SHEAVES AND SYMPLECTIC GEOMETRY OF COTANGENT BUNDLES

STÉPHANE GUILLERMOU

Abstract. We recall several results of the microlocal theory of sheaves of Kashiwara-Schapira and apply them to study the symplectic geometry of cotangent bundles. We explain how we can recover the Gromov nonsqueezing theorem, the Gromov-Eliashberg rigidity theorem, the existence of graph selectors, we prove a three cusps conjecture about curves on the sphere and we recover more recent results on the topology of exact Lagrangian submanifolds of cotangent bundles.

As the title suggests this paper explains some applications of the microlocal theory of sheaves of Kashiwara and Schapira to the symplectic geometry of cotangent bundles. The main notions of the microlocal theory of sheaves are Sato’s microlocalization, introduced in the 70’s, and the notion of microsupport of a sheaf, introduced by Kashiwara and Schapira in the 80’s. These notions were motivated by the study of modules over the ring of (micro-)differential operators. The link with the symplectic geometry was noticed (a deep result of [29] says that the microsupport of any sheaf is coisotropic) but not used to study global aspects of symplectic geometry until the papers [39] of Nadler-Zaslow and [43] of Tamarkin. The paper [39], together with [37], show that the dg-category of constructible sheaves on a real analytic manifold $M$ is equivalent to the triangulated envelope of a version of the Fukaya category of $T^*M$. The paper [43] proves non-displaceability results in symplectic geometry using the properties of the microsupports of sheaves. Building on the ideas of this paper it is explained in [21] how to associate a sheaf with a Hamiltonian isotopy of a cotangent bundle. In this paper we go on in this direction and use sheaves to recover some classical results of symplectic geometry (the Gromov non-squeezing theorem and the Gromov-Eliashberg rigidity theorem) and a more recent result, which says that a compact exact Lagrangian submanifold of a cotangent bundle is homotopically equivalent to the base. We also prove a result about cusps of curves on the sphere (Arnol’d three cusps conjecture).
Before we give more details we recall some facts about the micros-
support. Let $M$ be a manifold of class $C^\infty$ and let $k$ be a ring. We
denote by $\mathcal{D}(k_M)$ the derived category of sheaves of $k$-modules over
$M$. The microsupport $\operatorname{SS}(F)$ of an object $F$ of $\mathcal{D}(k_M)$ is introduced
in [28]. It is a closed subset of the cotangent bundle $T^*M$, conic for the
action of $\mathbb{R}^+$ on $T^*M$. It is defined as the closure of the set of singular
directions with respect to $F$, where $(x; \xi) \in T^*M$ is said non singular
if the restriction maps from a neighborhood $B$ of $x$ to $B \cap \{ f < f(x) \}$
induce isomorphisms between $H^i F_x$ and $\lim_{\rightarrow B \ni x} H^i (B \cap \{ f < f(x) \}; F)$,
for all functions $f$ with $df(x) = \xi$ and all $i \in \mathbb{Z}$. The easiest example
is $\operatorname{SS}(k_N) = T^*_N M$, where $k_N$ is the constant sheaf on a submanifold
$N$ of $M$. In general the microsupport can be a very singular set but it
is coisotropic in some sense (see Theorem 1.3.6). If $M$ is real analytic
and $F$ is constructible, then $\operatorname{SS}(F)$ is Lagrangian. Any smooth conic
Lagrangian submanifold of $T^*M$ is locally the microsupport of some
sheaf on $M$.

The microsupport is well-behaved with respect to the standard sheaf
operations. An important example is the composition. Let $M_i$, $i = 1, 2, 3$, be three manifolds and let $q_{ij}$ be the projection from $M_1 \times M_2 \times M_3$ to $M_i \times M_j$. For $K_1 \in \mathcal{D}(k_{M_1 \times M_2})$ and $K_2 \in \mathcal{D}(k_{M_2 \times M_3})$ we set
$K_1 \circ K_2 = \mathbb{R} q_{13}! (q_{12}^{-1} K_1 \otimes q_{23}^{-1} K_2)$. We can define a set theoretic analog
of the composition where direct and inverse images are replaced by the
same set operations and the tensor product by the intersection. Then,
under some geometric hypothesis, we have $\operatorname{SS}(K_1 \circ K_2) \subset \operatorname{SS}(K_1) \circ \operatorname{SS}(K_2)$.

In [43] a sheaf version of the Chekanov-Sikorav theorem (see [10]
and [42]) is given. A more functorial version is given in [21] as follows.
Let $\Phi$ be a $\mathbb{R}_{>0}$-homogeneous Hamiltonian isotopy of $\dot{T}^*M = T^*M \setminus T^*_M$. Then there exists a sheaf $K_\Phi$ on $M^2$ which is invertible for the
composition (there exists $K'$ such that $K_\Phi \circ K' = k_{\Delta_M}$) and such
that $\operatorname{SS}(K_\Phi)$ is the graph of $\Phi$. Here we let $\operatorname{SS}(F)$ be $\operatorname{SS}(F)$ with the
zero section removed. We then have $\operatorname{SS}(K_\Phi \circ F) = \Phi(\operatorname{SS}(F))$ for any
$F \in \mathcal{D}(k_M)$ and $F \mapsto K_\Phi \circ F$ is an auto-equivalence of $\mathcal{D}(k_M)$. We
recall this in Part 2.

Since the microsupport is conic it is rather related with the con-
tact geometry of the sphere cotangent bundle than the symplectic ge-
ometry of the cotangent bundle. We can also consider a Legendrian
submanifold of the 1-jet space $J^1(M)$ as a conic Lagrangian subman-
ifold in $T^*(M \times \mathbb{R})$ contained in $\{ \tau > 0 \}$, where we use the coordi-
nates $(t; \tau)$ on $T^*\mathbb{R}$. In [43] Tamarkin also remarks that a sheaf $F$
on $M \times \mathbb{R}$ with a microsupport in $\{\tau \geq 0\}$ comes with natural morphisms $\tau_c : F \to T_{c\ast}(F)$, where $c \geq 0$ and $T_c$ is the vertical translation in $M \times \mathbb{R}$, $T_c(x, t) = (x, t + c)$. A useful invariant of $F$ is then $e(F) = \sup\{c \geq 0; \tau_c(F) \neq 0\}$. It is introduced in [43] and used in [7] to obtain displacement energy bounds. We use it in Part 6 to prove classical nonsqueezing results. Our proof is a baby case of the proof of Chiu of a contact nonsqueezing theorem in [12].

In Part 6 we use some operations on sheaves introduced in [30] (cut-off lemmas) to reduce the size of a microsupport. These operations are compositions with the constant sheaf on a cone. We recall them in Part 3 where we also prove that a sheaf $F$ whose microsupport can be decomposed into two disjoint (and unknotted) subsets, say $\mathcal{S}(F) = S_1 \sqcup S_2$, can itself be locally decomposed, up to constant sheaves, as $F_1 \oplus F_2$ with $\mathcal{S}(F_i) = S_i$.

We also use the cut-off results in Part 5 to prove that a Legendrian submanifold of $J^1(M)$ has a graph selector as soon as it is the microsupport of a sheaf $F$ satisfying some conditions at infinity. The graph selector is given by the boundary of the support of a section of $F$.

In Part 7 we prove the Gromov-Eliashberg rigidity theorem as a consequence of the involutivity theorem of Kashiwara-Schapira. The starting point is very simple. Let $M$ be a manifold and let $\phi_n$ be a sequence of homogeneous Hamiltonian isotopies of $T^\ast M$ which converges in $C^0$ norm to a diffeomorphism $\phi_\infty$ of $T^\ast M$. Let $K_n \in D(k_{M^2})$ be the sheaf associated with $\phi_n$ as recalled above. Then we can consider a kind of limit $K_\infty$ of $K_n$ and the microsupport of $K_\infty$ is contained in the graph of $\phi_\infty$. We deduce from the involutivity theorem that this graph is Lagrangian, hence that $\phi_\infty$ is a symplectic map. This idea does not work directly to prove a local statement but we can cut-off the microsupport (using the cut-off results recalled in Part 3) and make it work.

The main result of this paper is a sheaf theoretic proof that a compact exact Lagrangian submanifold $L$ of a cotangent bundle $T^\ast M$ is homotopically equivalent to $M$. This is done in Parts 9-13. This result was previously obtained with Floer homology methods (see the beginning of Part 13 for references). However we do not recover the more precise results of Abouzaid and Kragh, who proved in [4] that the map $L \to M$ is a simple homotopy equivalence and gave some conditions on the higher Maslov classes in [3] (we only prove the vanishing of the first two classes; for the other classes we should use sheaves of spectra – see [26, 25]).
An important tool for our proof is the Kashiwara-Schapira stack \( \mu \text{Sh}(k_\Lambda) \) of a Lagrangian submanifold \( \Lambda \) of a cotangent bundle \( T^*M \). In [30] Kashiwara and Schapira consider the “microlocal” category \( D(k_M; \Omega) \) where \( \Omega \) is a subset of \( T^*M \). It is defined as the quotient of \( D(k_M) \) by the subcategory formed by the \( F \) such that \( SS(F) \cap \Omega = \emptyset \). When \( \Omega \) runs over the open subsets of \( T^*M \) this gives a prestack on \( T^*M \) and we consider its associated stack, say \( \mu \text{Sh}(k_{T^*M}) \). In [30] it is proved that the \( \mathcal{H}om \) sheaf in \( \mu \text{Sh}(k_{T^*M}) \) is \( H^0_{\mu \text{hom}} \) where \( \mu \text{hom} \) is a variant of Sato’s microlocalization (our stack has a very poor structure because the triangulated structure does not survive in the stackification and we only obtain \( H^0_{\mu \text{hom}} \), not \( \mu \text{hom} \)). The stack \( \mu \text{Sh}(k_{T^*M}) \) is the substack of \( \mu \text{Sh}(k_{T^*M}) \) formed by the objects with microsupport contained in \( \Lambda \). One step in the proof of the homotopy equivalence \( L \simeq M \) is the construction of a sheaf representing a given global object of \( \mu \text{Sh}(k_\Lambda) \), where \( \Lambda \) is a conic Lagrangian submanifold of \( T^*(M \times \mathbb{R}) \) deduced from \( L \) by adding one variable. This is done in Part 12. A similar result is obtained by Viterbo in [51] using Floer homology methods. More precisely, any given \( F \in \mu \text{Sh}(k_\Lambda)(\Lambda) \) is represented by \( F \in D(k_{M \times \mathbb{R}}) \) such that \( F_- := F|_{M \times \{t\}}, t \ll 0 \), vanishes and \( F_+ := F|_{M \times \{t\}}, t \gg 0 \), is locally constant. Then we prove that \( F \mapsto F_+ \) gives an equivalence between the category \( D_{\Lambda,+} \) formed by the \( F \) such that \( SS(F) \subset \Lambda \) and \( F_- \simeq 0 \) and the subcategory \( D_{lc}(k_M) \) of \( D(k_M) \) of locally constant sheaves. We prove another equivalence between \( D_{\Lambda,+} \) and \( D_{lc}(k_\Lambda) \). Hence \( D_{lc}(k_M) \) is equivalent to \( D_{lc}(k_\Lambda) \) and it follows that \( L \rightarrow M \) is a homotopy equivalence. Actually the proof is not so straightforward. We first prove the fully faithfulness of \( F \mapsto F_+ \) in Part 12 then use this fully faithfulness in the beginning of Part 13 to prove some result on the Poincaré groups and the vanishing of the first Maslov class. For this we need to know that \( \mu \text{Sh}(k_\Lambda)(\Lambda) \) has many objects. But the first Maslov class is an obstruction to the existence of a global object in \( \mu \text{Sh}(k_\Lambda) \). To bypass this problem we first work in the orbit category of sheaves (see Part 9) where there is no such obstruction. The orbit category contains less information than \( D(k_M) \) but the above argument works well enough in this framework to obtain the vanishing of the Maslov class. Then we can go back to the usual category of sheaves and we can prove \( D_{lc}(k_M) \simeq D_{lc}(k_\Lambda) \), as claimed.

Acknowledgments. The starting point of this paper is a discussion with Claude Viterbo. He explained me his construction of a quantization in the sense of this paper using Floer homology and asked whether it was possible to obtain it with the methods of algebraic analysis. Masaki Kashiwara gave me the idea to glue locally defined simple
sheaves under the assumption that the Maslov class vanishes. Claire Amiot explained me that we can use the orbit category to work without this vanishing assumption. The idea of applying the involutivity theorem to the $C^0$-rigidity emerged after several discussions with Claude Viterbo, Pierre Schapira and Vincent Humilière. The work on the three cusps conjecture was motivated by discussions with Emmanuel Giroux and Emmanuel Ferrand. I also thank Sylvain Courte, Pierre Schapira and Nicolas Vichery for several remarks and many stimulating discussions.

Part 1. Microlocal theory of sheaves

We recall here some results of [30] that will used very often. The notion of microsupport of a sheaf is in particular very important. We recall its definition and its behaviour under sheaf operations. We also recall quickly the definition of Sato’s microlocalization and the $\mu$hom functor, later introduced by Kashiwara and Schapira; it will be used in particular in \[\text{(10)}\] to define a category of sheaves associated with a Lagrangian submanifold of a cotangent bundle.

When [30] was written, it was not well understood how to deal with unbounded derived categories. In particular the theory of microsupport is written for bounded derived categories of sheaves. Moreover one of the fundamental lemmas was proved using an induction on the cohomological degree and its extension to the unbounded case could be unclear. However this problem has been solved in [41] and we will state the results on the microsupport for unbounded categories (although the sheaves we consider later are always locally bounded).

1.1. Notations

We mainly follows the notations of [30].

Geometry. We denote by $\pi_M: T^*M \to M$ the cotangent bundle of $M$. If $N \subset M$ is a submanifold, we denote by $T^*_N M$ its conormal bundle. We identify $M$ with $T^*_0 M$, the zero-section of $T^*M$. We set $\dot{T}^*M = T^*M \setminus T^*_M M$ and we denote by $\dot{\pi}_M: \dot{T}^*M \to M$ the projection. For any subset $A$ of $T^*M$ we define its antipodal $A^a = \{(x; \xi) \in T^*M; (x; -\xi) \in A\}$.

The cotangent bundle $T^* M$ carries an exact symplectic structure. We denote the Liouville 1-form by $\alpha_M$. It is given in local coordinates $\langle x; \xi \rangle$ by $\alpha_M = \sum_i \xi_i dx_i$. We denote by $H: T^* T^* M \simeq T T^* M$ the Hamiltonian isomorphism. We have $H(dx_i) = -\partial / \partial \xi_i$ and $H(d\xi_i) =$
\[ \text{Let } f: M \to N \text{ be a morphism of real manifolds. It induces morphisms on the cotangent bundles:} \]
\[ (1.1.1) \quad T^*M \leftarrow f^* M \times_N T^*N \to T^*N. \]

Let \( N \subset M \) be a submanifold and \( A \subset M \) any subset. We denote by \( C_N(A) \subset T_NM \) the cone of \( A \) along \( N \). If \( M \) is a vector space, \( x_0 \in N \) and \( q: M \to T_{N,x_0}M \) denotes the natural quotient map, then
\[ (1.1.2) \quad C_N(A) \cap T_{N,x_0}M = \bigcap_U \bigcup_{x \in A \cap (U \setminus \{x_0\})} q([x_0, x]), \]
where \( U \) runs over the neighborhoods of \( x_0 \) and \([x_0, x]\) denotes the half line starting at \( x_0 \) and containing \( x \).

If \( A, B \) are two subsets of \( M \), we set \( C(A, B) = C_{\Delta_M}(A \times B) \). Identifying \( T_{\Delta_M}(M \times M) \) with \( TM \) through the first projection, we consider \( C(A, B) \) as a subset of \( TM \). If \( M \) is a vector space and \( x_0 \in M \), we have
\[ (1.1.3) \quad C(A, B) \cap T_{x_0}M = \bigcap_U \bigcup_{x \in A \cap U} \bigcup_{y \in B \cap U, x \neq y} q([y, x]), \]
where \( U \) runs over the neighborhoods of \( x_0 \).

Sheaves. We consider a commutative unital ring \( k \) of finite global dimension (we will use \( k = \mathbb{Z} \) or \( k = \mathbb{Z}/2\mathbb{Z} \)). We denote by \( \text{Mod}(k) \) the category of \( k \)-modules and by \( \text{Mod}(k_M) \) the category of sheaves of \( k \)-modules on \( M \). We denote by \( \text{D}(k_M) \) (resp. \( \text{D}^b(k_M), \text{D}^b(k_M) \)) the derived category (resp. bounded derived category, locally bounded derived category) of \( \text{Mod}(k_M) \). (Hence \( \text{D}^b(k_M) \) is the subcategory of \( \text{D}(k_M) \) formed by the \( F \) such that \( F|_C \in \text{D}^b(k_C) \), for any compact subset \( C \subset M \).)

We recall some standard notations (following mainly [30]). For a morphism of manifolds \( f: M \to N \), we denote by \( Rf_* , Rf^1: \text{D}(k_M) \to \text{D}(k_N) \) the direct image and proper direct image functors. We denote by \( f^{-1} , f^!: \text{D}(k_N) \to \text{D}(k_M) \) their adjoint functors. We thus have adjunctions \( (f^{-1} , Rf_*) \) and \( (Rf^1 , f^!) \). We let \( \otimes \) (or \( \otimes \) if there is no need to derive) and \( \text{RHom} \) the tensor product and internal \( \text{Hom} \) sheaf. We have an adjunction \( (\otimes , \text{RHom}) \). For the inclusion \( j: Z \to M \) of a subset of \( M \) and \( F \in \text{D}(k_M) \) we often write
\[ F|_Z = j^{-1}F. \]
When $Z$ is locally closed we define

$$F_Z = j_! j^{-1} F,$$

$$\Gamma_Z(F) = Rj_* j^! F.$$

When $F = k_M$ is the constant sheaf we set for short $k_Z = (k_M)_Z = j_!(k_Z)$. (In case of ambiguity we write $k_{M,Z} = (k_M)_Z$, but in general the ambient manifold $M$ is understood.) We have natural isomorphisms

$$F_Z \simeq F \otimes k_Z, \quad \Gamma_Z(F) \simeq \mathsf{RHom}(k_Z, F).$$

We recall that, if $Z$ is closed and $U$ is open, then $\Gamma(U; k_Z) = \{ f : Z \cap U \to k ; f \text{ is locally constant} \}$. If $Z'$ is locally closed and $Z$ is a closed subset of $Z'$, we have an exact sequence $0 \to k_{Z \setminus Z} \to k_{Z'} \to k_Z \to 0$. We deduce the excision distinguished triangles, for any $F \in \mathcal{D}(k_M)$,

$$F_{Z' \setminus Z} \to F_{Z'} \to F_Z \xrightarrow{+1},$$

$$\Gamma_Z(F) \to \Gamma_{Z'}(F) \to \Gamma_{Z' \setminus Z}(F) \xrightarrow{+1}.$$

If $U$ is open, we let $\Gamma(U; -)$ be the derived section functor. We set $H^i(U; F) = H^i \Gamma(U; F)$. We let $\Gamma_c(\cdot)$ be the functor of sections with compact support and $\Gamma_c(\cdot)$ its derived functor. If $a: M \to \{ \text{pt} \}$ is the map to a point, we thus have $\Gamma(M; F) \simeq \mathsf{R}a_*(F)$ and $\Gamma_c(M; F) \simeq \mathsf{R}a_!(F)$. We also set $\Gamma_Z(U; F) = \Gamma(U; \Gamma_Z(F))$ and $H^i_Z(U; F) = H^i \Gamma_Z(U; F)$.

We denote by $\omega_M$ the dualizing complex on $M$. Since $M$ is a manifold, $\omega_M$ is actually the orientation sheaf shifted by the dimension, that is, $\omega_M \simeq or_M[d_M]$. (In general it is defined by $\omega_M = a^!(k_{\{\text{pt} \}})$, where $a: M \to \{ \text{pt} \}$ is the map from $M$ to a point.) We also use the notation $\omega_{M|N} = f^!(k_N)$ for the relative dualizing complex. We have $\omega_{M|N} \simeq \omega_M \otimes f^{-1}(\omega_{N}^{\otimes -1}) \simeq or_M \otimes f^{-1}(or_N)[d_M - d_N]$. The duality functors are defined by

\[
\mathsf{D}_M(\cdot) = \mathsf{RHom}(\cdot, \omega_M), \quad \mathsf{D}'_M(\cdot) = \mathsf{RHom}(\cdot, k_M).
\]

For two manifolds $M, N$ and $F \in \mathcal{D}(k_M), G \in \mathcal{D}(k_N)$ we define $F \boxtimes G \in \mathcal{D}(k_{M \times N})$ by

$$\frac{L}{B} F \boxtimes G = q_1^{-1} F \otimes q_2^{-1} G,$$

where $q_i$ ($i = 1, 2$) is the $i$-th projection defined on $M \times N$.

We recall some useful facts (see [30, §2, §3]).

**Proposition 1.1.1.** Let $f: M \to N$ be a morphism of manifolds, $F,G,H \in \mathcal{D}(k_M), F',G' \in \mathcal{D}(k_N)$. Then we have

(a) $\mathsf{RHom}(k_U, F) \simeq \Gamma(U; F)$, for $U \subset M$ open,

(b) $\Gamma(U; \mathsf{RHom}(F,G)) \simeq \mathsf{RHom}(F|_U, G|_U)$, for $U \subset M$ open,

(c) $H^i F$ is the sheaf associated with $V \mapsto H^i(V; F)$,
(d) $H^i \mathcal{R} \text{Hom}(F, G)$ is the sheaf associated with $V \mapsto \text{Hom}(F|_V, G|_V)$,

(e) $\mathcal{R} \text{Hom}(F \times G, H) \simeq \mathcal{R} \text{Hom}(F, \mathcal{R} \text{Hom}(G, H))$,

(f) $\mathcal{R} f_!(F \otimes f^{-1} F') \simeq (\mathcal{R} f_! F) \otimes F'$, \textit{(projection formula)},

(g) $f'_* \mathcal{R} \text{Hom}(F', G') \simeq \mathcal{R} \text{Hom}(f^{-1} F', f' G')$,

(h) $R f_* \mathcal{R} \text{Hom}(F, G) \simeq \mathcal{R} \text{Hom}(R f_! F, R f_* G)$, if $f$ is an embedding,

(i) for a Cartesian diagram $\xymatrix{ M \ar[r]^f & N \ar[d]^{g'} \ar[d]_g \ar[r]^{f'} & N'}$ we have the base change

formula $f'^{-1} R g'_! (F') \simeq R g_! f^{-1} (F')$.

The adjunction between $\otimes$ and $\mathcal{R} \text{Hom}$ together with $k_U \otimes k_T \simeq k_U$ give $\text{Hom}(k_U, \mathcal{D}'(k_T)) \simeq \text{Hom}(k_U, k_M) \simeq H^0(U; k_M)$. The canonical section of this last group gives a morphism $k_U \to \mathcal{D}'(k_T)$. Similarly we have a natural morphism $k_T \to \mathcal{D}'(k_U)$. In the following case they are isomorphisms.

If the inclusion $U \subset M$ is locally homeomorphistic to the inclusion $]-\infty, 0[ \times \mathbb{R}^{n-1} \subset \mathbb{R}^n$ (for example, if $\partial U$ is smooth), then (a) and (b) yield the first isomorphism in (1.1.5) below. The second one follows from the first one applied to $M \setminus U$ and the exact sequence $0 \to k_M \setminus T \to k_M \to k_T \to 0$.

(1.1.5) $k_T \simeq \mathcal{D}'(k_U), \quad k_U \simeq \mathcal{D}'(k_T)$.

1.2. Microsupport

1.2.1. Definition and first properties. We recall the definition of the microsupport (or singular support) $\text{SS}(F)$ of a sheaf $F$, introduced by M. Kashiwara and P. Schapira in [28] and [29].

Let $F \in \mathcal{D}(k_M)$ and $p = (x_0; \xi_0) \in T^* M$ be given. We choose a real $C^1$-function $\phi$ on $M$ satisfying $d\phi(x_0) = \xi_0$ and we consider the restriction morphism “in the direction $p$” for a given degree $i \in \mathbb{Z}$:

(1.2.1) $H^i F_{x_0} \simeq \lim_{U} H^i(U; F) \to \lim_{U} H^i(U \cap \{x; \phi(x) < \phi(x_0)\}; F)$,

where $U$ runs over the open neighborhoods of $x$. We are interested in the points $p$ where this morphism is not an isomorphism (for some $\phi$ and $i$). Taking the cone of the restriction morphism we obtain the following definition.

Definition 1.2.1. (see [30], Def. 5.1.2]) Let $F \in \mathcal{D}(k_M)$. We define $\text{SS}(F) \subset T^* M$ as the closure of the set of points $(x_0; \xi_0) \in T^* M$ such
that there exists a real $C^1$-function $\phi$ on $M$ satisfying $d\phi(x_0) = \xi_0$ and 
$$(\text{R}\Gamma_{\{x; \phi(x) \geq \phi(x_0)\}}(F))_{x_0} \neq 0.$$
We set $\text{SS}(F) = \text{SS}(F) \cap T^*M$.

The following properties are easy consequences of the definition:
(a) the microsupport is closed and $\mathbb{R}^+$-conic, that is, invariant by the 
action of $(\mathbb{R}^+, \times)$ on $T^*M$,
(b) $\text{SS}(F) \cap T_M^* = \pi_M(\text{SS}(F)) = \text{supp}(F),$
(c) the microsupport satisfies the triangular inequality: if $F_1 \to F_2 \to F_3 \overset{\pm 1}{\to}$ is a distinguished triangle in $D(k_M)$, then $\text{SS}(F_i) \subset \text{SS}(F_j) \cup \text{SS}(F_k)$ for all $i, j, k \in \{1, 2, 3\}$ with $j \neq k$.

**Example 1.2.2.** (i) If $F$ is a non-zero local system on a connected manifold $M$, then $\text{SS}(F) = T^*_M$, the zero-section. Conversely, if $\text{SS}(F) \subset T^*_M$, then the cohomology sheaves $H^i(F)$ are local systems, for all $i \in \mathbb{Z}$. (We say that $F$ is *locally constant* for short.)

(ii) If $N$ is a smooth closed submanifold of $M$ and $F = k_N$, then 
$\text{SS}(F) = T^*_NM$.

(iii) Let $U \subset M$ be an open subset with smooth boundary. Then 
$$\text{SS}(k_U) = (U \times_M T^*_M) \cup T^*_M \times \partial U,$$
$$\text{SS}(k_U^*) = (U \times_M T^*_M) \cup (T^*_M \times \partial U),$$
where $T^*_M \times \partial U = \{(x; \lambda d\phi(x)); f(x) = 0, \lambda \geq 0\}$, if $U = \{f < 0\}$ and 
$df \neq 0$ on $\partial U$.

(iv) Let $\lambda$ be a closed convex cone with vertex at 0 in $E = \mathbb{R}^n$. Then 
$\text{SS}(k_\lambda) \cap T_0^*E = \lambda^0$, where $\lambda^0$ is the polar cone of $\lambda$:

$$(1.2.2) \quad \lambda^0 = \{\xi \in E^*; \langle v, \xi \rangle \geq 0 \text{ for all } v \in E\}.$$ 

For a given $a > 0$ we define $h_a : E \to E, x \mapsto ax$. We clearly have 
$h_a^{-1}(k_\lambda) \simeq k_\lambda$. Hence $\text{SS}(k_\lambda)$ is invariant by the map induced by $h_a$ 
on $T^*E$. Since the microsupport is closed, we deduce the rough bound 
$\text{SS}(k_\lambda) \subset E \times \lambda^0$ by letting $a \to 0$.

(v) Let $F \in D(k_\lambda)$ be such that $\text{SS}(F) = \{(0; \xi); \xi \geq 0\}$. It follows 
from (i) that $F|_{\mathbb{R}\setminus\{0\}}$ is locally constant, hence $F|_{U_\pm}$ is constant, where 
$U_{\pm} = \{\pm x > 0\}$. In particular $\text{(R}\Gamma_{\{x; \phi(x) \geq \phi(x_0)\}}(F))_{x_0} \simeq 0$ for any 
x_0 \neq 0 and any function $\phi$ with $d\phi(x_0) \neq 0$. Hence the only possi-
bility to have a non trivial microsupport is $\text{(R}\Gamma_{\{x; \phi(x) \geq \phi(0)\}}(F))_0 \neq 0$ for some function $\phi$ with $d\phi(0) > 0$. This means $\text{(R}\Gamma_Z(F))_0 \neq 0$, where $Z = \overline{U_\pm}$. Let us set $B_r = [-r, r[$. Since $F|_{U_\pm}$ is constant, $\text{R}\Gamma(B_r; \text{R}\Gamma_ZF)$ is independent of $r > 0$. Hence we have in fact
constant sheaf on an isomorphism \( (\mathbb{R}\Gamma Z) \) by a distinguished triangle \( G \).

Conclusion there exist \( u \) another morphism \( u : E_Z \to F \).

By the adjunction \((\otimes, R\mathcal{H}om)\) we obtain from \( u \) another morphism \( u : E_Z \to F \). We have \( (R\Gamma_Z(E_Z))_0 \simeq E \) and the morphism \( u \) induces an isomorphism \( (R\Gamma_Z(E_Z))_0 \simeq (R\Gamma_ZF)_0 \). In other words, defining \( G \) by a distinguished triangle \( G \to E_Z \to F \xrightarrow{+1} \), we have \( (R\Gamma ZG)_0 \simeq 0 \).

By the triangle equality we deduce that \( SS(G) = \emptyset \), hence \( G \) is a constant sheaf on \( \mathbb{R} \) and we can write \( G = E'_{\mathbb{R}} \) for some \( E' \in \mathcal{D}(k) \). In conclusion there exist \( E, E' \in \mathcal{D}(k) \) and a distinguished triangle

\[
E'_R \to E_Z \to F \xrightarrow{+1} .
\]

Conversely a sheaf \( F \) defined by such a distinguished triangle satisfies \( SS(F) = \{(0; \xi); \xi > 0\} \) and \( (R\Gamma_ZF)_0 \simeq E \).

1.2.2. Functorial operations.

**Proposition 1.2.3.** (See [30, Prop. 5.4.4].) Let \( f : M \to N \) be a morphism of manifolds and let \( F \in \mathcal{D}(k_M) \). We assume that \( f \) is proper on \( \text{supp}(F) \). Then \( SS(R_f;F) \subset f_!f^{-1}SS(F) \), with equality when \( f \) is a closed embedding.

**Example 1.2.4.** With the notations of Proposition 1.2.3 we assume that \( f \) is an embedding. Let \( F \in \mathcal{D}(k_N) \) be such that \( SS(F) \subset T^*_MN \). Then there exists a locally constant \( G \in \mathcal{D}(k_M) \) such that \( F \simeq f_!G \).

Indeed, since \( SS(F) \cap T^*(N \setminus M) = \emptyset \), we have \( F|_{N \setminus M} \simeq 0 \), by the property (b) after Definition 1.2.1. Hence \( F \simeq f_!G \) where \( G = f^{-1}F \). Then \( SS(F) = f_!f^{-1}SS(G) \) by Proposition 1.2.3 and we deduce \( SS(G) \subset T^*_N\mathbb{R} \). Now the result follows from Example 1.2.2 (i).

We recall some notations of [30, Def. 6.2.3].

Let \( M \) and \( N \) be two real manifolds and \( f : M \to N \) a morphism. Let \( \Gamma_f \subset M \times N \) be the graph of \( f \). We have \( T^*_f(M \times N) \simeq M \times N \). If \( X \) is a manifold and \( \Lambda \) a Lagrangian submanifold of \( T^*X \), the Hamiltonian isomorphism identifies \( T^*_\Lambda T^*X \) with \( T^*\Lambda \). Applying this to \( X = M \times N \) and \( \Lambda = T^*_f(M \times N) \), we obtain a natural identification

\[
T^*_f(M \times N)T^*(M \times N) \simeq T^*(M \times N)T^*_N(N) .
\]

We also remark that \( T^*M \) has a natural embedding in \( T^*(M \times N)T^*_N(N) \) as \( T^*M = T^*(M \times N)T^*_N(N) \). For a conic subset \( A \subset T^*_N \) we set

\[
f^A(A) = T^*M \cap C(T^*_f(M \times N))(T^*M \times A) .
\]
Example 1.2.5. Let $f$ be the embedding of $\mathbb{R}^m$ in $\mathbb{R}^{n+m}$. We take coordinates $(x', x''; \xi', \xi'')$ on $T^*\mathbb{R}^{n+m}$ such that $\mathbb{R}^m = \{x' = 0\}$. Then $(x''_{\infty}, \xi''_{\infty}) \in f^*(A)$ if and only if there exists a sequence $\{(x'_n, x''_n, \xi'_n, \xi''_n)\}$ in $A$ such that $x'_n \to 0$, $x''_n \to x''_{\infty}$, $\xi''_n \to \xi''_{\infty}$ and $|x'_n| |\xi'_n| \to 0$.

Example 1.2.6. With the notations of (1.2.3) we say that $f$ is non-characteristic for $A$ if

$$f^{-1}(A) \cap f_d^{-1}(T^*_M M) \subset M \times_N T^*_N N.$$ 

If $A \subset T^*N$ is closed conic and $f$ is non-characteristic for $A$, then $f^*(A) = f_d f^{-1}(A)$.

Theorem 1.2.7. (See [30, Cor. 6.4.4].) Let $f: M \to N$ be a morphism of manifolds and let $F \in D(k_N)$. Then

$$SS(f^{-1}F) \subset f^*(SS(F)) \quad \text{and} \quad SS(f^*F) \subset f^*(SS(F)).$$

If $f$ is smooth, these inclusions are equalities. If $f$ is non-characteristic for $SS(F)$, then the natural morphism

$$f^{-1}F \otimes \omega_{M|N} \to f^!(F)$$

is an isomorphism, where $\omega_{M|N} \simeq or_M \otimes f^{-1}(or_N)[d_M - d_N]$ is the relative dualizing complex.

Proposition 1.2.8. (See [30, Prop. 5.4.5].) Let $N, I$ be manifolds. We assume that $I$ is contractible. Let $f: N \times I \to I$ be the projection. Let $F \in D(k_{N \times I})$. Then $SS(F) \subset T^*N \times T^*_I I$ if and only if $f^{-1}RF_s(F) \simeq F$.

Example 1.2.9. We set $M = \mathbb{R}^n$, $S = \{x_n = 0\}$, $Z = \{x_n \geq 0\}$ and $\Lambda = \{(x_1, \ldots, x_{n-1}, 0; 0, \xi_n); \xi_n > 0\}$. Let $F \in D(k_M)$ be such that $SS(F) = \Lambda$. Then there exist $E, E' \in D(k)$ and a distinguished triangle

$$E'_M \to E_Z \to F \to +1.$$ 

Indeed, we can identify $M$ with a product $I \times N$, where $I = \mathbb{R}^{n-1}$ and $N = \mathbb{R}$. Then $\Lambda = T^*_I I \times \{(0; \xi_n); \xi_n > 0\}$. By Proposition 1.2.8 we can write $F \simeq f^{-1}G$ for some $G \in D(k_N)$, where $f: N \times I \to I$ is the projection. By Theorem 1.2.7 we must have $SS(G) = \{(0; \xi_n); \xi_n > 0\}$ and we conclude with Example 1.2.2(v).

Let $\delta_M: M \to M^2$ be the diagonal embedding. For conic subsets $A, B \subset T^*M$ we set

$$(1.2.4) \quad A \hat{+} B = \delta_M^*(A \times B).$$

In local coordinates $A \hat{+} B$ is the set of $(x; \xi)$ such that there exist two sequences $(x_n; \xi_n)$ in $A$ and $(y_n; \eta_n)$ in $B$ such that $x_n, y_n \to x$, $\xi_n + \eta_n \to \xi$ and $|x_n - y_n||\xi_n| \to 0$ when $n \to \infty$. 
**Example 1.2.10.** If $A, B \subset T^*M$ are closed conic subsets such that $A^a \cap B \subset T^*_M$, then $A \hat{\oplus} B = A + B$.

For the definition of *cohomologically constructible* we refer to [30 §3.4]. An example of a cohomologically constructible sheaf $F$ is given by the case where $F$ is constructible with respect to a Whitney stratification (that is, the restriction of $F$ to each stratum is locally constant and of finite rank).

**Theorem 1.2.11.** (See [30, Cor. 6.4.5].) Let $F, G \in D(k_M)$. Then

\[
\begin{align*}
SS(F \overset{\mathbb{L}}{\otimes} G) &\subset SS(F) \hat{\oplus} SS(G), \\
SS(R\mathcal{H}om(F, G)) &\subset SS(F)^a \hat{\oplus} SS(G), \\
SS(D'F) &\subset SS(F)^a.
\end{align*}
\]

We assume that $SS(F) \cap SS(G) \subset T^*_M$ and that $F$ is cohomologically constructible. Then the natural morphism $D'F \overset{\mathbb{L}}{\otimes} G \to R\mathcal{H}om(F, G)$ is an isomorphism.

**Remark 1.2.12.** Let $M, N$ be manifolds and let $q_1, q_2$ be the projections from $M \times N$ to $M, N$. For $F \in D(k_M)$ and $G \in D(k_N)$ Theorem 1.2.11 implies $SS(R\mathcal{H}om(q_1^{-1}F, q_2^{-1}G)) \subset SS(F)^a \times SS(G)$ and $SS(q_1^{-1}F \overset{\mathbb{L}}{\otimes} q_2^{-1}G) \subset SS(F) \times SS(G)$.

Using the $\hat{\oplus}$ operation we can give a version of Proposition 1.2.3 for an open embedding. We only state the case where the boundary of the open subset is smooth (see [30] for the general case).

**Theorem 1.2.13.** (See [30, Thm. 6.3.1].) Let $j: U \hookrightarrow M$ be the embedding of an open subset with a smooth boundary. Let $F \in D(k_U)$. Then $SS(Rj_*F) \subset SS(F) \hat{\oplus} SS(k_U)^a$ and $SS(Rj!F) \subset SS(F) \hat{\oplus} SS(k_U)$.

The next result follows immediately from Proposition 1.2.3 and Example 1.2.2 (i). It is a particular case of the microlocal Morse lemma (see [30, Cor. 5.4.19]), the classical theory corresponding to the constant sheaf $F = k_M$.

**Corollary 1.2.14.** Let $F \in D(k_M)$, let $\phi: M \to \mathbb{R}$ be a function of class $C^1$ and assume that $\phi$ is proper on supp($F$). Let $a < b$ in $\mathbb{R}$ and assume that $d\phi(x) \notin SS(F)$ for $a \leq \phi(x) < b$. Then the natural morphisms $R\Gamma(\phi^{-1}([-\infty, b]); F) \to R\Gamma(\phi^{-1}([-\infty, a]); F)$ and $R\Gamma(\phi^{-1}([a, +\infty])); (M; F) \to R\Gamma(\phi^{-1}([a, +\infty])); (M; F)$ are isomorphisms.

Here is another useful consequence of the properties of the micro-support which appears in [38].
Corollary 1.2.15. Let $M$ be a manifold and $I$ an open interval of $\mathbb{R}$. Let $F, G \in \mathcal{D}(k_{M \times I})$. We assume

(i) the projection $\text{supp}(F) \cap \text{supp}(G) \to I$ is proper,
(ii) $F, G$ are non-characteristic for all maps $i_t : M \times \{t\} \to M \times I$, $t \in I$, that is, $\text{SS}(H) \cap (T^*_M M \times T^*_I I) = \emptyset$ for $H = F, G$,
(iii) setting $\Lambda_t = i^*_t(\text{SS}(F))$ and $\Lambda'_t = i^*_t(\text{SS}(G))$, we have $\Lambda_t \cap \Lambda'_t = \emptyset$ for all $t \in I$.

Then $\text{RHom}(i^{-1}_t F, i^{-1}_t G)$ is independent of $t$.

Proof. We set $H = \text{RHom}(F, G)$. Since $\Lambda := \text{SS}(F)$ and $\Lambda' := \text{SS}(G)$ are non-characteristic for $i_t$ and $\Lambda_t \cap \Lambda'_t = \emptyset$, we can see that $\Lambda \cap \Lambda' \subset 0_{M \times I}$ and then $\text{SS}(H) \subset \Lambda + \Lambda'$. We can see moreover that $\Lambda^a + \Lambda'$ is also non-characteristic for $i_t$. Hence Theorem 1.2.7 gives $i^{-1}_t G \simeq i^*_t G[1]$ and $i^{-1}_t H \simeq i^*_t H[1]$. Then it follows from Proposition 1.1.1\(g\) that $\text{RHom}(i^{-1}_t F, i^{-1}_t G) \simeq i^{-1}_t H$. By the base change formula we have $\Gamma(M ; i^{-1}_t H) \simeq (\text{Rq}_{q_t} H)_t$, where $q : M \times I \to I$ is the projection. Hence it is enough to check that $\text{Rq}_q H$ is locally constant, that is, $\text{SS}(\text{Rq}_q H) \subset 0_I$. By Proposition 1.2.3 this follows from the fact that $\text{SS}(H)$ is non-characteristic for each $i_t$. \(\square\)

Remark 1.2.16. The particular case $F = k_{M \times I}$ of Corollary 1.2.15 gives the following. Let $G \in \mathcal{D}(k_{M \times I})$. We assume that $G$ is non-characteristic for all maps $i_t : M \times \{t\} \to M \times I$, $t \in I$, and that the map $\text{supp}(G) \to I$ is proper. Then the sections $\Gamma(M ; i^{-1}_t G)$ are independent of $t$.

1.3. Sato’s microlocalization

We quickly review the definition of the specialization and microlocalization functors as introduced in \[30\]. We first recall the notion of deformation to the normal cone. Let $M$ be a manifold and $N$ a closed submanifold of $N$. The deformation of $M$ to the normal cone of $N$ is a manifold $\tilde{M}_N$ together with three maps

$$ s : T_N M \to \tilde{M}_N, \quad p : \tilde{M}_N \to M, \quad t : \tilde{M}_N \to \mathbb{R}, $$

such that

\[
\begin{cases}
  s \text{ is an embedding and } \text{im}(s) = t^{-1}(0), \\
p(\text{im}(s)) = N \text{ and } p \circ s \text{ is the projection } T_N M \to N, \\
p^{-1}(M \setminus N) \simeq (M \setminus N) \times (\mathbb{R} \setminus \{0\}), \\
t^{-1}(\mathbb{R} \setminus \{0\}) \simeq M \times (\mathbb{R} \setminus \{0\}), \\
p|_{t^{-1}(u)} : t^{-1}(u) \to M \text{ is a diffeomorphism, for all } u \neq 0.
\end{cases}
\]
We can define $\tilde{M}_N$ as an open subset of some blow-up:
\[
\tilde{M}_N = B_{N\times\{0\}}(M \times \mathbb{R}) \setminus (P^N_{\infty}M \cup ((M \setminus N) \times \{0\})),
\]
where $P^N_{\infty}M$ denotes the hyperplane at infinity in the projectivization of the vector bundle $T_NM \times \mathbb{R} \to N$.

We set $\Omega = t^{-1}(]0, +\infty[)$ and $p_+ = p|_{\Omega}$. We have the following formula for the cone of a subset $A \subset M$ along $N$: $C_N(A) = s^{-1}(p_+^{-1}(A))$. The sheaf counterpart of the cone construction is the following specialization functor.

**Definition 1.3.1.** (See [30, Def. 4.2.2].) With the above notations we define the functor $\nu_N : D(k_M) \to D(k_{T_NM})$ by $\nu_N(F) = s^{-1}R\pi_+^*(F)$.

The sheaf $\nu_N(F)$ is conic, that is, invariant by the multiplicative action of $\mathbb{R}_{>0}$ on the fibers of $T_NM$. We can deduce a sheaf over $T^*_NM$ using the Fourier-Sato transform defined as follows.

**Definition 1.3.2.** (See [30, Def. 3.7.8].) Let $q_i$ be the $i^{th}$ projection from $T_NM \times N T^*_NM$ and let $P \subset T_NM \times N T^*_NM$ be the subset $P = \{(\nu, \xi) : \langle \nu, \xi \rangle \leq 0\}$. For $F \in D(k_{T_NM})$ we define $F^\wedge \in D(k_{T^*_NM})$ by $F^\wedge = Rq_{2!}(q_1^{-1}F \otimes k_P)$.

In [30] the Fourier-Sato transform is actually defined for general vector bundles. It is proved that it gives an equivalence between conic sheaves on a vector bundle and conic sheaves on its dual.

**Definition 1.3.3.** (See [30, Def. 4.3.1].) The microlocalization functor $\mu_N : D(k_M) \to D(k_{T^*_NM})$ is defined by $\mu_N(F) = (\nu_N(F))^\wedge$.

If $V \subset T^*_NM$ is a convex open cone, we have
\[
H^i(V; \mu_N(F)) \simeq \lim_{\substack{\to \cr \Omega \to Z}} H^i_{Z\cap U}(U; F),
\]
where $U$ runs over the open subsets of $M$ containing $\pi_M(V)$ and $Z$ over the closed subsets of $M$ such that $C_N(Z) \subset V^\circ$ (recall that $V^\circ$ is the polar cone of $V$).

In [30] we also find a generalization of Sato’s microlocalization which will be important when we consider the Kashiwara-Schapira stack. Let $\Delta_M$ be the diagonal of $M \times M$. Let $q_1, q_2 : M \times M \to M$ be the projections. We identify $T^*_{\Delta_M}(M \times M)$ with $T^*M$ through the first projection.

**Definition 1.3.4.** (See [30, Def. 4.4.1].) For $F, G \in D(k_M)$ we define $\mu_{\text{hom}}(F, G) \in D(k_{T^*M})$ by
\[
(1.3.1) \quad \mu_{\text{hom}}(F, G) = \mu_{\Delta_M}(R\text{Hom}(q_2^{-1}F, q_1^*G)).
\]
For a submanifold $N$ of $M$ we have $\mu_N(G) \simeq \mu_{\text{hom}}(k_N, G)$, for any $G \in \mathcal{D}(k_M)$. The functor $\mu_{\text{hom}}$ is a refinement of the functor $R\mathcal{H}om$ in view of the following properties:

\begin{align}
R\pi_M^* \mu_{\text{hom}}(F, G) &\simeq R\mathcal{H}om(F, G), \\
R\pi_M^! \mu_{\text{hom}}(F, G) &\simeq \delta^1_M R\mathcal{H}om(q^{-1}_2 F, q^{-1}_1 G),
\end{align}

where $\delta_M: M \to M \times M$ is the diagonal embedding. For a conic sheaf $H$ on $T^*M$ (or on any vector bundle) we have a natural isomorphism

\begin{align}
R\pi_M^! (H) &\simeq R\pi_M^* R\Gamma_M (H)
\end{align}

and the natural morphism $R\pi_M^! (H) \to R\pi_M^* (H)$ coincides with the morphism deduced from $R\Gamma_M (H) \to H$. The excision distinguished triangle associated with the inclusion $M \subset T^*M$ then gives a version of Sato’s distinguished triangle:

\begin{align}
\delta^1_M R\mathcal{H}om(q^{-1}_2 F, q^{-1}_1 G) &\to R\mathcal{H}om(F, G) \\
&\to R\pi_M^* (\mu_{\text{hom}}(F, G)|_{T^*M}) +1.
\end{align}

If $F$ is cohomologically constructible, then the first term of (1.3.4) is isomorphic to $D'(F) \otimes G$ by Theorem 1.2.11 and we obtain

\begin{align}
D'(F) \otimes G &\to R\mathcal{H}om(F, G) \\
&\to R\pi_M^* (\mu_{\text{hom}}(F, G)|_{T^*M}) +1.
\end{align}

**Proposition 1.3.5.** (Cor. 6.4.3 of [30].) Let $F, G \in \mathcal{D}(k_M)$. Then

\begin{align}
\text{supp}(\mu_{\text{hom}}(F, G)) &\subset SS(F) \cap SS(G), \\
SS(\mu_{\text{hom}}(F, G)) &\subset -H^{-1}(C(SS(G), SS(F))),
\end{align}

where $H$ is the Hamiltonian isomorphism.

