + X(s, \tau_0, \xi')] ds \right\|
$$

$$
+ \left\| \int_0^\tau \Phi(\tau, s)[f_0(s, X(s, \tau_0, \xi)) - f_0(s, X(s, \tau_0, \xi'))] ds \right\|
$$

$$
\leq \int_0^\tau K L_f \exp(-\alpha(\tau - s) - \mu s)[\|Z_j(s, (\tau_0, \xi)) - Z_j(s, (\tau_0, \xi'))\| + \|X(s, \tau_0, \xi) - X(s, \tau_0, \xi')\|]
$$

$$
+ \int_0^\tau K L_{f_0} \exp(-\alpha(\tau - s) - \mu s)[\|X(s, \tau_0, \xi) - X(s, \tau_0, \xi')\|],
$$

$$
\leq \frac{\varepsilon}{3} K L_f \int_0^\tau \exp(-\alpha(\tau - s) - \mu s + \mu s) ds
$$

$$
+ K(2L_f) \int_0^\tau \exp(-\alpha(\tau - s)) \|\xi - \xi'\| \exp(L_F(\tau - s)) ds,
$$

and (57) is satisfied for $j + 1$ when we choose

$$
\delta_{j+1} = \min \left\{ \delta_j, \left( 1 - \frac{K L_f}{\alpha} \right) \exp(-L_f \tau) \frac{\alpha}{K(2L_f)} \frac{\varepsilon}{3} \right\}
$$

and we can prove the continuity of $\xi \mapsto Z(\tau, (\tau_0, \xi))$. All of the above allows us to conclude that $H$ is continuous for any fixed $\tau$.

\[\square\]

**Remark 6.** We note that if $Y(t, \tau, \xi)$ is the unique solution of (14) passing through $\xi$ at $t = \tau$, we can define the function $\tilde{F} : \mathbb{R}^+_0 \times \mathbb{R}^n \times \mathbf{B} \to \mathbb{R}^n$ as

$$
\tilde{F}(t, \tilde{y}, (\tau, \xi)) = f_0(t, \tilde{y} + Y(t, \tau, \xi)) - f(t, Y(t, \tau, \xi)),
$$

$$
= f(t, \tilde{y} + Y(t, \tau, \xi)) - f(t, 0) - f(t, Y(t, \tau, \xi)).
$$

and obtain

$$
\left\{ \begin{array}{l}
\left\| \tilde{F}(t, \tilde{y}, (\tau, \xi)) \right\| \leq L_f \exp(-2\beta t) \|\tilde{y}\| + K_0, \\
\left\| \tilde{F}(t, \tilde{y}_1, (\tau, \xi)) - \tilde{F}(t, \tilde{y}_2, (\tau, \xi)) \right\| \leq L_f \exp(-2\beta t) \|\tilde{y}_1 - \tilde{y}_2\|.
\end{array} \right.
$$

In the same way $\tilde{F}$ satisfies the hypothesis of Proposition 3 which implies that the system

$$
\dot{z} = A(t)z + \tilde{F}(t, z, (\tau, \xi))
$$
has a unique bounded solution \( \tilde{Z}(t, \tau, \xi) \) defined by

\[
\tilde{Z}(t, \tau, \xi) = \int_0^t \Phi(t, s)[f_0(s, \tilde{Z}(s, \tau, \xi)) + Y(s, \tau, \xi)] - f(s, Y(s, \tau, \xi)] ds.
\]

As a consequence of the previous remark, we can construct the map

\[
G : \mathbb{R}_0^+ \times \mathbb{R}^n \rightarrow \mathbb{R}^n
\]

as

\[
G(\tau, \xi) = \xi + \tilde{Z}(\tau, \xi).
\]

and we prove the following results that are similar to the previous one.

**Lemma 4.** For any \((r, t) \in \mathbb{R}_0^+ \times \mathbb{R}_0^+ \) and \((\tau, \xi) \in \mathbb{R}_0^+ \times \mathbb{R}^n \) we have that

\[
\tilde{Z}(r, (t, Y(t, \tau, \xi))) = \tilde{Z}(r, (\tau, \xi)).
\]

**Lemma 5.** If \( t \mapsto Y(t, \tau, \xi) \) is solution of (4a) such that \( Y(\tau, \tau, \xi) = \xi \), then \( t \mapsto G(t, Y(t, \tau, \xi)) \) is solution of (33).

**Lemma 6.** The map \( \xi \mapsto G(\tau, \xi) \) is continuous for any fixed \( \tau \in \mathbb{R}_0^+ \).

Finally, from all these Lemmas, we can conclude that the systems (4b) and (33) are topologically equivalent, which is enough to prove the result.