When $F = G$, the inclusion (1.3.6) is an equality. More precisely, by (1.3.2), $id_F \in \text{Hom}(F, F)$ gives a global section of $\mu_{\text{hom}}$, say

\begin{align}
id_F^\mu \in H^0(T^*M; \mu_{\text{hom}}(F, F))
\end{align}

and [30, Cor. 6.1.3] says that

\begin{align}
\text{supp}(id_F^\mu) = \text{supp} \mu_{\text{hom}}(F, G) = SS(F).
\end{align}

An important consequence of (1.3.7) and (1.3.9) is the following involutivity theorem.

**Theorem 1.3.6** (Thm. 6.5.4 of [30].) Let $M$ be a manifold and $F \in \mathcal{D}(k_M)$. Then $S = SS(F)$ is a coisotropic subset of $T^*M$ in the sense that $C_p(S)$ contains the symplectic orthogonal of $C_p(S, S)$, for all $p \in S$.

When $\Lambda \subset T^*M$ is a Lagrangian submanifold we have $H^{-1}(T\Lambda) = T^*_\Lambda T^*M$. Hence (1.3.6), (1.3.7) and Example 1.2.4 give the following result.
Corollary 1.3.7. Let $\Lambda$ be a conic Lagrangian submanifold of $\mathring{T^*M}$. Let $F, G \in D(k_M)$. We assume that there exists a neighborhood $\Omega$ of $\Lambda$ such that $SS(F) \cap \Omega \subset \Lambda$ and $SS(G) \cap \Omega \subset \Lambda$. Then $\mu_{hom}(F, G)|_{\Omega}$ is supported on $\Lambda$ and is locally constant on $\Lambda$.

By the following result we can see $\mu_{hom}$ as a microlocal version of $R\mathcal{H}om$. Let $p \in T^*M$ be a given point. By the triangular inequality the full subcategory $N_p$ of $D(k_M)$ formed by the $F$ such that $p \notin SS(F)$ is triangulated and we can set $D(k_M; p) = D(k_M)/N_p$ (see the more general Definition 6.1.1 of [30]). The functor $\mu_{hom}(\cdot, \cdot)_p$ induces a bifunctor on $D(k_M; p)$ and we have

Theorem 1.3.8 (Theorem 6.1.2 of [30]). For all $F, G \in D(k_M)$, the morphism $\text{Hom}_{D(k_M;p)}(F, G) \to H^0(\mu_{hom}(F, G))_p$ is an isomorphism.

We also give the following useful consequence of Theorem 1.3.6.

Corollary 1.3.9. Let $\Lambda$ be a conic connected Lagrangian submanifold of $\mathring{T^*M}$. Let $F \in D(k_M)$ be such that $\mathring{SS}(F) \neq \emptyset$ and $\mathring{SS}(F) \subset \Lambda$. Then $\mathring{SS}(F) = \Lambda$.

Proof. Arguing by contradiction we assume that $U = \Lambda \setminus \mathring{SS}(F)$ is non empty. The set $U$ is open in $\Lambda$ with a non empty boundary $\partial U$. We choose a chart $V$ in $\Lambda$ around a point of $\partial U$ and we choose a point $p_0 \in V \cap U$. Let $B$ be the open ball in $V$ with center $p_0$ and maximal radius such that $B \cap \mathring{SS}(F) = \emptyset$. Then $\partial B \cap \mathring{SS}(F)$ is non empty and we let $p$ be any of its points.

Since $\mathring{SS}(F) \subset \Lambda$ and $\Lambda$ is smooth, we have $C_p(\mathring{SS}(F), \mathring{SS}(F)) \subset C_p(\Lambda, \Lambda) = T_p\Lambda$. Since $\Lambda$ is Lagrangian, it follows that the symplectic orthogonal of $C_p(\mathring{SS}(F), \mathring{SS}(F))$ contains $T_p\Lambda$. On the other hand $C_p(\mathring{SS}(F))$ is contained in $C_p(V \setminus B)$ which is a half space of $T_p\Lambda$. Hence $C_p(\mathring{SS}(F))$ does not contain $T_p\Lambda$ and this contradicts Theorem 1.3.6. $\square$

1.4. SIMPLE SHEAVES

Let $\Lambda$ be a closed conic Lagrangian submanifold of $\mathring{T^*M}$. We recall the definition of simple and pure sheaves along $\Lambda$ and give some of their properties. We first recall some notations from [30]. For a function $\varphi: M \to \mathbb{R}$ of class $C^\infty$ we define

\begin{equation}
\Lambda_\varphi = \{(x; d\varphi(x)); \ x \in M\}.
\end{equation}

We notice that $\Lambda_\varphi$ is a closed Lagrangian submanifold of $T^*M$. For a given point $p = (x; \xi) \in \Lambda \cap \Lambda_\varphi$ we have the following Lagrangian
subspaces of $T_p(T^*M)$
\begin{equation}
\lambda_0(p) = T_p(T^*_x M), \quad \lambda_\Lambda(p) = T_p \Lambda, \quad \lambda_\varphi(p) = T_p \Lambda_\varphi.
\end{equation}
We recall the definition of the inertia index (see for example §A.3 in [30]). Let $(E, \sigma)$ be a symplectic vector space and let $\lambda_1, \lambda_2, \lambda_3$ be three Lagrangian subspaces of $E$. We define a quadratic form $q$ on $\lambda_1 \oplus \lambda_2 \oplus \lambda_3$ by $q(x_1, x_2, x_3) = \sigma(x_1, x_2) + \sigma(x_2, x_3) + \sigma(x_3, x_1)$ and
\begin{equation}
\tau_E(\lambda_1, \lambda_2, \lambda_3) = \text{sgn}(q)
\end{equation}
where \text{sgn}(q) is the signature of $q$, that is, $p_+ - p_-$, where $p_\pm$ is the number of $\pm 1$ in a diagonal form of $q$. We set
\[
\tau_\varphi = \tau_{p, \varphi} = \tau_{\pi, T^*M}(\lambda_0(p), \lambda_\Lambda(p), \lambda_\varphi(p)).
\]

**Proposition 1.4.1** (Proposition 7.5.3 of [30]). Let $\varphi_0, \varphi_1 : M \to \mathbb{R}$ be functions of class $C^\infty$, let $p = (x; \xi) \in \Lambda$ and let $F \in D(k_M)$ be such that $\Omega \cap \mathcal{S}(F)$ is contained in $\Lambda$, for some neighborhood $\Omega$ of $\Lambda$. We assume that $\Lambda$ and $\Lambda_{p_i}$ intersect transversally at $p$, for $i = 0, 1$. Then there exists an isomorphism
\[
(R\Gamma_{\{\varphi_1 \leq \varphi(x)\}}(F))_x \simeq (R\Gamma_{\{\varphi_0 \geq \varphi_0(x)\}}(F))_x \left[\frac{1}{2}(\tau_{\varphi_0} - \tau_{\varphi_1})\right].
\]

**Definition 1.4.2** (Definition 7.5.4 of [30]). In the situation of Proposition 1.4.1 we say that $F$ is pure at $p$ if $(R\Gamma_{\{\varphi_0 \geq \varphi_0(x)\}}(F))_x$ is concentrated in a single degree and free, that is, $(R\Gamma_{\{\varphi_0 \geq \varphi_0(x)\}}(F))_x \simeq L[d]$, for some free module $L \in \text{Mod}(k)$ and $d \in \mathbb{Z}$. If moreover $L \simeq k$, we say that $F$ is simple at $p$.

If $F$ is pure (resp. simple) at all points of $\Lambda$ we say that it is pure (resp. simple) along $\Lambda$.

We denote by $D^f_\Lambda(k_M)$ the full subcategory of $D(k_M)$ formed by the $F$ such that $F$ is simple along $\mathcal{S}(F)$ and the stalks of $F$ at the points of $M \setminus \pi_M(\Lambda)$ are finite dimensional.

**Proposition 1.4.3** (Cor. 7.5.7 in [30]). We assume that $\Lambda$ is connected and $F \in D(k_M)$ is pure at some $p \in \Lambda$. Then $F$ is pure along $\Lambda$. Moreover the $L \in \text{Mod}(k)$ in the above definition is the same at every point.

Since $k$ is a field, we know that $F$ is pure along $\Lambda$ if and only if $\mu_{\text{hom}}(F, F)|_{T_p M}$ is concentrated in degree 0 and $F$ is simple along $\Lambda$ if and only if the natural morphism $k_\Lambda \to \mu_{\text{hom}}(F, F)|_{T_p M}$ induced by (1.3.2) and the section $id_F$ of $R\text{Hom}(F, F)$ is an isomorphism:
\begin{equation}
k_\Lambda \cong \mu_{\text{hom}}(F, F).
\end{equation}
For coefficients in a field the property (1.4.4) could be a definition of a simple sheaf.
Definition 7.5.4 of [30] is actually more precise than Definition 1.4.2 above: $F$ is simple at $p$ with shift $d$ ($d$ a half-integer) if

\begin{equation}
(1.4.5) \quad (R\Gamma_{\varphi_0 \geq \varphi_0(x)}(F))_x \simeq k[d - \frac{1}{2}d_M - \frac{1}{2}\tau_{\varphi_0}].
\end{equation}

**Example 1.4.4.** In Example 1.2.2 (iii) the sheaf $k_U$ has shift $-1/2$ and the sheaf $k_Z$ has shift $1/2$ (see Example 7.5.5 of [30]).

For $i \in \mathbb{N}$ we let $\Lambda_i \subset \Lambda$ be the set of points such that the rank of $d\pi_M|_\Lambda$ is $(\dim M - 1 - i)$. For a generic closed conic Lagrangian connected submanifold $\Lambda$ in $\tilde{T}^*M$, $\Lambda_0$ is an open dense subset of $\Lambda$ and, for a given simple sheaf $F \in D_\Lambda(k_M)$, the shift of $F$ at $p$ is locally constant on $\Lambda_0$ and changes by 1 when $p$ crosses $\Lambda_1$.

We can also compute the germs of $\mu\text{hom}$ for sheaves in $D^b_{(\Lambda)}(k_M)$. Let $p = (x; \xi) \in \Lambda$ and $\varphi_0: M \to \mathbb{R}$ be as in Proposition 1.4.1. For $F, G \in D^b_{(\Lambda)}(k_M)$, we have

\begin{equation}
(1.4.6) \quad \mu\text{hom}(F, G)_p \simeq \text{RHom}((R\Gamma \varphi_0(F))_x, (R\Gamma \varphi_0(G))_x),
\end{equation}

where $Z_0 = \{ \varphi_0 \geq \varphi_0(x) \}$.

1.5. COMPOSITION OF SHEAVES

We will use several times a usual operation associated with sheaves called “composition” or “convolution”. We refer to [30, §3.6] for more details, or [21, §1.6, §1.10].

Let $M_i, i = 1, 2, 3$, be three manifolds. We denote by $q_{ij}$ the projection from $M_1 \times M_2 \times M_3$ to $M_i \times M_j$. For $K_1 \in D(k_{M_1 \times M_2})$ and $K_2 \in D(k_{M_2 \times M_3})$ we denote by $K_1 \circ K_2 \in D(k_{M_1 \times M_3})$ the composition of $K_1$ and $K_2$:

\begin{equation}
(1.5.1) \quad K_1 \circ K_2 = Rq_{13!}(q_{12}^{-1} K_1 \otimes q_{23}^{-1} K_2).
\end{equation}

The Fourier-Sato transform of Definition 1.3.2 is an example of composition of sheaves.

Using the base change formula we see that the composition product is associative in the sense that, for another manifold $M_4$ and $K_3 \in D(k_{M_3 \times M_1})$, we have a natural isomorphism $(K_1 \circ K_2) \circ K_3 \simeq K_1 \circ (K_2 \circ K_3)$. If $M_1 = M_2$, the constant sheaf on the diagonal $K_1 = k_{\Delta_{M_1}}$ is a left unit for this product: we have $k_{\Delta_{M_1}} \circ K_2 \simeq K_2$ for any $K_2 \in D(k_{M_2 \times M_1})$. Similarly, if $M_2 = M_3$, the sheaf $k_{\Delta_{M_2}}$ is a right unit.

The base change formula gives a useful expression for the germs of the composition. For $(x, z) \in M_1 \times M_3$ we have

\begin{equation}
(1.5.2) \quad (K_1 \circ K_2)_{(x, z)} \simeq R\Gamma_c(M_2; (K_1|_{\{x\} \times M_2}) \boxtimes (K_2|_{M_2 \times \{z\}})).
\end{equation}
For $K_1 \in \mathcal{D}(k_{M_1 \times M_2})$ we have a natural candidate for an inverse, denoted $K_1^{-1}$ and defined as follows. Let $q_2 : M_1 \times M_2 \to M_2$ be the projection and $v : M_1 \times M_2 \cong M_2 \times M_1$ the swap isomorphism. We recall that $q_2^2(k_{M_2}) \simeq \omega_{M_1} \boxtimes k_{M_2}$. We define

\begin{equation}
K_1^{-1} = v^{-1}\mathcal{R}\mathcal{H}\text{om}(K_1, q_2^2(k_{M_2})) \in \mathcal{D}(k_{M_2 \times M_1}).
\end{equation}

Let $\delta_2 : M_2 \to M_2 \times M_2$ and $\delta_1 : M_1 \times M_2 \to M_2 \times M_1 \times M_2$ be the diagonal embeddings. The base change formula $\delta_2^{-1}\mathcal{R}q_{23!} \simeq \mathcal{R}q_{22!}\delta_1^{-1}$ implies

\[ \delta_2^{-1}(K_1^{-1} \circ K_1) \simeq \mathcal{R}q_{22!}(K_1 \boxtimes \mathcal{R}\mathcal{H}\text{om}(K_1, q_2^2(k_{M_2}))). \]

Using the contraction $K_1 \boxtimes \mathcal{R}\mathcal{H}\text{om}(K_1, L) \to L$ and the adjunction morphisms for $(\mathcal{R}q_{22!}, q_2^!)$ and $(\delta_1^{-1}, \mathcal{R}\delta_2)$ we deduce the first morphism in (1.5.4) below; the second morphism is obtained in the same way.

\begin{equation}
K_1^{-1} \circ K_1 \to k_{\Delta M_2}, \quad K_1 \circ K_1^{-1} \to k_{\Delta M_1}.
\end{equation}

Using the bounds given by Proposition 1.2.3 and Theorem 1.2.7 for the behaviour of the microsupport under sheaves operations we obtain the following result. We denote by $p_{ij}$ the projections from $T^*(M_1 \times M_2 \times M_3)$ similar to the $q_{ij}$. We also define $a_2$ on $T^*(M_1 \times M_2)$ by $a_2(x, y; \xi, \eta) = (x, y; \xi, -\eta)$.

**Lemma 1.5.1.** Let $K_1 \in \mathcal{D}(k_{M_1 \times M_2})$ and $K_2 \in \mathcal{D}(k_{M_2 \times M_3})$ be given. We assume that $q_{13}$ is proper on $q_{12}^{-1}\text{supp}(K_1) \cap q_{23}^{-1}\text{supp}(K_2)$ and $p_{12}^{-1}a_2^{-1}\text{SS}(K_1) \cap p_{23}^{-1}\text{SS}(K_2) \cap (T_{M_1}^*M_1 \times T^*M_2 \times T_{M_3}^*M_3)$ is contained in the zero-section of $T^*(M_1 \times M_2 \times M_3)$. Then

\begin{equation}
\text{SS}(K_1 \circ K_2) \subset \text{SS}(K_1) \circ \text{SS}(K_2),
\end{equation}

where the operation $\circ$ for $A_1 \subset T^*(M_1 \times M_2)$ and $A_2 \subset T^*(M_2 \times M_3)$ is defined by $A_1 \circ A_2 = p_{12}^{-1}a_2^{-1}(A_1) \cap p_{23}^{-1}(A_2)$.

We will also use a relative version of the composition. For a manifold $I$ we denote by $q_{ijI}$ the projections from $M_1 \times M_2 \times M_3 \times I$ to $M_i \times M_j \times I$ similar to the $q_{ij}$. For $K_1 \in \mathcal{D}(k_{M_1 \times M_2 \times I})$ and $K_2 \in \mathcal{D}(k_{M_2 \times M_3 \times I})$ we set

\begin{equation}
K_1 \circ |_I K_2 = \mathcal{R}q_{13!}(q_{12I}^{-1}K_1 \boxtimes q_{23I}^{-1}K_2).
\end{equation}

The definition is chosen so that $(K_1 \circ |_I K_2)|_{M_1 \times M_3 \times \{t\}} \simeq K_{1,t} \circ K_{2,t}$ for all $t \in I$, where $K_{1,t} = K_1|_{M_1 \times M_2 \times \{t\}}$, $K_{2,t} = K_1|_{M_2 \times M_3 \times \{t\}}$.

The previous results generalize to the relative setting (see [21]). In particular we can define $K_1^{-1} = v^{-1}\mathcal{R}\mathcal{H}\text{om}(K_1, q_2^2(k_{M_2 \times I}))$ (an object of $\mathcal{D}(k_{M_2 \times M_1 \times I})$) and we have natural morphisms

\begin{equation}
K_1^{-1} \circ |_I K_1 \to k_{\Delta M_2 \times I}, \quad K_1 \circ |_I K_1^{-1} \to k_{\Delta M_1 \times I}.
\end{equation}
We also have $K_1^{-1}|_{M_1 \times M_2 \times \{t\}} \simeq K_1^{-1}$.

**Remark 1.5.2.** For $K_1 \in D(k_{M_1 \times M_2})$ the composition $\Phi_{K_1}: F \mapsto K \circ F$ is a functor $D(k_{M_2}) \to D(k_{M_1})$ and we have $\Phi_{K_1 \circ K_2} = \Phi_{K_2} \circ \Phi_{K_1}$. When $M_1 = M_2 = M$, $\Phi_{\Delta_M}$ is the identity functor. When $M_1 = M_2 = M_3 = M$, if $K_1 \circ K_2 \simeq k_{\Delta_M}$, then $K_2 \circ K_1 \simeq k_{\Delta_M}$ and $\Phi_{K_1}$, $\Phi_{K_2}$ are mutually inverse equivalences of categories.

**Part 2. Sheaves associated with Hamiltonian isotopies**

In this part we recall the main result of [21], which, following ideas of Tamarkin in [43], gives a sheaf version of the Chekanov-Sikorav theorem about generic functions (see [10] and [42]). Let $\Psi: J(W) \to \mathcal{D}(k_N)$, for any $s \in I$. The Chekanov-Sikorav theorem says that, if a Legendrian submanifold $L$ of $J(W)$ has a generic function, so does $\Phi_s(L)$, for any $s \in I$. The sheaf version is more functorial. We can associates a sheaf $K_\Psi$ on $N^2 \times I$ with $\Psi$. This sheaf acts by composition on $\mathcal{D}(k_N)$ and induces equivalences of categories, $F \mapsto (K_\Psi|_{N^2 \times \{s\}}) \circ F$. We state this result with homogeneous Hamiltonian isotopies of $T^*N$ (which is the same thing as contact isotopies of the sphere bundle of $T^*N$). We recall how it implies the non homogeneous case and give some complementary remarks.

### 2.1. Homogeneous case

Let $N$ be a manifold and $I$ an open ball of $\mathbb{R}^d$ containing 0 (in general $I$ will be an open interval of $\mathbb{R}$ containing 0). We consider a homogeneous Hamiltonian isotopy $\Psi: T^*N \times I \to T^*N$ of class $C^\infty$. For $s \in I$, $p \in T^*N$ we set $\Psi_s(p) = \Psi(p, s)$. Hence $\Psi_0 = \text{id}_{T^*N}$ and, for each $s \in I$, $\Psi_s$ is a symplectic diffeomorphism such that $\Psi_s(x; \lambda \xi) = \lambda \cdot \Psi_s(x; \xi)$, for all $(x; \xi) \in T^*N$ and $\lambda > 0$. We let $\Lambda_{\Psi_s} \subset T^*N^2$ be the twisted graph of $\Psi_s$, that is,

\begin{equation}
\Lambda_{\Psi_s} = \{(\Psi(x, \xi, s), (x, -\xi)); (x; \xi) \in T^*N\}.
\end{equation}

We can see that there exists a unique conic Lagrangian submanifold $\Lambda_{\Psi} \subset T^*(N^2 \times I)$, described in (2.1.2) below, such that $\Lambda_{\Psi_s} = \psi_s(\Lambda_{\Psi})$, for all $s \in I$, where $\psi_s$ is the embedding $N^2 \times \{s\} \to N^2 \times I$. Our homogeneous Hamiltonian isotopy $\Psi$ is the flow of some $h: T^*N \times I \to \mathbb{R}$ and there is a unique such $h$ which is homogeneous of degree 1 in the variable $\xi$. Then we have

\begin{equation}
\Lambda_{\Psi} = \{(\Psi(x, \xi, s), (x, -\xi), (s; -h(\Psi(x, \xi, s), s))); (x; \xi) \in T^*N, s \in I\}.
\end{equation}
We also remark that $\Lambda_\Psi$ is non-characteristic for the inclusion $i_s$, for any $s \in I$.

**Theorem 2.1.1** (Theorem. 4.3 of [21]). There exists a unique $K_\Psi \in D^b(k_{N^2 \times I})$ such that $\dot{S}\dot{S}(K_\Psi) \subset \Lambda_\Psi$ and $K_\Psi|_{N^2 \times \{0\}} \simeq k_{\Delta_N}$ Moreover we have $\dot{S}\dot{S}(K_\Psi) = \Lambda_\Psi$, $K_\Psi$ is simple along $\Lambda_\Psi$, both projections $\text{supp}(K_\Psi) \to N \times I$ are proper and the natural morphisms \[ \text{(1.5.7)} \] are isomorphisms:

$$K_\Psi^{-1} \circ \origin\ K_\Psi \simeq k_{\Delta_N \times I}, \quad K_\Psi \circ \origin\ K_\Psi^{-1} \simeq k_{\Delta_N \times I}.$$ 

By Remark \[ \text{(1.5.2)} \] the composition with $K_{\Psi,s} = K_\Psi|_{N^2 \times \{s\}}$ gives an equivalence of categories $D(k_N) \to D(k_N), F \mapsto K_{\Psi,s} \circ F$.

**Remarks 2.1.2.** (1) The equivalence between $\dot{S}\dot{S}(K_\Psi) \subset \Lambda_\Psi$ and $\dot{S}\dot{S}(K_\Psi) = \Lambda_\Psi$ follows from Corollary \[ \text{(1.3.9)} \]

(2-a) The fact that $K_\Psi$ is simple along $\Lambda_\Psi$ is not explicitly stated in [21] (although it is used in the proof of the Arnol’d conjecture about the intersection of the zero section of a cotangent bundle which its image under a Hamiltonian isotopy). However it is easily deduced from the construction of $K_\Psi$ which is obtained as a composition of constant sheaves over open subsets with smooth boundaries. Such sheaves are simple and a composition of simple sheaves is simple by [30 Thm. 7.5.11].

(2-b) We can also check the simplicity without going back to the construction of $K_\Psi$ and using only the properties $\dot{S}\dot{S}(K_\Psi) = \Lambda_\Psi$ and $K_\Psi|_{N^2 \times \{0\}} \simeq k_{\Delta_N}$. Indeed, by Proposition \[ \text{(1.4.3)} \] it is enough to check the simplicity at one point of $\Lambda_\Psi$. The map $i_{s,\pi}: T^*N^2 \times T^*_s I \to T^*N^2 \times I$ is transverse to $\Lambda_\Psi$, for any $s \in I$, and the projection $i_{s,d}: \Lambda_\Psi \cap (T^*N^2 \times T^*_s I) \to \Lambda_{\Psi,s}$ is a bijection. By [30 Cor. 7.5.13] it follows that the type of $K_\Psi|_{N^2 \times \{s\}}$ at a point $p \in \Lambda_{\Psi,s}$ is the same as the type of $K_\Psi$ at the point $p' \in \Lambda_\Psi$ such that $i_{s,d}(p') = p$. For $s = 0$ we deduce from $K_\Psi|_{N^2 \times \{0\}} \simeq k_{\Delta_N}$ that $K_\Psi$ is simple at any point of $\Lambda_\Psi \cap (T^*N^2 \times \{0\})$.

(3) We can define the isotopy $\Psi': T^*N \times I \to T^*N$ by $\Psi'_s = \Psi_{s,-1}$ for all $s \in I$. Using Lemma \[ \text{(1.5.1)} \] we see that $\dot{S}\dot{S}(K_\Psi \circ \origin\ K_\Psi') \subset T^*\Delta_N \times I$. Since $(K_\Psi \circ \origin\ K_\Psi')|_{N^2 \times \{0\}} \simeq k_{\Delta_N}$, Proposition \[ \text{(1.2.8)} \] gives $K_\Psi \circ \origin\ K_\Psi' \simeq k_{\Delta_N \times I}$. The unicity of the inverse then implies that $K_\Psi^{-1} \simeq K_\Psi$.

**Example 2.1.3.** The easiest illustration of Theorem \[ \text{2.1.1} \] is the sheaf associated with the (normalized) geodesic flow of $T^*\mathbb{R}^n$. It is Example 3.10 of [21] and we recall it briefly. We set $I = \mathbb{R}$ and define $\Psi: T^*\mathbb{R}^n \times I \to T^*\mathbb{R}^n$, by $\Psi_s(x; \xi) = (x + s\frac{\xi}{||\xi||}; \xi)$. It is the Hamiltonian flow of $h(x; \xi) = ||\xi||$. For $s > 0$ we define $U_s = \{(x, y) \in \mathbb{R}^2n;$. 
We can compute its restriction to $-L||K$ (see the lines before (1.5.7) for the definition of the composition $K$ where $U$ that is not split, that is, $\Delta_{\Psi,s}$ contractible. It follows that $\Delta_{\Psi,s} \approx K$ since $\Delta_{\Psi,s} \approx K$. Thus have a bound for the microsupport of a composition (Lemma 1.5.1) which says in our case that $K_s \circ K_t \approx K_{s+t}$ and we can expect that the sheaf associated with $\Psi$ is given on $s > 0$ by $K = k_U[n]$, where $U = \{(x,y,t) \in \mathbb{R}^{2n+1}; s > 0, ||x - y|| < s\}$.

What about negative times? For $s > 0$ we have

$$K_s^{-1} \simeq v^{-1} R\mathcal{H}om(K_s, q_2^!(\mathcal{O}_{\mathbb{R}^n})) \simeq v^{-1} R\mathcal{H}om(K_s, k_{\mathbb{R}^{2n}}[n]) \simeq k_{\mathbb{R}^{2n}},$$

(see the lines before (1.5.7) for the definition of $K_s^{-1}$ and use (1.1.5)). The composition $K_s^{-1} \circ K$ is a sheaf on $\mathbb{R}_{>0}$. We shift it by $s$ to the left and get a sheaf, say $L(s)$, on $]-s, +\infty[$, whose restriction to $\mathbb{R}_{>0}$ is $K$. We can compute its restriction to $]-s, 0]$ and find $L(s)|_{]-s, +\infty[} \simeq k_{(\mathcal{O}_{\mathbb{R}^n})}$ where $i(x, y, t) = (x, y, -t)$. The microsupport of $L(s)$ is again given by Lemma 1.5.1 and thus is the graph of $\Psi$. Since $L(s)|_{\mathbb{R}^{2n} \times \{0\}} \simeq k_{\Delta_{\mathbb{R}^n}}$ we deduce that $L(s) \simeq K_\Psi$. We can take $s$ arbitrarily big and obtain

$$\begin{cases}
K_\Psi|_{\mathbb{R}^{2n} \times [0, +\infty[} \simeq k_U[n], \\
K_\Psi|_{\mathbb{R}^{2n} \times [-\infty, 0]} \simeq k_Z,
\end{cases}$$

where $U = \{(x, y, s) \in \mathbb{R}^{2n+1}; s > 0, ||x - y|| < s\}$ and $Z = \{(x, y, s) \in \mathbb{R}^{2n+1}; s \leq 0, ||x - y|| \leq -s\}$. We remark that we have a distinguished triangle

$$\text{2.1.3} \quad k_U[n] \rightarrow K_\Psi \rightarrow k_Z \overset{u}{\rightarrow} k_U[n + 1]$$

which is not split, that is, $K_\Psi \not\approx k_Z \oplus k_U[n]$. Indeed this would imply $\text{SS}(K_\Psi) = \text{SS}(k_U) \cup \text{SS}(k_Z)$. But Example 1.2.2 (iv) says that $\text{SS}(k_Z)$ is bigger than the graph of $\Psi$ at the points $T^*\mathbb{R}^{2n+1}$ above $\Delta_{\mathbb{R}^n} \times \{0\}$. In particular the morphism $u$ in (2.1.3) is non zero. The computation

$$R\mathcal{H}om(k_Z, k_U) \simeq R\mathcal{H}om(k_Z, D'(k_\mathcal{O})) \simeq R\mathcal{H}om(k_Z \otimes k_\mathcal{O}, k_{\mathbb{R}^{2n+1}})$$

$$\simeq R\mathcal{H}om(k_{\Delta_{\mathbb{R}^n} \times \{0\}}, k_{\mathbb{R}^{2n+1}}) \simeq k_{\Delta_{\mathbb{R}^n} \times \{0\}}[-n - 1]$$
shows that \( \text{Hom}(k_Z, k_U[n+1]) \simeq k \). Hence, if \( k \) is a field, we have only one non trivial distinguished triangle like (2.1.4) up to isomorphism (see Lemma 4.4.4 below).

For a conic subset \( A \) of \( \tilde{T}^*(N) \) we let \( D_A(k_N) \) be the full subcategory of \( D(k_N) \) formed by the \( F \) with \( SS(F) \subset A \) (this is denoted \( D_{A,T^*_N}(k_N) \) in [30]). Using the notation \( o^a \) of (1.5.3) we define \( \Lambda' \subset \tilde{T}^*(N \times I) \) by \( \Lambda' = \Lambda \circ o^a A \). More explicitly we have

\[
(2.1.5) \quad A' = \{(\Psi(x, \xi, s), (s; -h(\Psi(x, \xi, s), s)); (x; \xi) \in A, s \in I\}.
\]

We see that \( A' \) is non-characteristic for the inclusion \( i_s \), for any \( s \in I \). Moreover \( i_s^{-1}(A') = \Psi_s(A) \). We obtain an inverse image

\[
(2.1.6) \quad i_s^{-1}: D_{A'}(k_{N \times I}) \to D_{\Psi_s(A)}(k_N).
\]

We can deduce from Theorem 2.1.1 that it is an equivalence (see [21, §3.4]), with an inverse induced by \( K_\Psi \) (however the categories involved in (2.1.6) and the functor \( i_s^{-1} \) only depend on the sets \( \Psi_s(A), A' \), not on \( \Psi \) itself):

**Corollary 2.1.4.** (i) For any \( s \in I \) the composition \( F \mapsto K_{\Psi,s} \circ F \) induces an equivalence of categories \( D:A(k_N) \rightleftharpoons D_{\Psi_s(A)}(k_N) \), where \( K_{\Psi,s} = K_{\Psi}|_{N \times \{s\}} \).

(ii) For any \( s \in I \) the inverse image functor (2.1.6) is an equivalence of categories, with an inverse given by \( F \mapsto K_{\Psi} \circ K_{\Psi,s}^{-1} \circ F \). In particular, for any \( F, G \in D(k_N) \), we have isomorphisms

\[
(2.1.7) \quad \text{Hom}(F, G) \rightleftharpoons \text{Hom}(K_{\Psi} \circ F, K_{\Psi} \circ G)
\]

and \( R\Gamma(N; G) \rightleftharpoons R\Gamma(N \times I; K \circ G) \rightleftharpoons R\Gamma(N; K_{\Psi,s} \circ G) \).

**Remark 2.1.5.** Instead of composing with \( K_{\Psi} \) on the left in Corollary 2.1.4 we can compose on the right. We can also add parameters, that is, consider \( F, G \) on a product \( N \times P \) or \( P \times N \) for some other manifold \( P \). We only quote the following formulas for later use: let \( F, G \in D(k_{N \times P}) \), \( F', G' \in D(k_{P \times N}) \) be given; then the restriction at time \( 0 \in I \) gives isomorphisms

\[
(2.1.8) \quad \text{Hom}_{D(k_{N \times P})}(K_{\Psi} \circ F, K_{\Psi} \circ G) \rightleftharpoons \text{Hom}_{D(k_{N \times P})}(F, G),
\]

\[
(2.1.9) \quad \text{Hom}_{D(k_{P \times N})}(F' \circ K_{\Psi}, G' \circ K_{\Psi}) \rightleftharpoons \text{Hom}_{D(k_{P \times N})}(F', G').
\]

### 2.2. Local behaviour

We check here that the restriction of \( K_{\Psi,s} \circ F \) to an open subset \( V \) of \( N \) only depends on \( F|_U \) for some bigger open subset \( U \).
Lemma 2.2.1. Let $U$, $V$ be two open subsets of $N$ and let $s \in I$ be given. We assume that $\Psi_t^{-1}(\hat{T}^*V) \subset \hat{T}^*U$ for all $t \in [0, s]$. Then, for any $F \in D(k_N)$, the morphism $F_U \rightarrow F$ induces an isomorphism

$$(K_\Psi \circ F_U)|_{V \times [0, s]} \simeq (K_\Psi \circ F)|_{V \times [0, s]}.$$

In particular $(K_\Psi, s \circ F_U)|_V \simeq (K_\Psi, s \circ F)|_V$.

Proof. Let us set $G = K_\Psi \circ F_{N \setminus U} \in D(k_{N \times I})$. We have a distinguished triangle $K_\Psi \circ F_U \rightarrow K_\Psi \circ F \rightarrow G \xrightarrow{+1} \rightarrow$ and the assertion of the lemma is equivalent to $G|_{V \times [0, s]} \simeq 0$. Since $G_0|_V \simeq 0$ it is enough to see that $G|_{V \times [0, s]}$ is locally constant.

We first remark that $G_t|_V$ is locally constant for each $t \in [0, s]$. Indeed $SS(G_t) = \Psi_t(\hat{SS}(F_{N \setminus U})) \subset \Psi_t(\hat{T}^*N \setminus \hat{T}^*U)$ and the hypothesis $T^*V \subset \Psi_t(\hat{T}^*U)$ implies $\hat{SS}(G_t) \cap \hat{T}^*V = \emptyset$. It follows that $G$ is locally on $V \times [0, s]$ of the form $G \simeq q^{-1}F$ for some $F \in D(k_I)$, where $q : N \times I \rightarrow I$ is the projection. Hence $SS(G|_{V \times [0, s]}) \subset T^*_N N \times T^*I$. On the other hand $G$ is non-characteristic for the inclusion of $N \times \{t\}$ in $N \times I$, for any $t \in I$. Hence $SS(G) = \emptyset$ as required.

Proposition 2.2.2. Let $F, G \in D(k_N)$. The restriction morphism

$$i_0^{-1}\text{RHom}(K_\Psi \circ F, K_\Psi \circ G) \rightarrow \text{RHom}(F, G)$$

is an isomorphism.

Proof. We set $F' = K_\Psi \circ F$, $G' = K_\Psi \circ G$. It is enough to check that the restriction morphism induces an isomorphism in each degree of the germs at any point $x \in N$. We recall that $H^0(U; \text{RHom}(F, G)) \simeq \text{Hom}(F|_U, G|_U) \simeq \text{Hom}(F_U, G)$. Hence

$$(H^k\text{RHom}(F, G))_x \simeq \lim_{x \in U} \text{Hom}(F|_U, G[k]|_U),$$

$$
(2.2.1) \quad (H^k\text{RHom}(F', G'))_{(x, 0)} \simeq \lim_{(x, 0) \in U \times J} \text{Hom}(F'|_{U \times J}, G'[k]|_{U \times J}),$$

where $U$ runs over the open neighborhoods of $x \in N$ and $J$ over the neighborhoods of $0 \in I$. For such $U$ and $J$, with $J$ contractible, we have $\text{Hom}(K_\Psi \circ F_U|_{N \times J}, G'|[k]|_{N \times J}) \simeq \text{Hom}(F_U, G[k])$ by (2.1.7). If $V \subset U$ satisfies $\Psi_t^{-1}(\hat{T}^*V) \subset \hat{T}^*U$ for all $t \in J$, then $K_\Psi \circ F_U|_{V \times J} \simeq K_\Psi \circ F|_{V \times J}$ by Lemma 2.2.1. We deduce a natural morphism $\text{Hom}(F_U, G[k]) \rightarrow \text{Hom}(F|_{V \times J}, G'[k]|_{V \times J})$ which gives a commutative diagram

$$
\begin{array}{ccc}
\text{Hom}(F'|_{U \times J}, G'[k]|_{U \times J}) & \rightarrow & \text{Hom}(F|_U, G[k]|_U) \\
\downarrow & & \downarrow \\
\text{Hom}(F'|_{V \times J}, G'[k]|_{V \times J}) & \rightarrow & \text{Hom}(F|_V, G[k]|_V).
\end{array}
$$
It follows that the two limits in (2.2.1) are isomorphic, which proves the proposition. □

Let $A$ be a conic subset of $\hat{T}^*N$ and let $A' \subset T^*(N \times I)$ be as in (2.1.5). Let $U$ be an open subset of $N$. We would like to find a neighborhood $V$ of $U \times \{0\}$ in $N \times I$ such that the inverse image by the inclusion of $U$ in $V$ is an equivalence of categories $D_{A \cap T^*U}(k_V) \sim D_{A' \cap T^*U}(k_U)$. We don’t know if such a $V$ always exists and give a weaker statement which will be sufficient for our purposes.

Proposition 2.2.3. Let $A \subset \hat{T}^*N$ and $A' \subset T^*(N \times I)$ be as in (2.1.5). Let $j: U \rightarrow N$ be the inclusion of an open subset.

(i) Let $F \in D_{A' \cap T^*V}(k_U)$. Then there exist a neighborhood $V$ of $U \times \{0\}$ in $N \times I$ and $G \in D_{A' \cap T^*V}(k_V)$ such that $F \simeq G|_{U \times \{0\}}$.

(ii) Let $V$ be a neighborhood of $U \times \{0\}$ in $N \times I$ and $G \in D_{A' \cap T^*V}(k_V)$. Then there exists a smaller neighborhood $V'$ of $U \times \{0\}$ such that $G|_{V'} \simeq (K_{\Psi} \circ F)|_{V'}$, where $F = R_{j_!}(G|_{U \times \{0\}})$. In particular, for $G, G' \in D_{A' \cap T^*V}(k_V)$ the inverse image by the inclusion gives an isomorphism

$$R\text{Hom}(G, G')|_{U \times \{0\}} \overset{\sim}{\rightarrow} R\text{Hom}(G|_{U \times \{0\}}, G'|_{U \times \{0\}})$$

and, if $G|_{U \times \{0\}} \simeq G'|_{U \times \{0\}}$, then there exists a smaller neighborhood $V''$ of $U \times \{0\}$ such that $G|_{V''} \simeq G'|_{V''}$.

Proof. (i) We set $F' = R_{j_!}F$ and $G' = K_{\Psi} \circ F'$. We have the rough bounds $SS(F') \subset A \cup \pi_N^{-1}(\partial U)$ and $SS(G') \subset A' \cup \pi_N^{-1}(Z)$ where $Z = \bigcup_{s \in I} Z_s \times \{s\}$ and $Z_s = \pi_N(\Psi_s(\pi_N^{-1}(\partial U)))$. Then $V = N \times I \setminus Z$ is a neighborhood of $U \times \{0\}$ and $G = G'|_V$ has the required property.

(ii) We let $k: V \rightarrow N \times I$ be the inclusion and set $G_1 = Rk_!G$, $H = K_{\Psi}^{-1} \circ |_I G_1$. Then $H \in D(k_{N \times I})$ and $H_s \simeq K_{\Psi,s}^{-1} \circ (G_1|_{N \times \{s\}})$. Using the notation $\Lambda_{\Psi} \circ a - (2.1.3)$ we have $SS(H) \subset \Lambda_{\Psi^{-1}} \circ a|_I SS(G_1)$.

Then

$$SS(H) \subset \Lambda_{\Psi^{-1}} \circ a|_I SS(G_1)$$

$$\subset \Lambda_{\Psi^{-1}} \circ a|_I (A' \cup \pi_N^{-1}(\partial V)) \subset (A \times T_I^*I) \cup B,$$

where $B = \Lambda_{\Psi^{-1}} \circ a|_I \pi_N^{-1}(\partial V)$. We remark that $W = (N \times I) \setminus \pi(B)$ is a neighborhood of $U \times \{0\}$. We let $V_1 \subset V \cap W \cap (U \times I)$ be a smaller neighborhood such that the fibers of the projection $p: V_1 \rightarrow U$ are intervals. Then $SS(H|_{V_1}) \subset A \times T_I^*I$ and Proposition (2.2.8) implies that $H|_{V_1} \simeq p^{-1}(F)$ for some $F \in D(k_U)$. Hence $K_{\Psi}^{-1} \circ |_I Rk_!G$ is isomorphic with $Rj_!F \boxtimes k_I$ on some neighborhood on $U$ in $N \times I$. It follows easily
that $Rk_i G$ is isomorphic with $K_\Psi \circ |_I (R_j F \boxtimes k_i) \simeq K_\Psi \circ R_j F$ on some smaller neighborhood $V'$.

In the same way $G'$ can be written $G'|_{V'} \simeq (K_\Psi \circ F')|_{V'}$, maybe up to shrinking $V'$. Now the last assertions of the proposition follow from Proposition 2.2.2 and Corollary 2.1.4.

2.3. Non homogeneous case

Now we consider the case of a non homogeneous Hamiltonian isotopy on the cotangent bundle $T^*M$ of some manifold $M$. We reduce this case to the homogeneous framework by a common trick of adding one variable. Let $(x; \xi)$ and $(t; \tau)$ be the coordinates on $T^*M$ and $T^*\mathbb{R}$. We define $\rho_M: T^* M \times T^* \mathbb{R} \rightarrow T^* M$ by

\[(2.3.1) \quad \rho_M(x; t; \xi, \tau) = (x; \xi/\tau)\]  

The fibers of $\rho_M$ have dimension 2. They are stable by the translation in the $t$ variable and are conic, that is, stable by the action of $\mathbb{R}_{>0}$ on the fibers of $\dot{T}^*(M \times \mathbb{R})$. Let $\Phi: T^* M \times I \rightarrow T^* M$ be a Hamiltonian isotopy of class $C^\infty$. We assume that $\Phi$ has compact support, that is, there exists a compact subset $C \subset T^* M$ such that $\Phi(p, s) = p$ for all $p \in T^* M \setminus C$ and all $s \in I$. Then $\Phi$ is the Hamiltonian flow of a function $h: T^* M \times I \rightarrow \mathbb{R}$ such that $h$ is locally constant outside $C \times I$. In particular, if $M$ does not have a connected component diffeomorphic to the circle $S^1$, then any Hamiltonian isotopy on $T^* M$ with compact support can be defined by a Hamiltonian function $h$ with compact support.

**Proposition 2.3.1** (See Prop. A.6 of [21]). Let $\Phi: T^* M \times I \rightarrow T^* M$ be a Hamiltonian isotopy with compact support and let $h: T^* M \times I \rightarrow \mathbb{R}$ be a function with Hamiltonian flow $\Phi$.

(i) Let $h': \dot{T}^*(M \times \mathbb{R}) \times I \rightarrow \mathbb{R}$ be the Hamiltonian function given by $h'((x; t; \xi, \tau), s) = \tau h((x; \xi/\tau), s)$. Then the flow $\Phi'$ of $h'$ is a homogeneous Hamiltonian isotopy $\Phi': \dot{T}^*(M \times \mathbb{R}) \times I \rightarrow \dot{T}^*(M \times \mathbb{R})$ whose restriction to $T^* M \times \dot{T}^* \mathbb{R} \times I$ gives the commutative diagram

\[(2.3.2) \quad \begin{array}{ccc}
T^* M \times \dot{T}^* \mathbb{R} \times I & \xrightarrow{\Phi'} & T^* M \times \dot{T}^* \mathbb{R} \\
\downarrow_{\rho_M \times \text{id}_I} & & \downarrow_{\rho_M} \\
T^* M \times I & \xrightarrow{\Phi} & T^* M .
\end{array}\]

(ii) The isotopy $\Phi'$ preserves the subset $\{\tau > 0\}$ of $\dot{T}^*(M \times \mathbb{R})$ and commutes with the vertical translations $T_c$ of $\dot{T}^*(M \times \mathbb{R})$ given by $T_c(x; t; \xi, \tau) = (x, t+c; \xi, \tau)$, for all $c \in \mathbb{R}$. Defining $q: (M \times \mathbb{R})^2 \times I \rightarrow$
Part a given sheaf with respect to a partition of its microsupport (see Proposition 3.3.2 below). One version of the cut-off lemma says that SS(\(G\)) \(\simeq\) SS(\(F\)) \(\cap\) \(T^*_0\mathbb{R}^n\) and a cone \(C \subset T^*_0\mathbb{R}^n\), a given neighborhood \(\Omega\) of SS(\(G\)) \(\cap\) \(\partial C\) in \(T^*M\), it is possible to find \(G\) with SS(\(G\)) = SS(\(F\)) \(\cap\) (SS(\(F\)) \(\cap\) \(C\)) \(\cup\) \(\Omega\) near \(T^*_0\mathbb{R}^n\) (see Proposition 3.3.2 below). One version of the cut-off lemma says
that the category of sheaves on $V = \mathbb{R}^n$ with microsupport in some convex cone $\gamma$ is equivalent to the category of sheaves on $V$ endowed with another topology. We use it to prove that $\text{SS}(H^i(F))$ is contained in the convex hull of $\text{SS}(F)$ (see Corollary 3.4.3 below — this will be used to construct a graph selector in Part 5).

3.1. Global cut-off

Let $V$ be a vector space and let $\gamma \subset V$ be a closed convex cone (with vertex at 0). We denote by $\gamma^o = - \gamma$ its opposite cone and by $\gamma^0 \subset V^*$ its polar cone (see (1.2.2)). We also define $\tilde{\gamma} = \{(x, y) \in V^2; x - y \in \gamma\}$. Let $q_i : V^2 \to V$, $i = 1, 2$, be the projection to the $i^{th}$ factor. The following functors are introduced in [30]:

\[ \begin{align*}
(3.1.1) & \quad P_\gamma : \text{D}(k_V) \to \text{D}(k_V), \quad F \mapsto Rq_{2*}(k_{\gamma} \otimes q_1^{-1} F), \\
(3.1.2) & \quad Q_\gamma : \text{D}(k_V) \to \text{D}(k_V), \quad F \mapsto Rq_{2!}(R\text{Hom}(k_{\gamma^o}, q_1^! F)), \\
(3.1.3) & \quad P'_\gamma : \text{D}(k_V) \to \text{D}(k_V), \quad F \mapsto Rq_{2!}(R\text{Hom}(k_{\gamma}, q_1^! F)),
\end{align*} \]

where $K_\gamma = k_{\gamma^0 \setminus \Delta V}[1]$. For $\gamma = \{0\}$, the set $\tilde{\gamma}$ is the diagonal of $V^2$ and we have $P_{\{0\}}(F) \simeq Q_{\{0\}}(F) \simeq F$. We also have a distinguished triangle $k_{\gamma^0} \to k_{\Delta V} \to k_\gamma[1]$. We deduce morphisms of functors

\[ \begin{align*}
(3.1.4) & \quad u_\gamma : P_\gamma \to \text{id}, \quad v_\gamma : \text{id} \to Q_\gamma, \quad u'_\gamma : P'_\gamma \to \text{id}
\end{align*} \]

and, for any $F \in \text{D}(k_V)$, a distinguished triangle

\[ \begin{align*}
(3.1.5) & \quad P'_\gamma(F) \xrightarrow{u'_\gamma(F)} F \xrightarrow{v_\gamma(F)} Q_\gamma(F) \xrightarrow{1}
\end{align*} \]

If $F$ has compact support we can write $P_\gamma(F) \simeq F \circ k_\gamma$ and (1.5.2) gives $(P_\gamma(F))_y \simeq R\Gamma(V; F \otimes k_{y+\gamma})$, for $y \in V$.

The easiest examples are the images of the skyscraper sheaf $k_{\{x\}}$ for a given $x \in V$: $P_\gamma(k_{\{x\}}) \simeq k_{-\gamma}$ and $Q_\gamma(k_{\{x\}}) \simeq k_{\text{Int}(x+\gamma)}[d_V]$, where $d_V$ is the dimension of $V$. The morphism $v_\gamma(k_{\{x\}})$ is given by the image of 1 in the sequence of isomorphisms: $\text{Hom}(k_{\{x\}}, k_{\text{Int}(x+\gamma)}[d_V]) \simeq \text{Hom}(k_{\{x\}}, \text{D}(k_{\gamma+\gamma})) \simeq \text{Hom}(k_{\{x\}} \otimes k_{x+\gamma}, k_{V}[d_V]) \simeq H^d_{\{x\}}(k_{V}) \simeq k$.

We use the identifications $T_x^V = V^*$ for any $x \in V$ and $T^*V = V \times V^*$. If $F$ has compact support, the results of Section 1.2.2 give, for any $x \in V$,

\[ \begin{align*}
(3.1.6) & \quad \text{SS}(P_\gamma(F)) \cap T_x^*V \subset p_2(\text{SS}(F) \cap \text{SS}(k_{x+\gamma}))_0), \\
(3.1.7) & \quad \text{SS}(Q_\gamma(F)) \cap T_x^*V \subset p_2(\text{SS}(F) \cap \text{SS}(k_{x+\gamma})),
\end{align*} \]

where $p_2 : T^*V \to T_x^*V$ is the projection. By Example 1.2.2 we obtain in particular (for $F$ with compact support)

\[ \begin{align*}
(3.1.8) & \quad \text{SS}(P_\gamma(F)) \cup \text{SS}(Q_\gamma(F)) \subset V \times \gamma^o.
\end{align*} \]
The first cut-off results say roughly that, conversely, a sheaf is of the form \( P_\gamma(F) \) or \( Q_\gamma(F) \) if its microsupport is contained \( V \times \gamma^{oa} \) (Propositions 3.1.1 and 3.1.2).

For a given subset \( \Omega \) of \( T^*V \), a morphism \( a: F \rightarrow G \) in \( D(k_V) \) is said to be an isomorphism on \( \Omega \) if \( SS(C(a)) \cap \Omega = \emptyset \), where \( C(a) \) is given by the distinguished triangle \( F \rightarrow G \rightarrow C(a) \rightarrow +1 \).

**Proposition 3.1.1** (see [30] Prop. 5.2.3). For \( F \in D(k_V) \) we let \( u_\gamma(F): P_\gamma(F) \rightarrow F \) be the morphism in (3.1.4). Then

(i) \( u_\gamma(F) \) is an isomorphism on \( V \times Int(\gamma^{oa}) \).
(ii) \( u_\gamma(F) \) is an isomorphism if and only if \( SS(F) \subset V \times \gamma^{oa} \).

**Proposition 3.1.2** (see [30] Lem. 6.1.5). We assume that \( \gamma \) is proper (that is, \( \gamma \) contains no line) and \( Int(\gamma) \neq \emptyset \). For \( F \in D(k_V) \) we let \( v_\gamma(F): F \rightarrow Q_\gamma(F) \) be the morphism in (3.1.4). We assume that \( F \) has compact support. Then

(i) \( v_\gamma(F) \) is an isomorphism on \( V \times Int(\gamma^{oa}) \).
(ii) \( v_\gamma(F) \) is an isomorphism if and only if \( SS(F) \subset V \times \gamma^{oa} \).

A reformulation of Proposition 3.1.1 is that we can embed a sheaf \( F \) in a distinguished triangle

\[
(3.1.9) \quad P_\gamma(F) \xrightarrow{u_\gamma(F)} F \rightarrow F' \xrightarrow{+1} G,
\]

where

\[
(3.1.10) \quad SS(P_\gamma(F)) \cap (V \times Int(\gamma^{oa})) = SS(F) \cap (V \times Int(\gamma^{oa})),
\]

\[
(3.1.11) \quad SS(F') \cap (V \times (V^* \setminus \gamma^{oa})) = SS(F) \cap (V \times (V^* \setminus \gamma^{oa})).
\]

However \( SS(P_\gamma(F)) \cap (V \times \partial \gamma^{oa}) \) could be bigger than \( SS(F) \cap (V \times \partial \gamma^{oa}) \). If we assume that \( SS(F) \) does not meet \( V \times \partial \gamma^{oa} \), then this still holds for \( SS(P_\gamma(F)) \) and (3.1.10) actually implies \( SS(P_\gamma(F)) = SS(F) \cap (V \times Int(\gamma^{oa})). \) Moreover, under the hypothesis of Proposition 3.1.2 the triangle (3.1.9) is split, up to a constant sheaf. We state this result in Proposition 3.1.3 below. For applications we will need a weaker hypothesis than \( SS(F) \cap (V \times \partial \gamma^{oa}) = \emptyset \). Before we explain the hypothesis we introduce some notations.

Let \( \gamma \subset V \) be a closed convex proper cone. For \( x \in V \) we define \( S_x^{\gamma} \subset T^*V \) by

\[
(3.1.12) \quad S_x^{\gamma} = (SS(k_{x+\gamma})^a \cup SS(k_{x+\gamma}^a)) \backslash \{ x \} \times Int(\gamma^{oa})
\]

\[
= (SS(k_{x+\gamma})^a \cup SS(k_{x+\gamma}^a)) \cap (V \times \partial \gamma^{oa}),
\]

where the second equality follows from Example 1.2.2(iv). We can give an easy description of \( S_x^{\gamma} \) when \( \gamma \) has a smooth boundary away
from 0. For example in $\mathbb{R}^n$ with coordinates $x = (x', x_n)$ we define 
$\gamma = \{(x', x_n) \in V; \ x_n \leq -\|x'\|\}$ and $C = \{(x', x_n) \in V; \ x_n = \pm \|x'\|\}$. Then $(x_0 + \gamma) \cup (x_0 + \gamma^o)$ has boundary $C_{x_0} = x_0 + C$, which is a smooth hypersurface except at $x_0$. We set $C_{x_0}' = C_{x_0} \setminus \{x_0\}$ and define 
$\Lambda = \bigcap_{C_{x_0}'} \mathbb{R}^n \cap T^*\mathbb{R}^n$. Then $\Lambda$ is a smooth closed conic Lagrangian submanifold of $T^*\mathbb{R}^n$ with two connected components and $S_{x_0}^\gamma$ is the component with $\xi_n > 0$.

We deduce from (3.1.6), (3.1.7) and Example 12.22(iv) that, if $F \in \mathcal{D}(k_V)$ has compact support, then, for $G = P_\gamma(F)$ or $G = Q_\gamma(F)$,

$$\dot{S}(G) \cap (T^*_x V \setminus \text{Int}(\gamma^o)) \subset p_2(\dot{S}(F) \cap S_x^\gamma).$$

Since $u_\gamma(F)$ and $v_\gamma(F)$ are isomorphisms on $V \times \text{Int}(\gamma^o)$, we also have

$$\dot{S}(G) \cap (V \times \text{Int}(\gamma^o)) = \dot{S}(F) \cap (V \times \text{Int}(\gamma^o)).$$

**Proposition 3.1.3.** Let $F \in \mathcal{D}(k_V)$ be such that $\text{supp}(F)$ is compact and let $W \subset V$ be an open subset such that

$$S_x^\gamma \cap \dot{S}(F) = \emptyset \quad \text{for any } x \in W.$$ 

Then $v_\gamma(F) \circ u_\gamma(F) |_W: P_\gamma(F)|_W \to Q_\gamma(F)|_W$ is an isomorphism on $T^*W$ and we have a distinguished triangle in $\mathcal{D}(k_W)$

$$P_\gamma(F)|_W \oplus P_\gamma'(F)|_W \xrightarrow{(u_\gamma(F), u_\gamma'(F))} F|_W \xrightarrow{L + 1} ,$$

where $L \in \mathcal{D}(k_W)$ is locally constant and

$$\dot{S}(P_\gamma(F)|_W) = \dot{S}(F) \cap (W \times \text{Int}(\gamma^o)),$$

$$\dot{S}(P_\gamma'(F)|_W) = \dot{S}(F) \cap (W \times (V \setminus \gamma^o)).$$

**Proof.** (i) For $G = P_\gamma(F)$ or $G = Q_\gamma(F)$, we have

$$\dot{S}(G) = \dot{S}(F) \cap (W \times \text{Int}(\gamma^o))$$

by (3.1.8), (3.1.13), (3.1.15) and (3.1.14).

(ii) We define $L \in \mathcal{D}(k_W)$ by the distinguished triangle

$$P_\gamma(F)|_W \xrightarrow{v_\gamma(F) \circ u_\gamma(F)} Q_\gamma(F)|_W \xrightarrow{L + 1} .$$

By (i) we have $\dot{S}(L) \subset W \times \text{Int}(\gamma^o)$. On the other hand $v_\gamma(F) \circ u_\gamma(F)$ is an isomorphism on $W \times \text{Int}(\gamma^o)$ by Propositions 3.1.1 and 3.1.2.

Hence $\dot{S}(L) \cap (W \times \text{Int}(\gamma^o)) = \emptyset$ and we find $\dot{S}(L) = \emptyset$. This proves the first assertion.

(iii) The distinguished triangle of the proposition follows from the triangles (3.1.5), (3.1.7) and Lemma 3.1.4 applied with $A = P_\gamma(F)|_W$, $B = F|_W$, $C = P_\gamma'(F)|_W$, $C' = Q_\gamma(F)|_W$, $D = L$. 

Since $\nu_F$ is an isomorphism on $V \times \text{Int}(\gamma \circ a)$, the triangle (3.1.5) gives $\tilde{\text{SS}}(P'_\gamma(F)|_W) \cap (W \times \text{Int}(\gamma \circ a)) = \emptyset$. It follows that $\tilde{\text{SS}}(P'_\gamma(F)|_W)$ and $\text{SS}(P_\gamma(F)|_W)$ are disjoint. Hence (3.1.10) implies
\[ \tilde{\text{SS}}(F) = \tilde{\text{SS}}(P'_\gamma(F)|_W) \cup \text{SS}(P_\gamma(F)|_W). \]
Since (3.1.15) implies in particular $\tilde{\text{SS}}(F) \cap (W \times \partial(\gamma \circ a)) = \emptyset$, the triangular inequality for the microsupport implies the last equalities of the proposition.

**Lemma 3.1.4.** We assume to be given a morphism $a: A \to B$ in a triangulated category and two distinguished triangles
\[ C \xrightarrow{c} B \xrightarrow{c'} C' \xrightarrow{+1}, \quad A \xrightarrow{c \circ a} C' \to D \xrightarrow{+1}. \]
Then there exists a distinguished triangle
\[ A \oplus C \xrightarrow{(a,c)} B \to D \xrightarrow{+1}. \]

**Proof.** We define $E$ by the distinguished triangle $A \oplus C \xrightarrow{(a,c)} B \to E \xrightarrow{+1}$. We also have the canonical triangle $C \xrightarrow{u} A \oplus C \xrightarrow{v} A \xrightarrow{+1}$ where $u = (0, \text{id}_C)$ and $v = (\text{id}_A, 0)$. Since $(a,c) \circ u = c: C \to B$, the octahedral axiom applied to this last two triangles and the first one in the statement gives a distinguished triangle
\[ A \xrightarrow{w} C' \to E \xrightarrow{+1} \]
such that $w \circ v = c' \circ (a,c)$. This implies $w = c' \circ a$. Hence $E \simeq D$ and the lemma follows.

### 3.2. Local cut-off

In order to use Propositions 3.1.1 and 3.1.2 we need a knowledge of the microsupport of $F$ over $V$. If we only have a bound $\text{SS}(F|_U) \subset U \times \gamma \circ a$ for some small open subset $U$ of $V$, we first try to replace $F$ by $F_Z$, for a subset $Z \subset U$ such that $\overline{Z} \subset U$; this $F_Z$ can then be extended by 0 without increasing its microsupport. However, near the boundary of $Z$, we lose the control of $\text{SS}(F)$, because we only have a general bound $\text{SS}(F_Z) \subset \text{SS}(F) + \text{SS}(k_Z)$ (under suitable hypothesis). In fact, it is possible to find $Z, W \subset U$ such that $F_Z$ and $W$ satisfies (3.1.15). This is done in [30, Prop. 6.1.4] for a convex cone $\gamma$. In Proposition 3.3.1 we will generalize this result to a more general cone, using Theorem 2.1.1 to reduce the situation to the case of a convex cone. Since we can as well reduce to a very special cone, we only explain a particular case of [30, Prop. 6.1.4] (the proof is not different from that of [30] but
the exposition is easier). This is Proposition 3.2.2 below. We first introduce some notations.

We write \( V = V' \times \mathbb{R} \), where \( V' = \mathbb{R}^{n-1} \). We take coordinates \( x = (x', x_n) \) on \( V \) and we endow \( V' \) and \( V \) with the natural Euclidean structure. For \( c > 0 \) we let \( \gamma_c \subset V \) be the cone
\[
\gamma_c = \{(x', x_n) \in V; \, x_n \leq -c \|x'n\|\}.
\]
We consider a sheaf \( F \) defined in a neighborhood \( U \) of \( 0 \in V \) satisfying \( SS(F) \subset U \times (\gamma_c^c \cup \gamma_c^{oa}) \). We look for other neighborhoods of \( 0, W, Z \subset U \), such that \( S_x^{2c} \cap SS(F_Z) = \emptyset \), for all \( x \in W \). We take for \( Z \) the union of a closed and an open cylinder:
\[
Z^h_r = \{(x', x_n) \in V; \, \|x'n\| \leq r, \, -h \leq x_n < 0\}
\]
\[
\sqcup \{(x', x_n) \in V; \, \|x'n\| < r, \, 0 \leq x_n < h\}.
\]
By Theorem 1.2.11 it is easy to bound \( SS(F \otimes k_{Z^h_r}) \) over the vertical boundary of \( Z^h_r \): for \( y = (y', y_n) \) with \( \|y'n\| = r \) and \( 0 < \|y_n\| < h \) we have
\[
SS(k_{Z^h_r}) \cap T^*_y V = \mathbb{R}_{\geq 0} \cdot (y; (\frac{y_n}{|y_n|}\xi', 0)),
\]
where \( \xi' \in (V')^* \) corresponds to \( y' \) through the identification \( V' \simeq (V')^* \) given by the Euclidean product; this gives
\[
SS(F \otimes k_{Z^h_r}) \cap T^*_y V \subset (\gamma_c^c \cup \gamma_c^{oa}) + \mathbb{R}_{\geq 0} \cdot (y; (\frac{y_n}{|y_n|}\xi', 0)).
\]

**Lemma 3.2.1.** Let \( c, r, h \) be positive numbers such that \( h > 2cr \). Then \( \pi_V(S_0^{2c}) \) meets the boundary of \( Z^h_r \) only along its vertical part and away from \( \{y_n = 0\} \) and we have
\[
S_0^{2c} \cap (SS(k_{Z^h_r}) + V \times (\gamma_c^c \cup \gamma_c^{oa})) = \emptyset.
\]

**Proof.** The first assertion follows from the hypothesis \( h > 2cr \). It is then enough to check the last part at points \( y = (y', y_n) \in \pi_V(S_0^{2c}) \) with \( \|y'n\| = r \) and \( 0 < \|y_n\| < h \). In \( T^*_y V \simeq V^* \) we have two half lines \( l_1 = S_0^{2c} \cap T^*_y V \) and \( l_2 = SS(k_{Z^h_r}) \cap T^*_y V \). Indeed \( \pi_V(S_0^{2c}) \) is a smooth hypersurface at \( y \) and \( S_0^{2c} \) is the half part of its conormal bundle contained in \( \{\xi_n > 0\} \); the half line \( l_2 \) is generated by \( \frac{y_n}{|y_n|}\xi' \) see (3.2.3). Let \( P \) be the plane in \( T^*_y V \) generated by \( l_1 \) and \( l_2 \). Then \( C = P \cap (\gamma_c^c \cup \gamma_c^{oa}) \) consists in two opposite cones and \( l_1, l_2 \) are not in the same connected component of \( P \setminus C \). The result follows. \( \square \)

**Proposition 3.2.2.** Let \( c, r, h \) be such that \( h > 2cr \) and let \( Z^h_r \) be as defined in (3.2.2). Let \( U \) be an open neighborhood of \( Z^h_r \). Then there exist an open neighborhood \( W \) of \( 0 \) in \( U \) and two functors \( P, P': D(k_U) \to \)
that, for any $r, h$

$Y$

Proof.

As in the proof of Lemma 3.2.1 we consider the half lines $SS(\cdot)$ of Lemma 3.2.1 holds with $S$ replaced by $S_t^{\gamma_2c}$. This condition on $x$ is open and Lemma 3.2.1 says that $0 \in W$. Hence $W$ is an open neighborhood of 0.

For $F \in D(k_U)$ we can extend $F \otimes k_{Z^p_0}^b$ by 0 as an object of $D(k_V)$. We define $P, P'$ by $P = P_* \otimes k_{Z^p_0}^b|_U$ and $P' = P'_* \otimes k_{Z^p_0}^b|_U$. The functors $u, u'$ are induced by $u_{\gamma_2c}, u'_{\gamma_2c}$.

If $F$ satisfies (3.2.5), then $F \otimes k_{Z^p_0}^b$ satisfies the hypothesis (3.1.15) of Proposition 3.1.3: this follows from the bound (3.2.4) and the last assertion of Lemma 3.2.1 (with $S_t^{\gamma_2c}$ replaced by $S_t^{\gamma_2c}$). Now the result follows from Proposition 3.1.3.

Lemma 3.2.3. Let $B \subset V^*$ be a closed conic subset and let $B' \subset V^*$ be a conic neighborhood of $B \cap \{\xi_n = 0\}$. Then there exists $d > 0$ such that, for any $r, h$ with $h > d r$ we have

$(SS(k_{\gamma_2}) \setminus T_0^*V) \cap (SS(k_{\gamma_2}) + V \times B) \subset V \times B'$,

where $Y_r^h = \{(x', x_n) \in V; \|x'\| < r, \|x_n\| < h\}$.

Proof. As in the proof of Lemma 3.2.1 we consider the half lines $l_1 = SS(k_{\gamma_2}) \cap T_0^*V$ and $l_2 = SS(k_{\gamma_2}) \cap T_0^*V$. We have $l_2 \subset \{\xi_n = 0\}$. We remark that $l_2 \cap (l_1 + B) = \emptyset$ if $B \cap (l_2 - l_1) = \emptyset$. If $l_2$ is close enough to $-l_1$ and $B \cap (l_2 - l_1) \neq \emptyset$, then $l_2 \subset B'$. Since $l_1$ converges to $-l_2$ when $d$ tends to $\infty$, the result follows.

Proposition 3.2.4. Let $B \subset V^*$ be a closed conic subset and let $B' \subset V^*$ be a conic neighborhood of $B \cap \{\xi_n = 0\}$. Let $c > 0$. Let $U$ be a neighborhood of 0. Then there exist an open neighborhood $W$ of 0 in $U$ and a functor $R: D(k_U) \to D(k_W)$, together with a morphism of functors $id \to R$, such that, for any $F \in D(k_U)$,
(i) if \( SS(F) \subset U \times B \), then
\[
SS(R(F)) \subset W \times ((B \setminus \{ \xi_n \geq 0 \}) \cup B'),
\]
(ii) if \( SS(F) \subset U \times \{ \xi_n \leq 0 \} \), then \( F|_W \xrightarrow{\sim} R(F) \).

**Proof.** (i) For a cone \( \gamma \) we define \( R_\gamma(F) = Rq_{2*}(k_{|_\gamma \Delta v} \otimes q_1^{-1}F) \). We have a distinguished triangle \( P_\gamma(F) \to F \to R_\gamma(F) \xrightarrow{+1} \) and the bound, as in \((3.1.6)\),
\[
SS(R_\gamma(F)) \cap T^*_x V \subset p_2(SS(F) \cap S_x),
\]
where \( S_x = (SS(k_{(x+\gamma)}\{x\}))^a \). We have \( S = (SS(k_{x+\gamma}))^a \) outside \( T^*_x V \) and \( S \cap T^*_x V = \mathcal{V}^* \setminus \gamma^\infty_a \). We choose \( d \) such that Lemma \(3.2.3\) holds and \( r, h \) such that \( Y^r_h \subset U \). We set \( R(F) = R_{r\gamma}(F_{Y^r_h}) \) and define \( W \) as the set of \( x \) such that the conclusion of Lemma \(3.2.3\) holds with \( \gamma_d \) replaced by \( x + \gamma_d \). Then \( R \) and \( W \) satisfy (i).

(ii) We prove that \( P_{\gamma\delta}(F_{Y^r_h}) \approx 0 \), which implies (ii) by the triangle given in (i). The microsupports of \( F \), \( k_{Y^r_h} \) and \( k_{y+\gamma_d} \), for \( y \in V \), are all contained in \( U \cap \{ \xi_n \leq 0 \} \), at least over \( \{ x_n < h \} \). We set \( E_y = Y^r_h \cap (y + \gamma_d) \). Then \( SS(F_{E_y}) \subset \{ \xi_n \leq 0 \} \) over \( \{ x_n < h \} \) and \( (P_{\gamma\delta}(F_{Y^r_h}))_y \approx R\Gamma(V; F_{E_y}) \) vanishes for \( y < h \), by Corollary \(1.2.14\) \( \Box \).

### 3.3. Local splitting

We prove that a sheaf \( F \) whose microsupport can be decomposed into two disjoint (and unknotted) subsets, say \( SS(F) = S_1 \sqcup S_2 \), can itself be locally decomposed, up to constant sheaves, as \( F_1 \oplus F_2 \) with \( SS(F_1) = S_i \). Moreover this is functorial in \( F \). Here is a more precise statement.

**Proposition 3.3.1.** Let \( U \) be an open subset of \( V = \mathbb{R}^n \) and let \( A, A' \subset V^* \setminus \{0\} \) be two disjoint closed conic contractible subsets. Let \( x_0 \in U \) be given. Then there exist a neighborhood \( W \) of \( x_0 \) and two functors \( P, P': D(k_U) \to D(k_W) \) together with morphisms of functors \( u: P \to r_U^W \), \( u': P' \to r_U^W \) (\( r_U^W \) denoting the restriction functor), such that, for any \( F \in D(k_U) \) satisfying
\[
SS(F) \subset U \times (A \sqcup A'),
\]
we have
\[
\hat{SS}(P(F)) = \hat{SS}(F|_W) \cap (W \times A),
\]
\[
\hat{SS}(P'(F)) = \hat{SS}(F|_W) \cap (W \times A')
\]
and the object \( L \in D(k_W) \) given by the distinguished triangle
\[
P(F) \oplus P'(F) \xrightarrow{(u(F),u'(F))} F|_W \to L \xrightarrow{+1}.
\]
Proof. (i) We may as well set $x_0 = 0$. We use the notation $\gamma_c$ of \eqref{3.2.1}. We choose $c > 0$ and a homogeneous Hamiltonian isotopy $\Phi: \dot{T}^*U \times I \to \dot{T}^*U$, where $I$ is an open interval containing 0 and 1, such that $\Phi_t(\dot{T}^*_0U) = \dot{T}^*_tU$ for all $t \in I$ and

$$\Phi_1(\{0\} \times A) \subset \{0\} \times \gamma^o_c, \quad \Phi_1(\{0\} \times A') \subset \{0\} \times \gamma^{oa}_c.$$ 

To see that such a $\Phi$ exists we choose local coordinates $(x; \xi)$ around 0 and a vector field $X_t = \sum_{i=1}^n a_i(\xi, t)\partial_{\xi_i}$ on $V^*$ which is homogeneous of degree 1 and whose flow at time 1 sends $A$ into $\gamma^o_c$ and $A'$ into $\gamma^{oa}_c$. Then we choose a Hamiltonian function $h: \dot{T}^*U \times I \to \mathbb{R}$ homogeneous of degree 1 in $\xi$ and with support in $C \times V^*$ for some compact set $C$ such that, near 0, we have $h(x; \xi) = -\sum_{i=1}^n a_i(\xi, t)x_i$. Then the Hamiltonian flow $\Phi$ of $h$ satisfies the above relations.

We let $R_\Phi: D(k_U) \to D(k_U)$, $F \mapsto K_{\Phi, 1} \circ F$, be the equivalence of categories given by Corollary\[2.1.4\]. We have in particular $SS(R_\Phi(F)) = \Phi_1(SS(F))$ for all $F \in D(k_U)$.

(ii) We can find a neighborhood $U_1$ of 0 such that

$$\Phi_1(U \times A) \cap \dot{T}^*U_1 \subset U_1 \times \gamma^o_{2c}, \quad \Phi_1(U \times A') \cap \dot{T}^*U_1 \subset U_1 \times \gamma^{oa}_{2c}.$$ 

We choose $r, h$ such that $h > 4cr$ and (using the notations of Proposition\[3.2.2\]) $Z^{\dot{h}}_t$ is contained in $U_1$. Applying Proposition\[3.2.2\] (with $\gamma_{2c}$ instead of $\gamma_c$) we find a neighborhood of 0, say $W_1$, and functors $P_1, P'_1: D(k_{U_1}) \to D(k_{W_1})$ together with morphisms of functors $u_1: P_1 \to id$, $u'_1: P'_1 \to id$ satisfying the conclusion of Proposition\[3.2.2\].

(iii) We let $W$ be an open neighborhood of 0 such that $\Phi_t(\dot{T}^*W) \subset T^*W_1$ for all $t \in I$. Let $j$ denote the inclusion of $W_1$ in $U$. We define the functor $P$ by

$$P(F) = (R_{\Phi, j}^{-1} P_1(R_{\Phi}(F)|_{U_1})))|_W$$ 

and $P'$ from $P'_1$ by the same formula. We let $u, u'$ be the morphisms of functors induced by $u_1, u'_1$. By Proposition\[3.2.2\] we have a distinguished triangle on $W_1$

$$P_1(R_{\Phi}(F)|_{U_1}) \oplus P'_1(R_{\Phi}(F)|_{U_1}) \to R_{\Phi}(F)|_{W_1} \to L \frac{+1}{-1},$$

where $L$ is locally constant on $W_1$. Since $\Phi_t(\dot{T}^*W) \subset \dot{T}^*W_1$ we see that $R_{\Phi, j}(L)|_W$ is locally constant. Applying $(R_{\Phi, j}(L)|_W)$ to the distinguished triangle, we find that $G = (R_{\Phi, j}(L)|_W)$ is isomorphic to $P(F) \oplus P'(F)$ up to a locally constant sheaf on $W$. 

satisfies $\dot{SS}(L) = \emptyset$. 

Theorem 3.2.1
It only remains to check that $G$ is isomorphic to $F|_W$. Lemma 2.2.1 applied with $\Psi_t = \Phi_t^{-1}$ and $U = W_1$ gives $G \simeq (R_{\Phi}^{-1}(R_{\Phi}(F)))|_W \simeq F|_W$, as required.

We deduced Proposition 3.3.1 from Proposition 3.2.2. In the same way we can deduce from Proposition 3.2.4 the following more general result.

**Proposition 3.3.2.** Let $U$ be an open subset of $V = \mathbb{R}^n$ and let $A \subset V^* \setminus \{0\}$ be an open contractible cone with a smooth boundary. Let $B \subset V^*$ be a closed conic subset and $B' \subset V^*$ be a conic neighborhood of $B \cap \partial A$. Let $x_0 \in U$ be given. Then there exist a neighborhood $W$ of $x_0$ and a functor $R : D(k_U) \to D(k_W)$, of the form $R(F) = K \circ F$ for some $K \in D(k_W \times U)$, together with a morphism of functors $id \to R$.

1. if $SS(F) \subset U \times B$, then $SS(R(F)) \subset W \times ((B \setminus A) \cup B')$,
2. if $SS(F) \cap (U \times A) = \emptyset$, then $F|_W \simeq R(F)$.

### 3.4. Cut-off and $\gamma$-topology

In [30] the Proposition 3.1.1 actually has another formulation which will be convenient. With the same notations as in Proposition 3.1.1 we define another topology on $V$, called the $\gamma$-topology, whose open sets are the usual open subsets of $V$ which are stable by addition of $\gamma$. We denote by $V_\gamma$ this topological space. Hence an open set in $V_\gamma$ is a usual open set $\Omega$ of $V$ such that $x + y \in \Omega$ for all $(x, y) \in \Omega \times \gamma$. The identity map induces a continuous map $\phi_{\gamma} : V \to V_\gamma$. Then Propositions 3.5.3 and 5.2.3 of [30] give

**Proposition 3.4.1.** (i) For any $G \in D(k_{V_\gamma})$ the adjoint morphism $G \to R_{\phi_{\gamma}} \phi_{\gamma}^{-1} G$ is an isomorphism.

(ii) For $F \in D(k_V)$ the adjoint morphism $\phi_{\gamma}^{-1} R_{\phi_{\gamma}} F \to F$ is an isomorphism if and only if $SS(F) \subset V \times \gamma^{oa}$.

In particular for any $G \in D(k_{V_\gamma})$ we have $SS(\phi_{\gamma}^{-1} G) \subset V \times \gamma^{oa}$.

In the above proposition the conditions on the microsupport are global on $V$. However we can also consider local situations using the following lemma.

**Lemma 3.4.2.** Let $U$ be an open subset of $V$ and $F \in D(k_U)$. We assume that $SS(F) \subset U \times \gamma^{oa}$. Let $x_0 \in U$. Then there exist a neighborhood $U'$ of $x_0$ in $U$ and $G \in D(k_V)$ such that $G|_{U'} \simeq F|_{U'}$ and $SS(G) \subset V \times \gamma^{oa}$. 

Corollary 3.4.3. (i) Let \( V \), \( \xi \in \gamma^\alpha \) and \( t > 0 \) we define the truncated cone \( C = C_{x,\xi,t} = (x - \gamma) \cap \{ y; \langle \xi, x - y \rangle < t \} \) with vertex at \( x \). We have \( \text{SS}(k_C) \subset V \times \gamma^\alpha \) by Example 1.2.2.

We can find \( x, \xi, t \) such that \( x_0 \in \text{Int}(C) \) and \( \overline{C} \subset U \). By Theorem 1.2.11 the sheaf \( G = F_C \) satisfies \( \text{SS}(G) \subset U \times \gamma^\alpha \). Since \( G \) has a compact support we can extend it by 0 on \( V \) and we still have \( \text{SS}(G) \subset V \times \gamma^\alpha \). Setting \( U' = \text{Int}(C) \), we also have \( G|_{U'} \simeq F|_{U'} \). \( \square \)

We thank Pierre Schapira for the following useful result.

Corollary 3.4.3. (i) Let \( U \) be an open subset of \( V \) and \( F \in \text{D}(k_U) \). We assume that \( \text{SS}(F) \subset U \times \gamma^\alpha \). Then \( \text{SS}(H^iF) \subset U \times \gamma^\alpha \) for all \( i \in \mathbb{Z} \).

(ii) Let \( M \) be a manifold and \( F \in \text{D}(k_M) \). Let \( C \subset T^*M \) be the convex hull of \( \text{SS}(F) \) in the sense that \( C \) is the intersection of all closed conic subsets \( S \) of \( T^*M \) which contain \( \text{SS}(F) \) and are fiberwise convex \((S \cap T_x^*M \text{ is convex for any } x \in M)\). Then \( \text{SS}(H^iF) \subset C \) for all \( i \in \mathbb{Z} \).

Proof. (i) The statement is local on \( U \). Let \( x_0 \in U \) be given and let \( U' \), \( G \) be given by Lemma 3.4.2. By Proposition 3.4.1 there exists \( G' \in \text{D}(k_{V_\gamma}) \) such that \( G \simeq \phi^{-1}_\gamma G' \) \((G' = R\phi_{\gamma} G)\). Since \( \phi^{-1}_\gamma \) is exact we have \( H^iG \simeq \phi^{-1}_\gamma H^iG' \). By Proposition 3.4.1 again we deduce \( \text{SS}(H^iG) \subset V \times \gamma^\alpha \). Since \( G|_{U'} \simeq F|_{U'} \), this gives the required bound for \( \text{SS}(H^iF) \) near \( x_0 \).

(ii) The statement is local on \( M \) and we can assume that \( M \) is open in a vector space \( V \). Then \( T^*M = M \times V^* \). For a given \( x \in M \) we can find a closed convex cone \( \delta \) in \( V^* \), contained in an arbitrarily small neighborhood of \( C \cap (\{ x \} \times V^*) \), and a neighborhood \( U \) of \( x \) such that \( \text{SS}(F|_U) \subset U \times \delta \). Then the result follows from (i). \( \square \)

Remark 3.4.4. 1) Let \( U \) be an open subset of \( V \) and \( F \in \text{Mod}(k_U) \). We assume that \( \text{SS}(F) \subset U \times \gamma^\alpha \). Then, for any \( s \in F(U) \), \( \text{supp}(s) \) is locally \( \gamma \)-closed, that is, for any \( x_0 \in \text{supp}(s) \), there exists a neighborhood \( B \) of \( x_0 \) such that \( B \cap \text{supp}(s) = B \cap Z \) for some \( Z \subset V \) which is closed for the \( \gamma \)-topology.

Indeed, we consider \( U' \), \( G \) given by Lemma 3.4.2. Then \( s|_{U'} \) is identified with a section of \( G \). By Proposition 3.4.1 there exists \( G' \in \text{Mod}(k_{V_\gamma}) \) such that \( G \simeq \phi^{-1}_\gamma G' \). Since \( G_{x_0} \simeq G'_{x_0} \), there exists a section \( s' \) of \( G' \) (over some \( \gamma \)-open set containing \( x_0 \)) and a neighborhood \( U'' \) of \( x_0 \) in \( V \) such that \( s|_{U''} \) is the section of \( G \) induced by \( s' \). In particular \( s_x \simeq s'_x \) for all \( x \in U'' \) and we get \( \text{supp}(s) \cap U'' = \text{supp}(s') \cap U'' \).

Since \( \text{supp}(s') \) is closed in \( V_\gamma \) we are done.
2) A subset $Z$ of $V$ is locally $\gamma$-closed if and only if, for any $x_0 \in Z$, there exists a neighborhood $B$ of 0 in $V$ such that $x_0 - y \in \text{supp}(s)$ for all $y \in B \cap \gamma$.

3.5. Variants of the cut-off functor - Tamarkin projector

The functors $P_\gamma$ of (3.1.1) and $\phi_\gamma$ of (3.4) are related as follows. It is proved in [30, Prop. 3.5.4] that there exists an isomorphism of functors $P_\gamma \simeq \phi_\gamma^{-1} \circ R\phi_\gamma^*$. The morphism $u_\gamma$ of (3.1.1) then corresponds to the adjunction morphism. By [30, Prop. 3.5.3] the composition $R\phi_\gamma^* \circ \phi_\gamma^{-1}$ is the identity functor of $D(k_{V^\gamma})$. It follows that $u_\gamma$ induces an isomorphism $P_\gamma \circ P_\gamma \simeq P_\gamma$, that is, $P_\gamma$ is a projector in the sense of [31, §4.1]. By Proposition 3.1 and (3.1.4) then corresponds to the adjunction morphism $\gamma$ of (3.1.1). It is replaced by an adjunction morphism $\gamma$ of (3.1.1).

End of the proof.

It should be noted that the cut-off functor is defined in [30] in a relative situation where $V$ is replaced by $M \times V$ for an arbitrary manifold $M$. In the case $V = \mathbb{R}$ we introduce coordinates $(t; \tau)$ on $T^*\mathbb{R}$ and local coordinates $(x,t; \xi, \tau)$ on $T^*(M \times \mathbb{R})$. We denote for short by $\{\tau \geq 0\}$ or $\{\tau > 0\}$ the subsets of $T^*(M \times \mathbb{R})$ defined by the corresponding conditions on $\tau$. In this relative setting the projector $P_{[0, +\infty]}^!: D(k_{M \times \mathbb{R}}) \to D_{\{\tau \geq 0\}}(k_{M \times \mathbb{R}})$ can be rewritten as

\[
(3.5.1) \quad P_{[0, +\infty]}^!(F) = Rs_t(p_1^{-1}(F) \otimes p_2^{-1}(k_{[0, +\infty]})),
\]

where $s, p_1: M \times \mathbb{R}^2 \to M \times \mathbb{R}$ and $p_2: M \times \mathbb{R}^2 \to \mathbb{R}$ are defined by $s(x, t_1, t_2) = (x, t_1 + t_2)$, $p_1(x, t_1, t_2) = (x, t_1)$ and $p_2(x, t_1, t_2) = t_2$.

In [43] Tamarkin introduces a projector, say $P_{[0, +\infty]}^\perp$ on the category $D(k_{M \times \mathbb{R}})$ whose image is

\[
(3.5.2) \quad D_{\{\tau \leq 0\}}(k_{M \times \mathbb{R}}) = \{ F \in D(k_{M \times \mathbb{R}}); \text{Hom}(F, G) \simeq 0 \text{ for all } G \in D_{\{\tau \leq 0\}}(k_{M \times \mathbb{R}}) \}.
\]

With the notations of (3.5.1) we have

\[
P_{[0, +\infty]}^\perp(F) = Rs_t(p_1^{-1}(F) \otimes p_2^{-1}(k_{[0, +\infty]})).
\]

An important remark of Tamarkin is that the objects of $D_{\{\tau \geq 0\}}(k_{M \times \mathbb{R}})$ or $D_{\{\tau \leq 0\}}(k_{M \times \mathbb{R}})$ have a natural morphism to their image by a nonnegative translation along $\mathbb{R}$. More precisely, for $c \in \mathbb{R}$, we define

\[
T_c: M \times \mathbb{R} \to M \times \mathbb{R}, \quad (x,t) \mapsto (x, t + c).
\]

We check easily that we have an isomorphism of functors $T^*_c \circ P_{[0, +\infty]}^! \simeq P_{[0, +\infty]}^! \circ T^*_c$ and that

\[
(3.5.3) \quad T^*_c \circ P_{[0, +\infty]}^!(F) = Rs_c(p_1^{-1}(F) \otimes p_2^{-1}(k_{[c, +\infty]})).
\]
For $c \geq 0$ the natural morphism $k_{[0, +\infty]} \to k_{[c, +\infty]}$ induces the morphism of functors (3.5.4) and hence the morphism (3.5.5) for sheaves in the image of $P_{[0, +\infty]}$: 

(3.5.4) \[ \tau_c: P_{[0, +\infty]} \to T_{c*} \circ P_{[0, +\infty]} ; \]

(3.5.5) \[ \tau_c(F): F \to T_{c*}(F), \quad \text{for } F \in D_{(r \geq 0)}(k_{M \times \mathbb{R}}). \]

We will also use a formulation of the cut-off functor as a convolution. We recall the convolution operation, for three manifolds $X, Y, Z$ and $K \in D(k_{X \times Y}), L \in D(k_{Y \times Z})$ 

$K \circ L = Rp_{13!}(p_{12}^{-1}K \otimes p_{23}^{-1}L)$, 

where $p_{ij}$ is the projection from $X \times Y \times Z$ to the $i \times j$-factor. Using the base change formula we see that the convolution is associative. Taking $X = \{pt\}$ and $Y = Z = V$, the functor $P_\gamma$ of (3.1.1) can be written $P_\gamma(F) = Rp_{13!}(p_{12}^{-1}F \otimes p_{23}^{-1}k_\gamma)$ which is almost $F \circ k_\gamma$ up to the change from $Rp_{13!}$ to $Rp_{13*}$. Under some hypothesis on $F$ both functors are the same:

**Lemma 3.5.1.** We take coordinates $(x_1, \ldots, x_n)$ on $V$ and assume that $\gamma \setminus \{0\} \subset \{x_n > 0\}$. Then, for any $F \in D(k_V)$ such that $\text{supp}(F) \subset \{x_n \geq x^0_n\}$ for some $x^0_n \in R$, we have $P_\gamma(F) \simeq F \circ k_\gamma$ and $\text{supp}(P_\gamma(F)) \subset \{x_n \geq x^0_n\}$.

**Part 4. Constructible sheaves in dimension 1**

In this part we apply Gabriel’s theorem to describe the constructible sheaves on the real line and the circle with coefficients in a field $k$.

**4.1. Gabriel’s theorem**

We give a quick reminder on a part of Gabriel’s theorem that we will use in this part. We follow the presentation of Brion’s lecture [9] on the subject and we refer the reader to loc. cit. for further details. In this section $k$ is a field.

A *quiver* is a finite directed graph, that is, a quadruple $Q = (Q_0, Q_1, s, t)$ where $Q_0, Q_1$ are finite sets (the set of vertices, resp. arrows) and $s, t: Q_1 \to Q_0$ are maps assigning to each arrow its source, resp. target. A *representation* of a quiver $Q$ consists of a family of $k$-vector spaces $V_i$ indexed by the vertices $i \in Q_0$, together with a family of linear maps $f_\alpha: V_{s(\alpha)} \to V_{t(\alpha)}$ indexed by the arrows $\alpha \in Q_1$.

For a representation $(\{V_i\}, f_\alpha)$ the dimension vector is $(\dim V_i)_{i \in Q_0}$. The space $\mathbb{R}^{Q_0}$ of dimension vectors is endowed with the Tits form
defined by
$$q_Q(d) = \sum_{i \in Q_0} d_i^2 - \sum_{\alpha \in Q_1} d_{s(\alpha)} d_{t(\alpha)}.$$ In our case we have
$$Q_0 = \{0, \ldots, 2n\}$$ and we find

\begin{equation}
q_Q(d) = \frac{1}{2}(d_0^2 + \sum_{i=1}^{2n} (d_i - d_{i-1})^2 + d_{2n}^2).
\end{equation}

A quiver is of finite orbit type if it has only finitely many isomorphism classes of representations of any prescribed dimension vector. Gabriel’s theorem describes the quivers of finite orbit type. It says that they are the quivers with a positive defined Tits form and also says that this is equivalent to be of type $A, D, E$.

We are actually only interested in quivers of type $A_n$, that is, quivers whose underlying graph is the linear graph with $n$ vertices and $n - 1$ edges.

Another part of Gabriel’s theorem gives the structure of the representations of the quivers of finite type. A representation is said indecomposable if it cannot be split as the sum of two non zero representations. A representation $V$ is Schur if $\text{Hom}(V, V) \simeq k \cdot \text{id}_V$.

**Theorem 4.1.1** (see Theorem 2.4.3 in [9]). Assume that the Tits form $q_Q$ is positive definite. Then:

(i) Every indecomposable representation is Schur and has no non-zero self-extensions.

(ii) The dimension vectors of the indecomposable representations are exactly those $d \in \mathbb{N}^{Q_0}$ such that $q_Q(d) = 1$.

(iii) Every indecomposable representation is uniquely determined by its dimension vector, up to isomorphism.

**Remark 4.1.2.** We assume that our quiver is of type $A_n$ with vertices $\{1, \ldots, n\}$. We can see on (4.1.1) that a dimension vector $d$ satisfies the condition $q_Q(d) = 1$ if and only if there exist $i \leq j \in \{1, \ldots, n\}$ such that $d_k = 1$ if $i \leq k \leq j$ and $d_k = 0$ else.

### 4.2. Constructible sheaves on the real line

We apply the results of Section 4.1 to sheaves on $\mathbb{R}$ with coefficients in a field $k$.

Let $\underline{x} = \{x_1 < \cdots < x_n\}$ be a finite family of points in $\mathbb{R}$. We denote by $\text{Mod}_{\underline{x}}(k_{\mathbb{R}})$ the category of constructible sheaves on $\mathbb{R}$ with respect to the stratification induced by $\underline{x}$.

Setting $x_0 = -\infty$ and $x_{n+1} = +\infty$, a sheaf $F$ belongs to $\text{Mod}_{\underline{x}}(k_{\mathbb{R}})$ if and only if the stalks $F_y$ are finite dimensional for all $y \in \mathbb{R}$ and the restrictions $F|_{[x_k, x_{k+1}]}$ are constant for $k = 0, \ldots, n$. Such a sheaf $F$ is
determined by the data of the spaces of sections
\[ V_{2i+1} = F([x_i, x_{i+2}]) \simto F_{x_{i+1}}, \quad \text{for } i = 0, \ldots, n - 1, \]
\[ V_{2i} = F([x_i, x_{i+1}]), \quad \text{for } i = 0, \ldots, n, \]
together with the restriction maps \( V_{2i+1} \to V_{2i} \) and \( V_{2i+1} \to V_{2i+2} \) for \( i = 0, \ldots, n - 1 \). Conversely, any such family of vector spaces \( \{ V_i \}_{i=0}^{2n+1} \) and linear maps defines a sheaf in \( \text{Mod}_x(k) \). Hence (4.2.1) gives an equivalence between \( \text{Mod}_x(k) \) and the category of representations of the quiver \( Q = (Q_0, Q_1, s, t) \) of type \( A_{2n+1} \) where \( Q_0 = \{0, \ldots, 2n\} \) and there is exactly one arrow in \( Q_1 \) from \( 2i - 1 \) to \( 2i - 2 \) and from \( 2i - 1 \) to \( 2i \), for \( i = 1, \ldots, n \).

Since \( Q \) is of type \( A_{2n+1} \), we can apply Gabriel’s theorem and Remark 4.1.2. Hence the indecomposable representations of \( Q \) are in bijective with the dimension vectors \( d \) such that \( d_k = 1 \) if \( i \leq k \leq j \) and \( d_k = 0 \) else, for some \( i \leq j \in \{0, \ldots, 2n\} \). Through the equivalence (4.2.1) the corresponding sheaves in \( \text{Mod}_x(k) \) are the constant sheaves \( k_I \) on the intervals \( I \) with ends \( -\infty, x_1, \ldots, x_n \) or \( +\infty \) (the intervals can be open, closed or half-closed).

Gabriel’s theorem gives the following decomposition result for constructible sheaves with compact support. Extensions of Gabriel’s theorem gives the general case (see for example Theorem 1.1 in [13]). We can also deduce the general case from the case of compact support; this is done [32, Thm. 1.17] and we reproduce the proof below.

**Corollary 4.2.1.** We recall that \( k \) is a field. Let \( F \in \text{Mod}_c(k) \). Then there exist a locally finite family of intervals \( \{ I_a \}_{a \in A} \) and integers \( \{ n_a \}_{a \in A} \) such that
\[ F \simeq \bigoplus_{a \in A} k_{I_a}^{n_a}. \]
Moreover this decomposition is unique in the following sense. If we have another decomposition \( F \simeq \bigoplus_{b \in B} k_{J_b}^{m_b} \) like (4.2.2) and we assume that the intervals \( I_a, a \in A \), are distinct as well as the intervals \( J_b, b \in B \), then there exists a bijection \( \sigma : A \to B \) such that \( J_{\sigma(a)} = I_a \) and \( m_{\sigma(a)} = n_a \) for all \( a \in A \).

**Proof.** (i) We first assume that \( F \) has compact support. Then \( F \) belongs to \( \text{Mod}_c(k) \) for some finite set of points \( x \). Through the equivalence (4.2.1) Gabriel’s theorem gives the decomposition (4.2.2). The unicity follows from (i) of Theorem 4.1.1 and the Krull-Schmidt theorem.

(ii) In general, for each \( n \in \mathbb{N} \) the part (i) yields a decomposition \( F_{[-n,n]} \simeq \bigoplus_{a \in A_n} k_{I_a} \), where \( A_n \) is a finite set of intervals (each factor
\( k \) has multiplicity 1, but we may have \( I_a = I_k \) for \( a, b \in A \). We can find maps \( \alpha_n: A_n \to A_{n+1} \) such that \( I_a = [-n, n] \cap I_{\alpha_n(a)} \), for each \( a \in A_n \). We set \( A = \lim_{\longrightarrow} A_n \). For \( a \in A \), represented by some \( a_0 \in A_{n_0} \), we set \( I_a = \bigcup_{n \geq n_0} I_{a_n} \), where \( a_n \) is defined inductively by \( a_{n+1} = \alpha_n(a_n) \).

(iii) For \( a \in A \) we claim that we can find morphisms \( i_a: k_{I_a} \to F \) and \( p_a: F \to k_{I_a} \) such that \( p_a \circ i_a = \text{id}_{k_{I_a}} \). We define

\[
E_n = \text{Hom}(k_{I_a \cap [-n,n]}, F_{[-n,n]}) \times \text{Hom}(F_{[-n,n]}, k_{I_a \cap [-n,n]}),
\]

\[
E'_n = \{(i,p) \in E_n; p \circ i = i_{k_{I_a \cap [-n,n]}}\}.
\]

The restriction morphisms induce \( e^n_{m}(E'_m) \to E'_n \) for \( m \geq n \). We clearly have \( e^n_{m}(E'_m) \subset E'_n \). Since \( \text{Hom}(k_{I_a \cap [-n,n]}, k_{I_a \cap [-n,n]}) \cong k \) as soon as \( I_a \cap [-n,n] \neq \emptyset \), the condition \( (i,p) \in E'_n \) can be checked on \([-n,n]\). It follows that \( e^n_{m}(E'_n) = e^n_{m}(E'_m) \cap E'_n \) if \( I_a \cap [-n,n] \neq \emptyset \).

Since \( E_n \) is a finite dimensional vector space for each \( n \), the family \( e^n_{m}(E'_m) \) stabilizes. We set \( E^n_{\infty} = \bigcap_{m \geq n} e^n_{m}(E'_m) \) and \( E^{n \infty}_{n} = E'_n \cap E^n_{\infty} \). We have \( e^n_{m}(E'_m) \neq \emptyset \) by the definition of \( I_a \). Since the family stabilizes, it follows that \( E^{n \infty}_{n} \neq \emptyset \) for all \( n \). The maps \( e^n_{m} \) induce surjective maps \( E^{n \infty}_{m} \to E^{n \infty}_{n} \) for all \( m \geq n \). Hence \( \lim_{\longleftarrow} E^{n \infty}_{n} \neq \emptyset \) and any element in this limit gives a pair \((i_a, p_a)\) as claimed.

(iv) For a given \( a \in A \) the maps \( i_a, p_a \) of (i) give a decomposition \( F \cong k_{I_a} \oplus F' \). We can define a similar set of intervals, say \( A' \), for \( F' \). We have \( A' = A \setminus \{a\} \). For \( a' \in A' \) we can find a decomposition \( F' \cong k_{I_{a'}} \oplus F'' \). Hence \( F \cong k_{I_a} \oplus k_{I_{a'}} \oplus F'' \). We go on inductively and end with the decomposition (4.2.2).

We also remark that (i) of Theorem 4.1.1 is given in our case by the following easy result, that we quote for later use, and the fact that \( \text{Ext}^1(k, k) \cong 0 \).

**Lemma 4.2.2.** Let \( I, J \) be two intervals of \( \mathbb{R} \). Then

\[
\text{Hom}(k_I, k_J) \cong \begin{cases} k & \text{if } I \cap J \text{ is closed in } I \text{ and open in } J, \\ 0 & \text{else.} \end{cases}
\]

In particular, if \( I \) and \( J \) are distinct, then we have \( \text{Hom}(k_I, k_J) \cong 0 \) or \( \text{Hom}(k_J, k_I) \cong 0 \) and, for all morphisms \( f: k_I \to k_J, g: k_J \to k_I \), we have \( g \circ f = 0 \).

**4.3. Constructible sheaves on the circle**

In this section we extend Corollary 4.2.1 to the circle. Like in the case of \( \mathbb{R} \) the result is also a particular case of quiver representation.
theory and Auslander-Reiten theory (see for example [40] § 3.6 p.153 and Theorem 5 p.158). However it is quicker to prove the facts we need than recall these general results.

We denote by $S^1$ the circle and we let $e: \mathbb{R} \to S^1 \simeq \mathbb{R}/2\pi\mathbb{Z}$ be the quotient map. We use the coordinate $\theta$ on $S^1$ defined up to a multiple of $2\pi$. We also denote by $T: \mathbb{R} \to \mathbb{R}$ the translation $T(x) = x + 2\pi$. We recall that $k$ is a field.

Since $e$ is a covering map, we have an isomorphism of functors $e^! \simeq e^{-1}$, hence an adjunction $(e_!, e^{-1})$. For any $n \in \mathbb{Z}$ we have $e_! T^n = e$, hence natural isomorphisms of functors $(T^n)^{-1} e^{-1} \simeq e^{-1}$ and $e_! (T^n) \simeq e_!$. For $G \in \text{Mod}(k)$ the isomorphism $e_! ((T^n)_! (G)) \simeq e_! (G)$ gives by adjunction $i_n(G): (T^n)_! (G) \to e^{-1} e_! (G)$. For $x \in \mathbb{R}$ we have $(e^{-1} e_! (G))_x \simeq (e_! (G))_x \simeq \bigoplus_{n \in \mathbb{Z}} G_{T^n(x)}$. We deduce that the sum of the $i_n(G)$ gives an isomorphism

\[(4.3.1) \quad \bigoplus_{n \in \mathbb{Z}} (T^n)_! (G) \simeq e^{-1} e_! (G).\]

Let $I$ be a bounded interval of $\mathbb{R}$. We have $e_! (k_I) \simeq e_! (k_I)$. Let $A_I$ be the algebra $A_I = \text{Hom}(e_! (k_I), e_! (k_I))$. The adjunction $(e^{-1}, e_!)$ gives a morphism $e^{-1} e_! (k_I) \to k_I$. Using also the adjunction $(e_!, e^{-1})$ we obtain a natural morphism

\[(4.3.2) \quad \varepsilon_I: A_I \simeq \text{Hom}(k_I, e^{-1} e_! (k_I)) \to \text{Hom}(k_I, k_I) \simeq k.\]

**Lemma 4.3.1.** Let $I$ be a bounded interval of $\mathbb{R}$ and let $A_I = \text{Hom}(e_! (k_I), e_! (k_I))$. Then the morphism $\varepsilon_I$ defined in (4.3.2) is an algebra morphism and $\ker(\varepsilon_I)$ is a nilpotent ideal of $A$.

More precisely, if $I$ is closed or open, then $\varepsilon_I$ is an isomorphism. If $I$ is half-closed, say $I = [a, x]$ or $I = [x, a]$ and we set $E_a = I \cap e^{-1}(e(a))$, then the identification $(e_! (k_I))_{e(a)} \simeq k^{E(a)}$ induces a morphism

\[A_I \to \text{Hom}(k^{E(a)}, k^{E(a)}), \quad \varphi \mapsto \varphi_{e(a)}\]

which identifies $A_I$ with the subalgebra of matrices generated by the standard nilpotent matrix of order $|E(a)|$; the eigenvalue of $\varphi_{e(a)}$ is then $\varepsilon_I(\varphi)$. Moreover,

(a) a morphism $u \in A_I$ is an isomorphism if and only if $\varepsilon_I(u) \neq 0$,

(b) for any $\theta \in e(I) \subset S^1$ and any $\varphi \in A_I$, the endomorphism $\varphi_\theta$ of $(e_! (k_I))_\theta$ has only one eigenvalue which is $\varepsilon_I(\varphi)$.

**Proof.** Using $e^{-1} e_! (k_I) \simeq \bigoplus_{n \in \mathbb{Z}} (T^n)_! (k_I)$ and Lemma 4.2.2 the cases $I$ closed or open are obvious. If $I$ is half-closed of length $l$, we find $A_I \simeq k^{E(a)}$ as a vector space. Assuming $I = [a, x]$ (the case $[x, a]$ is similar), a basis of $A_I$ is given by the morphisms $e_! (u_n)$, for $n = 0, \ldots, |E(a)| - 1$, where $u_n: k_I \to k_{T^n(l)}$ is the natural morphism
and we use the natural identification \( \phi_n : e_*(k_{T^n(I)}) \simeq e_*(k_I) \). At the level of germs \( \phi_n \) identifies the summands \((k_I)_{a+2\pi k}\) of \((e_*(k_I))_{a+2\pi k}\) and \((e_*(k_{T^n(I)}))_{a+2\pi (k+n)}\). We obtain that \((e_*(u_n))\) acts on \( k^{E(a)} \) by \((s_1, s_2, \ldots) \mapsto (s_1+n, s_2+n, \ldots)\). We deduce that the image of \( A_I \) in \( \text{End}(k^{E(a)}) \) is as claimed in the lemma.

The assertions (a) and (b) follow from the structure of \( A_I \). For (b) we remark that \( A_I \to \text{End}((e_*(k_I))_\theta)\), \( \varphi \mapsto \varphi_\theta \), is an algebra morphism. \( \square \)

**Lemma 4.3.2.** Let \( F \in \text{Mod}(k_{S^1}) \). Let \( I \) be a bounded interval of \( \mathbb{R} \) such that \( k_I \) is a direct summand of \( e^{-1}F \). Then \( e_*k_I \) is a direct summand of \( F \).

**Proof.** We let \( i_0 : k_I \to e^{-1}F \simeq e^1F \) and \( p_0 : e^{-1}F \to k_I \) be morphisms such that \( p_0 \circ i_0 = \text{id}_{k_I} \) and we denote by \( i'_0 : e_*k_I \simeq e_1k_I \to F \) and \( p'_0 : F \to e_*k_I \) their adjoint morphisms. In general \( p'_0 \circ i'_0 \neq \text{id}_{e_*k_I} \), but it is enough to see that \( p'_0 \circ i'_0 \) is an isomorphism. For this we use Lemma 4.3.1(a). Let us compute \( \varepsilon_I(p'_0 \circ i'_0) \). Let \( a : e^{-1}e_*k_I \to k_I \) and \( b : k_I \to e^{-1}e_*k_I \) be the adjunction morphisms. Then

\[
\varepsilon_I(p'_0 \circ i'_0) = a \circ e^{-1}(p'_0 \circ i'_0) \circ b = p_0 \circ i_0 = \text{id}_{k_I}
\]

and we deduce that \( p'_0 \circ i'_0 \) is an isomorphism. \( \square \)

**Lemma 4.3.3.** Let \( F \in \text{Mod}_c(k_{S^1}) \). We assume that \( F \) is not locally constant. Then there exists a bounded interval \( I \) of \( \mathbb{R} \) such that \( k_I \) is a direct summand of \( e^{-1}F \).

**Proof.** By Corollary 4.2.1 there exist a locally finite family of intervals \( \{I_a\}_{a \in A} \) and integers \( \{n_a\}_{a \in A} \) such that \( e^{-1}F \simeq \bigoplus_{a \in A} k_{I_a}^{n_a} \). Since \( F \) is not locally constant, one of these intervals, say \( I \), is not \( \mathbb{R} \). Let \( T \) be the translation \( T(x) = x + 2\pi \). Since \( T^{-1}e^{-1}F \simeq e^{-1}F \), the intervals \( T^n(I) \) also appear in the decomposition, for all \( n \in \mathbb{Z} \). If \( I \) were not bounded, this would contradict the constructibility of \( F \). \( \square \)

**Proposition 4.3.4.** Let \( F \in \text{Mod}_c(k_{S^1}) \). Then there exist a finite family \( \{(I_a, n_a)\}_{a \in A} \), of bounded intervals and integers, and a locally constant sheaf of finite rank \( L \in \text{Mod}(k_{S^1}) \) such that

\[
F \simeq L \oplus \bigoplus_{a \in A} e_*(k_{I_a}^{n_a}).
\]

**Proof.** (i) If \( F \) is not locally constant, let \( \theta \in S^1 \) be a point around which \( F \) is not constant. We can find a small arc \( I \) around \( \theta \) such that \( F \) is constant on the two components of \( I \setminus \{\theta\} \), of rank say \( n_1^2 \) and \( n_2^2 \). We set \( r_0(F) = n_1^2 + n_2^2 + \dim(F_\theta) \). We define \( r(F) = \sum_\theta r_\theta(F) \), where \( \theta \) runs over the points around which \( F \) is not constant. If \( F \) is locally
constant we set \( r(F) = 0 \). We prove the proposition by induction on \( r(F) \).

(ii) We assume \( r(F) \neq 0 \). Then \( F \) is not locally constant. By Lemmas 4.3.3 and 4.3.2 there exists a bounded interval \( I \) of \( \mathbb{R} \) such that \( F \cong e_*(\mathbf{k}_I) \oplus F' \) for some \( F' \in \text{Mod}_c(\mathbf{k}_{S^1}) \). Then \( r(F') < r(F) \) and the induction proceeds. \qed

4.4. Cohomological dimension 1

The decomposition results for sheaves in dimension 1 extend to the derived category. We first recall a well-known decomposition result (see for example [31, Ex. 13.22]).

**Lemma 4.4.1.** Let \( \mathcal{C} \) be an abelian category and \( X \in D^b(\mathcal{C}) \) a complex such that \( \text{Ext}^k(H^iX, H^jX) \cong 0 \) for all \( i, j \in \mathbb{Z} \) and all \( k \geq 2 \). Then \( X \) is split, that is, there exists an isomorphism \( X \cong \bigoplus_{i \in \mathbb{Z}} H^iX[-i] \) in \( D^b(\mathcal{C}) \).

This applies in particular to constructible sheaves in dimension 1. Indeed, if \( M = \mathbb{R} \) or \( M = S^1 \) and \( k \) is a field, we have \( \text{Ext}^k(F, G) \cong 0 \) for all \( F, G \in \text{Mod}_c(k_M) \) and for all \( k \geq 2 \). We deduce:

**Lemma 4.4.2.** Let \( M = \mathbb{R} \) or \( M = S^1 \) and let \( k \) be a field. Then, for all \( F \in D_c^b(k_M) \) we have \( F \cong \bigoplus_{i \in \mathbb{Z}} H^iF[-i] \) in \( D_c^b(k_M) \).

Using Corollary 4.2.1 and Proposition 4.3.4 we obtain immediately:

**Corollary 4.4.3.** Let \( k \) be a field. Let \( M \) be \( \mathbb{R} \) or \( S^1 \) and let \( F \in D^b(k_M) \) be a constructible object.

(i) If \( M = \mathbb{R} \), then there exist a locally finite family of intervals \( \{I_a\}_{a \in A} \) and integers \( \{n_a\}_{a \in A}, \{d_a\}_{a \in A} \) such that

\[
F \cong \bigoplus_{a \in A} \mathbf{k}_{I_a}^{n_a}[d_a].
\]

(ii) If \( M = S^1 \), then there exist a finite family of bounded intervals \( \{I_a\}_{a \in A}, \) integers \( \{n_a\}_{a \in A}, \{d_a\}_{a \in A} \) and \( L \in D^b(k_{S^1}) \) with locally constant cohomology sheaves of finite rank such that

\[
F \cong L \oplus \bigoplus_{a \in A} e_*(\mathbf{k}_{I_a}^{n_a})[d_a],
\]

where \( e: \mathbb{R} \to S^1 \cong \mathbb{R}/2\pi\mathbb{Z} \) is the quotient map.

The next lemma is related with the results of this section and was already used in Example 2.1.3. This is a classical result (see [31, Ex. 13.20, 13.21]). Let \( \mathcal{C} \) be an Abelian category. For \( A \in \mathcal{D}(\mathcal{C}) \) we let
\(\text{Aut}(A) \subset \text{Hom}(A, A)\) be the isomorphism group of \(A\). For another \(B \in \mathcal{D}(\mathcal{C})\) the product \(\text{Aut}(A) \times \text{Aut}(B)\) acts on \(\text{Hom}(A, B)\) by composition. We recall that we have truncation functors \(\tau_{\leq i}, \tau_{\geq i} : \mathcal{D}^b(\mathcal{C}) \to \mathcal{D}^b(\mathcal{C})\) together with morphisms of functors which yield for any \(X \in \mathcal{D}^b(\mathcal{C})\) and \(n \in \mathbb{Z}\) a distinguished triangle

\[
\tau_{\leq n}(X) \xrightarrow{a(X)} X \xrightarrow{b(X)} \tau_{\geq n+1}(X) \xrightarrow{c(X)} \tau_{\leq n}(X)[1].
\]

For \(A, B \in \mathcal{C}\) and \(n \geq 1\), we let \(E^n_{A,B} \subset \mathcal{D}^b(\mathcal{C})\) be the full subcategory of objects \(X\) such that \(H^0(X) \simeq B, H^n(X) \simeq A\) and \(H^i(X) \simeq 0\) for \(i \neq 0, n\). For \(X \in E^n_{A,B}\) we have isomorphisms \(a : B \xrightarrow{\simeq} \tau_{\leq 0}(X)\) and \(b : A[-n] \xrightarrow{\simeq} \tau_{\geq 1}(X)\). We define \(\phi_{a,b}(X) = b^{-1} \circ c(X) \circ a \in \text{Hom}(A[-n], B[1]) \simeq \text{Hom}(A, B[n+1])\).

**Lemma 4.4.4.** Let \(\mathcal{C}\) be an abelian category and let \(A, B \in \mathcal{C}\) and \(n \geq 1\) be given. Let \(\bar{E}_{A,B}\) be the set of isomorphism classes in \(E_{A,B}\). For a given \(X \in E_{A,B}\) and isomorphisms \(a : A \xrightarrow{\simeq} \tau_{\geq n+1}(X), b : B \xrightarrow{\simeq} \tau_{\leq n}(X)[1]\), the image of \(\phi_{a,b}(X)\) in \(\text{Hom}(A, B[n+1]) / \text{Aut}(A) \times \text{Aut}(B)\) is independent of the choice of \(a\) and \(b\) and yields a bijection between \(\bar{E}_{A,B}\) and \(\text{Hom}(A, B[n+1]) / \text{Aut}(A) \times \text{Aut}(B)\).

**Proof.** (i) Changing \(a\) and \(b\) modifies \(b^{-1} \circ c(X) \circ a\) by the action of an element in \(\text{Aut}(A) \times \text{Aut}(B)\). This proves that the image of \(b^{-1} \circ c(X) \circ a\) in the quotient only depend on \(X\).

(ii) If \(u : X \to Y\) is an isomorphism in \(E_{A,B}\), then \(\tau_{\geq n+1}(u)\) and \(\tau_{\leq n}(u)[1]\) are isomorphisms and make a commutative square with \(c(X)\) and \(c(Y)\). Hence \(c(X)\) is conjugate to \(c(Y)\) through \(\text{Aut}(A) \times \text{Aut}(B)\). This defines a map \(\bar{c} : \bar{E}_{A,B} \to \text{Hom}(A, B) / \text{Aut}(A) \times \text{Aut}(B)\).

(iii) Let \(X, Y \in E_{A,B}\) be given. If \(\bar{c}(X) = \bar{c}(Y)\), then there exists \((a, b)\) such that the square \((S)\) below commutes:

\[
\begin{array}{ccc}
\tau_{\leq n}(X) & \longrightarrow & X \\
\downarrow & & \downarrow \\
\downarrow & & \downarrow \\
\tau_{\leq n}(Y) & \longrightarrow & Y \\
\end{array}
\begin{array}{ccc}
& & \tau_{\geq n+1}(X) \\
& & \downarrow a \\
& & \tau_{\leq n}(Y)[1] \\
\end{array}
\begin{array}{ccc}
& & \tau_{\geq n+1}(Y) \\
& & \downarrow b \\
& & \tau_{\leq n}(Y)[1] \\
\end{array}
\]

By the axioms of triangulated categories, we deduce that \(X \simeq Y\). Hence \(\bar{c}\) is injective.

(iv) For \(\phi \in \text{Hom}(A, B)\) we define \(X_\phi\) such that \(X_\phi[1]\) is the cone of \(\phi\). Then \(\bar{c}(X_\phi) = [\phi]\) in \(\text{Hom}(A, B) / \text{Aut}(A) \times \text{Aut}(B)\). Hence \(\bar{c}\) is surjective.

\(\square\)
Part 5. Graph selectors

Let $M$ be a manifold and let $\Lambda \subset J^1(M)$ a closed Legendrian submanifold. We let $\Gamma$ be the projection of $\Lambda$ on $M \times \mathbb{R}$. A graph selector for $\Lambda$ is a continuous function $\varphi: M \to \mathbb{R}$ whose graph is contained in $\Gamma$. If $\Lambda$ is generic, then $\Gamma$ is a union of transverse immersed hypersurfaces outside a set of codimension 1. In this case $\varphi$ is differentiable on a dense open set and the graph of $df$ is contained in the Lagrangian projection of $\Lambda$ in $T^*M$. We see $\Lambda$ as a closed conic Lagrangian submanifold of $\dot{T}^*(M \times \mathbb{R})$. We choose coordinates $(t; \tau)$ on $T^*\mathbb{R}$ and denote by $T^*_{\tau > 0}(M \times \mathbb{R})$ the open set $\{ \tau > 0 \}$ in $T^*(M \times \mathbb{R})$. Then $\Lambda \subset T^*_{\tau > 0}(M \times \mathbb{R})$. In this short section we prove that $\Lambda$ has a graph selector as soon as it is the microsupport of a sheaf $F$ satisfying some conditions at infinity; the graph of $\varphi$ is then the boundary of the support of a section of $F$. Using Theorem 13.5.1 below, we recover Theorem 1.2 of [5] which says that a compact exact Lagrangian submanifold of a cotangent bundle has a graph selector.

For a map $\varphi: M \to \mathbb{R}$ we set $\Gamma_\varphi = \{ t = \varphi(x) \}$ and $\Gamma_\varphi^+ = \{ t \geq \varphi(x) \}$. We assume in this section that $M$ is connected. For $F \in D(k_{M \times \mathbb{R}})$ we consider the following condition:

(5.0.1) there exists $A > 0$ such that $\text{supp}(F) \subset M \times [-A, +\infty[$ and $\text{SS}(F) \subset T^*_{\tau > 0}(M \times [-A, A])$.

Proposition 5.0.1. Let $F \in \text{Mod}(k_{M \times \mathbb{R}})$ and let $s \in F(M \times \mathbb{R})$ be a non-zero section. We assume that $F$ satisfies (5.0.1). Then there exists a unique map $\varphi: M \to \mathbb{R}$ such that $\text{supp}(s) = \Gamma_\varphi^+$. Moreover, for a given $x_0 \in M$, if $U$ is a coordinate chart around $(x_0, \varphi(x_0))$, with coordinates $(x, t; \xi, \tau)$ on $T^*U$, and $C \in \mathbb{R}$ satisfies $\text{SS}(F) \cap T^*U \subset \{ \tau > C ||\xi|| \}$, then the map $\varphi$ is $C^1$-Lipschitz at $x_0$. In particular $\varphi$ is continuous.

The link between the Lipschitz condition and the assumption on the microsupport can also be found in [18] and [27].

Proof. (i) To prove that $\text{supp}(s)$ is of the form $\Gamma_\varphi^+$ it is enough to check that $\text{supp}(s) \cap \{ x \} \times \mathbb{R}$ is an interval of the form $[a, +\infty[$ for any $x \in M$. Let $z = (x_0, \varphi(x_0)) \in M \times \mathbb{R}$ such that $s_z \neq 0$. We set $i: \mathbb{R} \to M \times \mathbb{R}$, $t \mapsto (x_0, t)$ and $G = i^{-1}F$. Then $\text{SS}(G) \subset \{ \tau \geq 0 \}$ by the hypothesis on $F$ and by Theorem 1.2.7. The section $s$ induces a section $s'$ of $G$ over $\mathbb{R}$ and we have $s'_t = s_{i(t)}$. Hence $\text{supp}(s') = i^{-1}(\text{supp}(s))$ and this is non empty since $s_z \neq 0$.

By Corollary 1.2.14 the restriction map $H^0[\{ a, c \}; G] \to H^0[\{ b, c \}; G]$ is an isomorphism for any $a \leq b < c$. It follows that $s'_t = 0$ implies
Corollary 1.2.14. Let Lemma 5.0.3. restriction morphism $\text{R}(\gamma) \in \text{R}(\gamma)$ be a morphism, for any $G$ in $\gamma$. We have $F$ if $B$ is a morphism, for any $\gamma$ in $\gamma$. Then $s'|_{a,b} = 0$ and in particular $s'_1 = 0$. Since $\text{supp}(s')$ is closed, non empty and contained in $[a, +\infty[$, this proves that it must be an interval of the form $[a, +\infty[$, as required.

It remains to check that, for any $x \in M$, there exists $t$ such that $s(x,t) \neq 0$. The hypothesis on $\text{SS}(F)$ implies that $F|_V$, where $V = M \times [A, +\infty[$, is a locally constant sheaf. Since $M$ is connected, the support of any global section of $F|_V$ is either empty or $V$. We have seen that $\text{supp}(s)$ contains $\{x_0\} \times [a, +\infty[ for some $a$. Hence it must contain $V$. Finally we obtain that $\text{supp}(s) = \Gamma_\varphi^+$ for some function $\varphi : M \to \mathbb{R}$.

(ii) Now we choose $x_0 \in M$ and a neighborhood $U$ of $x_0 = (x_0, \varphi(x_0))$ in $M \times \mathbb{R}$. We choose coordinates around $x_0$ and assume that $\text{SS}(F) \cap T^*U \subset U \times \{t \geq C||\xi||\}$ for $C > 0$. We identify $U$ with an open set in $\mathbb{R}^n$ and let $\gamma \subset \mathbb{R}^{n+1}$ be the closed convex cone $\{t \leq -C^{-1}||x||\}$. We have $\gamma^a = \{t \geq C||\xi||\}$. By Remark 3.4.4 $\text{supp}(s)$ is locally $\gamma$-closed and hence contains $(z_0 - \gamma) \cap B$ for some neighborhood $B$ of $z_0$. The complement $U \setminus \text{supp}(s)$ is locally $\gamma$-open. Since $z_0^* = (x_0, \varphi(x_0) - \varepsilon)$ is not in $\text{supp}(s)$ for $\varepsilon > 0$, we deduce up to shrinking $B$ that $B \cap \text{supp}(s) \cap (z_0^\varepsilon + \gamma) = \emptyset$. Hence $B \cap \Gamma_\varphi$ is contained in $B \setminus ((z_0 - \gamma) \cup (z_0 + \gamma))$, which means that $\varphi$ is $C^{-1}$-Lipschitz at $x_0$.

(iii) Since $\overline{\text{SS}}(F)$ is conic and closed in $\overline{T^*(M \times \mathbb{R})}$ and contained in $\{t > 0\}$, for any compact subset $K$ of some coordinate chart of $M \times \mathbb{R}$ we can find $C > 0$ such that $\overline{\text{SS}}(F) \cap \pi_{M \times \mathbb{R}}^{-1}(K) \subset K \times \{t \geq C||\xi||\}$. By (ii) it follows that $\varphi$ is continuous everywhere.

**Lemma 5.0.2.** Let $F \in \mathcal{D}(k_{M \times \mathbb{R}})$ which satisfies (5.0.1). Then, for any $i \in \mathbb{Z}$, the sheaf $H^i F$ also satisfies (5.0.1) and moreover we have $\pi_{M \times \mathbb{R}}^*(\overline{\text{SS}}(H^i F)) \subset \pi_{M \times \mathbb{R}}^*(\overline{\text{SS}}(F))$.

**Proof.** The condition on $\text{supp}(H^i F)$ is obvious. The condition on $\overline{\text{SS}}(H^i F)$ and the inclusion $\pi_{M \times \mathbb{R}}(\overline{\text{SS}}(H^i F)) \subset \pi_{M \times \mathbb{R}}(\overline{\text{SS}}(F))$ both follow from the following fact: for any $G \in \mathcal{D}(k_{M \times \mathbb{R}})$, a point $x$ is not in $\pi_{M \times \mathbb{R}}(\overline{\text{SS}}(G))$ if and only if $G$ is constant in a neighborhood of $x$. Now, if $F$ is constant, so is $H^i F$. 

**Lemma 5.0.3.** Let $F \in \mathcal{D}(k_{M \times \mathbb{R}})$ which satisfies (5.0.1). Then the restriction morphism $\text{R}(\gamma)(M \times \mathbb{R}; F) \to \text{R}(\gamma)(M \times [B, +\infty[; F)$ is an isomorphism, for any $B \in \mathbb{R}$.

We remark that if $M$ were compact, this would follow directly from Corollary 1.2.14.
Proof. We set \( Z = M \times [-\infty, B] \) and \( U = M \times ]B, +\infty[. \) We have to prove that \( r: \Gamma (M \times \mathbb{R}; F) \to \Gamma (M \times \mathbb{R}; R \Gamma _{U} (F)) \) is an isomorphism. The cone of \( r \) is \( \Gamma (M \times \mathbb{R}; R \Gamma _{Z} (F)) \). Let \( p: M \times \mathbb{R} \to M \) be the projection. It is enough to prove \( Rp_{*} \Gamma _{Z} (F) \simeq 0 \).

We remark that \( p \) is proper on \( \text{supp}(R \Gamma _{Z} (F)) \). For a given \( x \in M \) and \( i_{x}: \mathbb{R} \to M \times \mathbb{R}, t \mapsto (x, t) \), we set \( G = i_{x}^{-1} \Gamma _{Z} (F). \) Then the base change formula gives \((R p_{*} \Gamma _{Z} (F))_{x} \simeq \Gamma (\mathbb{R}; G)\). By Theorems 1.2.11 and 1.2.7 we have \( \text{SS}(G) \subset \{ \tau \geq 0 \} \). Since \( G \) has compact support, we have \( \Gamma (\mathbb{R}; G) \simeq \Gamma ([a, +\infty[; G) \) for some \( a \in \mathbb{R} \). By Corollary 1.2.14 we also have \( \Gamma ([b, +\infty[; G) \simeq \Gamma ([b, +\infty[; G) \) for \( a \leq b \) and this vanishes for \( b \gg 0 \) since \( \text{supp}(G) \) is compact. \( \square \)

Corollary 5.0.4. Let \( \Lambda \subset T_{\tau>0}^{*} (M \times \mathbb{R}) \) be a closed conic Lagrangian submanifold. We assume that \( \Lambda \subset T_{\tau>0}^{*} (M \times [-A, A]) \) for some \( A \) and that there exists \( F \in \mathcal{D}(k_{M \times \mathbb{R}}) \) such that \( \text{SS}(F) = \Lambda \), \( \text{supp}(F) \subset M \times [-A, +\infty[ \) and \( F|_{M \times [-A, +\infty[} \simeq k_{M \times [-A, +\infty[} \). Then \( \Lambda \) has a graph selector: there exists a continuous map \( \varphi : M \to \mathbb{R} \) such that \( \Gamma _{\varphi} \subset \pi_{M \times \mathbb{R}} (\Lambda) \). Moreover, for a given \( x_{0} \in M \), if \( u \) is a coordinate chart around \( (x_{0}, \varphi (x_{0})) \), with coordinates \((x, t; \xi, \tau)\) on \( T^{*}U \), and \( C \in \mathbb{R} \) satisfies \( \Lambda \cap T^{*}U \subset \{ \tau > C||\xi|| \} \), then the map \( \varphi \) is \( C^{-1} \)-Lipschitz at \( x_{0} \).

Proof. (i) The sheaf \( F|_{M \times [-A, +\infty[} \simeq k_{M \times [-A, +\infty[} \simeq H^{0} F|_{M \times [-A, +\infty[} \) has a section over \( M \times [-A, +\infty[ \), say \( s \), corresponding to \( 1 \in k \). By Lemma 5.0.2 \( H^{0} F \) satisfies (5.0.1) and by Lemma 5.0.3 the section \( s \) can be extended to \( s \in H^{0} (M \times \mathbb{R}; H^{0} F) \). Proposition 5.0.1 associates a continuous function \( \varphi \) to \( s \) and we have \( \Gamma _{\varphi} \subset \pi_{M \times \mathbb{R}} (\Lambda) \) by Lemma 5.0.2 again.

(ii) Let \( \Xi \subset T^{*} (M \times \mathbb{R}) \) be the convex hull of \( \Lambda \) in the sense that \( \Xi \) is the intersection of all closed conic subsets \( S \) of \( T^{*} M \) which contain \( \Lambda \) and are fiberwise convex. For a local chart as in the statement we also have \( \Xi \cap T^{*} U \subset \{ \tau > C||\xi|| \} \). By Corollary 3.4.3 we have \( \text{SS}(H^{0} F) \subset \Xi \). Hence the Lipschitz constant given in Proposition 5.0.1 for \( H^{0} F \) is the same as the one given in the current corollary. \( \square \)

An example of a sheaf satisfying the hypothesis of Corollary 5.0.4 is given by Corollary 2.1.4 as follows. We start with \( \Lambda _{0} = T_{M \times \{ 0 \}}^{*} (M \times \mathbb{R}) \) which is the microsupport of \( F^{0} = k_{[0, +\infty[} \). Let \( \Phi _{t}, t \in I, \) be a homogeneous Hamiltonian isotopy of \( \hat{T}^{*} (M \times \mathbb{R}) \) which preserves \( \hat{T}^{*}_{\tau>0} (M \times \mathbb{R}) \) (for example the homogeneous lift of a Hamiltonian isotopy of \( T^{*} M \), or the lift of a contact isotopy of \( J^{1} M \), whose support is proper over \( M \)). We deduce a sheaf \( F \) on \( M \times \mathbb{R} \times I \) with \( F_{0} = F^{0} \) and \( \text{SS}(F_{t}) = \Phi _{t} (\Lambda _{0}) \), where \( F_{t} = F|_{M \times \mathbb{R} \times \{ t \}} \). We remark that \( \text{SS}(F) \cap T^{*} N = \emptyset \) for
$N = (M \times ]B, +\infty[ \times I)$ and $B \gg 0$. Hence $F|_N$ is locally constant. Since $F_0|_N \simeq k_N$ we deduce $F_t|_N \simeq k_N$ for all $t \in I$. So Corollary 5.0.4 implies that $\Phi_t(\Lambda_0)$ has a graph selector, for all $t \in I$.

More generally, using Corollary 5.0.4 and Theorem 13.5.1 below, we recover Theorem 1.2 of [5]:

**Corollary 5.0.5.** Let $\Lambda \subset T^*_\tau > 0(M \times \mathbb{R})$ be a closed conic Lagrangian submanifold which is the conification of a compact exact Lagrangian submanifold of $T^*M$. Then $\Lambda$ has a graph selector.

### Part 6. The Gromov nonsqueezing theorem

In this part we use the microlocal theory of sheaves to give a proof of the famous Gromov nonsqueezing theorem (see [19]), which says that there is no Hamiltonian isotopy of $\mathbb{R}^{2n}$ which sends the ball of radius $R$ into a cylinder $D_r \times \mathbb{R}^{2n-2}$, where $D_r$ is the disc of radius $r$, if $r < R$. There is already a proof with generating funtions by Viterbo [49] and it is no wonder that we can also find a proof with sheaves. The proof we give is inspired by the papers of Chiu [12], to define a projector associated with a square in §6.1, and Tamarkin [43] to define a displacement energy (see Definition 6.2.1 – this displacement energy is also used in [7]). It is in fact a baby case of the main result of [12] which is the nonsqueezing in the contact setting (see also [15] for another proof). We also give a non squeezing result for a Lagrangian submanifold of the ball; this is related with a result of Théret in [44].

#### 6.1. Cut-off in fiber and space directions

In Part 3 we have seen several functors on the category of sheaves whose effect is to change the microsupport and make it avoid some given set. For a vector space $V$ and a closed convex cone $\gamma \subset V$, we have seen $P_\gamma: D(k_V) \to D(k_V)$ which is a projector, in the sense that $P_\gamma \circ P_\gamma \simeq P_\gamma$, and satisfies $SS(P_\gamma(F)) \subset V \times \gamma^{o_a}$. More usual functors reduce the support of a sheaf, for example $D(k_M) \to D(k_M)$, $F \mapsto F_Z$, for a locally closed set $Z \subset M$. This functor is also a projector and satisfies $SS(F_Z) \subset \mathbb{Z} \times V^*$. If $Z$ is closed, a sheaf satisfying $SS(F) \subset Z \times \gamma^{o_a}$ is stable by both functors $P_\gamma$ and $(\cdot)_Z$, hence by the composition $Q: F \mapsto P_\gamma(F_Z)$. This $Q$ is not a projector but we will see in a special case that $Q^{o_i}$ converges when $i \to \infty$ and gives a projector (in fact we will work with a variant of $Q$).

The construction we give in this section is in fact a baby case of a construction by Chiu in [12] who defines a projector corresponding to a subset $C$ of $T^*\mathbb{R}^{n+1}$ which is the cone over a ball in $T^*\mathbb{R}^n$, here we do
the case where $C$ is the cone over a square $[-1, 1]^2$ in $T^*\mathbb{R} = \mathbb{R} \times \mathbb{R}^*$. We will use this projector to recover nonsqueezing results in the symplectic case.

It will be more convenient to use a convolution functor $F \mapsto F \circ k_\gamma$ rather than $P_\gamma$ (the difference is a proper direct image instead of a usual direct image - see (3.1.1)) because the convolution is associative. This is similar to the Tamarkin projector of $\{3.3\}$. This convolution $- \circ k_\gamma$ is still a projector and its image is $D_{A^\gamma}(k_V)$, where $A^\gamma = V \times (V^* \setminus \text{Int}(\gamma^{\text{out}}))$ and $D_B(k_V) = \{F \in D(k_V); \text{SS}(F) \subset B\}$ (see [22, Prop. 4.10]). We have $D_{A^\gamma}(k_V) \subset D_{V \times \gamma^{\text{out}}}(k_V)$.

We introduce some notations. Let $n \geq 2$ be given. We consider the vector spaces $V' = \mathbb{R}^{n-2}$, $V = \mathbb{R}^2 \times V'$ and put coordinates $(x; \xi)$ on $T^*V$. We let $\gamma \subset V$ be the cone

$$\gamma = \{(x) \in \mathbb{R}^n; x_2 \leq -|x_1|, x_3 = \cdots = x_n = 0\}.$$ 

Hence $\gamma^\circ \subset V^*$ is given by $\gamma^\circ = \{(\xi) \in \mathbb{R}^n; \xi_2 \leq -|\xi_1|\}$. We recall the notation $\tilde{\gamma} = \{(x, y) \in V^2; x - y \in \gamma\}$ of $\{3.3\}$. We let $Z \subset V$ be the open strip $Z = ]-1, 1[ \times \mathbb{R}^{n-1}$. Let $R_\gamma, R_Z: D(k_V) \to D(k_V)$ be the functors $R_\gamma(F) = F \circ k_\gamma$ and $R_Z(F) = F_Z$. They come with natural morphisms $R_\gamma(F) \to F$ and $R_Z(F) \to F$. We remark that $R_Z$ can also be written as a convolution $R_Z(F) \simeq F \circ k_{\delta_V(Z)}$, where $\delta_V$ is the diagonal embedding. We define $R = R_Z \circ R_\gamma \circ R_Z$ and we find

$$R(F) \simeq F \circ k_W,$$

where

$$W = \tilde{\gamma} \cap (Z \times Z)$$

$$= \{(x, y) \in \mathbb{R}^{2n}; y_2 - x_2 \geq |x_1 - y_1|, |x_1| < 1, |y_1| < 1, x_i = y_i, i = 3, \ldots, n\}.$$ 

Since $W \cap \Delta_V$ is closed in $W$ and open in $\Delta_V$, we have a natural morphism $k_W \to k_{\Delta_V}$, which gives a morphism of functors $R \to \text{id}$. If a sheaf satisfies $R_\gamma(F) \leadsto F$ and $F_Z \leadsto F$, then $R(F) \leadsto F$ and $R^{\circ i}(F) \leadsto F$ for all $i \in \mathbb{N}$. We now compute $R^{\circ i}$; of course this is the convolution with $K_i = k_W \circ \cdots \circ k_W$ ($i$ factors $k_W$). For $c \in \mathbb{R}$ we define $f, s, T_c: V \to V$ by $f(y) = (-y_1, y_2 + 2, y_3, \ldots, y_n)$, $s(y) = (y_1, -y_2, y_3, \ldots, y_n)$, and $T_c(y) = (y_1, y_2 + c, y_3, \ldots, y_n)$.

Let $Z_\pm \subset \mathbb{R}^2$ be the closed half planes $Z_\pm = \{y_2 \geq \pm y_1\}$. We have natural morphisms $u_\pm: k_{\mathbb{R}^2} \to k_{Z_\pm}$ and we define $L \in D(k_{\mathbb{R}^2})$ by

$$L = 0 \to k_{\mathbb{R}^2} \to k_{Z_+} \oplus k_{Z_-} \to 0,$$
Lemma 6.1.1. We set $C_1 = W \cap (\text{id}_V \times f)((\text{id}_V \times s)(\text{Int}(W)))$ and $W_2 = (\text{id}_V \times f)(W)$. The sheaf $K_2 = k_W \circ k_W$ appears in a distinguished triangle

\[(6.1.3) \quad k_{C_1} \xrightarrow{k} K_2 \rightarrow k_{W_2}[−1] \rightarrow k_{C_1}[1]\]

and, in a small enough neighborhood of $\{y_1 = −x_1, y_2 = x_2 + 2\} \times \Delta_{V'}$, we have $K_2 \simeq p^{-1}(L) \otimes k_{\Delta_{V'}}$, with $p : \mathbb{R}^4 \rightarrow \mathbb{R}^2$, $(x_1, x_2, y_1, y_2) \mapsto (x_1 + y_1, y_2 - x_2 - 2)$. Moreover $k_{C_1} \circ k_W \cong k_{C_1}$.

Proof. (i) Let us forget the variables $x_i, y_i$ for $i \geq 3$. Let $q : \mathbb{R}^6 \rightarrow \mathbb{R}^4$ be the projection $q(x, y, z) = (x, z)$. Then $K_2 = Rq(k_A)$ where $A = (W \times \mathbb{R}^2) \cap (\mathbb{R}^2 \times W)$. For a subset $E \subset \mathbb{R}^6$ and $(x, z) \in \mathbb{R}^4$ we set $E_{(x, z)} = E \cap q^{-1}(x, z)$. If $x \notin Z$ or $z \notin Z$ we have $A_{(x, z)} = \emptyset$. This proves that $(K_2)_{Z \times Z} \simeq K_2$. Now we assume $(x, z) \in Z^2$ and we find $A_{(x, z)} = \{y \in \mathbb{R}^2, y_2 - x_2 \geq |x_1 - y_1|, |y_1| < 1, z_2 - y_2 \geq |y_1 - z_1|\}$. Then $A_{(x, z)}$ is a bounded convex polytope, but the cohomology of $k_{A_{(x, z)}}$ depends on $(x, z)$ because we have two types of boundary conditions (open or closed).

(ii) We define $A', A^± \subset q^{-1}(Z^2) \subset \mathbb{R}^6$ by their fibers $A'_{(x, z)} = A_{(x, z)}$. We have an exact sequence $0 \rightarrow k_A \rightarrow k_{A'} \rightarrow k_{A^+} \oplus k_{A^-} \rightarrow 0$. Now the fibers of $A'$, $A^±$ are always compact convex polytopes. For any such polytope $B$ we have $Rq_B(k_B) \simeq k_{q(B)}$ and we deduce a resolution of $K_2$ as the complex $0 \rightarrow k_{q(A')} \xrightarrow{d_1} k_{q(A^+)} \oplus k_{q(A^-)} \rightarrow 0$. We have $q(A') = W$ and

$$q(A^±) = \{(x, z) \in \mathbb{R}^4, z_2 - x_2 \geq 2 \mp (x_1 + z_1), |x_1| < 1, |z_1| < 1\}.$$ 

Hence $\ker(d_1) \simeq k_{C_1}$, $\text{coker}(d_1) = k_{W_2}$ and, up to a change of coordinates, we have the complex \((6.1.2)\) defining $L$.

(iii) To prove the last assertion we can compute $k_{C_1} \circ k_W$ directly or use the fact that $(k_{C_1})_Z \simeq k_{C_1}$, because $C_1 \subset \mathbb{R}^2$ and $R_*(k_{C_1}) \simeq k_{C_1}$, because $C_1$ is relatively compact and $\text{SS}(k_{C_1}) \subset T^*V \times (V \times \gamma^{ca})$. We deduce $k_{C_1} \circ k_W \simeq k_{C_1}$ and this proves the lemma. \(\Box\)

We can see that $− \circ k_W$ commutes with the translation $T_c$. More precisely $T_{c*}(F) \circ k_W \simeq T_{c*}(F \circ k_W) \simeq F \circ k_{(\text{id}_V \times T_c)(W)}$. The same holds.
for the map $f$ and, since $W_2 = (id_V \times f)(W)$, we can deduce $k_{W_2} \circ k_W$ from the triangle (6.1.3). We find a similar triangle

\[(6.1.4) \quad k_{C_2} \to k_{W_2} \circ k_W \to k_{W_3}[-1] \to k_{C_2}[1],\]

where $C_2 = (id_V \times f)(C_1)$, $W_3 = (id_V \times f)(W_2)$. Since $k_{C_1} \circ k_W \simeq k_{C_1}$, applying $- \circ k_W$ to (6.1.3) gives the triangle

\[(6.1.5) \quad k_{C_1} \to k_3 \to k_{W_2} \circ k_W[-1] \to k_{C_1}[1].\]

The triangle (6.1.4) implies that $H^0(k_{W_2} \circ k_W) \simeq k_{C_2}$ and $H^1(k_{W_2} \circ k_W) \simeq k_{W_3}$. Then (6.1.5) gives $H^0(K_3) \simeq k_{C_1}$, $H^1(K_3) \simeq k_{C_2}$ and $H^2(K_3) \simeq k_{W_3}$. Now we can compute $k_{W_3} \circ k_W$ in the same way and an induction gives the following result.

**Proposition 6.1.2.** For $i \geq 1$ we define $C_i = (id_V \times f)^i(C_1)$ and $W_i = (id_V \times f)^{i-1}(W)$. Then, for any $n \geq 1$,

(i) we have a distinguished triangle

\[k_{C_1} \to K_{n+1} \to (id_V \times f)_*(K_n)[-1] \to k_{C_1}[1],\]

(ii) $K_n$ is concentrated in degrees $0, \ldots, n-1$ and $H^i K_n \simeq k_{C_i+1}$ for $i = 0, \ldots, n-2$, $H^{n-1} K_n \simeq k_{W_n}$,

(iii) setting $\Delta_i^i := \{y_1 = (-1)^i x_1, y_2 = x_2 - 2i\} \times \Delta_V$, and $p_i : \mathbb{R}^2 \to \mathbb{R}^2$, $(x_1, x_2, y_1, y_2) \mapsto (x_1 - (-1)^i y_1, y_2 - x_2 - 2i)$, we have $K_n \simeq p_i^{-1}(L) \boxtimes k_{\Delta_V}$, in a small enough neighborhood of $\Delta_i^i$, for $i = 1, \ldots, n$,

(iv) setting $Y_i = \{y_2 - x_2 \geq 2i\}$, we have, for $i = 1, \ldots, n-1$,

\[(K_n|_{Y_i}) \simeq (id_V \times f)_i(K_{n-i})[-i],\]

\[\text{Lemma 6.1.3.} We set } S_n = \text{supp}(K_n) = \overline{W_n} \cup \bigcup_{i=1}^{n-1} \overline{C_i}. \text{ Then we have } R\text{Hom}(K_n, K_n) \simeq k_{S_n}.\]

**Proof.** (i) The statement is local on $V^2$. In a neighborhood of a point $x_0$ which is away from the sets $\Delta_i^i$ defined in Proposition 6.1.2, our sheaf $K_n$ is up to shift a constant sheaf on some subset $Y$ of $V^2$ with $Y = C_i$ or $Y = W_n$. Since the sets $C_i$ and $W_n$ are locally closed convex, we get $R\text{Hom}(K_n, K_n) \simeq k_{S_n}$ near $x_0$.

(ii) In a neighborhood of some $\Delta_i^i$ the lemma is reduced to the proof of $R\text{Hom}(L, L) \simeq k_D$, where $D = \text{supp}(L)$. Let us set $H = R\text{Hom}(L, L)$. We can compute $H$ directly from the triangle (6.1.2). Alternatively we can remark that $SS(L) = \Delta_0 \circ \hat{\tau}_0^* \mathbb{R}$ (see the notation (2.1.3)), where $\Psi$ is the Hamiltonian isotopy of $T^*\mathbb{R}$. It follows from Corollary 2.1.4 that the restriction morphisms $R\text{Hom}(L, L) \to R\text{Hom}(L_s, L_s)$, where $L_s = L|_{\mathbb{R}^2 \times \{s\}}$ are all isomorphisms. We deduce that $R\text{Hom}(L, L) \simeq k$. Since $H$ is a conic sheaf, we also have $H_0 \simeq R\text{Hom}(\mathbb{R}^2; H)$, hence $H_0 \simeq k$.
On the other hand, away from 0 we clearly have $H \simeq k_D$. Hence $H$ is concentrated in degree 0. The above condition on the restriction morphisms then implies $H \simeq k_D$ everywhere. □

We define an increasing sequence of open subsets $U_i = \{y_2 - x_2 < 2i\} \subset \mathbb{R}^{2n}$, $i \in \mathbb{Z}$. By Lemma 6.1.3, the natural morphism $u_j : K_{j+1} \to K_j$, induced by $k_W \to k_{\Delta V}$, gives an isomorphism $K_{j+1}|_{U_i} \simeq K_j|_{U_i}$ if $j > i$. Hence we can define a sheaf $K_\infty \in \mathcal{D}(k_{\mathbb{R}^{2n}})$ such that $K_\infty|_{U_i} \simeq K_j|_{U_i}$ if $j > i$, for example as follows. We set $U'_i = U_i \setminus U_{i-1}$ and $U''_i = U_i \setminus \overline{U}_{i-2}$. The natural restriction morphism and $u_j$ induce $v_i : (K_{i+1})|_{U''_{i-1}} \to (K_{i+1})|_{U_i}$ and $v'_i : (K_{i+1})|_{U'_{i-1}} \to \oplus(K_i)|_{U''_i}$, whose restrictions to $U'_i$ are isomorphisms. Now we define $K_\infty$ by the distinguished triangle

$$\bigoplus_{i \in \mathbb{Z}} (K_i)|_{U''_{i-2}} \xrightarrow{v} \bigoplus_{i \in \mathbb{Z}} (K_i)|_{U'_{i-1}} \to K_\infty \xrightarrow{+1}.$$

Proposition 6.1.4. We set $S_\infty = \text{supp}(K_\infty) = \overline{\bigcup_{i=1}^{\infty} C_i}$ and $Y_i = \{y_2 - x_2 \geq 2i\}$. Then we have $R\text{Hom}(K_\infty, K_\infty) \simeq k_{S_\infty}$ and

$$(K_\infty)_Y \simeq R\Gamma_{\text{Int}(Y)}(K_\infty) \simeq (\text{id}_Y \times f)^i(K_\infty)[-i], \text{ for } i \geq 1.$$

In particular

$$R\text{Hom}(K_\infty, T_4s(K_\infty)) \simeq k[2].$$

Proof. The first assertion follows from Lemma 6.1.3, Proposition 6.1.2, (iv) gives $(K_\infty)_Y \simeq (\text{id}_Y \times f)^i(K_\infty)[-i]$. The inductive description of $K_n$ in-(i) of the same proposition shows that $SS(K_\infty) \subset \{\xi_2 + \eta_2 \geq 0\}$. Hence $SS(K_\infty)$ does not meet $SS(k_{\text{Int}(Y_i)})$ and Theorem 1.2.11 gives $(K_\infty)_Y \simeq R\Gamma_{\text{Int}(Y)}(K_\infty)$. For the last assertion we remark that $T_4 = (\text{id}_Y \times f)^2$. Hence

$$R\text{Hom}(K_\infty, T_4s(K_\infty)) \simeq R\text{Hom}(K_\infty, R\Gamma_{\text{Int}(Y_2)}(K_\infty))$$

$$\simeq R\Gamma_{\text{Int}(Y_2)}R\text{Hom}(K_\infty, K_\infty[2])$$

$$\simeq R\Gamma_{\text{Int}(Y_2)}(k_{S_\infty})[2]$$

$$\simeq (k_{S_\infty \cap Y_2})[2]$$

and the result follows. □

The morphism $k_W \to k_{\Delta V}$ gives by iteration $K_i \to k_{\Delta V}$ and then $K_\infty \to k_{\Delta V}$. In particular for any $F \in \mathcal{D}(k_V)$ we have a natural morphism $F \circ K_\infty \to F$.

Proposition 6.1.5. Let $F \in \mathcal{D}(k_V)$. We assume that $F_Z \simeq F$, $SS(F) \subset V \times \gamma^0a$ and $\text{supp}(F) \subset \{x_2 \geq x_2^0\}$ for some $x_2^0 \in \mathbb{R}$. Then $F \circ K_\infty \simeq F$. 
Proof. By Proposition 3.1.1 we have \( P_\gamma(F) \simrightarrow F \), where \( P_\gamma \) is defined in (3.1.1) by \( P_\gamma(F) = Rq_{2*}(k_\gamma \otimes q^{-1}_2 F) \). Since \( \text{supp}(F) \subset \{ x_2 \geq x_0^2 \} \) we can replace \( Rq_{2*} \) by \( Rq_{2!} \) in this expression and we find \( F \circ k_\gamma \simrightarrow F \). Composing with \( k_\delta_v(z) \) we find \( F \circ k_\tau \simrightarrow F \). Iterating \( i \) times we get \( F \circ K_i \simrightarrow F \) for all \( i \in \mathbb{N} \).

We recall that \( K_\infty|_{U_i} \simeq K_j|_{U_i} \) if \( j > i \), where \( U_i = \{ y_2 - x_2 < 2i \} \subset \mathbb{R}^{2n} \), \( i \in \mathbb{Z} \). For any sheaf \( K \) on \( V^2 \) supported in \( V^2 \setminus U_i \) we have \( \text{supp}(F \circ K) \subset \{ x_2 \geq x_0^2 + 2i \} \). Using the triangle \( (K_\infty)|_{U_i} \rightarrow K_\infty \rightarrow (K_\infty)_{V^2 \setminus U_i} \overset{+1}{\rightarrow} \) and the same one with \( K_\infty \) replaced by \( K_i \), we deduce that, for any given \( x' \in V \) if \( j > i > x_2 - x_0^2 \), we have \( (F \circ K_\infty)_{x'} \simrightarrow (F \circ (K_\infty)|_{U_i})_{x'} \simeq (F \circ (K_j)|_{U_i})_{x'} \simrightarrow (F \circ (K_j)_{x'}) \). Hence \( (F \circ K_\infty)_{x'} \simeq F_{x'} \) which proves that the morphism \( F \circ K_\infty \rightarrow F \) is an isomorphism.

For a manifold \( N \) and a real number \( c \) we let \( T_c: N \times V \rightarrow N \times V \) be the translation along the direction \( y_2 \) of \( V \), \( T_c(x, y_1, \ldots, y_n) = (x, y_1, y_2 + c, y_3, \ldots, y_n) \). For \( F \in D(k_{N \times V}) \) such that \( SS(F) \subset \{ y_2 \geq 0 \} \) we let \( \tau_c(F): F \rightarrow T_c(F) \) be the morphism (3.5.5).

**Proposition 6.1.6.** We have \( \tau_c(K_\infty) = 0 \) for all \( c \geq 4 \). In particular, for any manifold \( N \) and \( F \in D(k_{N \times V}) \) such that \( F \circ K_\infty \simrightarrow F \) we have \( \tau_c(F) = 0 \) for all \( c \geq 4 \).

**Proof.** By (6.1.7) we have \( \text{Hom}(K_\infty, T_c*K_\infty) \simeq 0 \) if \( c \geq 4 \) and a fortiori \( \tau_c(K_\infty) = 0 \). The second assertion then follows from the fact that \( \tau_c(F) \) coincides with \( \text{id}_F \circ \tau_c(K_\infty) \).

### 6.2. Nonsqueezing Results

Here we use the projector \( K_\infty \) to prove classical nonsqueezing results in the symplectic case. The morphism \( \tau_c \) of (3.5.4), introduced by Tamarkin in [43], gives the following invariant, that we can call a displacement energy. We refer to [7] where this invariant is used to obtain bounds on the displacement energy of some subsets of a cotangent bundle and to [52] for a survey of Tamarkin’s and Chiu’s results.

**Definition 6.2.1.** Let \( M \) be a manifold and \( F \in D_{\{ c \geq 0 \}}(k_{M \times \mathbb{R}}) \). We set \( e(F) = \sup \{ c \geq 0; \tau_c(F) \neq 0 \} \). For \( a < b \) we set \( M^a_b = M \times [a, b] \) and define and \( e'(F) = \sup \{ e(F_{M^a_b}); \ (a, b) \in \mathbb{R}^2, \ a < b \} \).

We check in Proposition 6.2.4 below that \( e(F) \) and \( e'(F) \) are invariant by Hamiltonian isotopies of \( T^*M \) with compact support. We introduce \( e'(F) \) because we will need compact support assumptions not always satisfied by the sheaf \( F \) that we consider.
Lemma 6.2.2. Let \( a < b \) be given and let \( A \) be the functor \( A(F) = F_{M_a^b} \). Then \( A(\tau_c(F)) = \tau_e(A(F)) \). In particular \( e(F) \geq e'(F) \).

Proof. (i) We first make the following remark: let \( Z \) be a closed subset of a manifold \( X \) and \( F,G \in D(k_X) \). Let \( a: F \to F_Z \) and \( b: G \to G_Z \) be the natural morphisms. Let \( u: F \to G \) be given. Then \( v = u_{Z} \) is the only morphism \( v: F_Z \to G_Z \) such that \( v \circ a = b \circ u \). Indeed this follows easily from \( \text{Hom}(F_Z,G_Z) \cong \text{Hom}(F,G) \).

(ii) Using (i) with \( X = M \times \mathbb{R} \) and \( Z = M \times [A, +\infty[ \) we see that \( A(\tau_c(F)) = \tau_e(A(F)) \) when \( b = +\infty \). We have a statement similar to (i) when \( Z \) is open (by reverting the arrows). Hence we also have \( A(\tau_c(F)) = \tau_e(A(F)) \) when \( a = -\infty \). Combining the two cases we obtain the result.

For the last claim of the lemma we choose \( c > e(F) \). Then \( \tau_e(F) = 0 \) and we deduce \( \tau_c(F_{M_a^b}) \) for all \( a < b \). \( \square \)

Proposition 6.2.3. Let \( N \) be a manifold, \( V = \mathbb{R}^n \) and \( M = N \times V \). We recall the notations \( Z = [-1,1[ \times \mathbb{R}^{n-1} \) and \( \gamma = \{ x_2 \leq -|x_1|, x_3 = \cdots = x_n = 0 \} \). Let \( F \in D(k_M) \). We assume that \( F_{N \times Z} \cong F \) and \( SS(F) \subset T^*N \times (V \times \gamma^{oa}) \). Then \( e'(F) \leq 4 \).

Proof. Let \( a < b \) and \( G = F_{M_a^b} \). We have \( G_{N \times Z} \cong G \). We recall that \( SS(k_{M_a^b}) = \{(x,t;0,\tau); t = a \text{ or } t = b \text{ and } \tau > 0 \} \). Hence Theorem 1.2.11 implies \( SS(G) \subset T^*N \times (V \times \gamma^{oa}) \). It follows that the morphism \( u: G \circ K_{\infty} \to G \) is an isomorphism. Indeed Proposition 6.1.5 implies that \( u|_{\{x\} \times V} \) is an isomorphism, for any \( x \in N \). Hence \( u \) is an isomorphism. Now we conclude with Proposition 6.1.6. \( \square \)

6.2.1. Invariance of the displacement energy. Let \( M \) be a manifold and let \( h: T^*M \times I \to \mathbb{R} \) be a function of class \( C^\infty \). We assume that its Hamiltonian flow \( \Phi: T^*M \times I \to T^*M \) is defined and has compact support. As in Proposition 2.5.1 we associate with \( h \) a homogeneous Hamiltonian isotopy \( \Phi': T^*(M \times \mathbb{R}) \times I \to T^*(M \times \mathbb{R}) \) lifting \( \Phi \) and we let \( K_{\Phi'} \in D(k_{(M \times \mathbb{R})^2 \times I}) \) be the sheaf given by Theorem 2.1.1.

By construction \( \Phi' \) commutes with the vertical translation \( T_c \), for any \( c \in \mathbb{R} \), defined by \( T_c(x,t;\xi,\tau) = (x,t + c;\xi,\tau) \). We can write \( T_c \simeq k_{\Delta_c} \circ \tau \), where \( \Delta_c = \Delta_M \times \{ t = t' + c \} \). We thus have \( K_{\Phi'} \circ k_{\Delta_c} \simeq k_{\Delta_c} \circ K_{\Phi'} \). We will use projector \( P_{[0,\infty[}^\perp: D(k_{M \times \mathbb{R}}) \to D(k_{M \times \mathbb{R}}) \) introduced by Tamarkin. It is defined by \( P_{[0,\infty[}^\perp(F) \simeq P^+ \circ F \) where \( P^+ \in D(k_{(M \times \mathbb{R})^2}) \) is given by

\[
P^+ = k_{\Delta^+} \circ P_{\Delta^+} \quad \text{where} \quad \Delta^+ = \{(t,t') \in \mathbb{R}^2; t \leq t' \}.
\]

Its image is \( D_{\{t \geq 0\}}(k_{M \times \mathbb{R}}) \) (see 3.3).
Lemma 6.2.4. There exists a unique isomorphism in $D(k_{(M \times \mathbb{R})^2}^I)$, $u: K_{\Phi'} \circ P^+ \xrightarrow{\sim} P^+ \circ K_{\Phi'}$, whose restriction to $(M \times \mathbb{R})^2 \times \{0\}$ is the identity morphism of $P^+$.

Proof. Since $K_{\Phi'}$ is invertible, it is enough to prove that $Q = (K_{\Phi'} \circ P^+) \circ |_I K_{\Phi'}^{-1}$ is isomorphic to $P^+ \boxtimes k_I$. Since $K_{\Phi'}: 0 \simeq k_{\Delta_0 \times \mathbb{R}}$, we have $Q|_{(M \times \mathbb{R})^2 \times \{0\}} \simeq P^+$. Hence, by Proposition 1.2.8, it is enough to see that $SS(Q) \subset T^*(M \times \mathbb{R})^2 \times T^*_I I$. This comes from the fact that $\Phi'$ commutes $T_c$. More precisely we have the very rough bounds (see (2.1.2))

$$SS(K_{\Phi'}) = \Lambda_{\Phi'} \subset A = \{(x, t, \xi, \tau), (x', t', \xi', \tau'), (s, -\tau h(x, \xi / \tau, s))\},$$

$$SS(P^+) \subset B = \{x = x', \xi = -\xi', \tau = -\tau'\}.$$

By Lemma 1.5.1 we have $SS(K_{\Phi'} \circ P^+) \subset A \circ^a B$. Since the function $-\tau h(x, \xi / \tau, s)$ does not depend on $t'$, we have $A \circ^a B \subset A$. We also have $SS(K_{\Phi'}^{-1}) \subset A^a$ and we find $SS(Q) \subset A \circ^a |_I A^a = T^*(M \times \mathbb{R})^2 \times T^*_I I$, as required.

Let us set $P_c^+ = k_{\Delta_c \times \{(t, t') \in \mathbb{R}^2; t \leq t' + c\}}$. Then $P_c^+ \simeq P^+ \circ k_{\Delta_c} \simeq k_{\Delta_c} \circ P^+$ and, since $K_{\Phi'}$ commutes with $k_{\Delta_c}$, Lemma 6.2.4 also gives an isomorphism $u_c: K_{\Phi'} \circ P^+ \simeq P^+_c \circ K_{\Phi'}$. For $c \geq 0$ the inclusion $\Delta_c \subset \Delta_0$ induces a morphism $P^+_c \rightarrow P^+_c$, which gives the vertical arrows in the diagram

$$K_{\Phi'} \circ P^+ \xrightarrow{u} P^+ \circ K_{\Phi'} \quad \xrightarrow{\sim} \quad K_{\Phi'} \circ P^+_c \xrightarrow{u_c} P^+_c \circ K_{\Phi'}.$$ (6.2.1)

Proposition 6.2.5. The diagram (6.2.1) is commutative. In particular, for any $F \in D^{|_I|}_{\{t \geq 0\}}(k_{M \times \mathbb{R}})$ (see (3.5.2)) and for any $c \geq 0$, the image of the morphism $\tau_c(F)$ by the functor $K_{\Phi'} \circ -$ is $\tau_c(K_{\Phi'} \circ F)$.

Proof. As in the proof of Lemma 6.2.4 it is enough to prove the commutativity of the diagram obtained from (6.2.1) by application of the functor $\cdot \circ |_I K_{\Phi'}^{-1}$. We then obtain a diagram where the entries are isomorphic to $P^+ \boxtimes k_I$ or $P^+_c \boxtimes k_I$. It is then enough to check the commutativity when we restrict to $(M \times \mathbb{R})^2 \times \{0\}$, which is clear.

Proposition 6.2.6. For any $F \in D^{|_I|}_{\{t \geq 0\}}(k_{M \times \mathbb{R}})$ we have $e(F) = e(K_{\Phi'}, s \circ F)$ and $e'(F) = e'(K_{\Phi'}, s \circ F)$, for any $s \in I$.

Proof. The equality $e(F) = e(K_{\Phi'} \circ F)$ follows from Proposition 6.2.5. Since $\Phi$ has compact support, for any $a < b$ we can find $a' < a < b < b'$ such that $\Phi'_s(T^*_a M^b_a) \subset T^*_a M^b_{a'}$ for all $s \in I$. Then $(K_{\Phi'}, s \circ F)_{M^b_a} \xrightarrow{\sim}$...
(K_{\Phi',s} \circ F_{M',}\right)_{M_0^k}$ by Lemma 2.2.1. It then follows from Lemma 6.2.2 that \( \tau_c(K_{\Phi',s} \circ F_{M',}) = 0 \) implies \( \tau_c((K_{\Phi',s} \circ F)_{M_0^k}) = 0 \). Since \( \tau_c(K_{\Phi',s} \circ F_{M',}) = \tau_c(F_{M',}) \) we deduce \( e'(F) \geq e'(K_{\Phi',s} \circ F) \). Since \( K_{\Phi',s} \) is invertible the reverse inequality holds. \( \square \)

**Remark 6.2.7.** The morphism \( \tau_c(F) \) for \( F \in D_{\{c \geq 0\}}(k_{M \times \mathbb{R}}) \) is functorial in \( M \) if \( N \subset M \) is a submanifold, then \( \tau_c(F)_{N \times \mathbb{R}} \leftarrow \left( \tau_c(F) \right)_{N \times \mathbb{R}} \). This implies \( e(F)_{N \times \mathbb{R}} \leftarrow e(F) \) and \( e'(F)_{N \times \mathbb{R}} \leftarrow e'(F) \).

### 6.2.2. Nonsqueezing for a Flying Saucer

We put the natural Euclidean structure on \( \mathbb{R}^n \) and \( T^*\mathbb{R}^n \simeq \mathbb{R}^{2n} \) and we denote by \( B_1(E) \) and \( S_1(E) \) the closed unit ball and unit sphere of an Euclidean space \( E \). We first define a subset \( \Lambda_0 \) of \( S_1(T^*\mathbb{R}^n) \) which is the image of a Legendrian of \( J^1(\mathbb{R}^n) \) whose front projection in \( \mathbb{R}^{n+1} \) is a flying saucer with conic points.

We define \( \Lambda_0 \) as the union of the graphs of the differential of two functions \( f_1, f_2 : B_1(\mathbb{R}^n) \rightarrow \mathbb{R} \). We choose these functions to be rotation invariant with a differential belonging to the unit sphere of \( T^*\mathbb{R}^n \). In other words we write \( f_i(x) = g_i(|x|) \) for a function \( g_i \) such that \( r^2 + (g_i'(r))^2 = 1 \). This determines \( f_i \) up to a constant and we find \( f_1(x) = \int_0^{|x|} \sqrt{1-u^2}du \) and \( f_2(x) = \pi/2 - f_1(x) \). We let \( W_0 = \{ f_1(|x|) \leq t < f_2(|x|) \} \) be the region in \( \mathbb{R}^{n+1} \) bounded by the graphs of \( f_1, f_2 \) and define

\[
\Lambda_0 = \rho_{\mathbb{R}^n}(\mathbb{S}(\mathbf{k}_{W_0})) \subset T^*\mathbb{R}^n.
\]

The functions \( f_i \) are not differentiable at 0 and \( W_0 \) has a conic point at \((0,0)\) and \((0, \pi/2)\):

\[
\mathbb{S}(\mathbf{k}_{W_0}) \cap T_{(0,0)}\mathbb{R}^{n+1} = \mathbb{S}(\mathbf{k}_{W_0}) \cap T_{(0,0)}\mathbb{R}^{n+1} = \{(\xi, \tau); \ \tau \geq ||\xi||\}
\]

and we have \( df_{i,x} = g_i'(|x|) \cdot x \) for a non zero \( x \). We deduce

\[
\begin{align*}
\Lambda_0 &= \{ (x;\xi) \in S_1(T^*\mathbb{R}^n); \ \xi \text{ is a scalar multiple of } x \},
\end{align*}
\]

We remark that \( L_0 \) is the image of \( S_1(T^*\mathbb{R}^n) \) by the characteristic flow of \( S_1(T^*\mathbb{R}^n) \). More precisely we have \( S_1(T^*\mathbb{R}^n) = \{ h = 1 \} \) where \( h(x;\xi) = ||x||^2 + ||\xi||^2 \). The flow of \( X_h = 2 \sum_i \xi_i \frac{\partial}{\partial x_i} - x_i \frac{\partial}{\partial \xi_i} \) has orbits of period \( \pi \). Identifying \( T^*\mathbb{R}^n \) with \( \mathbb{C}^n \) by \( (x;\xi) \mapsto x + i\xi \) the flow is given by \( \Phi_{h,s}(x+i\xi) = \exp(2si) \cdot (x+i\xi) \). For an orbit \( \gamma \) of the flow the action is \( A = \int_0^\pi \alpha \) where \( \alpha = \sum \xi_i dx_i \) is the Liouville form. Here we find \( A = \pi \) for all orbits in \( S_1(T^*\mathbb{R}^n) \). We have also another expression of \( L_0 \)

\[
L_0 = \{ \exp(2si) \cdot (0;\xi) \in T^*\mathbb{R}^n \simeq \mathbb{C}^n; \ s \in [0, \pi], \ ||\xi|| = 1 \}.
\]
If we smooth our functions $f_i$ near the origin (in which case the front looks like a flying saucer), we obtain an approximation of $\Lambda_0$ by an immersed Lagrangian sphere with one double point.

**Proposition 6.2.8.** Let $r < 1/\sqrt{2}$ be given and let $D_r \subset \mathbb{R}^2$ be the closed disc of radius $r$. There is no Hamiltonian isotopy $\Phi: \mathbb{R}^{2n} \times I \to \mathbb{R}^{2n}$ such that $\Phi_1(\Lambda_0) \subset D_r \times \mathbb{R}^{2n-2}$, where $\Lambda_0$ is defined in (6.2.2).

**Proof.** (i) Let us assume that such an isotopy $\Phi$ exists. We can find an isotopy $\Psi$ of $\mathbb{R}^{2n} = T^*\mathbb{R}^n$ such that $\Psi_1(D_r \times \mathbb{R}^{2n-2}) \subset ]-a, a[^2 \times T^*\mathbb{R}^{n-1}$, for some $a$ with $(2a)^2 < \pi/2$. Hence we can as well assume that $\Phi_1(\Lambda_0) \subset ]-a, a[^2 \times T^*\mathbb{R}^{n-1}$. We can also assume that $\Phi$ has compact support. We let $\Phi'$ be a homogeneous isotopy of $T^*\mathbb{R}^{n+1}$ lifting $\Phi$ as in Proposition 2.3.1 and we let $K_{\Phi'} \in \mathcal{D}(k_{\mathbb{R}^{2n+2} \times I})$ be the sheaf associated with $\Phi'$ by Theorem 2.1.1.

(ii) We set $F_0 = k_{W_0}$ and define $F_1 = K_{\Phi'}, F_0$. Hence $\mathcal{S}(F_1) = \Phi'_1(\mathcal{S}(F_0))$ and $F_1$ has compact support. In particular $\rho_{\mathbb{R}^n}(\mathcal{S}(F_1)) = \Phi_1(\Lambda_0)$. By Proposition 6.2.6 we have $e(F_0) = e(F_1)$.

(iii) Let $\Gamma_1 = \pi_{\mathbb{R}^{n+1}}(\mathcal{S}(F_1))$ be the projection of $\mathcal{S}(F_1)$ to the base. Since $\rho_{\mathbb{R}^n}(\mathcal{S}(F_1)) \subset ]-a, a[^2 \times T^*\mathbb{R}^{n-1}$, we have $\Gamma_1 \subset Z_a = ]-a, a[ \times \mathbb{R}^n$. Hence $F_1$ is locally constant outside $Z_a$. Since it has compact support, it has to vanish outside $Z_a$ and we find $(F_1)_{Z_a} \simeq F_1$. Hence $F_1$ satisfies the hypothesis of Proposition 6.2.3 up to a rescaling of $Z$ and $\gamma$ by $a$. Hence $e(F_1) < 4a^2 < \pi/2$.

On the other hand $R\mathcal{H}om(F_0, T_{cs}(F_0)) \simeq k_{W_0 \cap T_{cs}(W_0)}$ for $c \in [0, \pi/2]$. Since the topology of $W_0 \cap T_{cs}(W_0)$ is unchanged when $c$ runs over $[0, \pi/2]$ we deduce that $e(F_0) = \pi/2$. We thus have a contradiction. $\square$
(with the notations $U$, $Z$ of (2.1.4)). Then, up to shifts, $f^{-1}(K_{\Psi}|_{V_0})$ gives a sheaf $F$ and a distinguished triangle

\begin{equation}
(6.2.5) \quad k_{W_0} \to F \to k_{W_1}[-n] \to k_{W_0}[1].
\end{equation}

The microsupport of $F$ is the image of $\text{SS}(K_{\Psi}|_{V_0})$ by $df$ and we find $\rho_{\mathbb{R}^n}(\text{SS}(F|_{\Omega})) \subset L_0$, as required.

However $F$ still has a too big microsupport at the conic points $(0, 0)$ and $(0, \pi)$. We can repeat the above gluing process at these points and iterate. We obtain a sheaf $G_0 \in \mathcal{D}^b_{\text{rh}}(k_{\mathbb{R}^{n+1}})$, in the same way we defined $K_\infty$ (see (6.1.6)), with the following property

\begin{equation}
(6.2.6) \quad G_0|_{\mathbb{R}^n \times k_{\mathbb{R}^{n+1}}[k+2]} \simeq (T_{k_{\mathbb{R}^{n+1}}})_*(F)[-kn], \text{ for any } k \in \mathbb{Z},
\end{equation}

where $F$ is defined in (6.2.5) and we have $\rho_{\mathbb{R}^n}(\text{SS}(G_0)) = L_0$.

**Proposition 6.2.9.** Proposition 6.2.8 holds with $\Lambda_0$ replaced by $L_0$.

**Proof.** It is enough to prove that $e'(G_0) \geq \pi/2$; the rest of the proof of Proposition 6.2.8 works the same. By Remark 6.2.7 we have $e'(G_0) \geq e'(G_0|_{\{x_0\} \times \mathbb{R}^n})$ for any $x_0 \in \mathbb{R}^n$. The above description of $G_0$ implies $G_0|_{\{0\} \times \mathbb{R}^n} \simeq \bigoplus_{k \in \mathbb{Z}} k_{\mathbb{R}^{n+1}}[k+2] \xi][-kn]$. Since $e'(k_{[a, b]}) = b - a$ we obtain $e'(G_0) \geq \pi/2$, as claimed. \qed

6.2.4. **nonsqueezing for the ball.** We set $B = \text{Int}(B_1(\mathbb{R}^n))$, $B' = B_1(\mathbb{R}^n)$ and $S = S_1(T^*\mathbb{R}^n)$. For $y \in B'$, let $L_y \subset S$ be the image of $T^*_{y(\mathbb{R}^n)} \cap S$ by the characteristic flow of $S$. Then $L_y$ is a Lagrangian submanifold of $T^*\mathbb{R}^n$. To prove the nonsqueezing for the ball we use the Lagrangian submanifolds $L_y$, $y \in B$, in family. We first prove that there exists a sheaf $G$ on $B \times \mathbb{R}^{n+1}$ such that $e(G) \geq \pi$ and $\rho_{\mathbb{R}^n}(\text{SS}(G_y)) = L_y$, where $G_y = G|_{\{y\} \times \mathbb{R}^{n+1}}$.

Let us describe the family $L_y$. For a given $y \in B'$ we can see $L_y$ as in (6.2.3) as the image of a map

\[ f_y: (\mathbb{R}/\pi\mathbb{Z}) \times S_{\tau}(T^*_{\mathbb{R}^n}) \to T^*\mathbb{R}^n, \quad (s, \xi) \mapsto \exp(2si) \cdot (y; \xi), \]

where $\tau = \sqrt{1 - ||y||^2}$. We set $L^0 = \bigcup_{y \in B'} L_y \subset \mathbb{R}^n \times T^*\mathbb{R}^n$. We can describe a Lagrangian submanifold $L \subset (T^*\mathbb{R}^n)^2$ above $L^0$ as follows. In $T^*\mathbb{R}^{2n}$ we consider the hypersurface $Z = T^*\mathbb{R}^n \times S$ and the Lagrangian submanifold $T^*\mathbb{R}^{2n}$. Then $L^1 = Z \cap T^*\mathbb{R}^{2n}$ is isotropic and its image $L$ by the characteristic flow of $Z$ is still isotropic, hence Lagrangian since it is of dimension $2n$. Like $L_y$ the Lagrangian $L$ is the image of a map

\[ f: (\mathbb{R}/\pi\mathbb{Z}) \times S \to (T^*\mathbb{R}^n)^2, \quad (s, (y; \xi)) \mapsto ((y; -\xi), \exp(2si) \cdot (y; \xi)). \]

The important point is that $f$ is injective whereas $f_y$ is not. Let $L' \subset J^1(\mathbb{R}^{2n}) = (T^*\mathbb{R}^{2n}) \times \mathbb{R}$ be a Legendrian lift of $L$. Then $L' \to L$ is an
infinite cyclic cover. A loop on \( \mathcal{L} \) given by a characteristic flow line lifts to a path \( l \) on \( \mathcal{L}' \) with \( l(1) = T_\pi(l(0)) \), where \( T_\pi \) is as before the translation in the last variable by \( \pi \). Hence \( T_\pi(L') = L' \).

For \( y \in \mathcal{B} \) we let \( \mathcal{L}_y \subset J^1(\{y\} \times \mathbb{R}^n) \) be the projection of \( L' \cap (\{y\} \times \mathbb{R}^n) \times \mathbb{R}_\mathbb{Z}, J^1(\mathbb{R}^2n) \) to \( J^1(\{y\} \times \mathbb{R}^n) \). Then \( \mathcal{L}_y \) is a Legendrian lift of \( \mathcal{L}_y \). For \( y \in \mathcal{B} \) these manifolds \( \mathcal{L}_y \) are all diffeomorphic to \( \mathcal{L}'_0 \) and there exists a \( C^\infty \) map \( u: B \times \mathcal{L}_0' \to J^1(\mathbb{R}^n) \) such that \( u(\{y\} \times \mathcal{L}_0') = \mathcal{L}_y \). We can lift this map \( u \) into a contact isotopy (see for example Theorem 2.6.2 of [13]). Indeed this is possible for a family of compact Legendrian manifolds. However, since \( T_\pi(L_y') = L_y' \) for all \( y \in \mathcal{B} \), we can find a family \( \mathcal{L}_y' \), \( y \in \mathcal{B} \), of compact Legendrian submanifolds of \((T^*\mathbb{R}^n) \times (\mathbb{R}/\pi\mathbb{Z}) \) such that \( \mathcal{L}_y' \) is a covering of \( \mathcal{L}_y'' \). Then we find a contact isotopy of \((T^*\mathbb{R}^n) \times (\mathbb{R}/\pi\mathbb{Z}) \) and lift it to \( J^1(\mathbb{R}^n) \). We thus have a contact isotopy \( \Phi: B \times J^1(\mathbb{R}^n) \to J^1(\mathbb{R}^n) \) such that \( \Phi_y(L_0') = L_y' \), for any \( y \in \mathcal{B} \).

A Legendrian submanifold of \( J^1(M) \) gives a conic Lagrangian submanifold of \( \{\tau > 0\} \subset T^*(M \times \mathbb{R}) \). Hence \( L', L_y' \) give conic Lagrangian submanifolds of \( \hat{T}^*\mathbb{R}^{2n+1} \) or \( \hat{T}^*\mathbb{R}^{n+1} \) that we also denote \( L', L_y' \). The equivalence of categories \((2.1.6) \) of Corollary \((2.1.4) \) applied with \( I = B \), \( A_0 = L, A' = L' \) gives a unique sheaf \( G \in \mathcal{D}_{L'}(k_{B \times \mathbb{R}^{n+1}}) \) such that \( G|_{\{0\} \times \mathbb{R}^{n+1}} \simeq G_0 \), where \( G_0 \) is defined in \((6.2.6) \).

**Remark 6.2.10.** This sheaf \( G \in \mathcal{D}_{L'}(k_{B \times \mathbb{R}^{n+1}}) \) is constructed in another way in \([12]\) and is shown to be a projector from sheaves on \( \mathbb{R}^{n+1} \) to sheaves with a microsupport contained in \( \rho_{\mathbb{R}^{n+1}}^{-1}(\mathcal{B}(T^*\mathbb{R}^n)) \).

**Proposition 6.2.11.** Let \( r < 1 \) be given and let \( D_r \subset \mathbb{R}^2 \) be the closed disc of radius \( r \). There is no Hamiltonian isotopy \( \Phi: \mathbb{R}^{2n} \times I \to \mathbb{R}^{2n} \) such that \( \Phi_1(B_1(\mathbb{R}^n)) \subset D_r \times \mathbb{R}^{2n-2} \).

**Proof.** (i) It is enough to prove that \( e'(G) \geq \pi \); the rest of the proof of Proposition \((6.2.8) \) works the same (recall that Proposition \((6.2.3) \) works with a parameter space \( N \) which is \( B \) in our case). To prove \( e'(G) \geq \pi \) we will use Corollary \((1.2.13) \) which require some properness condition on the support. We set \( \Omega = B \times \mathbb{R}^{n+1} \) and let \( j: \Omega \to \mathbb{R}^{2n+1} \) be the inclusion. We choose \( a < b \) and we set \( Z = B \times \mathbb{R}^n \times [a, b] \). We let \( u \in \text{Hom}(Rj_!(G_Z), Rj_*((G_Z))) \) be the natural morphism. It is enough to prove that \( u_c := Rj_!(\tau_c(G_Z)) \circ u \) is non zero for \( 0 < c < \pi \), if \( b - a \) is big enough.

(ii) We set \( F = Rj_!G, H_c = T_{cc}(Rj_!G) \) and \( H'_c = T_{cc}(Rj_*G_Z) \). Restricting \( F \) and \( H_c \) to \( \{0\} \times \mathbb{R}^{n+1} \) and using Remark \((6.2.7) \) as in the proof of Proposition \((6.2.9) \) we see that \( u_{c0} \neq 0 \) for some \( c_0 > 0 \) (in fact for \( 0 < c_0 < \pi/2 \)).
(ii-a) Over \( \Omega \) we have \( \hat{\mathcal{S}}S(F) \subset L' \) and \( \hat{\mathcal{S}}S(H_\omega) \subset T_\omega(L') \). We recall that \( L' \) is contained in \( T^*B \times \rho_{\mathbb{R}^n}^{-1}(S_1(T^*\mathbb{R}^n)) \) and that \( L' \cap T_\omega(L') = \emptyset \) for \( 0 < c < \pi \). By Theorem 1.2.13 we have \( \hat{\mathcal{S}}S(F_Z) \subset L' + \mathcal{S}S(k_Z) \). Since \( \hat{\mathcal{S}}S(k_Z) = (B \times \mathbb{R}^n) \times \{ \{a, b\} \times \{\tau > 0\} \} \) we deduce that \( \hat{\mathcal{S}}S(F_Z) = L' \) except over the set \( \{ t = a \text{ or } b \} \) where we have \( \mathcal{S}S(F_Z) \setminus \mathcal{S}S(F) \subset T^*B \times \rho_{\mathbb{R}^n}^{-1}(\text{Int}(B_1(T^*\mathbb{R}^n))) \). The same remark holds for \( \mathcal{S}S(H_\omega') \). In particular, if \( b - a > \pi \) we still have \( \mathcal{S}S(F_Z) \cap \mathcal{S}S(H_\omega') = \emptyset \) for \( 0 < c < \pi \).

(ii-b) We set \( L_\Omega = \mathcal{S}S(k_\Omega) \). We recall that \( L_\Omega \) is the union of the zero section over \( \Omega \) and one half of \( T^*_\partial \mathbb{R}^{2n+1} \). By Theorem 1.2.13 we have \( \hat{\mathcal{S}}S(F) \subset L' + L_\Omega \) and \( \hat{\mathcal{S}}S(T_\omega R_{j_*}G) \subset T_\omega(L') + L_\Omega^a \). We set \( \Sigma = \pi_{\mathbb{R}^{2n+1}}(L') \cap \partial \Omega \) and we define \( \lambda \subset (\mathbb{R}^{2n+1})^* \) by \( \lambda = \{ (\xi, \xi', \tau) ; \tau \geq ||\xi|| \text{ and } \tau \geq ||\xi'|| \} \). Since \( \rho_{\mathbb{R}^{2n+1}}(L') = L \subset B_1(T^*\mathbb{R}^n) \times B_1(T^*\mathbb{R}^n) \) we have \( L' \subset \mathbb{R}^{2n+1} \times \lambda \). Hence, on the boundary of \( \Omega \) we have the rough bounds

\[
\hat{\mathcal{S}}S(F) \cap (\partial \Omega \times \mathbb{R}^{2n+1} T^*\mathbb{R}^{2n+1}) \subset L_\Omega \cup (L_\Omega + \Sigma \times \lambda),
\]

\[
\hat{\mathcal{S}}S(T_\omega R_{j_*}G) \cap (\partial \Omega \times \mathbb{R}^{2n+1} T^*\mathbb{R}^{2n+1}) \subset L_\Omega^a \cup (L_\Omega^a + T_\omega(\Sigma) \times \lambda)).
\]

When we replace \( F \) by \( F_Z \) and \( T_\omega R_{j_*}G \) by \( H_\omega \) we increase the microsupports by adding \( (B \times \mathbb{R}^n) \times (\{ \tau > 0 \} \) but the above bounds do not change.

We see that \( (L_\Omega + \Sigma \times \lambda) \cap L_\Omega^a \) and \( (L_\Omega^a + \Sigma \times \lambda) \cap L_\Omega \) are contained in the zero section. We can check also that \( \Sigma \cap T_\omega(\Sigma) = \emptyset \) for \( 0 < c < \pi \).

(iii) By the bounds in (ii) for the microsupports we can apply Corollary 1.2.15 and we obtain \( \text{Hom}(F_Z, (H_\omega)_Z) \simeq \text{Hom}(F_Z, (H_\omega)_Z) \), for \( 0 < c < \pi \). It follows that \( u_c \neq 0 \) for \( c < \pi \), as required.

\[\square\]

Part 7. The Gromov-Eliashberg theorem

The Gromov-Eliashberg theorem (see 14 20) says that the group of symplectomorphisms of a symplectic manifold is \( C^0 \)-closed in the group of diffeomorphisms. This can be translated into a statement about the Lagrangian submanifolds which are graphs of symplectomorphisms. It can be deduced from the Gromov nonsqueezing theorem but we want to stress the relation with the involutivity theorem of Kashiwara-Schapira (stated here as Theorem 1.3.6).

Let us explain the idea of the proof. We assume for a while a stronger assumption than the Gromov-Eliashberg theorem: let \( M \) be a manifold and let \( \phi_n \) be a sequence of homogeneous Hamiltonian isotopies of \( T^*M \) which converges in \( C^0 \) norm to a diffeomorphism \( \phi_\infty \) of \( T^*M \). Let \( K_n \in \mathcal{D}(k_M) \) be the sheaf associated with \( \phi_n \) by Theorem 2.1.1.

Hence \( \hat{\mathcal{S}}S(K_n) = \Gamma_{\phi_n}, \) the graph of \( \phi_n \), and \( H^0(M^2; K_n) \simeq k \). We
define a kind of limit $K_\infty$ by the distinguished triangle $\bigoplus_{n \in \mathbb{N}} K_n \to \prod_{n \in \mathbb{N}} K_n \to K_\infty \xrightarrow{+1}$. Then we can check that $\bar{\text{SS}}(K_\infty) \subset \Gamma_{\phi_\infty}$ and $H^0(M^2; K_\infty) \simeq \prod_{k \in \mathbb{N}} k / \bigoplus_{k \in \mathbb{N}} k$. Hence $K_\infty \neq 0$ and we can deduce from the involutivity theorem that $\Gamma_{\phi_\infty}$ is coisotropic. It follows that $\phi_\infty$ is a symplectic map.

However the Gromov-Eliashberg theorem is a local version of the previous result and the $\phi_n$ are only symplectic diffeomorphisms. It is not difficult to modify the $\phi_n$ away from a given point to turn them into Hamiltonian isotopies and make them homogeneous by adding a variable. Our sheaves $K_n$ live now on $M^2 \times \mathbb{R}$. The problem is that the convergence of $\Gamma_{\phi_n}$ to $\Gamma_{\phi_\infty}$ is now true only in a neighborhood of a point and we have no control on $\Gamma_{\phi_n}$ away from this point; more precisely we have a subset $\Gamma'_n$ of $\Gamma_{\phi_n}$ such that $\Gamma'_n$ converges to a subset of $\Gamma_{\phi_\infty}$. We use a cut-off lemma of Part 3 to split $K_n$ in a small ball $B$ as $K_n = K'_n \oplus K''_n$, with $\text{SS}(K'_n) \subset \Gamma'_n$. The main difficulty is to prove that the above “limit” of $K'_n$ is non zero. The previous argument fails since we have no control on the global sections. Instead with restrict $K_n$ to a line $D = \{x_0\} \times \mathbb{R}$ and decompose $K_n$ as a sum of constant sheaves on intervals using Corollary 4.4.3 say $K_n|_D \simeq \bigoplus_{a \in A_n} k_{I^*_a}[a^n]$.

To insure that $K'_n$ does not vanish when $n \to \infty$, we prove that there are intervals $I^*_a$ bigger than $B \cap D$ as follows. Let $\pi$ be the projection from $T^*(M^2 \times \mathbb{R})$ to the base. If an interval $I^*_a$ is contained in $B$, the splitting $K_n = K'_n \oplus K''_n$ prevents it from having one end in $\pi(\Gamma'_n)$ and the other in $\pi(\Gamma_{\phi_n} \setminus \Gamma'_n)$. In other word, the intervals with exactly one end in $\pi(\Gamma'_n)$ are big. Hence it is enough to see that the projection of $\Gamma'_n$ to $M^2$ is of degree one to find a big interval.

### 7.1. The involutivity theorem

The main tool in our proof of the Gromov-Eliashberg theorem is the involutivity theorem of [30]. We recall its statement (see Theorem 6.5.4 of [30] restated here as Theorem 1.3.6). For a manifold $N$, a subset $S$ of $N$ and $p \in N$, we use the notations $C_p(S), C_p(S,S) = C(S,S) \cap T_pN$ of (1.1.2) and (1.1.3) for the tangent cones of $S$ at $p$. Let $M$ be a manifold, $k$ any coefficient ring and $F \in D(k_M)$. The involutivity theorem says that the microsupport $S = \text{SS}(F)$ of $F$ is a coisotropic subset of $T^*M$ in the sense that $(C_p(S,S))^{-\omega_p} \subset C_p(S)$, for all $p \in S$.

We quote the following lemmas.

**Lemma 7.1.1.** Let $X$ be a symplectic manifold and let $S \subset S'$ be locally closed subsets of $X$. Let $p \in S$. We assume that $S$ is coisotropic at $p$. Then $S'$ is also coisotropic at $p$. 

Proof. This is obvious since we have the inclusions 
\((C_p(S', S'))^{\omega_p} \subset (C_p(S, S))^{\omega_p} \subset C_p(S) \subset C_p(S')\).

We recall the map \(\rho_M : T^*M \times T^*\mathbb{R} \to T^*M\), \((x, t; \xi, \tau) \mapsto (x; \xi/\tau)\), defined in (2.3.1).

Lemma 7.1.2. Let \(M\) be a manifold and \(S \subset T^*M\) a locally closed subset. Let \(p \in S\) and \(q \in \rho_M^{-1}(p)\). Then \(S\) is coisotropic at \(p\) if and only if \(\rho_M^{-1}(S)\) is coisotropic at \(q\).

Proof. We use coordinates \((x, t; \xi, \tau)\) on \(T^*(M \times \mathbb{R})\) and corresponding coordinates \((X, T; \Xi, \Sigma)\) on \(T_q T^*(M \times \mathbb{R})\). We set \(S' = \rho_M^{-1}(S)\) and we write \(q = (x_0, t_0; \xi_0, \tau_0)\). We have \(d\rho \circ \rho^{-1}_M(X, T; \Xi, \Sigma) = (X; \frac{1}{\tau_0} \Xi - \frac{\Xi_0}{\tau_0} \Sigma)\). Since \(S'\) is conic, we may assume \(\tau_0 = 1\). Using the symplectic transformations \((x; \xi) \mapsto (x; \xi - \xi_0)\) on \(T^*M\) and \((x, t; \xi, \tau) \mapsto (x, t + \langle \xi_0, x \rangle; \xi - \tau \xi_0, \tau)\) on \(T^*(M \times \mathbb{R})\), which commute with \(\rho_M\), we may also assume \(\xi_0 = 0\). Then we have \(d\rho \circ \rho^{-1}_M(X, T; \Xi, \Sigma) = (X; \Xi)\) and we deduce \(C_q(S') = C_p(S) \times T_{(t_0; 1)} T^*\mathbb{R}\) and \(C_q(S', S') = C_p(S, S) \times T_{(t_0; 1)} T^*\mathbb{R}\). Now the result follows easily. \(\square\)

7.2. APPROXIMATION OF SYMPLECTIC MAPS

Let \((E, \omega)\) be a symplectic vector space which we identify with \(\mathbb{R}^{2n}\). We recall a standard application of the Alexander trick which says that a symplectic map \(\varphi : B^E_R \to E\) defined on some ball of \(E\) coincides with a Hamiltonian isotopy of \(E\) on some smaller ball \(B^E_R\).

We endow \(E\) with the Euclidean norm of \(\mathbb{R}^{2n}\). For an open subset \(U \subset E\) and a map \(\psi : U \to E\) we set
\[
\|\psi\|_U = \sup\{|\psi(x)|; \ x \in U\},
\]
\[
\|\psi\|_U^1 = \sup\{|\psi(x)|, |d\psi_x(v)|; \ x \in U, \|v\| = 1\}, \text{ if } \psi \text{ is } C^1.
\]

Lemma 7.2.1. Let \(R > r\) and \(\varepsilon\) be positive numbers. Let \(\varphi : B^E_R \to E\) be a symplectic map of class \(C^1\). Then there exists \(R' > r\) and a symplectic map \(\psi : B^E_{R'} \to E\) which is of class \(C^\infty\) such that \(\|\varphi - \psi\|_{B^E_{R'}} \leq \varepsilon\).

Proof. We set \(r_1 = (R + r)/2\) and we choose a (non symplectic) map \(\varphi' : B^E_{R} \to E\) of class \(C^\infty\) such that \(\|\varphi - \varphi'\|_{B^E_{R_1}} \leq \varepsilon\). We set \(\omega' = \varphi'^* (\omega)\). We have \(\omega - \omega' = (\varphi - \varphi')^* \omega\). Hence, if we consider \(\omega\) and \(\omega'\) as maps from \(E\) to \(\wedge^2 E\) and we endow \(\wedge^2 E\) with the Euclidean structure induced by \(E\), we have \(\|\omega - \omega'\|_{B^E_{R_1}} \leq C \varepsilon\), where the constant \(C\) only depends on \(n\).

We set \(r_2 = (r_1 + r)/2\). By Moser’s argument for the Darboux theorem we can find a flow \(\Phi : B^E_{r_1} \times [0, 1] \to E\) such that \(\Phi_t(B^E_{r_2}) \subset B^E_{r_1}\).
for all \( t \in [0, 1] \) and \( \omega|_{B_{r_2}^E} = \Phi_t^*(\omega')|_{B_{r_2}^E} \). The flow \( \Phi \) is the flow of a vector field \( X_t \) which satisfies \( tX_t(\omega_t) = -\alpha \) over \( B_{r_1}^E \), where \( \omega_t = tw - (1 - t)\omega \) and \( d\alpha = \omega' - \omega \). We can assume that \( \alpha \) satisfies the bound \( \|\alpha\|_{B_{r_1}^E} \leq C'\|\omega' - \omega\|_{B_{r_1}^E} \) for some \( C' > 0 \) only depending on \( r_1 \).

Hence \( X_t \) satisfies \( \|X_t\|_{B_{r_1}^E} \leq C''\varepsilon \), for some constant \( C'' > 0 \) and all \( t \in [0, 1] \).

We may assume from the beginning that \( C''\varepsilon < r_1 - r_2 \). Hence \( \Phi_1(B_{r_2}^E) \subset B_{r_1}^E \) and we have \( \|\Phi_1 - \text{id}\|_{B_{r_1}^E} \leq C''\varepsilon \). The map \( \psi = \varphi' \circ \Phi_1 : B_{r_2}^E \to E \) is a symplectic map such that \( \|\varphi - \psi\|_{B_{r_2}^E} \leq (1 + C'')\varepsilon \), which gives the lemma (up to replacing \( \varepsilon \) by \( \varepsilon/(1 + C'') \)).

**Proposition 7.2.2.** Let \( R > r > 0 \) be given. Let \( \varphi : B_r^E \to E \) be a symplectic map of class \( C^\infty \). Then there exists a Hamiltonian isotopy \( \Phi : E \times \mathbb{R} \to E \) of class \( C^\infty \) and with compact support such that \( \Phi_1|_{B_r^E} = \varphi|_{B_r^E} \).

**Proof.** (i) For any map \( u : E \to E \) which is a translation or a symplectic linear map and for any compact subset \( C \subset E \), we can find a Hamiltonian isotopy \( \Psi : E \times \mathbb{R} \to E \) with compact support such that \( \Psi_1|_C = u|_C \). Hence, up to composing with such a \( \Psi \), we may assume that \( \varphi(0) = 0 \) and \( d\varphi_0 = \text{id}_E \).

(ii) We first show that there exists a Hamiltonian isotopy \( \Phi : E \times \mathbb{R} \to E \) with compact support such that \( \Phi_1^* \circ \varphi = \text{id}_E \) near 0. We choose a symplectic isomorphism \( E^2 \simeq T^*\Delta \) where \( \Delta \) is the diagonal. Through this isomorphism the graph of \( \varphi \) is a Lagrangian subset, say \( \Lambda \), of \( T^*\Delta \). Since \( \varphi(0) = 0 \) and \( d\varphi_0 = \text{id}_E \), the set \( \Lambda \) is tangent to the zero section at 0 and there exists a 1-form \( \alpha \) on \( \Delta \) such that \( \Lambda \) coincides with the graph of \( \alpha \) near 0. Since \( \Lambda \) is Lagrangian, \( \alpha \) is closed and we can find a function \( f : \Delta \to \mathbb{R} \) with compact support such that \( \alpha \) coincides with the graph of \( df \) in some neighborhood \( U \) of 0. Up to restricting \( U \) we can assume that \( f \) is small enough in \( C^2 \)-norm so that the graph \( \Lambda_t \) of \( tf \), viewed as a subset of \( E^2 \), is the graph of a diffeomorphism \( \Phi_t : E \to E \) for all \( t \in [-1, 2] \). Then \( \Phi \) is a Hamiltonian isotopy with compact support and \( \Phi_1^* \circ \varphi = \text{id}_E \) near 0.

(iii) By (ii) we can assume that \( \varphi|_{B_r^E} = \text{id}_E \) for some small ball \( B_r^E \).

We define \( U \subset E \times ]0, +\infty[ \) and \( \psi : U \to E \) by

\[
U = \{ (x, t); \|x\| < R/t \}, \quad \psi(x, t) = t^{-1}\varphi(tx).
\]

Then \( \psi(\cdot, t) \) is a symplectic map for all \( t > 0 \). We let \( V = \{ (\psi(x, t), t); (x, t) \in U \} \) be the image of \( U \) by \( \psi \times \text{id}_\mathbb{R} \). Then \( V \) is contractible and we can find \( h : V \to \mathbb{R} \) such that \( \psi \) is the Hamiltonian flow of \( h \).
We define \( U_0 \subset U \) by \( U_0 = \{(x,t); \ t > 0, \ ||x|| < \varepsilon/t\} \). Since \( \varphi|_{B_r^E} = \text{id}_E \), we have \( \psi(x,t) = x \) for all \((x,t) \in U_0 \). Hence \( U_0 \subset V \). Moreover \( h \) is constant on \( U_0 \). We can assume \( h|_{U_0} = 0 \) and extend \( h \) by 0 to a \( C^\infty \) function defined on \( V' = ]-\infty,0[ \cup V \).

We set \( Z = \{(\psi(x,t),t); \ t \in ]0,1[ \) and \( ||x|| \leq r \). For \( t \leq \varepsilon/r \) and \( ||x|| \leq r \) we have \( \psi(x,t) = x \). Hence

\[
Z = (\overline{B_r^E} \times ]0,\varepsilon/r[) \cup (\psi \times \text{id}_R)(\overline{B_r^E} \times [\varepsilon/r,1])
\]

and it follows that \( \overline{Z} \) is compact. We choose a compact subset \( C \subset E \) such that \( Z \subset \text{Int}(C) \times [0,1] \) and a \( C^\infty \) function \( g: E \times \mathbb{R} \to \mathbb{R} \) such that \( g = h \) on \( Z \) and \( g = 0 \) outside of \( C \times [0,2] \). Then the Hamiltonian isotopy \( \Phi \) defined by \( g \) has compact support contained in \( C \) and satisfies \( \Phi_1 = \varphi \) on \( B_r^E \). This proves the proposition. \( \square \)

7.3. Degree of a continuous map

We recall the definition of the degree of a continuous map. Let \( M, N \) be two oriented manifolds of the same dimension, say \( d \). We assume that \( N \) is connected. We have a morphism \( H^d_c(M;\mathbb{Z}_M) \to \mathbb{Z} \) and an isomorphism \( H^d_c(N;\mathbb{Z}_N) \overset{\sim}{\to} \mathbb{Z} \). Let \( f: M \to N \) be a proper continuous map. Applying \( H^d_c(N;\cdot) \) to the morphism \( \mathbb{Z}_N \to Rf_*f^{-1}\mathbb{Z}_N \simeq Rf_*\mathbb{Z}_M \) we find

\[
\mathbb{Z} \overset{\sim}{\to} H^d_c(N;\mathbb{Z}_N) \to H^d_c(M;\mathbb{Z}_M) \to \mathbb{Z}.
\]

The degree of \( f \), denoted \( \text{deg} f \), is the image of 1 by this morphism.

**Lemma 7.3.1.** Let \( M, N \) be two oriented manifolds of dimension \( d \). We assume that \( N \) is connected.

(i) Let \( f: M \to N \) be a proper continuous map and let \( V \subset N \) be a connected open subset. Then \( \text{deg} f = \text{deg}(f|_{f^{-1}(V)}): f^{-1}(V) \to V \).

(ii) Let \( I \subset \mathbb{R} \) be an interval. Let \( U \subset M \times I \), \( V \subset N \times I \) be open subsets and let \( f: U \to V \) be a continuous map which commutes with the projections \( U \to I \) and \( V \to I \). We set \( U_t = U \cap (M \times \{t\}) \), \( V_t = V \cap (N \times \{t\}) \) and \( f_t = f|_{U_t}: U_t \to V_t \), for all \( t \in I \). We assume that \( f \) is proper and that \( V \) and all \( V_t \), \( t \in I \), are non empty and connected. Then \( \text{deg} f = \text{deg} f_t \), for all \( t \in I \).

**Proof.** (i) and (ii) follow respectively from the commutative diagrams

\[
\begin{array}{ccc}
\mathbb{Z} & \overset{\sim}{\leftarrow} & H^d_c(N;\mathbb{Z}_V) \\
& & \downarrow \\
& \mathbb{Z} & \overset{\sim}{\leftarrow} & H^d_c(N;\mathbb{Z}_N) \\
& & \downarrow \\
& & \mathbb{Z},
\end{array}
\]

\[
\begin{array}{ccc}
H^d_c(M;\mathbb{Z}_{f^{-1}(V)}) & \to & H^d_c(M;\mathbb{Z}_M) \\
\downarrow \\
H^d_c(M;\mathbb{Z}_{f^{-1}(V)}) & \to & H^d_c(M;\mathbb{Z}_M)
\end{array}
\]
Proposition 7.3.2. Let $B_R$ be the open ball of radius $R$ in $\mathbb{R}^d$. Let $U, V \subset \mathbb{R}^d$ be open subsets and let $f : U \to B_R$, $g : V \to B_R$ be proper continuous maps. We assume that there exists $r < R$ such that $f^{-1}(B_r) \subset U \cap V$, and that $d(f(x), g(x)) < r/2$, for all $x \in U \cap V$. Then $\deg f = \deg g$.

Proof. (i) We define $h : (U \cap V) \times [0, 1] \to \mathbb{R}^{d+1}$ by $h(x, t) = (tf(x) + (1-t)g(x), t)$. Let us prove that $h^{-1}(B_{r/2} \times [0, 1])$ is compact. Since $f^{-1}(B_r)$ is compact and contained in $U \cap V$, it enough to prove that $h^{-1}(B_{r/2} \times [0, 1]) \subset f^{-1}(B_r) \times [0, 1]$. Let $(x, t) \in (U \cap V) \times [0, 1]$ be such that $\|h(x, t)\| \leq r/2$. Since $h(x, t)$ belongs to the line segment $[f(x), g(x)]$ which is of length $< r/2$, we deduce $f(x) \in B_r$, as required.

(ii) We define $W = h^{-1}(B_{r/2} \times [0, 1])$, $W_t = W \cap (\mathbb{R}^d \times \{t\})$ for $t \in [0, 1]$ and $h_t = h|_{W_t} : W_t \to B_{r/2}$. By (i) $h|_W : W \to B_{r/2} \times [0, 1]$ is proper. Hence Lemma 7.3.1(ii) implies that $\deg h_0 = \deg h_1$. We conclude with Lemma 7.3.1(i) which implies $\deg h_0 = \deg g$ and $\deg h_1 = \deg f$. □

7.4. The Gromov-Eliashberg theorem

Let $(E, \omega)$ be a symplectic vector space which we identify with $\mathbb{R}^{2n}$. We endow $E$ with the Euclidean norm of $\mathbb{R}^{2n}$. For $R > 0$ we let $E_R$ be the open ball of radius $R$ and center 0. For a map $\psi : E_R \to E$ we set $\|\psi\|_{E_R} = \sup\{\|\psi(x)\| : x \in E_R\}$.

For a map $f : E \to E$ we denote by $i_f : E \to E \times E$ the embedding $x \mapsto (x, i_f(x))$ and by $\Gamma_f = i_f(E)$ the graph of $f$.

Lemma 7.4.1. Let $V = \mathbb{R}^n$ and $E = T^*V$. Let $f : E \to E$ be a map of class $C^1$ and $0 < R$ be given. Then there exist a Hamiltonian isotopy $\Phi : T^*V \times \mathbb{R} \to T^*V$ with compact support, $\varepsilon > 0$ and three balls centered at 0: $B_V \subset V^2$ and $B_{0}^* \subset B_{0}^* \subset (V^*)^2$ such that for any other map $g : E \to E$ with $\|f - g\|_{E_R} < \varepsilon$ we have

(a) $\Phi_1 \circ i_f(0) = (0, 0)$,
(b) $\Phi_1(\Gamma_g) \cap (B_V \times (B_{0}^* \setminus B_{0}^*)) = \emptyset$,
(c) $\Gamma_g := \Phi_1(\Gamma_g) \cap (B_V \times B_{0}^*)$ is contained in $\Phi_1(i_g(E_R))$,
(d) the restriction of $\pi_{V^2}$ to $\Gamma_g$ gives a proper map $\Gamma_g' \to B_V$ of degree 1.
Proof. (i) We set \( p = (0, f(0)) \in E^2 \); \( q = (0; 0) \in T^*V^2 \) and \( F = T_p \Gamma_f \). We can find a symplectic map \( \psi: T_p E^2 \to T_q E^2 \) such that \( d(\pi_{12}) q: T_q E^2 \to T_q V^2 \) induces an isomorphism \( \psi(F) \cong T_0 V^2 \). We choose a Hamiltonian isotopy \( \Phi \) such that \( \Phi(1) = q \) and \( d\Phi_1 = \psi \).

(ii) We can find balls \( B_V, B_0^*, B_1^* \) such that (b-d) hold for \( g = f \). Indeed we first choose a neighborhood \( W \subset B_{E_0}^* \) of \( 0 \) in \( E \) such that \( \pi_{12} \circ \Phi_1 \circ i_f \) induces a diffeomorphism from \( W \) to \( W' = \pi_{12}(\Phi(1)(i_f(W))) \). Then \( \pi_{12} \) is a diffeomorphism from \( \Gamma' = \Phi_1(i_f(W)) \) to \( W' \) and it is easy to find \( B_V, B_0^* \) such that (c) and (d) hold. Up to shrinking \( B_V, B_0^* \), we can also find \( B_1^* \) such that (b-d) hold.

(iii) For \( g \) close enough to \( f \) the property (d) holds by Proposition 7.3.2 (apply the proposition with \( f', g' \), \( U', V' \) where \( f' := \pi_{12} \circ \Phi_1 \circ i_f \), \( g' := \pi_{12} \circ \Phi_1 \circ i_g \), \( U' = f'^{-1}(B_V), V' = g'^{-1}(B_V) \)).

To check (c), we ask the additional condition \( \Phi_1^{-1}(B_V \times B_1^*) \subset B_E^* \times E \), which is satisfied up to shrinking \( B_V, B_1^* \).

For (b) we choose balls \( B_V', B_1' \) slightly smaller than \( B_V, B_1^* \) and \( B_0^* \) slightly bigger than \( B_0^* \). Let us assume that there exists \( x \in E \) such that \( \Phi_1(x, g(x)) \in B_V' \times (B_1' \setminus B_0^*) \). Then \( (x, g(x)) \in B_E^* \times E \) and \( ||f(x) - g(x)|| < \varepsilon \). For \( \varepsilon \) small enough this implies \( \Phi_1(x, f(x)) \in B_V \times (B_1' \setminus B_0^*) \) which is empty. Hence, up to replacing \( B_V, B_0^*, B_1^* \) by \( B_V', B_0^*, B_1' \), we also have (b) for \( g \). \( \square \)

Now we can give a proof of the Gromov-Eliashberg rigidity theorem (see [14, 20]).

**Theorem 7.4.2.** Let \( R > 0 \). Let \( \varphi_k: B_R^E \to E, k \in \mathbb{N} \), and \( \varphi_\infty: B_R^E \to E \) be \( C^1 \) maps. We assume

(i) \( \varphi_k \) is a symplectic map, that is, \( \varphi_k^* (\omega) = \omega \), for all \( k \in \mathbb{N} \),

(ii) \( ||\varphi_k - \varphi_\infty||_{B_R^E} \to 0 \) when \( k \to \infty \),

(iii) \( d\varphi_\infty \circ T_x E \to T_{\varphi_\infty(x)} E \) is an isomorphism, for all \( x \in B_R^E \).

Then \( \varphi_\infty \) is a symplectic map.

**Proof.** (i) We will prove \( d\varphi_\infty \circ x \) is a symplectic linear map for any given \( x \in B_R^E \). Up to composition with a translation we can as well assume \( x = 0 \). By Lemma 7.2.1 and Proposition 7.2.2 we can also assume, up to shrinking \( R \), that \( \varphi_k = \Phi_k \circ_{B_R^E} \) is the restriction of (the time 1 of) a globally defined Hamiltonian isotopy \( \Phi_k: E \times \mathbb{R} \to E \) with compact support, for each \( k \in \mathbb{N} \).

Let us choose an isomorphism \( E \simeq T^*V \) where \( V = \mathbb{R}^n \). We let \( \Gamma_k \subset T^*V^2 \) be the graph of \( \Phi_k \), twisted by \( (x, x'; \xi, \xi') \mapsto (x, x'; \xi, -\xi') \). We let \( \Gamma_\infty \) be the graph of \( \varphi_\infty \) with the same twist. It is enough to prove that \( \Gamma_\infty \) is coisotropic at \( (0; \varphi_\infty(0)) \).
We assume $n \geq 2$ (the case $n = 1$ is about volume preserving maps and is easy). Then $\Phi^k$ can be defined by a compactly supported Hamiltonian function.

(ii) We recall the map $\rho: T^*V^2 \times \mathbb{T}^*\mathbb{R} \to T^*V^2$, $(x,t; \xi, \tau) = (x; \xi/\tau)$, defined in (2.3.1). By Corollary 2.3.2 there exists $F_k \in D^b(k_{V^2 \times \mathbb{R}})$ such that $SS(F_k)$ is a conic Lagrangian submanifold of $\mathcal{T}^*(V^2 \times \mathbb{R})$ contained in $\{\tau \geq 0\}$ and $\rho(\text{SS}(F_k) \cap \{\tau > 0\}) = \Gamma_k$.

(iii) We apply Lemma 7.4.1 with the function $f: E \to E$ given by $f(x; \xi) = \varphi_\infty(x; \xi)^a$. It yields a Hamiltonian isotopy $\Phi$ with compact support and three balls centered at 0: $B_V \subset V^2$ and $B_0^* \subset B_1^* \subset (V^*)^2$ such that the conditions (a-d) of the lemma hold for $g(x; \xi) = \varphi_k(x; \xi)^a$ if $k$ is big enough.

By Proposition 2.3.1 we can lift $\Phi$ to a homogeneous Hamiltonian isotopy $\Psi$ of $\mathcal{T}^*(V^2 \times \mathbb{R})$ such that the diagram (2.3.2) commutes. Then Theorem 2.1.1 gives $K \in D^b(k_{V^2 \times \mathbb{R}})$ such that $SS(K)$ is the graph of $\Psi_1$. We set $G_k = K \circ F_k$ and $\Lambda_k = SS(G_k)$ for each $k \in \mathbb{N}$. Then $G_k \in D^b(k_{V^2 \times \mathbb{R}})$ and $\Lambda_k = \Psi(\text{SS}(F_k))$. We still have

$$\Lambda_k \subset \{\tau \geq 0\}, \quad \rho(\Lambda_k) = \Phi_1(\Gamma_k).$$

(iv) We can find a point $x_0 \in B_V \subset V^2$, as closed to 0 as we want, such that, for any $k$, the Lagrangian submanifold $\Lambda_k \subset \mathcal{T}^*(V^2 \times \mathbb{R})$ is in generic position with respect to the line $D = \{x_0\} \times \mathbb{R}$ in the following sense: there exists a neighborhood $W_k$ of $D$ and a hypersurface $S_k$ of $W_k$ meeting $D$ transversely such that $\Lambda_k \cap \mathcal{T}^*W_k = \mathcal{T}^*S_k \cap \{\tau > 0\}$. (This implies that $x_0$ is not on the diagonal.) Since $\Phi^k$ and $\Phi$ have compact supports and $x_0$ is not on the diagonal, $S_k$ has finitely many connected components.

Then $G_k|_D$ is a constructible sheaf and we can decompose it as a finite sum of constant sheaves on intervals $G_k|_D \simeq \bigoplus_{a \in A_k} k_{I^a_k}[d^k_a]$ by Corollary 4.4.3. Since $SS(G_k) \subset \{\tau \geq 0\}$, the $I^k_a$ are of the form $[a,b]$ or $]-\infty, b]$ with $b \in \mathbb{R} \cup \{+\infty\}$. The finite ends of the intervals $I^k_a$ are in bijection with

$$E_k = \Phi_1(\Gamma_k) \cap T^*_{x_0}(V^2) = (\Lambda_k \cap (T^*_{x_0}(V^2) \times T^*\mathbb{R})/\mathbb{R}_{>0}.$$

(v) We set $\Gamma^0_k = \Phi_1(\Gamma_k) \cap (B_V \times B_0^*)$ and $E_k^0 = E_k \cap \Gamma^0_k$. By Lemma 7.4.1 the map $\Gamma^0_k \to B_V$ is of degree 1 and it follows that $E_k^0$ is of odd cardinality. Hence there exists one interval $I^k_a$ with one end, say $a_k$, in $E_k^0$ and the other, say $b_k$, in $(E_k \setminus E_k^0) \cup \{\pm\infty\}$. We translate $G_k$ vertically so that $a_k = 0$ and we shift it degree so that $d^k_a = 0$ (we still have $\rho(\Lambda_k) = \Phi_1(\Gamma_k)$).
Now $G_k|_D$ has one direct summand which is $\mathbf{k}_{k'}$ with $I^k_\alpha = [0, b_k]$ or $]b_k, 0[\), $b_k$ finite or infinite. One of these possibilities occurs infinitely many times and, up to taking a subsequence, we assume $I^k_\alpha = [0, b_k]$ with $b_k \in \mathbb{R}$, for all $k$, the other cases being similar.

(vi) By Lemma 7.4.1 again $\rho(\hat{\mathcal{S}}(G_k)) \cap (B_V \times (B^*_1 \setminus B^*_0)) = \emptyset$. Hence, by Proposition 3.3.1, there exists an open ball $W$ with center $(x_0, 0)$ and radius $r$ such that, for any $k$, we have a distinguished triangle on $W$

\[
G_k' \oplus G_k'' \to G_k|_W \to L_k \xrightarrow{+1},
\]

where $L_k$ is a constant sheaf, $\hat{\mathcal{S}}(G_k') = \Lambda_k'$ with

\[
\Lambda_k' = \Lambda_k \cap \rho^{-1}(B_V \times B^*_0) \cap T^*W
\]

and $\hat{\mathcal{S}}(G_k'') = (\Lambda_k \cap T^*W) \setminus \Lambda_k'$. In particular $\hat{\mathcal{S}}(G_k'')$ does not meet $T^*(x_0, 0)$ and $G_k''$ is constant near $(x_0, 0)$. In the same way, if $(x_0, b_k)$ belongs to $W$, then $G_k'$ is constant near $(x_0, b_k)$.

On the other hand, if $(x_0, b_k)$ belongs to $W$, Lemma 7.4.3 below implies that the direct summand $\mathbf{k}_{[0,b_k]|_{D \cap W}}$ of $G_k|_{D \cap W}$ is also a direct summand of $H$ with $H = G_k'|_{D \cap W}$ or $H = G_k''|_{D \cap W}$. Then $H$ would be non constant at $(x_0, 0)$ and $(x_0, b_k)$, which gives a contradiction.

It follows that $b_k \not\in W$ and $G_k'|_{D \cap W}$ has a direct summand which is $\mathbf{k}_{[0,r]}$ (recall $r$ is the radius of $W$).

(vii) We define $G \in D(\mathbf{k}_W)$ by the distinguished triangle

\[
\bigoplus_{k \in \mathbb{N}} G_k' \to \prod_{k \in \mathbb{N}} G_k' \to G \xrightarrow{+1}.
\]

For any $N \in \mathbb{N}$ we also have the triangle $\bigoplus_{k \geq N} G_k' \to \prod_{k \geq N} G_k' \to G \xrightarrow{+1}$. We have $\hat{\mathcal{S}}(\bigoplus_{k \geq N} G_k') \subset \bigcup_{k \geq N} \Lambda_k'$ and the same bound holds for $\mathcal{S}(\prod_{k \geq N} G_k')$. Hence the same bound also holds for $\mathcal{S}(G)$ and, when $N \to \infty$, we obtain

\[
\hat{\mathcal{S}}(G) \subset \rho^{-1}(\Phi_1(\Gamma_\infty) \cap (W \times B^*_0)).
\]

We let $i : D \cap W \to W$ be the inclusion. We remark that $i$ is non-characteristic for $\rho^{-1}(W \times B^*_0)$. Hence $i$ is non-characteristic for $F = G_k'$ or $F = \prod_{k \in N} G_k'$ and Theorem 14.2.7 gives $i^{-1}F \simeq i^*F[1]$. Since $i$ commutes with $\prod_{k}$ we deduce the following distinguished triangle by applying $i^{-1}$ to (7.4.1)

\[
\bigoplus_{k \in \mathbb{N}} (G_k'|_{D}) \to \prod_{k \in \mathbb{N}} (G_k'|_{D}) \to G|_D \xrightarrow{+1}.
\]
We set \( l = \prod_{k \in \mathbb{N}} k / \bigoplus_{k \in \mathbb{N}} k \). Since \( k_{[0, r]} \) is a direct summand of \( G_k \mid_{D \cap W} \), the sheaf \( l_{[0, r]} \) is a direct summand of \( G \mid_{D \cap W} \). In particular \( G \) is not constant around \((x_0, 0)\) and \( \tilde{S}S(G) \cap T^{* \times \mathbb{R}}((V^2 \times \mathbb{R}) \neq \emptyset \).

We choose \( p \in \tilde{S}S(G) \cap T^{* \times \mathbb{R}}((V^2 \times \mathbb{R}) \). By the involutivity Theorem and Lemma \[7.1.2\] we obtain that \( \Phi(1) \) is coisotropic at \( \rho(p) \). Since \( \rho(p) \in T_x V^2 \) and \( \Phi(1) \) consists of a single point, we have \( \rho(p) = (x_0; \xi(x_0)) \). The point \( x_0 \) can be chosen arbitrarily close to 0. Hence \( \Phi(1) \) is coisotropic at \( (0; \xi(0)) \) and it follows that \( \Gamma_\infty \) is coisotropic at \( (0; \varphi_\infty(0)) \), as required. \( \square \)

**Lemma 7.4.3.** Let \( k \) be a field. Let \( I \) be an interval in \( \mathbb{R} \) and let \( a, b \in I \) with \( a < b \). Let \( F_1, F_2, F, L \in D^b(k_I) \). We assume that \( \tilde{S}S(L) = \emptyset \), that we have a distinguished triangle
\[
F_1 \oplus F_2 \xrightarrow{u} F \xrightarrow{v} L \xrightarrow{+1}
\]
and that \( k_{[a, b]} \) is a direct summand of \( F \). Then \( k_{[a, b]} \) is a direct summand of \( F_1 \) or \( F_2 \).

**Proof.** By hypothesis there exist \( i : k_{[a, b]} \to F \) and \( p : F \to k_{[a, b]} \) such that \( p \circ i = \text{id}_{k_{[a, b]}} \). Since \( L \) has constant cohomology sheaves, we have \( \text{Hom}(k_{[a, b]}, L) \simeq 0 \). Hence \( v \circ i = 0 \) and there exists \( i' = (1 \ i) : k_{[a, b]} \to F_1 \oplus F_2 \) such that \( i = u \circ i' \). Let \( p_1 : F_1 \to k_{[a, b]} \), \( p_2 : F_2 \to k_{[a, b]} \) be the components of \( p \circ u \). Then \( \text{id}_{k_{[a, b]}} = p_1 \circ i_1 + p_2 \circ i_2 \) and we deduce \( p_1 \circ i_1 \neq 0 \) or \( p_2 \circ i_2 \neq 0 \). Since \( \text{Hom}(k_{[a, b]}, k_{[a, b]}) = k \), we can multiply our morphisms by a scalar to have \( p_1 \circ i_1 \) or \( p_2 \circ i_2 \) equals id, proving the lemma. \( \square \)

**Part 8. The three cusps conjecture**

In [6] Arnol’d states a theorem of Möbius “a closed smooth curve sufficiently close to the projective line (in the projective plane) has at least three points of inflection” and conjectures that “the three points of flattening of an immersed curve are preserved so long as under the deformation there does not arise a tangency of similarly oriented branches”. This is a statement about oriented curves in \( \mathbb{R}P^2 \). Under the projective duality it is turned into a statement about Legendrian curves in the projectivized cotangent bundle of \( \mathbb{R}P^2 \): if \( \{ \Lambda_t \}_{t \in [0, 1]} \) is a generic path in the space of Legendrian knots in \( PT^*(\mathbb{R}P^2) = (T^*\mathbb{R}P^2 \setminus \mathbb{R}^2)/\mathbb{R}^2 \) such that \( \Lambda_0 \) is a fiber of the projection \( \pi : PT^*(\mathbb{R}P^2) \to \mathbb{R}P^2 \), then the front \( \pi(\Lambda_t) \) has at least three cusps. This statement is given in [11], where the authors prove a local version, replacing \( \mathbb{R}P^2 \) by the plane \( \mathbb{R}^2 \), and also another similar conjecture “the four cusps conjecture”.
Here we prove the conjecture when the base is the sphere $S^2$ (which implies the case of $\mathbb{R}P^2$ since we can lift a deformation in $PT^*(\mathbb{R}P^2)$ to a deformation in $PT^*(S^2)$).

Let us sketch the proof. A contact isotopy of $PT^*(S^2)$ lifts to a Hamiltonian isotopy $\Phi$ of $T^*S^2$ which is homogeneous for the action of $\mathbb{R}^\times$. By Theorem 2.1.1 $\Phi$ induces an equivalence, say $R_\Phi = K_\Phi \circ -$ , of the category $\mathcal{D}(k_{S^2})$. The fact that $\Phi$ is homogeneous for the action of $\mathbb{R}^\times$, and not only $\mathbb{R}_{>0}$, implies that $R_\Phi$ commutes with the duality functor $\mathcal{D}_{S^2}$. We have $\Lambda_0 = T^*_x S^2$ for some point $x_0 \in S^2$. The sheaf $F_0 = k_{\{x_0\}}$ is self-dual and simple. Hence so is $F = R_\Phi(F_0)$. Now we prove the following: if $F \in \mathcal{D}(k_{S^2})$ is self-dual and simple and $\Lambda = SS(F)/\mathbb{R}_{>0}$ is a smooth curve whose projection to $S^2$ is a generic curve with only one cusp, then $\text{Ext}^1(F, F) \neq 0$. Since $\text{Ext}^1(F_0, F_0) = 0$ there can not exist an auto-equivalence $R$ of $\mathcal{D}(k_{S^2})$ such that $R(F_0) = F$ (recall that $\text{Ext}^1(F, F) \simeq \text{Hom}(F, F[1])$).

Actually an important part of our proof is a study of a bifurcation problem for constructible sheaves in dimension 2. By this we mean the following. Let $C$ be the cylinder $C = S^1 \times I$, with $I = ]-1, 1[$. Let $\Sigma \subset C$ be a curve, $\Lambda = T^*_\Sigma C$ and let $F \in \mathcal{D}^b(k_C)$ be a simple sheaf with $SS(F) = \Lambda$. By Corollary 4.3 we can decompose the restriction $F|_{C_t}$ on the circle $C_t = S^1 \times \{t\}$ as $F|_{C_t} \simeq L \oplus \bigoplus_{a \in A} e_*(k_{I_a}^{n_a})[d_a]$, where $e : \mathbb{R} \to S^1 \simeq \mathbb{R}/2\pi\mathbb{Z}$ is the quotient map, the $I_a$ are intervals of $\mathbb{R}$ and $L$ is locally constant. If $\Sigma$ meets all the circles $C_t$ transversely, this decomposition is independent of $t$ (up to a reparametrization of $S^1$ since the ends of the intervals move). In the technical section 8.3 below, we study what happens near $C_0$ when one branch of $\Sigma$, say $\Sigma_0$, is tangent to $C_0$ and the direct image of $F$ by the projection to $I$ has $k_{\{0\}}$ has a direct summand. The main result of this section says the following: let $\varepsilon \neq 0$ be such that $C_\varepsilon$ meets $\Sigma_0$ and let $J_1, \ldots, J_s$ be the intervals $I_a$ in the decomposition of $F|_{C_\varepsilon}$ having one end in $C_\varepsilon \cap \Sigma_0$; if one of these intervals $J_k$ is open or closed, then $\text{Ext}^1(F, F) \neq 0$. More precisely the image of $H^1_{C_0}(\mathcal{C} ; R\mathcal{H}om(F, F))$ in $\text{Ext}^1(F, F)$ is no zero, which implies that any sheaf $G$ defined on a manifold containing $C$ and isomorphic to $F$ on $C$ satisfies $\text{Ext}^1(G, G) \neq 0$.

Another part of the proof gives a more global criterion to insure $\text{Ext}^1(F, F) \neq 0$. We define a notion of $F$-linked and $F$-conjugate points of $\Lambda$ in 8.3.1 and 8.2. Identifying $\Lambda/\mathbb{R}_{>0}$ with a circle $S^1$, our criterion is roughly that, if there exist a pair $(p_0, p_1)$ of $F$-linked points and a pair $(q, q')$ of $F$-conjugate points such that $(p_0, p_1)$ and $(q, q')$ are intertwined on $S^1$, then $\text{Ext}^1(F, F) \neq 0$ (see Proposition 8.1.5). Examples of conjugate points are the points of $\Lambda$ corresponding to the ends of
one interval \( I_a \) in the decomposition of \( F|_{C_\varepsilon} \) recalled above. In Proposition 8.3.8 we see that in our situation we can situate some \( F \)-linked points.

Now the hypothesis that the projection of \( \Lambda \) has one cusp is used as follows. The sheaf \( F \) has a shift at each point of \( \Lambda \), which is a half integer and changes by 1 when we cross a cusp (see (1.4.5)). If the projection of \( \Lambda \) has only one cusp, then \( \Lambda \) is decomposed in two intervals, say \( \Lambda^+ \), \( \Lambda^- \) according to the value of the shift. In the decomposition of \( F|_{C_\varepsilon} \), the points above the ends of an interval \( I_a \) which is half-closed are not in the same component \( \Lambda^\pm \). In particular, if we can not apply the first criterion for \( \text{Ext}^1(F,F) \neq 0 \), that is, if all the intervals \( J_k \) above are half-closed, then we find several pairs of conjugate points \((q^+, q^-)\) with \( q^\pm \in \Lambda^\pm \). Using the linked points of Proposition 8.3.8 it is then possible to find two intertwined pairs of linked/conjugate points and apply the second criterion.

In this part we will use Gabriel’s theorem and we assume that \( k \) is a field.

### 8.1. Microlocal linked points

Let \( M \) be a surface and let \( \Lambda \) be a smooth conic Lagrangian submanifold of \( \dot{T}^*M \). We consider \( F \in D^b(k_M) \) such that \( \dot{SS}(F) = \Lambda \) and \( F \) is simple along \( \Lambda \). In this section we give a criterion which implies that \( H^1 R\text{Hom}(F,F) \) is non zero (see Proposition 8.1.5).

For \( U, V \) two open subsets of \( M \) such that \( M = U \cup V \) and for \( G \in D^b(k_M) \) we denote by
\[
(8.1.1) \quad H^1(\{U, V\}; G) = H^0(U \cap V; G)/(H^0(U; G) \times H^0(V; G))
\]
the first Čech group of \( G \) associated with the covering \( \{U, V\} \) of \( M \). By the Mayer-Vietoris long exact sequence we have an injective map
\[
(8.1.2) \quad H^1(\{U, V\}; G) \hookrightarrow H^1(M; G).
\]
In particular it is enough for our purpose to find a covering \( \{U, V\} \) with \( H^1(\{U, V\}; R\text{Hom}(F,F)) \neq 0 \). To better understand this latter group, we use the natural morphism from \( R\text{Hom}(F,F) \) to \( R(\dot{\pi}_M)_{*}\mu\text{hom}(F,F) \).

Since \( F \) is simple we have a canonical isomorphism
\[
k_\Lambda \xrightarrow{\sim} \mu\text{hom}(F,F)|_{\dot{T}^*M}
\]
sending 1 to \( \text{id}_F \). We deduce morphisms \( R\text{Hom}(F,F) \rightarrow R(\dot{\pi}_M)|_{*}(k_\Lambda) \) and
\[
H^1(\{U, V\}; R\text{Hom}(F,F)) \rightarrow H^1(\{U', V'\}; k_\Lambda),
\]
where \( U' = T^*U \cap \Lambda, V' = T^*V \cap \Lambda \). However we loose to much information in this way and we consider a map to another Čech group.
The construction of this map relies on the notion of linked points in $\Lambda$ introduced in Definition 8.1.1 below.

We first introduce a general notation. For $G, G' \in D^b(k_M)$ we recall the canonical isomorphism $\muhom(G, G')$.

\[(8.1.3) \quad \mathcal{R}\text{Hom}(G, G') \simeq \mathcal{R}(\pi_M)_! \muhom(G, G').\]

For an open subset $W$ of $M$ and $p \in T^*W$, we deduce the morphisms

\[(8.1.4) \quad \text{Hom}(G|_W, G'|_W) \to H^0(T^*W; \muhom(G, G')), \quad u \mapsto u^\mu,\]

\[(8.1.5) \quad \text{Hom}(G|_W, G'|_W) \to H^0 \muhom(G, G')_p, \quad u \mapsto u^\mu_p.\]

For our simple sheaf $F$ and for $p \in \mathcal{SS}(F)$ we obtain

\[(8.1.6) \quad \text{Hom}(F|_W, F|_W) \to H^0(\tilde{T}^*W; k), \quad u \mapsto u^\mu,\]

\[(8.1.7) \quad \text{Hom}(F|_W, F|_W) \to k, \quad u \mapsto u^\mu_p\]

and we have $u^{\mu+}_p = u^\mu_p \cdot (\text{id}_F)^{\mu+}_p$.

**Definition 8.1.1.** Let $W \subset M$ be an open subset and let $p, q \in \Lambda \cap T^*W$ be given points. We say that $p$ and $q$ are $F$-linked over $W$ if $u^\mu_p = u^\mu_q$ for all $u \in \text{Hom}(F|_W, F|_W)$.

We remark that $u^\mu_p$ only depends on the component of $\Lambda \cap T^*W$ containing $p$ and we could also speak of $F$-linked connected components of $\Lambda \cap T^*W$.

**Remark 8.1.2.** Let $p = (x; \xi) \in \Lambda$. Let $\varphi: M \to \mathbb{R}$ be a function of class $C^\infty$ such that $\Lambda$ and $\Lambda_{\varphi}$ intersect transversally at $p$. We set $Z = \{\varphi \geq \varphi(x)\}$. For $F, G \in D^b(\Lambda)_!(k_M)$, we have by (1.4.6)

\[H^0 \muhom(F, G)_p \simeq \text{Hom}((R\Gamma Z(F))_x, (R\Gamma Z(G))_x).\]

If $F = G$ is simple at $p$, then $(R\Gamma Z(F))_x$ is $k$ in some degree. For $u \in \text{Hom}(F, F)$ the morphism $(R\Gamma Z(u))_x$ is the multiplication by the scalar $u^\mu_p$.

By Theorem 1.3.8 the functors $u \mapsto u^{\mu+}_p$ or $u \mapsto u^\mu_p$ are well-defined in the quotient category $D^b(k_M; p)$. We can also express this result as follows.

**Lemma 8.1.3.** Let $G, G' \in D^b(k_M)$ be such that $\mathcal{SS}(G), \mathcal{SS}(G') \subset \Lambda$ and let $p \in \Lambda$ be given. We assume that there exists a distinguished triangle $G \xrightarrow{g} G' \to H \xrightarrow{+1}$ and that $p \notin \mathcal{SS}(H)$. Then the composition with $g$ induces isomorphisms

\[\muhom(G, G)_p \xrightarrow{\cong} \muhom(G, G')_p \xleftarrow{\cong} \muhom(G', G)_p\]
and we have \( a((\text{id}_G)\mu_p^+) = g_p^+ = b((\text{id}_{G'})\mu_p^+) \). In particular, if \( G \) and \( G' \) are simple and \( u : G \to G \) and \( v : G' \to G' \) satisfy \( v \circ g = g \circ u \) then \( u_p^\mu = v_p^\mu \).

**Proof.** We apply the functor \( \mu\text{hom}(G, \cdot) \) to the given distinguished triangle and we take the germs at \( p \). By the bound \( \text{(1.3.3)} \) we have \( \mu\text{hom}(G, H)_p \simeq 0 \) and we deduce the isomorphism \( a \). The isomorphism \( b \) is obtained in the same way. Then the last assertion follows from the relations \( u_p^\mu = u_p^\mu \cdot (\text{id}_G)\mu_p^+ \) and \( v_p^\mu = v_p^\mu \cdot (\text{id}_{G'})\mu_p^+ \). \( \square \)

We recall that \( U, V \) are two open subsets of \( M \) such that \( M = U \cup V \). Let \( \gamma : [0, 1] \to \Lambda \) be a path such that

\[
\tag{8.1.8} p_0 = \gamma(0) \text{ and } p_1 = \gamma(1) \text{ belong to } (T^*U \setminus T^*V) \cap \Lambda \text{ and are } F \text{-linked over } U.
\]

We define a circle \( C \) by identifying 0 and 1 in \([0, 1]\). The natural orientation of \([0, 1]\) induces an orientation on \( C \). We let \( U' \) and \( V' \) be the images of \( \gamma^{-1}(T^*U \cap \Lambda) \) and \( \gamma^{-1}(T^*V \cap \Lambda) \) by the quotient map \([0, 1] \to C \). We have a canonical isomorphism \( H^1([U', V']; k_C) \simeq H^1(C; k_C) \).

For \( u \in H^0(U; \mathcal{R}\text{Hom}(F, F)) \) the inverse image of \( u^\mu \) by \( \gamma \) gives a well-defined section of \( H^0(U'; k_C) \) because \( p_0 \) and \( p_1 \) are \( F \)-linked over \( U \). An element of \( H^0(V; \mathcal{R}\text{Hom}(F, F)) \) also induces a section of \( H^0(V'; k_C) \) because \( p_0, p_1 \notin T^*V \cap \Lambda \). We deduce a well-defined map

\[
\tag{8.1.9} m_\gamma : H^1([U, V]; \mathcal{R}\text{Hom}(F, F)) \to H^1([U', V']; k_C) \simeq k.
\]

Now we describe a situation where the map \( m_\gamma \) is surjective. We will use the following hypothesis

\[
\tag{8.1.10} \begin{cases} F|_{U \cap V} \text{ has a decomposition } F|_{U \cap V} \simeq F' \oplus F'' \text{ such that } \\ \gamma^{-1}((\text{SS}(F'))) \text{ is a (connected) subinterval of } ]0, 1[. \end{cases}
\]

**Remark 8.1.4.** Since \( F \) is simple, the hypothesis \( \text{(8.1.10)} \) \( F|_{U \cap V} \simeq F' \oplus F'' \) implies that we have a disjoint union \( \text{SS}(F|_V) = \text{SS}(F') \sqcup \text{SS}(F'') \). Indeed we have \( \text{SS}(F|_V) = \text{SS}(F') \cup \text{SS}(F'') \) and, moreover, both \( \mu\text{hom}(F', F') \) and \( \mu\text{hom}(F'', F'') \) are direct summands of \( \mu\text{hom}(F, F) \). For any sheaf \( G \) we have \( \text{SS}(G) = \text{supp}((\mu\text{hom}(G, G)) \). Since \( \mu\text{hom}(F, F)|_{T^*M} \simeq k_\Lambda \), the result follows.

In particular \( \text{SS}(F') \) is a union of connected components of \( T^*(U \cap V) \cap \Lambda \). The hypothesis \( \text{(8.1.10)} \) says that \( \gamma^{-1}(\text{SS}(F')) \) is a single connected component of \( \gamma^{-1}(T^*(U \cap V) \cap \Lambda) \).
Let $a \in \mathbf{k}^\times$ be given. Using the decomposition of $F|_{U \cap V}$ given in (8.1.10) we define a diagonal morphism $\alpha(a): F|_{U \cap V} \to F|_{U \cap V}$ by

$$\alpha(a) = \begin{pmatrix} a \cdot \text{id}_F & \text{id}_F \end{pmatrix}.$$ 

(8.1.11)

Proposition 8.1.5. We make the hypothesis (8.1.8) and (8.1.10). For a given $a \in \mathbf{k}$, we define

$$\alpha(a) \in H^0(U \cap V ; \mathbf{R}\text{Hom}(F,F)) \simeq \text{Hom}(F|_{U \cap V}, F|_{U \cap V})$$

by (8.1.11) and we let $[\alpha(a)]$ be its class in $H^1(\{U,V\}; \mathbf{R}\text{Hom}(F,F))$. Then we have $m_\gamma([\alpha(a)]) = \pm(a - 1)$. In particular $H^1 \mathbf{R}\text{Hom}(F,F)$ is non zero.

Proof. We use the notations $C$, $U'$ and $V'$ described after (8.1.8). We let $I \subset U' \cap V'$ be the connected component given by the image of $\gamma^{-1}(\text{SS}(F'))$ by the quotient map $[0,1] \to C$ (see Remark 8.1.4).

By the definition of $\alpha(a)$, the section $\alpha(a)^\mu$ of $\mu\text{hom}(F,F) \simeq \mathbf{k}_I$ is the scalar $a$ over $I$ and $1$ over all other components of $U' \cap V'$. It represents the same class as the Čech cocyle which is $a - 1$ over $I$ and $0$ over all other components of $U' \cap V'$. The result follows. (The sign $\pm 1$ depends on the relative positions of $I$ and the other components of $U' \cap V'$ in $C$.) \qed

8.2. Examples of microlocal linked points

We begin with the following easy example over $\mathbb{R}$. In higher dimension we give Propositions 8.2.5 and 8.2.6 below which reduce to this case by inverse or direct image.

Proposition 8.2.1. Let $t_0 \leq t_1 \in \mathbb{R}$ and $p_0 = (t_0; \tau_0)$, $p_1 = (t_1; \tau_1) \in T^*\mathbb{R}$ be given. Let $F \in \mathbf{D}^b(\mathbf{k}_{\mathbb{R}})$ be a constructible sheaf with $p_0, p_1 \in \text{SS}(F)$ such that $F$ is simple at $p_0, p_1$. We assume that there exists a decomposition $F \simeq G \oplus \mathbf{k}_I[d]$ where $G \in \mathbf{D}^b(\mathbf{k}_{\mathbb{R}})$, $d \in \mathbb{Z}$ and $I$ is an interval with ends $x_0, x_1$ such that $p_0, p_1 \in \text{SS}(\mathbf{k}_I)$. Then $p_0$ and $p_1$ are $F$-linked over any interval containing $\overline{I}$.

Proof. Let $i: \mathbf{k}_I[d] \to F$ and $q: F \to \mathbf{k}_I[d]$ be the morphism associated with the decomposition of $F$. Then $i$ and $q$ give a morphism $\text{Hom}(F,F) \to \text{Hom}(\mathbf{k}_I, \mathbf{k}_I) \simeq \mathbf{k}$. Since $F$ is simple at $p_k$, for $k = 0, 1$, and $p_k \in \text{SS}(\mathbf{k}_I)$, we have $p_k \not\in \text{SS}(G)$. Let $u: F \to F$ be given and let $Iu: \mathbf{k}_I[d] \to \mathbf{k}_I[d]$ be the morphism induced by $u$. Then $u^\mu_{p_k} = (Iu)^\mu_{p_k}$ by Lemma 8.1.3. Since $\text{Hom}(\mathbf{k}_I, \mathbf{k}_I) \simeq \mathbf{k}$ we have $(Iu)^\mu_{p_0} = (Iu)^\mu_{p_1}$ for any $u$ defined in a neighborhood of $\overline{I}$. The result follows. \qed
Let $f: M \to N$ be a morphism of manifolds. We recall the notations $f_d: M \times_N T^*N \to T^*M$ and $f_{\pi}: M \times_N T^*N \to T^*N$ for the natural maps induced on the cotangent bundles.

We study easy cases of inverse or direct image of simple sheaves. We let $F \in D^b(k_M)$ be such that $\Lambda = SS(F)$ is a smooth Lagrangian submanifold and $F$ is simple along $\Lambda$. More general, but local, statements are given in [30] (see Corollaries 7.5.12 and 7.5.13).

**Lemma 8.2.2.** Let $i: L \to M$ be an embedding and let $x_0$ be a point of $L$. We assume that there exist a neighborhood $U \subset M$ of $i(x_0)$ and a submanifold $N \subset U$ such that $\Lambda \cap T^*U \subset T^*_N U$ and $N$ is transverse to $L$ at $x_0$. Then, up to shrinking $U$ around $x_0$, the set $\Lambda' = SS((i^{-1}F)|_{U \cap L})$ is contained in $T^*_{\Lambda \cap L} L$ and $(i^{-1}F)|_{U \cap L}$ is simple along $\Lambda'$.

Moreover, if $u: F \to F$ is defined in a neighborhood of $x_0$ and $v: i^{-1}F \to i^{-1}F$ is the induced morphism, then for any $p = (x_0; \xi_0) \in \Lambda$ and $q = (x_0; i_d(\xi_0))$ we have $v^\mu_p = u^\mu_p$.

We note that the inclusion $\Lambda \cap T^*U \subset T^*_N U$ implies that $\Lambda$ is a union of components of $T^*_N U$ (hence this is an equality if $N$ is connected of codimension $\geq 2$).

**Proof.** Up to shrinking $U$ we can find a submersion $f: U \to L \cap U$ such that $N = f^{-1}(L \cap N)$. By Proposition 1.2.8 we can write $F|_U \simeq f^{-1}G$ for some $G \in D^b(k_{L \cap U})$. Then $\mu_{hom}(F, F) \simeq (f_d)_*f^{-1}(\mu_{hom}(G, G))$ and the lemma follows. □

**Lemma 8.2.3.** Let $q: M \to \mathbb{R}$ be a function of class $C^2$ and let $t_0$ be a regular value of $q$. We assume that there exist an open interval $J$ around $t_0$, a connected hypersurface $L$ of $U := q^{-1}(J)$ and a connected component $\Lambda_0$ of $T^*_L U$ such that

(i) $q|_U$ is proper on supp $F$,

(ii) $q|_L$ is Morse with a single critical point $x_0$ and $q(x_0) = t_0$,

(iii) $\Lambda_0 \subset \Lambda \cap T^*U$ and $T^*_{x_0} M \cap \Lambda = T^*_{x_0} M \cap \Lambda_0$,

(iv) $((\Lambda \cap T^*U) \setminus \Lambda_0) \cap q_d(M \times_\mathbb{R} \mathbb{R}^\times) = \emptyset$.

Let $p = (x_0; \xi_0)$ be the point of $\Lambda_0$ ($\xi_0$ is unique up to a positive scalar) above $x_0$. We have $p \in \text{im}(q_d)$ and we set $p' = (t_0; \tau_0) = q_d(\xi_0)^{-1}(p)$.

Then $p' \in SS(Rq_*(u))$ and $SS(Rq_*(u))$ is simple at $p'$. Moreover, for any morphism $u: F|_U \to F|_U$, denoting by $v = Rq_*(u): Rq_*F|_J \to Rq_*F|_J$ the induced morphism, we have $v^\mu_p = u^\mu_p$.

**Proof.** We set $N = q^{-1}(t_0)$. Then $N$ is a smooth hypersurface of $M$ and, up to shrinking $J$ and restricting to a neighborhood of supp($F$) $\cap U$ we can assume that $U = N \times J$. We can also find a neighborhood
V of \( x_0 \) in \( N \) and a Morse function \( \varphi : V \to \mathbb{R} \) such that, in some neighborhood of \( x_0 \), \( L \) is the graph of \( \varphi \).

By (iii) we can find a small open ball \( B \subset N \) around \( x_0 \) such that \( T^*(B \times J) \cap \Lambda = T^*(B \times J) \cap \Lambda_0 \). We set \( W = B \times J \) and \( Z = U \setminus W \).

We have a distinguished triangle \( F_W \to F \to F_Z \xrightarrow{+1} \). By (iii) again \( \text{SS}(F_Z) \subset \text{SS}(F) \cup (\Lambda_0 + T_{\partial W}^* U) \), where \( T_{\partial W}^* U \) is the outer conormal bundle of \( \partial W \) in \( U \). By (iv) we deduce that \( \text{SS}(F_Z) \cap q_d(M \times \mathbb{R}^* \mathbb{R}) = \emptyset \). Hence \( R_{q_\ast}(F_Z) \) is a constant sheaf on \( J \) and we can assume from the beginning that \( F = F_W \).

By (iii) we have \( F|_W \simeq G \oplus k_{W'}/d \), where \( G \in \mathcal{D}^b(k_W) \) has constant cohomology sheaves, \( d \) is some integer and \( W' \) is one of the following subsets of \( W: W^+ = \{(x, t) \in W; t > \varphi(x)\}, \mathbb{R}^+ \setminus W^+ \) or \( W \setminus W^+ \).

Now the problem is reduced to the computation of \( R_{q_\ast}(k_{W'}) \) which is a classical computation in Morse theory (in our case this is done in the proof of Proposition 7.4.2 of [30]). □

**Definition 8.2.4.** Let \( M \) be a manifold, \( \mathbf{k} \) a field and \( F \in \mathcal{D}^b(k_M) \). Let \( p_0 = (x_0; \xi_0) \) and \( p_1 = (x_1; \xi_1) \) be given points of \( \text{SS}(F) \), generating two distinct half-lines \( \mathbb{R}_{>0} \cdot p_0 \neq \mathbb{R}_{>0} \cdot p_1 \). Let \( I \) be either an open interval of \( \mathbb{R} \) or the circle \( S^1 \) and let \( i : I \to M \) be an immersion. We say that \( p_0 \) and \( p_1 \) are \( F \)-conjugate with respect to \( i \) if

(i) there exist \( t_0, t_1 \in I \) such that \( i(t_k) = x_k \) and \( i \) is an embedding near \( x_k \) for \( k = 0, 1 \),

(ii) for \( k = 0, 1 \), there exist a neighborhood \( U_k \subseteq M \) of \( x_k \) and a submanifold \( N_k \subseteq U_k \) such that \( \text{SS}(F) \cap T^* U_k \subseteq T^* N_k U_k \) and \( N_k \) is transverse to \( I \) at \( x_k \),

(iii) \( F \) is simple along \( \text{SS}(F) \) at \( p_k \) for \( k = 0, 1 \),

(iv) \( i^{-1} F \) has a direct summand \( F' \) such that \( (t_k; i_d(\xi_k)) \in \text{SS}(F') \) for \( k = 0, 1 \) and \( F' \) is isomorphic to

\[
\begin{align*}
&\{ k_{i[J]} [d] \text{ for some subinterval } J \text{ of } I \text{ if } I \text{ is an interval,} \\
&\{ e_*(k_J) [d] \text{ for some subinterval } J \text{ of } \mathbb{R} \text{ if } I = S^1,
\end{align*}
\]

where \( d \in \mathbb{Z} \) and \( e : \mathbb{R} \to S^1 \) is the covering map.

Proposition 8.2.1 and Lemmas 8.2.2 and 8.2.3 imply the following results.

**Proposition 8.2.5.** Let \( M \) be a manifold, \( \mathbf{k} \) a field and \( F \in \mathcal{D}^b(k_M) \). Let \( p_0, p_1 \in SS(F) \) be given. We assume that there exists an immersion \( i : I \to M \) of the circle or an open interval of \( \mathbb{R} \) such that \( p_0 \) and \( p_1 \) are \( F \)-conjugate with respect to \( i \). Then \( p_0 \) and \( p_1 \) are \( F \)-linked over any open subset containing \( i(I) \).
Proposition 8.2.6. Let \( q : M \to \mathbb{R} \) be a map of class \( C^2 \) and let \( t_0 \leq t_1 \) be regular values of \( q \). For \( k = 0, 1 \) we assume that there exist an open interval \( J_k \) around \( t_k \), a connected hypersurface \( L_k \) of \( U_k := q^{-1}J_k \) and a connected component \( \Lambda_k \) of \( T_{q_k}U_k \) such that the hypothesis (i)-(iv) of Theorem 8.3.1 are satisfied. We assume moreover that \( Rq_* F \) has a decomposition \( Rq_* F \cong G \oplus k_f[d] \) where \( G \in D^b(k_{\mathbb{R}}) \), \( d \in \mathbb{Z} \) and \( J \) is an interval with ends \( t_0, t_1 \). Let \( p_k = (x_k; \xi_k) \in \Lambda \) be such that \( q(x_k) = t_k \) and \( q_n(q^{-1}_a(p_k)) \in SS(k_f) \). Then \( p_0 \) and \( p_1 \) are \( F \)-linked over any open subset containing \( q^{-1}([t_0, t_1]) \).

8.3. Simple sheaf at a generic tangent point

In this section we consider a sheaf on the 2-sphere \( M = \mathbb{S}^2 \) whose microsupport \( \Lambda \subset \hat{T}^*M \) is a smooth Lagrangian submanifold. We let \( q \) be a \( C^\infty \) function on \( M \) and assume that \( \pi_M(\Lambda) \) has a tangent point with \( C_0 = q^{-1}(0) \). Our aim is to prove in the next section that some hypothesis on \( F \) implies the non vanishing of \( \text{Ext}^1(F, F) \) (see Theorem 8.4.1). In the proof of this result we will distinguished two cases, depending on \( F|_{q^{-1}(1/2)} \). One case will use the notion of linked points and Lemma 8.3.1 Proposition 8.3.8 below. The other case will use Proposition 8.3.6.

8.3.1. Generic tangent point - notations. We set \( M = \mathbb{S}^2 \) and we denote by \( q : M \to \mathbb{R} \) a Morse function with only two critical points, say \( x_- \) and \( x_+ \) such that \( q(x_-) = -2 \) and \( q(x_+) = 2 \). We let \( \Lambda \subset \hat{T}^*M \) be a smooth closed conic Lagrangian submanifold. We assume that \( \Lambda^a = \Lambda \) (that is, \( \Lambda \) is stable by the antipodal map \( (x; \xi) \mapsto (x; -\xi) \)). We also assume that \( \Lambda \) is in generic position with respect to the projection \( T^*M \to M \). In particular \( \pi_M(\Lambda) \) is a smooth curve in a neighborhood of \( C_0 = q^{-1}(0) \) which is tangent at one point to \( C_0 \). We introduce some notations to describe the geometric situation. We choose a diffeomorphism \( M \setminus \{x_\pm\} \cong S^1 \times [-2, 2] \) such that \( q \) is identified with the second projection. We take the coordinates \( \theta \in [-\pi, \pi] \) on \( S^1 \), \( t \) on \( \mathbb{R} \) and \( (\theta; \xi) \) on \( T^*S^1 \), \((t, \tau)\) on \( T^*\mathbb{R} \). We set

\[
\begin{align*}
M_t &= q^{-1}([-\infty, t]), \quad t \in \mathbb{R}, \\
J_1 &= [-1, 1] \subset S^1, \quad J_2 = [-1, 1] \subset \mathbb{R}, \\
U &= S^1 \times J_2, \quad U_0 = J_1 \times J_2, \\
E_0 &= \{ (\theta, t) \in U_0; \quad t = \theta^2 \}, \quad \Omega = \{ (\theta, t) \in U_0; \quad t > \theta^2 \}, \\
\Lambda_0 &= T^*E_0 U_0, \quad \Omega^\pm = (0, 0; 0, \pm 1) \in \Lambda_0.
\end{align*}
\]

(8.3.1)
We assume that our conic Lagrangian submanifold $\Lambda$ satisfies the following (besides $\Lambda^e = \Lambda$):

\[
\begin{align*}
\Lambda \cap \dot{T}^*_x M &= \Lambda \cap \dot{T}^*_x M = \emptyset \\
\text{and there exist a finite set of points } A &\subset S^1 \setminus J_1 \text{ such that, setting } E = (A \times J_2) \cup E_0, \\
\text{we have } \Lambda \cap T^*U &= \dot{T}^*_E U.
\end{align*}
\]

(8.3.2)

Let $F \in D^s_{\Lambda}(k_M)$ (see Definition 2.4.2). Then $F|_{C_{1/2}}$ is constructible and we can decompose $F|_{C_{1/2}}$ according to Corollary 4.4.3: there exist a finite family $\{(I_a, d_a)\}_{a \in A}$ of bounded intervals and integers and $L \in D^b(k_{C_{1/2}})$ with locally constant cohomology sheaves of finite rank such that

\[
F|_{C_{1/2}} \simeq L \oplus \bigoplus_{a \in A} e_*(k_{I_a})[d_a],
\]

where $e: \mathbb{R} \to C_{1/2} \simeq \mathbb{R}/2\pi \mathbb{Z}$ is the quotient map (we remark that each $k_{I_a}$ appears with multiplicity only 1 because $F$ is simple). We recall that $p_0 = (\theta_0, 1/2; \xi_0, \tau_0)$, $p_1 = (\theta_1, 1/2; \xi_1, \tau_1) \in \Lambda$ are $F$-conjugate with respect to $C_{1/2}$ if $F$ is simple at $p_0$ and $p_1$ and there exists an interval $I_a$ such that $(\theta_0; \xi_0)$ and $(\theta_1; \xi_1)$ both belong to $\mathcal{SS}(e_*(k_{I_a}))$ (see Definition 3.2.4).

We will often make the following hypotheses on $F$

\[
\begin{align*}
&\text{(8.3.4)} \quad D_M(F) \simeq F, \\
&\text{(8.3.5)} \quad (Rq_*)|_{J_2} \simeq k_{\{0\}} \oplus L_{J_2}, \quad \text{for some } L \in D^b(k).
\end{align*}
\]

8.3.2. Generic tangent point - local study.

Lemma 8.3.1. Let $\Lambda \subset \dot{T}^*M$ be a Lagrangian submanifold satisfying (8.3.2). Let $F \in D^s_{\Lambda}(k_M)$ satisfying (8.3.5). Let $V$ be any neighborhood of $C_0$. Then the points $p^+$ and $p^-$ are $F$-linked over $V$.

Proof. This is a special case of Proposition 8.2.6 with $t_0 = t_1 = 0$ and $J = \{0\}$. \hfill \square

For any sheaf $G$ and closed subset $Z$ we have natural morphisms $R\Gamma_Z G \to G$ and $G \to G_Z$ and their composition gives $R\Gamma_Z G \to G_Z$. We also remark $\text{Hom}(k_Z, G) \simeq \text{Hom}(k_Z, R\Gamma_Z G)$. For $G = Rq_* F$ and $Z = \{0\}$, let $j_0: R\Gamma_{\{0\}} Rq_* F \to (Rq_* F)_{\{0\}}$ be the natural morphism. The decomposition (8.3.5) of $Rq_* F$ gives a morphism $k_{\{0\}} \to Rq_* F$, hence $v_0: k_{\{0\}} \to R\Gamma_{\{0\}} Rq_* F$. We have $j_0 \circ v_0 \neq 0$ because the restriction of $j_0 \circ v_0$ to the summand $k_{\{0\}}$ of $Rq_* F$ is the identity morphism. Using the adjunction $(q^{-1}, Rq_*)$ and $q^{-1} R\Gamma_{\{0\}} Rq_* F \simeq Rq_* R\Gamma_{\{0\}} (F)$,
Lemma 8.3.3. Let $H$ satisfies (8.3.5) sheaf on $J$. Since $\Lambda \subset T^*U$ such that $R\Gamma_c(F \cap \Omega)$, we obtain: there exists $u_0: k_{C_0} \to R\Gamma_{C_0}(F)$ such that the composition

$$k_{C_0} \xrightarrow{u_0} R\Gamma_{C_0}(F) \xrightarrow{i_0} F_{C_0}$$

is non zero, where $i_0$ is the natural morphism.

**Proof.** (i) Let $a: F \to F_{C_0}$ be the natural morphisms. Then $i_0 = a \circ b$. If $H$ is a sheaf with support contained in $C_0$, we have an adjunction isomorphism

$$\text{Hom}(F_{C_0}, H) \cong \text{Hom}(F, R\Gamma_{C_0}H) \cong \text{Hom}(F, H)$$

which is actually given by the composition with $a$; in particular a morphism $\varphi: F_{C_0} \to H$ is non zero if and only if $\varphi \circ a$ is non zero.

(ii) We define $c = b \circ w_0 \circ (a[-1]): F[-1] \to F$. We find $a \circ c = i_0 \circ w_0 \circ (a[-1])$. By the last assertion in (i) (with $H = F_{C_0}[1]$) we see that $i_0 \circ w_0 \circ a$ is non zero if $i_0 \circ w_0$ is non zero; this is the case since $i_0 \circ w_0 \circ v_0 = i_0 \circ u_0$ is non zero by (8.3.6). Hence $a \circ c \neq 0$ and a fortiori $c \neq 0$ which proves $\text{Hom}(F, F[1]) \neq 0$. 

**Lemma 8.3.2.** If there exist $v_0: k_{C_0} \to F_{C_0}[-1]$ and $w_0: F_{C_0}[-1] \to R\Gamma_{C_0}(F)$ such that $u_0 = v_0 \circ v_0$, then $H^1 \text{RHom}(F, F) \neq 0$.

**Proof.** (i) Let $a: F \to F_{C_0}$ and $b: R\Gamma_{C_0}(F) \to F$ be the natural morphisms. Then $i_0 = a \circ b$. If $H$ is a sheaf with support contained in $C_0$, we have an adjunction isomorphism

$$\text{Hom}(F_{C_0}, H) \cong \text{Hom}(F, R\Gamma_{C_0}H) \cong \text{Hom}(F, H)$$

which is actually given by the composition with $a$; in particular a morphism $\varphi: F_{C_0} \to H$ is non zero if and only if $\varphi \circ a$ is non zero.

(ii) We define $c = b \circ w_0 \circ (a[-1]): F[-1] \to F$. We find $a \circ c = i_0 \circ w_0 \circ (a[-1])$. By the last assertion in (i) (with $H = F_{C_0}[1]$) we see that $i_0 \circ w_0 \circ a$ is non zero if $i_0 \circ w_0$ is non zero; this is the case since $i_0 \circ w_0 \circ v_0 = i_0 \circ u_0$ is non zero by (8.3.6). Hence $a \circ c \neq 0$ and a fortiori $c \neq 0$ which proves $\text{Hom}(F, F[1]) \neq 0$. 

**Lemma 8.3.3.** Let $F \in \mathcal{D}^b_{\text{c},T^*U}(k_U)$. Then $F \cong \bigoplus_{i \in \mathbb{Z}} H^i F[-i]$ and $H^1 F \in \mathcal{D}^b_{\text{c},T^*U}(k_U)$, for each $i \in \mathbb{Z}$. If, moreover, $F$ is simple and satisfies (8.3.5), then $H^{-1} F$ satisfies (8.3.5) and $Rq_*(H^i F)$ is a constant sheaf on $J_2$, for all $i \neq -1$. Moreover, near the tangency point $z_0 = (0, 0)$, $H^{-1} F$ has $k_{U \cap \Omega}$ and $k_{U \cap \Pi}$ as direct summands.

**Proof.** (i) Since $\Lambda \cap T^*U \subset T^*E \cap T^*U$ where $E$ is a smooth curve, $F$ is constructible for the stratification $U = E \cup (U \setminus E)$. It follows that the same holds for all $H^i F$. Now, for two such constructible sheaves $G$, $G'$ (in degree 0), the complex $H = R\text{Hom}(G, G')$ satisfies: $H_{U \cap E}$ is concentrated in degree 0 and $H_{E}$ in degrees 0 and 1. Since $E$ consists only of segments, we deduce $H^2(U; H_E) \cong 0$. We can check that the same vanishing holds for $H^2(U; H_{U \cap E})$ and we deduce by excision that $\text{Ext}^2(G, G') \cong 0$. Lemma 4.1.4 gives $F \cong \bigoplus_i H^i(F)[-i]$ and this implies the bound for $\text{SS}(H^i(F))$.

(ii) Now we assume $F$ is simple and satisfies (8.3.5). By (i) we have $Rq_* F \cong \bigoplus_{i \in \mathbb{Z}} Rq_*(H^i F)[-i]$. By Gabriel’s theorem (or Corollary 4.2.1) there exists $i_0$ such that $Rq_*(H^{i_0}F)[-i_0]$ has $k_{\{0\}}$ as a direct summand and $Rq_*(H^{i_0}F)$, $i \neq i_0$, are constant sheaves on $J_2$. Let us check that $i_0 = -1$. 

\[(Rq_*)_{\{0\}} \cong Rq_* (F_{\{0\}})\]
Let us set $G = H^{i_0} F$. Then $G$ is concentrated in degree 0 and $Rq_\ast(G)$ is a sum of constant sheaves and $k_{[0][i_0]}$. It follows that $(R\Gamma_Z Rq_\ast(G))_0 \simeq k_{[0]}$, where $Z = [0, 1]$. We set $H = (R\Gamma_Y G)_{c_0}$, where $Y = q^{-1}(Z)$. Then $Rq_\ast H \simeq (R\Gamma_Z Rq_\ast(G))_0 \simeq k_{[0]}$. Since $SS(G) \subset \Lambda$, the sheaf $H$ vanishes everywhere except maybe at the tangency point $z_0 = (0, 0)$ of $C_0$ and $\pi_M(\Lambda)$.

This implies that $SS(G)$ must contain one component of $\Lambda_0$. Hence, in a neighborhood of $z_0$, $G$ has a direct summand of the type $k_0$, $k_{\overline{\pi}}$, $k_{U \setminus \Omega}$ or $k_{U \setminus \overline{\pi}}$. The first two cases would imply that $k_{[0,1]}[-1]$ or $k_{[0,1]}$ are direct summands of $Rq_\ast G$. Hence only the last two cases can hold.

Let us compute $R\Gamma_Y(k_{\overline{\pi}})|_{c_0}$ with $W = U \setminus \Omega$ or $W = U \setminus \overline{\pi}$. Using $R\Gamma_Y(k_{\overline{\pi}})|_{c_0} \simeq 0$ and the exact sequence $0 \to k_\Omega \to k_U \to k_{U \setminus \Omega} \to 0$ we find $R\Gamma_Y(k_{\overline{\pi}}||_{c_0} \simeq R\Gamma_Y(k_{\Omega})|_{c_0}[1]$. Since supp$(k_\Omega) \subset Y$ and $Y$ is closed, we have $R\Gamma_Y(k_{\Omega}) \simeq k_\Omega$. Finally $R\Gamma_Y(k_{\overline{\pi}})|_{c_0} \simeq 0$. A similar computation gives $R\Gamma_Y(k_{U \setminus \Omega})|_{c_0} \simeq R\Gamma_Y(k_{\Omega})|_{c_0}[-1] \simeq k_{[\alpha]}[-1]$. Hence in the only non trivial case we see that $(R\Gamma_Z Rq_\ast(G))_0 \simeq k_{[-1]}$, which proves $i_0 = -1$. We have also found that $k_{U \setminus \overline{\pi}}$ is a summand of $H^{-1} F$ near $z_0$.

Replacing $Z = [0, 1]$ by $Z = [-1, 0]$ in the above argument, we also find that $k_{U \setminus \Omega}$ is a summand of $H^{-1} F$ near $z_0$.

**Proposition 8.3.4.** Let $\Lambda \subset \dot{T}^\ast M$ be a Lagrangian submanifold satisfying (8.3.2). Let $F \in D^c_{\dot{T}^\ast}(k_M)$ satisfying (8.3.3) and (8.3.5). We assume that $H^{-1} F|_{c_0}$ has a direct summand which is a locally constant sheaf with unipotent monodromy. Then $H^1 R\text{Hom}(F, F) \neq 0$.

**Proof.** By Lemma 8.3.2 it is enough to find $v_0 : k_{c_0} \to F_{c_0}[-1]$ and $w_0 : F_{c_0}[-1] \to R\Gamma_{c_0}(F)$ such that $u_0 = w_0 \circ v_0$, where $u_0$ is defined in (8.3.6). Using Corollary 1.4.3 we decompose $F|_{c_0}$ as

$$F|_{c_0} \simeq L_u[1] \oplus L[1] \bigoplus_{a \in A} e_*(k_{I_a})[1],$$

where $L_u$, $L$ are locally constant sheaves, $L_u$ has unipotent monodromy, no summand of $L$ has unipotent monodromy, and the $I_a$'s are bounded intervals or $\mathbb{R}$. Since $DF \simeq F$ and $D'L_u \simeq L_u$, we have

$$R\Gamma_{c_0}(D_M F)|_{c_0} \simeq D_{c_0}(F|_{c_0}) \simeq L_u \oplus D'L \bigoplus_{a \in A} e_*(k_{I^*_a}),$$

where $I^*_a$ is the interval such that $D'k_{I_a} \simeq k_{I^*_a}$. We see $u_0$ as a section of $R\Gamma_{c_0}(D_M F)$ through the isomorphism $\text{Hom}(k_{c_0}, R\Gamma_{c_0} F) \simeq H^0(c_0; R\Gamma_{c_0}(D_M F))$. An indecomposable locally constant sheaf has a section if and only if its monodromy is unipotent. A sheaf $k_{I^*_a}$ has a section if and only if $I^*_a$ is closed. In both cases the section is then
unipotent monodromy given by a Jordan block of size $r \times r$. Then $u_0 = \sum_i \alpha_i v_i + \sum_\alpha \beta_\alpha w_\alpha$, where $v_i$, $w_\alpha$ are the canonical sections of $L_{r_i}$ and $e_*(k_{I_i}^*)$.

We define $v_0 = \sum_i v_i : k_{c_0} \to F[-1] \simeq L_{r_i} \oplus L \oplus \bigoplus_{\alpha \in A} e_*(k_{I_\alpha})$. (Thus $v_0$ is given by the canonical section of $L_u$ and has no non-zero component with respect to the other direct summands.) Since $L_{r_i}$ is non-zero by hypothesis, Lemma 8.3.5 below gives $w_0 : L_{r_i} \to e_*(k_{I_\alpha})$ such that $w_\alpha = w_{i}' \circ v_0$. We set $w_0 = \sum_\alpha \alpha_i\text{id}_{L_{r_i}} + \sum_\beta \beta_\alpha w_{\alpha}'$. Then $u_0 = w_0 \circ v_0$, as required.

**Lemma 8.3.5.** Let $r$ be an integer and let $L_r \in \text{Mod}(k_{S^1})$ be the locally constant sheaf on $S^1$ with unipotent monodromy given by a Jordan block of size $r \times r$. Let $I \subset \mathbb{R}$ be a closed interval. Let $a : k_{S^1} \to L_r$ be the canonical section of $L_r$ and $b : k_{S^1} \to e_*(k_{I})$ be any morphism. Then there exists $c : L_r \to e_*(k_{I})$ such that $c \circ a = b$.

**Proof.** We apply the functor $\text{Hom}(-, e_*(k_{I}))$ to the distinguished triangle $k_{S^1} \rightarrow L_r \rightarrow L_{r+1} \rightarrow$ and get a long exact sequence. It is then enough to check that $\text{Ext}^1(L_{r+1}, e_*(k_{I}))$ vanishes. By the adjunction $(e^{-1}, e_*)$ this follows from $\text{Ext}^1(k_{r+1}, k_{I}) \simeq 0$.

**Proposition 8.3.6.** Let $\Lambda \subset \tilde{T}^*M$ be a smooth closed conic Lagrangian submanifold satisfying (8.3.2). We use the notations (8.3.1). Let $F \in D^f_{\Lambda}(k_U)$ satisfying (8.3.3). We assume that, in the decomposition (8.3.3) of $F|_{C_{1/2}}$, one interval $I_a$ with one end in $e^{-1}(E_0 \cap C_{1/2})$ is closed. Then there exists a decomposition $F|_{C_0} \simeq F' \oplus L[1]$ such that $L \in \text{Mod}(k_{C_0})$ is a locally constant sheaf with unipotent monodromy.

**Proof.** (i) We set $I_a = [\alpha, \beta]$ and prove the proposition by induction on $[(\beta - \alpha)/2\pi]$. We first introduce some notations. We set $C = C_{1/2}$ for short. We write $F|_C \simeq e_*(k_{[a,b]})[1] \oplus F'$ and define $s = (1,0) \in H^{-1}(C; F|_C)$ according to this decomposition, where 1 is the natural section of $e_*(k_{[a,b]})$.

By the base change formula we have $H^{-1}(C; F|_C) \simeq H^{-1}(Rq_*F)_{1/2}$ and the hypothesis (8.3.5) implies that there exists a unique $s' \in H^{-1}(U; F)$ such that $s'|_C = s$. We interpret the sections $s$ and $s'$ as morphisms

$$u : k_C[1] \to F|_C, \quad u' : k_U[1] \to F.$$ (ii) If $[(\beta - \alpha)/2\pi] = 0$, then $I' = e((a,b))$ is an arc of $C$ (smaller than $C$). Then $S = \text{supp}(s')$ is a subset of $U$ which satisfies $S \cap C = I'$. On the other hand $S \cap U_0$ is a union of some of the three subsets of $U_0$
made by \(E_0\) and the two components of \(U_0 \setminus E_0\). By Lemma 8.3.3 we have \(S \cap U_0 = U_0 \setminus \Omega\), hence \(S = U \setminus \Omega\). The morphism \(u'\) factorizes through \(k_U[1] \to k_S[1]\) and gives \(v : k_S[1] \to F\). We denote by \(\Lambda_0^-\) the connected component of \(\Lambda_0\) which contains \(p^{-}\). We have \(\Lambda_0^- = \text{SS}(k_S)\) and, by construction, the morphism \(v\) is an isomorphism at the points of \(\Lambda_0^- \cap T^*_e(a)\). Since \(\Lambda_0^-\) is connected, \(v\) is an isomorphism over \(\Lambda_0^-\). Let us define \(G \in \mathcal{D}^b(k_U)\) by the distinguished triangle

\[
(8.3.7) \quad k_S[1] \to F \to G \xrightarrow{+1}.
\]

Then \(\text{SS}(k_G) \subset (\Lambda \cap T^*U) \setminus \Lambda_0^-\) and this implies \(\text{SS}(Rq_*(G)) \subset \{(0; \tau) ; \tau > 0\}\). On the other hand the image of the triangle \((8.3.7)\) by \(Rq_*\) gives

\[
k_{[-1,0]} \oplus k_{J_2}[1] \xrightarrow{w} k_{[0]} \oplus L_{J_2} \to Rq_*(G) \xrightarrow{+1},
\]

where \(w = Rq_*(v)\). Let us write \(w = (w_1, w_2, w_3, w_4)\). The entry \(w_1 : k_{[-1,0]} \to k_{[0]}\) vanishes for degree reason. If \(w_1 : k_{[-1,0]} \to k_{[0]}\) were also 0, then \((k)_{[0]}\) would be a direct summand of \(Rq_*(G)\), contradicting the above bound on \(SS(Rq_*(G))\). By the base change formula this means that the morphism \(H^0(C_0; v|_{C_0}) : H^1(C_0; k_{C_0}) \to H^0(C_0; F|_{C_0})\) is non zero. This implies that \((k|_{C_0})\) is a direct summand of \(F|_{C_0}\), as claimed, by the following general remark:

(iii) Now we assume \([ (b - a) / 2\pi ] > 0\). We define \(G \in \mathcal{D}^b(k_U)\) by the distinguished triangle \(k_U[1] \to F \to G \xrightarrow{+1}\). We have \(G|_{C} \simeq e_* k_{[a,b-2\pi]} \oplus F'\). We also have the distinguished triangle

\[
k_{J_2} \oplus k_{J_2}[1] \xrightarrow{w} k_{[0]} \oplus L_{J_2} \to Rq_*(G) \xrightarrow{+1}.
\]

We write \(w = (w_1, w_2, w_3, w_4)\) as in (ii). We also have \(w_2 = 0\).

If \(w_1 \neq 0\), we conclude as in (ii) that \((k|_{C_0})\) is a direct summand of \(F|_{C_0}\).

If \(w_1 = 0\), we obtain that \((k)_{[0]}\) is a direct summand of \(Rq_*(G)\). In this case \(G\) satisfies the same hypothesis as \(F\) with \((b - a) / 2\pi\) replaced by \((b - a) / 2\pi - 1\). Hence \(G|_{C_0}\) has a direct summand which is a locally constant sheaf with unipotent monodromy. Since \(F|_{C_0}\) is an extension of \(G\) by \((k|_{C_0})\), the same result holds for \(F|_{C_0}\).

\[\square\]

8.3.3. Generic tangent point - global study. We recall that the minimal value of \(q\) is \(-2\) and we set \(M_t = q^{-1}([-2,t])\) for \(t \in [-2,2]\).
Lemma 8.3.7. Let $F \in \mathcal{D}^b_{\Lambda}(k_M)$ and let $u: F|_{M_1} \to F|_{M_1}$ be a morphism. We assume that $F$ satisfies \([8.3.5]\) and that $u$ is an isomorphism on $\Lambda \cap \hat{T}^*M_0$. Then $u$ is an isomorphism at $p^+$ and $p^-$.

Proof. (i) For any $k \in \mathbb{N}$, $u^k$ is an isomorphism on $\Lambda \cap \hat{T}^*M_0$. It follows that the cone of $u^k$ is locally constant on $M_0$, hence constant since $M_0$ is a disc. We choose a point $x_0 \in M_0$. We identify $\mathcal{D}^b(k)$ with the category of graded $k$-vector spaces. Let $n \in \mathbb{N}$ be the size of the generalized 0-eigenspace of $u_{x_0}$. Let $K$ be the kernel of $u_{x_0}^n$, considered as a graded $k$-vector space. Let $L$ be the cone of $u_{x_0}^n$. Then $L \cong K \oplus K[-1]$. We define $G \in \mathcal{D}^b(k_M)$ by the distinguished triangle

\[
(8.3.8) \quad G \xrightarrow{u} F|_{M_1} \xrightarrow{b} F|_{M_1} \to G[1].
\]

We have seen that $G$ is constant on $M_0$. Hence there exists an isomorphism

\[
(8.3.9) \quad G|_{M_0} \cong L_{M_0} \cong K_{M_0} \oplus K_{M_0}[-1].
\]

We let $i: K_{M_0} \to G|_{M_0}$ and $p: G|_{M_0} \to K_{M_0}[-1]$ be the morphisms associated with the decomposition \([8.3.9]\). We set $i_0 = a \circ i$, $p_0 = p[1] \circ b$. By our choice of $n$ we have

\[
(8.3.10) \quad (u^n + i_0 \circ p_0)_{x_0} \text{ is an isomorphism}.
\]

(ii) We claim that the morphisms $i_0$ and $p_0$ can be extended over $M_1$. Indeed, setting $I_t = (-\infty, t]$ and using $K_{M_1} \cong q^{-1}K_1$, we have the commutative diagram of adjunction morphisms

\[
\begin{array}{ccc}
\text{Hom}(K_{M_1}, F) & \cong & \text{Hom}(K_{I_1}, Rq_* F) \\
\downarrow r_1 & & \downarrow r_2 \\
\text{Hom}(K_{M_0}, F) & \cong & \text{Hom}(K_{I_0}, Rq_* F) \\
\end{array}
\]

\[
\cong H^0(I_1; Rq_* F \otimes K^*) \\
\cong H^0(I_0; Rq_* F \otimes K^*).
\]

By the hypothesis \([8.3.5]\) we have

\[
\text{R}\Gamma(I_1; Rq_* F \otimes K^*) \cong \text{R}\Gamma(I_0; Rq_* F \otimes K^*) \oplus K^*.
\]

Hence the right vertical arrow $r_2$ is surjective. Hence so is $r_1$, which means that there exists $i_1: K_{M_1} \to F$ such that $i_1|_{M_0} = i_0$. In the same way there exists $p_1: F \to K_{M_1}$ such that $p_1|_{M_0} = p_0$.

(iii) Now we define $v = u^n + i_1 \circ p_1: F \to F$ and $G_1 \in \mathcal{D}^b(k_{M_1})$ by the distinguished triangle

\[
(8.3.11) \quad G_1 \to F|_{M_1} \xrightarrow{\mu} F|_{M_1} \to G_1[1].
\]

Since $i_1 \circ p_1$ factorizes through a constant sheaf, we have $v^p = (u^n)^p = (u^n_p)^{n}$ for any $p \in \Lambda$. Hence $v$ is an isomorphism at each $p \in \Lambda \cap \hat{T}^*M_0$.
and it follows that $\overline{S}(G_1) \cap T^*M_1 \subset \Lambda_0$ (we use the notations $\Lambda_0$, $\Omega$ of (8.3.1)). In particular $G_1$ is constant on $W = M_1 \setminus \overline{\Omega}$. By (8.3.10) it follows that $G_1|_W$ vanishes.

We can find a submersion $f: \Omega^+ \to \mathbb{R}$ defined on a neighborhood $\Omega^+ \cap M_1$ such that $\Omega = f^{-1}([0, +\infty[)$. By Corollary 4.4.3 we deduce that $G_1$ is a direct sum of sheaves of the type $k_\Omega$, $k_{\overline{\Omega}}$ and $k_{\mathcal{E}}$ with some shifts in degree. It follows easily that either $G_1 \simeq 0$ or $\text{supp}(Rq_*(G_1)) = [0, 1]$.

On the other hand, applying $Rq_*$ to the triangle (8.3.11), we obtain the distinguished triangle $Rq_*(G_1)|_{j_2} \twoheadrightarrow (k_{(0)} \oplus L_{j_2}) \xrightarrow{w} (k_{(0)} \oplus L_{j_2}) \xrightarrow{\eta_1}$. Whatever the morphism $w$ this implies $\text{supp}(Rq_*(G_1)) \cap j_2 = j_2$, $\{0\}$ or $\emptyset$. This prevents $\text{supp}(Rq_*(G_1)) = [0, 1]$ and proves that $G_1 \simeq 0$. Hence $v$ is an isomorphism and so are $v_{p_+}^\mu$ and $v_{p_-}^\mu$.

**Proposition 8.3.8.** Let $F \in D^\dagger_\Lambda(k_M)$ satisfying (8.3.5). We assume that $k$ is infinite. Then there exists $p \in \Lambda \cap T^*M_0$ such that $p$, $p^-$ and $p^+$ are $F$-linked over $M_1$.

**Proof.** (i) By Lemma 8.3.1 we already know that $p^-$ and $p^+$ are $F$-linked over $M_1$. Hence it is enough to find $p$ which is $F$-linked with $p^+$. We argue by contradiction and assume that there exists no such $p \in \Lambda \cap T^*M_0$. Since $\Lambda/\mathbb{R}_{>0}$ is compact and $\Lambda \cap T^*U$ has the form given in (8.3.2), we see that $\Lambda \cap T^*M_0$ is a finite union of connected components, say $\Lambda \cap T^*M_0 = \bigsqcup_{\alpha \in A} \Lambda_\alpha$. We choose $p_\alpha \in \Lambda_\alpha$ for each $\alpha \in A$. By Definition 8.1.1 there exists $u_\alpha: F|_{M_1} \to F|_{M_1}$ such that $(u_\alpha)_{p_\alpha}^\mu \neq (u_\alpha)_{p_+}^\mu$, for each $\alpha \in A$. Adding a multiple of $\text{id}_F$ and rescaling we can even assume $(u_\alpha)_{p_\alpha}^\mu = 1$ and $(u_\alpha)_{p_+}^\mu = 0$.

(ii) Since $k$ is infinite, we can find $\lambda = (\lambda_\alpha)_{\alpha \in A} \in k^A$ outside $\bigcup_{\alpha \in A} P_\alpha$, where $P_\alpha$ is the hyperplane $P_\alpha = \{\lambda: \sum_{\beta \in A} \lambda_\beta (u_\beta)^\mu_{p_\alpha} = 0\}$ (we remark that $P_\alpha \neq k^A$ because the coefficient of $\lambda_\alpha$ is 1). Then $u = \sum_{\alpha \in A} \lambda_\alpha u_\alpha$ satisfies

\begin{equation}
(8.3.12)
\begin{align*}
u_{p_+}^\mu &= 0 \\
u_{p_\alpha}^\mu &= 0 \quad \text{for all } \alpha \in A.
\end{align*}
\end{equation}

This contradicts Lemma 8.3.7 and proves the proposition. \qed

8.4. FRONT WITH ONE Cusp

We assume that the projection $\Lambda \to M$ is as generic as possible. In particular, the set $C_\Lambda = \pi_M(\Lambda)$ is an immersed curve, with transverse double points, outside a finite set of points consisting of simple cusps. In this section we consider the case where $C_\Lambda$ has only one cusp, say $c$. We remark that $\Lambda \cap T^*_c M$ consists of two half lines and $\Lambda \setminus (\Lambda \cap T^*_c M)$ has
two connected components. We recall that \( \Lambda^a = \Lambda \). The antipodal map has no fixed point and it follows that it exchanges the two connected components of \( \Lambda \setminus (\Lambda \cap T^*_c M) \).

We consider \( F \in D^f_{\Lambda}(k_M) \) satisfying (8.3.4) and (8.3.5). Since \( F \) is simple along \( \Lambda \), it has a shift \( s(p) \in \dfrac{1}{2} \mathbb{Z} \) at any \( p \in \Lambda \) (see (1.4.4)). As recalled in Example 1.4.4 the shift is locally constant outside the cusps and changes by 1 when \( p \) crosses a cusp. Hence \( s(p) \) takes two distinct values over \( \Lambda \setminus (\Lambda \cap T^*_c M) \), one for each connected component. We recall that we have distinguished two points \( p_{\pm} \) of \( \Lambda \) (see notations (8.3.1)) and have \( p^+_+ = p_- \). Hence \( F \) has different shifts at the points \( p^+ \) and \( p^- \). We denote by \( \Lambda^\pm \) the connected component of \( \Lambda \setminus (\Lambda \cap T^*_c M) \) containing \( p^\pm \).

By Example 1.4.4, the sheaf \( k_{]-\infty,0]} \) on \( \mathbb{R} \) has shift \(-\frac{1}{2}\) at \((0;1)\) and the sheaf \( k_{]-\infty,0]} \) has shift \( \frac{1}{2} \) at \((0;-1)\). In particular the constant sheaf on a closed or open interval has the same shifts at both ends. The constant sheaf on a half-closed interval has different shifts at both ends.

We denote by \( z_1 = (-1/\sqrt{2}, 1/2) \), \( z_r = (1/\sqrt{2}, 1/2) \) the intersections of \( E_0 \) and \( C_{1/2} \). We also denote by \( p^+_l \), \( p^-_r \) the points of \( \Lambda_0 \) (well-defined up to a positive multiple) above \( z_l \), \( z_r \) in the same connected component as \( p^\pm \).

**Theorem 8.4.1.** We assume that \( C_\Lambda = \hat{\pi}_M(\Lambda) \) is a curve with only cusps and ordinary double points as singularities. We assume that \( C_\Lambda \) has exactly one cusp. Let \( F \in D^f_{\Lambda}(k_M) \) satisfying (8.3.4) and (8.3.5). Then \( H^1 \text{RHom}(F, F) \neq 0 \).

**Proof.** (i) We will apply Proposition 8.1.5. We set \( U = M_1 \) and \( V = q^{-1}(]1/4, 2]) \). Then we can find a diffeomorphism \( f : U \cap V \simeq C_{1/2} \times ]1/4, 1] \) such that the first projection \( p : C_{1/2} \times ]1/4, 1] \to C_{1/2} \) satisfies \((p \circ f)|_{C_{1/2}} = \text{id}_{C_{1/2}} \) and \( f(C_\Lambda) = (C_\Lambda \cap C_{1/2}) \times ]1/4, 1[ \). Through this diffeomorphism \( f \) we have, by Proposition 1.2.8,

\[
(8.4.1) \quad F|_{U \cap V} \simeq (F|_{C_{1/2}}) \boxtimes k_{]1/4,1[}.
\]

Now we prove that there exists a path \( \gamma : [0, 1] \to \Lambda \), such that \( \gamma, U, V \) and \( F \) satisfy (8.1.8) and (8.1.10).

(ii) By Proposition 8.3.8 there exists \( p_0 = (z_0; \xi_0) \in \Lambda \cap T^* M_0 \) such that \( p^+ \), \( p^- \) and \( p_0 \) are \( F \)-linked over \( U \). The point \( p_0 \) is in \( \Lambda^+ \) or \( \Lambda^- \). We assume \( p_0 \in \Lambda^+ \), the other case being similar. Let \( \gamma : [0, 1] \to \Lambda \) be an embedding such that \( \gamma(0) = p^+ \), \( \gamma(1) = p_0 \), \( \gamma([0, 1]) \subset \Lambda^+ \) and \( \pi_M \circ \gamma \) is an immersion (hence \( \pi_M \circ \gamma \) describes the portion of the curve \( C_\Lambda \) between \((0, 0)\) and \( z_0 \) which does not contain the cusp). Then the image of \( \gamma \) meets either the half-line \( \mathbb{R}^+ \cdot p^+_l \) or the half-line \( \mathbb{R}^+ \cdot p^-_l \). We assume it meets \( \mathbb{R}^+ \cdot p^+_l \), the other case being similar.
Let \( q_i^+ \in \Lambda \) be the point which is \( F \)-conjugate to \( p_i^+ \) with respect to the immersion of \( C_{1/2} \) in the sense of Definition \[8.2.4\]. This means that there exists an interval \( I_a \) in the decomposition \[8.3.3\] of \( F|_{C_{1/2}} \) such that \( \text{SS}(e_*(k_{I_a})) = \mathbb{R}^+ \cdot p_i^+ \cup \mathbb{R}^+ \cdot q_i^+ \).

(iii) If the interval \( I_a \) is open or closed, then the non vanishing of \( H^1 \text{RHom}(F, F) \) follows from Propositions \[8.3.6\] and \[8.3.4\].

(iv) If the interval \( I_a \) is half-closed, then \( F \) has different shifts at the points \( p_i^+ \) and \( q_i^+ \). Hence \( q_i^+ \) belongs to \( \Lambda^- \) and the path \( \gamma \) does not meet \( \mathbb{R}^+ \cdot q_i^+ \). We write \( F|_{C_{1/2}} = F'_0 \oplus F''_0 \) where \( F'_0 = e_*(k_{I_a})[1] \) and \( F''_0 \) is the remaining part of the decomposition \[8.3.3\]. Using \[8.4.1\] we deduce \( F|_{UV} \simeq F'' \oplus F'' \) with \( F' = F'_0 \boxtimes k_{1/4,1} \) and \( F'' = F''_0 \boxtimes k_{1/4,1} \). Then the hypotheses \[8.1.8\] and \[8.1.10\] are satisfied and the result follows from Proposition \[8.1.9\].

\[ \Box \]

8.5. PROOF OF THE THREE CUSPS CONJECTURE

We will use a general remark about the sheaf associated with a homogeneous Hamiltonian isotopy \( \Phi \) by Theorem \[2.1.1\] in the case where \( \Phi \) is homogeneous for the action of \( \mathbb{R}^x \) and not only \( \mathbb{R}_{\geq 0} \). Let \( I \) be an open interval containing 0 and let \( \Phi : \hat{T}^* \times I \rightarrow \hat{T}^* \) be a Hamiltonian isotopy such that \( \Phi_0 = \text{id} \) and \( \Phi_t(x; \lambda \xi) = \lambda \cdot \Phi_t(x; \xi) \) for all \( \lambda \in \mathbb{R}^x \) and all \( (x; \xi) \in \hat{T}^* \), where we set as usual \( \Phi_1(\cdot) = \Phi(\cdot, t) \).

**Lemma 8.5.1.** Let \( K_\Phi \in \mathcal{D}^b(k_{M^2 \times I}) \) be the sheaf associated with \( \Phi \) by Theorem \[2.1.1\]. Then \( K_\Phi \simeq \text{RHom}(K_\Phi, \omega_M \boxtimes k_{M^2}) \), where \( \omega_M \simeq \sigma_M[d_M] \) is the dualizing sheaf. Moreover, for any \( F \in \text{D}(k_M) \) and any \( t \in I \), we have \( \text{D}_M(K_{\Phi,t} \circ F) \simeq K_{\Phi,t} \circ \text{D}_M(F) \).

**Proof.** (i) We use the unicity part of Theorem \[2.1.1\]. We set \( K' = \text{RHom}(K_\Phi, \omega_M \boxtimes k_{M^2}) \). Then we have \( K'|_{M^2 \times \{0\}} \simeq \text{RHom}(k_{\Delta M}, \omega_M \boxtimes k_M) \simeq k_{\Delta M} \). Moreover \( \text{SS}(K') = (\text{SS}(K_\Phi))^a \) by Theorem \[1.2.1\]. But \( \text{SS}(K') \) is the graph of \( \Phi \) and this graph is stable by the antipodal map because \( \Phi \) is \( \mathbb{R}^x \)-homogeneous. Hence \( \text{SS}(K') = \text{SS}(K_\Phi) \) and the first result follows from the unicity of \( K_\Phi \).

(ii) The proof is the same as (i). We define two sheaves \( F', F'' \) on \( M \times I \) by \( F' = K_\Phi \circ \text{D}_M(F) \) and \( F'' = \text{RHom}(K_\Phi \circ F, \omega_M \boxtimes k_I) \). Then \( F'|_{M \times \{0\}} \simeq F''|_{M \times \{0\}} \) and \( F', F'' \) have the same microsupport, which is \( \Delta_\Phi \circ^a \text{SS}(F) \) in the notation \[2.1.5\]. Then Corollary \[2.1.4\] gives \( F' \simeq F'' \). In particular \( F'|_{M \times \{t\}} \simeq F''|_{M \times \{t\}} \), which is the required isomorphism. \[ \Box \]
Lemma 8.5.2. Let $G \in \mathcal{D}^b(k_{\mathbb{A}})$ be a constructible sheaf. We assume that $G$ has compact support, that there exists an isomorphism $G \cong D(G)$ and that $R\Gamma(\mathbb{R}; G) \cong k$. Then there exist $x_0 \in \mathbb{R}$ and a decomposition $G \cong k_{\{x_0\}} \oplus \bigoplus_{a \in A} k_{I_a}^{\alpha}[d_a]$ where the $I_a$ are half-closed intervals.

Proof. By Lemma 4.4.2 and Corollary 4.2.1, there exists a decomposition of $G_t$ as a finite sum $G_t \cong \bigoplus_{a \in A} k_{I_a}^{\alpha}[d_a]$. Then $R\Gamma(\mathbb{R}; G_t) \cong \bigoplus_{a \in A} R\Gamma(\mathbb{R}; k_{I_a})^{\alpha}[d_a]$. Since $R\Gamma(\mathbb{R}; G_t) \cong k$ all the intervals $I_a$ but one, say $I_b$, have cohomology zero, which means that they are half-closed. For $\alpha < \beta$ and $J = [\alpha, \beta]$, $J = [\alpha, \beta]$, we set $J^* = J$, $J^* = I$. We have $D_\mathbb{A}(k_t[d]) \cong k_t[1 - d]$. If the remaining interval $I_b$ is open or is closed with non empty interior, then $I_b^*$ also appears in the family $I_a$, $a \in A$, because $D(G_t) \cong G_t$. Then $k_{I_b}^*$ also contributes to $R\Gamma(\mathbb{R}; G_t)$ and it would imply that $\bigoplus_{k \in \mathbb{Z}} H^k(\mathbb{R}; G_t)$ has dimension at least 2. Hence $I_b$ is reduced to one point, say $x_0$, and we obtain the lemma.

Now we can prove the three cusps conjecture. We let $PT^*S^2 = T^*S^2/\mathbb{R}^\times$ be the projectivized cotangent bundle of $S^2$. Let $I$ be an open interval containing 0 and let $\overline{\Psi}: PT^*S^2 \times I \to PT^*S^2$ be a contact isotopy of $PT^*S^2$. It lifts to a homogeneous Hamiltonian isotopy $\Psi: \tilde{T}^*S^2 \times I \to \tilde{T}^*S^2$ which satisfies $\Psi_0 = \text{id}$ and $\Psi_t(x; \lambda \xi) = \lambda \cdot \Psi_t(x; \xi)$ for all $\lambda \in \mathbb{R}^\times$ (not only for $\lambda \in \mathbb{R}^+$) and all $(x; \xi) \in \tilde{T}^*S^2$. Let $P_0 \in S^2$ be a given point. We set $\alpha_0 = 1_{P_0} S^2$, $\alpha_t = \Psi_t(\alpha_0)$ and $C_t = \pi_{S^2}(\alpha_t)$.

Theorem 8.5.3. Let $t \in I$ be such that $C_t$ is a curve with only cusps and double points as singularities. Then $C_t$ has at least three cusps.

Proof. (i) Let $K = K_\Psi \in \mathcal{D}^b(C_{(\mathbb{R}^2)^2})$ be the sheaf associated with $\Psi$ by Theorem 2.1.1. For $t \in I$ we set $K_t = K_{|(\mathbb{R}^2)^2 \times t]} \in \mathcal{D}^b(C_{(\mathbb{R}^2)^2})$. We also set $F_0 = C_{P_0}[1]$ and $F_t = K_t \circ F_0$. Then $SS(F_t) = \alpha_t$. We have $D(F_0) \cong F_0$ and by Lemma 8.5.2 we deduce that $D(F_t) \cong F_t$. By Corollary 2.1.4 we also have $R\Gamma(S^2; F_t) \cong R\Gamma(S^2; F_0) \cong C$ for all $t \in I$. (ii) We choose a Morse function $q: S^2 \to \mathbb{R}$ with only one minimum $P_-$ and one maximum $P_+$ such that $P_-, P_+ \notin C_\Lambda$. We can choose $q$ such that any fiber $q^{-1}(x)$ contains at most one of the following special points: tangent point between $q^{-1}(x)$ and $C_\Lambda$, double point or cusp. (iii) We set $G_t = Rq_*(F_t)$. We have isomorphisms $D(G_t) \cong Rq_*(DF_t) \cong G_t$ and $R\Gamma(\mathbb{R}; G_t) \cong R\Gamma(S^2; F_t) \cong C$. By Lemma 8.5.2 there exist $x_0 \in \mathbb{R}$ and a decomposition $G_t \cong C_{\{x_0\}} \oplus \bigoplus_{a \in A} C_{I_a}^{\alpha}[d_a]$ where the $I_a$ are half-closed intervals. We set $x_\pm = q(P_\pm)$. Since $F_t$ is constant near $P_\pm$, we have $G_t \cong L \otimes (C_{[x_-, +\infty]} \oplus C_{[x_-, +\infty]}[-1])$ near $x_-$, where $L = (F_t)_{P_-}$. The same holds near $x_+$. Hence $x_0 \neq x_-$ and $x_0 \neq x_+$. 
Since $C_{\{x_0\}}$ is a direct summand of $G_t$, we have $T_0 \mathbb{R} \subset SS(G'_t)$. By Proposition 1.2.3 this implies $\Lambda \cap T_{q^{-1}(x_0)}^* \mathbb{S}^2 \neq \emptyset$. By the assumption on $q$ it follows that $q^{-1}(x_0)$ contains no cusp or double point and that $q^{-1}(x_0)$ is tangent to $C_\Lambda$ at one point. In particular the intervals $I_a$ cannot have an end at $x_0$.

Up to a change of coordinates we are in the situation of (8.3.2) and $F_t$ satisfies (8.3.4) and (8.3.5). By Corollary 2.1.4 we have

$$\text{Hom}(F_t, F_t[1]) \simeq \text{Hom}(F_0, F_0[1]) \simeq 0$$

and the result follows from Theorem 8.4.1. \hfill \Box

Part 9. Triangulated orbit categories for sheaves

In the study of Lagrangian exact submanifolds of cotangent bundles in Part 13 we will use triangulated orbit categories. For a triangulated category $T$, the triangulated envelope of the orbit category of $T$ is a triangulated category $T'$ with a functor $\iota: T \to T'$ such that $\iota(F) \cong F[1]$ for any $F \in T$ and $\text{Hom}_{T'}(\iota(F), \iota(G)) \cong \bigoplus_{i \in \mathbb{Z}} \text{Hom}_T(F, G[i])$. Such categories are constructed by Keller in [33]. We specify his construction in the case of categories of sheaves and check that we can define a microsupport in this framework.

9.1. Definition of triangulated orbit categories

We will use a very special case of the triangulated hull of an orbit category as described by Keller in [33]. More precisely Definition 9.1.1 below is inspired by §7 of [33] that we apply to the simple case where we quotient $D_b(k_M)$ by the autoequivalence $F \mapsto F[1]$ (in [33] much more general equivalences are considered). However we apply this construction for sheaves instead of modules over an algebra. We use the name triangulated orbit category for the category $D_{b/1}(k_M)$ introduced in Definition 9.1.1 by analogy with the categories introduced by Keller. However we only show that we have a functor $\iota_M: D_b(k_M) \to D_{b/1}(k_M)$ such that $\iota_M(F) \cong \iota_M(F)[1]$ and which satisfies Corollary 9.1.9 below (the proof of this result is also inspired by [33]).

In this section we set $k = \mathbb{Z}/2\mathbb{Z}$ and $\mathbb{K} = k[X]/\langle X^2 \rangle$. We let $\varepsilon$ be the image of $X$ in $\mathbb{K}$. Hence $\mathbb{K} = k[\varepsilon]$ with $\varepsilon^2 = 0$. Let $M$ be a manifold. The natural ring morphisms $k \to \mathbb{K}$ and $\mathbb{K} \to k$ induce two pairs of adjoint functors $(e_M, r_M)$ and $(E_M, R_M)$, where $e_M, E_M$ are
scalar extensions and \( r_M, R_M \) restrictions of scalars:
\[
\begin{align*}
\mathsf{D}^b(\mathbb{k}_M) & \xrightarrow{e_M} \mathsf{D}^b(\mathbb{K}_M), & e_M(F) = \mathbb{K}_M \otimes_{\mathbb{k}_M} F, & r_M(G) = G, \\
\mathsf{D}^b(\mathbb{K}_M) & \xleftarrow{R_M} \mathsf{D}^b(\mathbb{k}_M), & R_M(F) = F, \\
\mathsf{D}^-((\mathbb{K}_M)) & \xrightarrow{E_M} \mathsf{D}^-(\mathbb{k}_M), & E_M(G) = \mathbb{k}_M \otimes_{\mathbb{K}_M} G, & R_M(F) = F.
\end{align*}
\]

We will sometimes use the fact that \( r_M \) is conservative, that is, for a morphism \( u : F \to G \) in \( \mathsf{D}^b(\mathbb{K}_M) \), if \( r_M(u) \) is an isomorphism, so is \( u \). Indeed \( r_M \) is the derived functor of an exact functor and the assertion follows from the case of the module categories \( \mathsf{Mod}(\mathbb{K}_M) \), \( \mathsf{Mod}(\mathbb{k}_M) \), where it is clear.

Choosing an isomorphism \( \mathcal{R}\mathsf{Hom}_{\mathbb{k}_M}(\mathbb{K}_M, \mathbb{k}_M) \simeq \mathbb{K}_M \) of \( \mathbb{K}_M \)-modules we have a canonical isomorphism, for all \( F \in \mathsf{D}^b(\mathbb{k}_M) \),
\[(9.1.1) \quad \mathbb{K}_M \otimes_{\mathbb{k}_M} F \simeq \mathcal{R}\mathsf{Hom}_{\mathbb{k}_M}(\mathbb{K}_M, F)
\]
and we deduce the isomorphisms:
\[
\begin{align*}
\mathsf{Hom}_{\mathsf{D}^b(\mathbb{K}_M)}(G, e_M(F)) & \simeq \mathsf{Hom}_{\mathsf{D}^b(\mathbb{k}_M)}(G, \mathcal{R}\mathsf{Hom}_{\mathbb{k}_M}(\mathbb{K}_M, F)) \\
& \simeq \mathsf{Hom}_{\mathsf{D}^b(\mathbb{k}_M)}(G \otimes_{\mathbb{K}_M} \mathbb{K}_M, F) \\
& \simeq \mathsf{Hom}_{\mathsf{D}^b(\mathbb{k}_M)}(r_M(G), F).
\end{align*}
\]

**Definition 9.1.1.** We let \( \text{perf}(\mathbb{K}_M) \) be the full triangulated subcategory of \( \mathsf{D}^b(\mathbb{K}_M) \) generated by the image of \( e_M \), that is, by the objects of the form \( \mathbb{K}_M \otimes_{\mathbb{k}_M} F \) with \( F \in \mathsf{D}^b(\mathbb{k}_M) \).

We denote by \( \mathsf{D}^b_{/[1]}(\mathbb{k}_M) \) the quotient \( \mathsf{D}^b(\mathbb{K}_M)/\text{perf}(\mathbb{K}_M) \). We let \( Q_M : \mathsf{D}^b(\mathbb{K}_M) \to \mathsf{D}^b_{/[1]}(\mathbb{k}_M) \) be the quotient functor and we set \( \iota_M = Q_M \circ R_M : \mathsf{D}^b(\mathbb{k}_M) \to \mathsf{D}^b_{/[1]}(\mathbb{k}_M) \).

An object of \( \text{perf}(\mathbb{K}_M) \) is obtained by taking iterated cones of objects in \( e_M(\mathsf{D}^b(\mathbb{k}_M)) \). There are objects in \( \text{perf}(\mathbb{K}_M) \) which are not of the form \( e_M(F) \). For example, when \( M \) is a point, the objects of \( \mathsf{D}^b(\mathbb{k}) \) are split (sum of their cohomology) and so are the objects of \( e_{\{pt\}}(\mathsf{D}^b(\mathbb{k})) \), but the object \( L^{p,q} \in \text{perf}(\mathbb{K}) \) defined in \([9.1.13]\) below is not split.

Let \( \text{perf}'(\mathbb{K}_M) \) be the subcategory of \( \mathsf{D}^b(\mathbb{K}_M) \) formed by the \( P \) such that \( Q_M(P) \simeq 0 \). Then \( \text{perf}(\mathbb{K}_M) \subset \text{perf}'(\mathbb{K}_M) \) and \( \mathsf{D}^b_{/[1]}(\mathbb{k}_M) \simeq \mathsf{D}^b(\mathbb{K}_M)/\text{perf}'(\mathbb{K}_M) \). We do not know whether \( \text{perf}'(\mathbb{K}_M) = \text{perf}(\mathbb{K}_M) \).

A general result (see \([31]\) Ex. 10.11) says that \( P \in \text{perf}'(\mathbb{K}_M) \) if and only if \( P \oplus P[1] \in \text{perf}(\mathbb{K}_M) \).

**Notation 9.1.2.** If the context is clear, we will not write the functor \( Q_M \) or \( R_M \), that is, for \( F \in \mathsf{D}^b(\mathbb{k}_M) \) we often write \( F \) instead of \( R_M(F) \).
and, for \( G \in \mathcal{D}^b(\mathcal{K}_M) \), we often write \( G \) instead of \( Q_M(G) \). In particular for a locally closed subset \( Z \subset M \), we consider \( k_Z = R_M(k_Z) \in \mathcal{D}^b(\mathcal{K}_M) \) and \( k_Z = Q_M(k_Z) \in \mathcal{D}^b_{/[1]}(k_M) \).

The exact sequence of \( \mathcal{K} \)-modules \( 0 \rightarrow k \rightarrow \mathcal{K} \rightarrow k \rightarrow 0 \) induces a morphism

\[
(9.1.3) \quad s_M : k_M \rightarrow k_M[1] \quad \text{in} \quad \mathcal{D}^b(\mathcal{K}_M)
\]

and a distinguished triangle, for any \( F \in \mathcal{D}^b(k_M) \),

\[
(9.1.4) \quad R_M(F) \rightarrow e_M(F) \rightarrow R_M(F) \xrightarrow{s_M \otimes \text{id}_F} R_M(F)[1].
\]

We thus obtain an isomorphism \( s_M \otimes \text{id}_F : R_M(F) \xrightarrow{\sim} R_M(F)[1] \) in \( \mathcal{D}^b_{/[1]}(k_M) \), for any \( F \in \mathcal{D}^b(k_M) \). This would work for any field \( k \). In characteristic 2 we can generalize this isomorphism to any \( F \in \mathcal{D}^b(\mathcal{K}_M) \) (see Remark 9.1.4).

**Internal tensor product and homomorphism.** For two \( \mathcal{K} \)-modules \( E_1, E_2 \) we define \( E_1 \otimes^\mathcal{K}_k E_2 \in \text{Mod}(\mathcal{K}) \) as follows. The underlying \( k \)-vector space is \( E_1 \otimes_k E_2 \) and \( \varepsilon \) acts by

\[
\varepsilon \cdot (x \otimes y) = (\varepsilon x) \otimes y + x \otimes (\varepsilon y).
\]

Since the characteristic is 2, we can check that \( \varepsilon^2 \) acts by 0 and this defines an object of \( \text{Mod}(\mathcal{K}) \) that we denote \( E_1 \otimes^\mathcal{K}_k E_2 \). We obtain in this way a bifunctor \( \otimes^\mathcal{K}_k : \text{Mod}(\mathcal{K}) \times \text{Mod}(\mathcal{K}) \rightarrow \text{Mod}(\mathcal{K}) \). For \( F_1, F_2 \in \text{Mod}(\mathcal{K}_M) \), we define \( F_1 \otimes_{k_M}^\mathcal{K}_k F_2 \in \text{Mod}(\mathcal{K}_M) \) as the sheaf associated with the presheaf \( U \mapsto F_1(U) \otimes_{k_M}^\mathcal{K}_k F_2(U) \). We remark that \( r_M(F_1 \otimes_{k_M}^\mathcal{K}_k F_2) \simeq r_M(F_1) \otimes_{k_M} r_M(F_2) \), where \( r_M \) is seen here as a functor \( \text{Mod}(\mathcal{K}_M) \rightarrow \text{Mod}(k_M) \), and it follows easily that \( \otimes_{k_M}^\mathcal{K}_k \) is an exact functor. We denote its derived functor in the same way:

\[
(9.1.5) \quad \otimes_{k_M}^\mathcal{K}_k : \mathcal{D}^b(\mathcal{K}_M) \times \mathcal{D}^b(\mathcal{K}_M) \rightarrow \mathcal{D}^b(\mathcal{K}_M).
\]

For any \( F, G \in \mathcal{D}^b(\mathcal{K}_M) \) we have canonical isomorphisms

\[
(9.1.6) \quad k_M \otimes_{k_M}^\mathcal{K}_k F \simeq F \otimes_{k_M}^\mathcal{K}_k k_M \simeq F \quad \text{in} \quad \mathcal{D}^b(\mathcal{K}_M),
\]

\[
(9.1.7) \quad r_M(F \otimes_{k_M}^\mathcal{K}_k G) \simeq r_M(F) \otimes_{k_M} r_M(G) \quad \text{in} \quad \mathcal{D}^b(k_M).
\]

Using (9.1.6) and the exact sequence \( 0 \rightarrow k \rightarrow \mathcal{K} \rightarrow k \rightarrow 0 \), we obtain as in (9.1.3) a morphism \( s_M(F) : F \rightarrow F[1] \), for any \( F \in \mathcal{D}^b(\mathcal{K}_M) \), and a distinguished triangle

\[
(9.1.8) \quad F \rightarrow k_M \otimes_{k_M}^\mathcal{K}_k F \rightarrow F \xrightarrow{s_M(F)} F[1].
\]
Using the adjunction \((e_M, r_M)\) and \((9.1.7)\) we have the isomorphism, for any \(F \in \mathcal{D}^b(k_M)\) and \(G \in \mathcal{D}^b(k_M)\),
\[
\operatorname{Hom}_{\mathcal{D}^b(k_M)}(e_M(F \otimes_{k_M} r_M(G)), e_M(F) \otimes_{k_M} G)
\cong \operatorname{Hom}_{\mathcal{D}^b(k_M)}(F \otimes_{k_M} r_M(G), (r_M e_M(F)) \otimes_{k_M} r_M(G)).
\]
(9.1.9)

By adjunction we have a morphism \(a_F : F \to r_M e_M(F)\). The inverse image of \(a_F \otimes \operatorname{id}_{r_M(G)}\) by \((9.1.9)\) gives a canonical morphism, for any \(F \in \mathcal{D}^b(k_M)\) and \(G \in \mathcal{D}^b(k_M)\),
\[
e_M(F \otimes_{k_M} r_M(G)) \to e_M(F) \otimes_{k_M} G.
\]
(9.1.10)

**Lemma 9.1.3.** Let \(F \in \mathcal{D}^b(k_M)\) and \(G \in \mathcal{D}^b(k_M)\). Then the morphism \((9.1.10)\) is an isomorphism. In the same way \(G \otimes_{k_M} e_M(F) \cong e_M(r_M(G) \otimes_{k_M} F)\). In particular, for \(F, G \in \mathcal{D}^b(k_M)\) such that \(F \) or \(G\) belongs to \(\mathcal{P}(k_M)\), we have \(F \otimes_{k_M} G \in \mathcal{P}(k_M)\) and \(\otimes_{k_M} \) induces a functor
\[
\otimes_{k_M} : \mathcal{D}^b_{[1]}(k_M) \times \mathcal{D}^b_{[1]}(k_M) \to \mathcal{D}^b_{[1]}(k_M).
\]

**Proof.** (i) Let us denote by \(u_{F,G}\) the morphism \((9.1.10)\). Using the distinguished triangle \(\tau_{\leq i} F \to F \to \tau_{>i} F \xrightarrow{\Delta} 1\) and the similar one for \(G\) we can argue by induction on the length of \(F\) and \(G\) to prove that \(u_{F,G}\) is an isomorphism. Then we are reduced to the case where \(F \) and \(G\) are concentrated in degree 0. Writing \(k = k \oplus \varepsilon k\) we have \(e_M(F \otimes_{k_M} r_M(G)) = (F \otimes G) \oplus \varepsilon(F \otimes G)\) and \(e_M(F) \otimes_{k_M} G = (F \oplus \varepsilon F) \otimes G\). For sections \(f\) and \(g\) of \(F\) and \(G\) we have
\[
u_{F,G}(f \otimes g) = f \otimes g,
\]
\[
u_{F,G}(\varepsilon(f \otimes g)) = \varepsilon(f \otimes g) = (\varepsilon f) \otimes g + f \otimes (\varepsilon g)
\]
and we can check directly that \(u_{F,G}\) is an isomorphism with inverse
\[
u_{F,G}^{-1}(f_0 + \varepsilon f_1 \otimes g) = (f_0 \otimes g + f_1 \otimes (\varepsilon g)) + \varepsilon(f_1 \otimes g).
\]
(ii) If \(F \in \mathcal{P}(k_M)\), there exist two sequences \(F_0, F_1, \ldots, F_n = F \in \mathcal{D}^b(k_M)\) and \(F'_0, F'_1, \ldots, F'_n \in \mathcal{D}^b(k_M)\) with \(F_0 = e_M(F'_0)\), and distinguished triangles involving \(F_i, e_M(F'_{i+1})\) and \(F_{i+1}\), for \(i = 0, \ldots, n - 1\). Then (i) and an induction on \(n\) give \(F \otimes_{k_M} G \in \mathcal{P}(k_M)\).

**Remark 9.1.4.** An easy case of Lemma \((9.1.3)\) is \(F = k_M\) in \((9.1.10)\). We obtain \(e_M r_M(G) \cong k_M \otimes_{k_M} G\), for any \(G \in \mathcal{D}^b(k_M)\). Hence the distinguished triangle \((9.1.8)\) becomes
\[
(9.1.11) \quad F \to e_M r_M(F) \to F' \xrightarrow{s_M(F)} F'[1] \quad \text{for any } F \in \mathcal{D}^b(k_M).
\]
Applying \(Q_M\) to this triangle gives an isomorphism \(s_M(F) : F \cong F'[1]\) in \(\mathcal{D}^b_{[1]}(k_M)\).
We can define an adjoint $\mathcal{Hom}^\varepsilon$ to $\otimes^\varepsilon$ by a similar construction. For $F_1, F_2 \in \text{Mod}(\mathbb{K}_M)$, we define $\mathcal{Hom}^\varepsilon(F_1, F_2) \in \text{Mod}(\mathbb{K}_M)$ as the sheaf of $k$-vector spaces $\mathcal{Hom}_k(F_1, F_2)$ with the action of $\varepsilon$ given by

$$(\varepsilon \cdot \varphi)(x) = \varepsilon \varphi(x) + \varphi(\varepsilon x),$$

where $\varphi$ is a section of $\mathcal{Hom}_k(F_1, F_2)$ over an open set $U$ and $x$ a section of $F_1$ over a subset $V$ of $U$. Then we see that $\mathcal{Hom}^\varepsilon$ is right adjoint to $\otimes^\varepsilon$, hence left exact. We check also that its derived functor $R\mathcal{Hom}^\varepsilon$ is right adjoint to $\otimes^\varepsilon$ in $D^b(\mathbb{K}_M)$ and that, for any $F, G \in D^b(\mathbb{K}_M)$,

$$(9.1.12) \quad r_M(R\mathcal{Hom}^\varepsilon(F, G)) \simeq R\mathcal{Hom}(r_M(F), r_M(G)).$$

We have the similar result as Lemma 9.1.3.

**Lemma 9.1.5.** Let $F, G \in D^b(\mathbb{K}_M)$. We assume that $F$ or $G$ belongs to $\text{perf}(\mathbb{K}_M)$. Then $R\mathcal{Hom}^\varepsilon(F, G) \in \text{perf}(\mathbb{K}_M)$. The induced functor

$$R\mathcal{Hom}^\varepsilon : D^b_{\lfloor\lfloor}(k_M)^{\text{op}} \times D^b_{\lfloor\lfloor}(k_M) \to D^b_{\lfloor\lfloor}(k_M).$$

is right adjoint to $\otimes^\varepsilon_{k_M}$.

**Morphisms in the triangulated orbit category.** We prove the formula (9.1.16) which describes the morphisms in $D^b_{\lfloor\lfloor}(k_M)$.

**Lemma 9.1.6.** Let $F, P \in D^b(\mathbb{K}_M)$. We assume that $P \in \text{perf}(\mathbb{K}_M)$. Then $R\mathcal{Hom}(P, F)$ and $R\mathcal{Hom}(F, P)$ belong to $D^b(\mathbb{K})$.

**Proof.** Since $\text{perf}(\mathbb{K}_M)$ is generated by $e_M(D^b(k_M))$, the same argument as in (ii) of the proof of Lemma 9.1.3 implies that we can assume $P = e_M(Q)$, for some $Q \in D^b(k_M)$. Then $R\mathcal{Hom}_k(P, F) \simeq R\mathcal{Hom}_k(Q, r_M(F))$ is bounded. Using (9.1.2) the same proof gives that $R\mathcal{Hom}(F, P)$ is bounded. \(\square\)

We define the following objects $L^{p,q}$ of $D^b(\mathbb{K})$, for any two integers $p \leq q$, by

$$(9.1.13) \quad L^{p,q} = 0 \to \mathbb{K} \to \mathbb{K} \to \ldots \to \mathbb{K} \to 0,$$

where the first $\mathbb{K}$ is in degree $p$ and the last one in degree $q$. Then $L^{p,q} \in \text{perf}(\mathbb{K})$ and there is a distinguished triangle in $D^b(\mathbb{K})$,

$$(9.1.14) \quad \mathbb{K}[-p] \to L^{p,q} \to \mathbb{K}[-q] \xrightarrow{s^{p,q}} \mathbb{K}[-p+1],$$

with $s^{p,q} = s^{q-p+1}_{(pt)}[-q]$, where $s^{q-p+1}_{(pt)}$ is (9.1.3). For $F \in D^b(\mathbb{K}_M)$ we define $s^{p,q}_M(F) := s^{p,q} \otimes \text{id}_F : F[-q] \to F[-p+1]$. We deduce the triangle, for any $F \in D^b(\mathbb{K}_M)$ and any $n \geq 1$,

$$L^{1,n}_{k_M} \otimes \mathcal{Hom}_k F \to F[-n] \xrightarrow{s^{1,n}_M(F)} F \xrightarrow{+1}.$$
Lemma 9.1.7. We consider a distinguished triangle $P \to F' \to F \xrightarrow{+1} \text{in } D^b(\mathbb{K}_M)$ and we assume that $P \in \text{perf}(\mathbb{K}_M)$. Then there exist $n \in \mathbb{N}$ and a morphism of triangles

\[
\begin{array}{ccc}
F^{1,n}_M \otimes_{\mathbb{K}_M} F & \longrightarrow & F[-n] \\
\downarrow & & \downarrow \\
\text{perf} P & \longrightarrow & F' \\
\downarrow & & \downarrow \\
& \longrightarrow & F \xrightarrow{+1} .
\end{array}
\]

Proof. We set for short $s_n = s^{1,n}_M(F)$. We consider the diagram

\[
\begin{array}{ccc}
F[-n] & \xrightarrow{s_n} & F \\
\downarrow & & \downarrow \\
\text{perf} P & \xrightarrow{1} & \text{perf} F' \\
\downarrow & & \downarrow \\
& \longrightarrow & F \xrightarrow{w} P[1].
\end{array}
\]

We have $w \circ s_n \in \text{Hom}(F[-n], P[1])$. Since $P \in \text{perf}(\mathbb{K}_M)$ this group vanishes for $n$ big enough, by Lemma 9.1.6. In this case we have $w \circ s_n = 0$ and there exists a morphism $a$ as in the diagram making the square commute. Then we can extend the square to a commutative diagram as in the lemma. □

For $F \in D^b(\mathbb{K}_M)$ we have $s^{n,n}_M(F) : F[-n] \to F[-n + 1]$. Then \{\text{Hom} \text{perf} F[-n, s^{n,n}_M(F)]\}_n \in \mathbb{N}$ gives a projective system. For $G \in D^b(\mathbb{K}_M)$ we define

\[
(9.1.15) \quad \lim_{n \to \mathbb{N}} \text{Hom}_{D^b(\mathbb{K}_M)}(F[-n], G) \to \text{Hom}_{D^b_{/\mathbb{I}}(\mathbb{K}_M)}(F, G),
\]

by sending $\varphi_n : F[-n] \to G$ to $\varphi_n \circ (s^{1,n}_M(F))^{-1}$. This is well defined since $s^{1,n}_M(F)$ becomes invertible in $D^b_{/\mathbb{I}}(\mathbb{K}_M)$ and $s^{1,n}_M(F) = s^{1,n-1}_M(F) \circ s^{n,n}_M(F)$.

Proposition 9.1.8. Let $F, G \in D^b(\mathbb{K}_M)$. Then the inductive limit in the left hand side of \((9.1.15)\) stabilizes and the morphism \((9.1.15)\) is an isomorphism. More precisely, if $H^i(F) = H^i(G) = 0$ for all $i$ outside an interval $[a, b]$, then

\[
(9.1.16) \quad \text{Hom}_{D^b(\mathbb{K}_M)}(F[-n], G) \xrightarrow{\sim} \text{Hom}_{D^b_{/\mathbb{I}}(\mathbb{K}_M)}(F, G),
\]

for all $n > 2(b-a) + \text{dim } M + 1$.

Proof. (i) We prove that the limit stabilizes. We chose $a \leq b$ such that $H^i(F) = H^i(G) = 0$ for all $i$ outside $[a, b]$. By \((9.1.11)\) we have the
distinguished triangle

\[
\Hom_{\Db(\mathbb{K}_M)}(e_M r_M(F)[n], G) \to \Hom_{\Db(\mathbb{K}_M)}(F[n], G)
\]

(9.1.17)

\[
s'_n : \Hom_{\Db(\mathbb{K}_M)}(F[-n-1], G) \xrightarrow{\Delta} \]

for all \( n \in \mathbb{Z} \). By adjunction we have

\[
\Hom_{\Db(\mathbb{K}_M)}(e_M r_M(F)[n], G) \simeq \Hom_{\Db(\mathbb{K}_M)}(r_M(F)[n], r_M(G))
\]

and this is zero for \( n > 2(b-a) + \dim M + 1 \) (recall that the flabby dimension of a manifold \( M \) is \( \dim M + 1 \) and that injective over a field is the same as flabby). It follows that the morphism \( s'_n \) in (9.1.17) is an isomorphism for \( n > 2(b-a) + \dim M + 1 \).

(ii) We prove that (9.1.15) is an isomorphism. We recall that

\[
\Hom_{\Db(\mathbb{K}_M)}(e_M r_M(F)[n], G) \simeq \lim_{i: F' \to F} \Hom_{\Db(\mathbb{K}_M)}(F', G),
\]

where the limit runs over the morphisms \( i: F' \to F \) whose cone belongs to \( \text{perf}(\mathbb{K}_M) \) (and a morphism \( u: F' \to G \) is send to \( u \circ i^{-1} \) in \( \Db(\mathbb{K}_M) \)). By Lemma 9.1.7 we can restrict to the family of morphisms \( s_{M,n}^1(F): F[-n] \to F \) for \( n \in \mathbb{N} \). This gives the result.

\[\square\]

**Corollary 9.1.9.** Let \( F, G \in \Db(\mathbb{k}_M) \). We recall that \( \iota_M = Q_M \circ R_M \). We have

\[
\Hom_{\Db(\mathbb{K}_M)}(\iota_M(F), \iota_M(G)) \simeq \bigoplus_{n \in \mathbb{Z}} \Hom_{\Db(\mathbb{K}_M)}(F[-n], G).
\]

**Proof.** By Proposition 9.1.8 the left hand side of the formula is isomorphic to

\[
\Hom_{\Db(\mathbb{K}_M)}(R_M(F)[-n_0], R_M(G)) \simeq \Hom_{\Db(\mathbb{k}_M)}(E_M R_M(F)[-n_0], G),
\]

for any big enough \( n_0 \in \mathbb{N} \). Using the resolution of \( \mathbb{k} \) as a \( \mathbb{K} \)-module given by \( \cdots \to \mathbb{K} \xrightarrow{\xi} \mathbb{K} \xrightarrow{\xi} \mathbb{K} \to \mathbb{k} \to 0 \), we see that \( E_M R_M(F) \simeq \bigoplus_{i \in \mathbb{N}} F[i] \). The result follows easily. \[\square\]

This last result says in particular that \( \iota_M \) is faithful. We define \( \iota^0_M : \text{Mod}(\mathbb{k}_M) \to \Db_{/\mathbb{K}_M}^0(\mathbb{k}_M) \) as the composition of \( \iota_M \) and the embedding \( \text{Mod}(\mathbb{k}_M) \to \Db(\mathbb{k}_M) \) which sends a sheaf to a complex concentrated in degree 0. For \( F \in \Db(\mathbb{k}_M) \) we let \( h_M^0(F) \) be the sheaf associated with the presheaf \( U \mapsto \Hom_{\Db(\mathbb{K}_M)}(\mathbb{k}_U, F|_U) \). This defines a functor \( h_M^0 : \Db_{/\mathbb{K}_M}^0(\mathbb{k}_M) \to \text{Mod}(\mathbb{k}_M) \).

**Corollary 9.1.10.** For all \( F \in \text{Mod}(\mathbb{k}_M) \) we have \( h_M^0(\iota^0_M(F)) \simeq F \). When \( M \) is a point, the functors \( \iota^0 \) and \( h^0 \) are mutually inverse equivalences of categories between \( \text{Mod}(\mathbb{k}) \) and \( \Db_{/\mathbb{K}}^0(\mathbb{k}) \).
Proof. (i) We have \( \text{Hom}_{\mathcal{D}_{\{[1]\}}(k)}(k_U, i_M(F)|_U) \simeq \bigoplus_{n \in \mathbb{Z}} H^n(U; F) \) by Corollary 9.1.9. The sheaf associated with \( U \mapsto H^n(U; F) \) is \( H^nF \) and we obtain \( h^0_M(i_M(F)) \simeq F \) when \( F \) is in degree 0.

(ii) When \( M \) is a point, Corollary 9.1.9 says that \( i^0 \) is fully faithful. Let us prove that it is essentially surjective. Any \( G \in \text{Mod}(k) \) can be written as an extension \( 0 \to R(F) \to G \to R(F') \to 0 \) with \( F, F' \in \text{Mod}(k) \). It follows that any object in \( \mathcal{D}_{\{[1]\}}(k) \) is obtained from objects in \( i^0(\text{Mod}(k)) \) by taking iterated cones. Hence to prove that \( i^0 \) is essentially surjective, it is enough to see that if we have a distinguished triangle \( i^0(F) \xrightarrow{\sim} i^0(F') \to G \xrightarrow{\sim} \) in \( \mathcal{D}_{\{[1]\}}(k) \), with \( F, F' \in \text{Mod}(k) \), then \( G \simeq i^0(F'') \) for some \( F'' \in \text{Mod}(k) \). Since \( i^0 \) is fully faithful, we have \( u \in \text{Hom}_{\text{Mod}(k)}(F,F') \). Then \( G \simeq \text{coker}(u) \oplus \ker(u)[1] \simeq \text{coker}(u) \oplus \ker(u) \) and the result follows.

Direct sums. We recall that we denote by \( Q_M \) the quotient functor \( \mathcal{D}^b(\mathbb{K}_M) \to \mathcal{D}^b_{\{[1]\}}(k_M) \).

Lemma 9.1.11. Let \( I \) be a small set and \( \{ F_i \}_{i \in I} \) a family in \( \mathcal{D}^b(\mathbb{K}_M) \). We assume that there exist two integers \( a \leq b \) such that \( H^k(F_i) = 0 \) for all \( k \) outside \([a, b]\) and all \( i \in I \). Then \( \bigoplus_{i \in I} Q_M(F_i) \) exists in \( \mathcal{D}^b_{\{[1]\}}(k_M) \) and \( \bigoplus_{i \in I} Q_M(F_i) \simeq Q_M(\bigoplus_{i \in I} F_i) \).

Proof. By the hypothesis on the degrees the sum \( \bigoplus_{i \in I} F_i \) exists in \( \mathcal{D}^b(\mathbb{K}_M) \) and we have \( H^k(\bigoplus_{i \in I} F_i) = 0 \) for \( k \) outside \([a, b]\). Let \( G \in \mathcal{D}^b(\mathbb{K}_M) \) and let \( a' \leq a, b' \geq b \) be such that \( H^k(G) = 0 \) for \( k \) outside \([a', b']\). We set \( n = 2(b' - a') + \dim M + 2 \). If \( F = F_i \) for some \( i \in I \), or \( F = \bigoplus_{i \in I} F_i \), we have

\[
\text{Hom}_{\mathcal{D}^b(\mathbb{K}_M)}(F[-n], G) \xrightarrow{\sim} \text{Hom}_{\mathcal{D}^b_{\{[1]\}}(k_M)}(Q_M(F), Q_M(G))
\]

by Proposition 9.1.8. Now the lemma follows from the universal property of the sum.

Direct and inverse images. Let \( f: M \to N \) be a morphism of manifolds. We have functors \( Rf_* \), \( Rf^! \), \( f^{-1} \), and \( f^! \), between \( \mathcal{D}^b(\mathbb{K}_M) \) and \( \mathcal{D}^b(\mathbb{K}_N) \). Indeed, the functors \( Rf_* \), \( Rf^! : \mathcal{D}(\mathbb{K}_M) \to \mathcal{D}(\mathbb{K}_N) \) commute with the functors \( r_N : \mathcal{D}(\mathbb{K}_N) \to \mathcal{D}(k_N) \) and \( r_M \). We remark that, for \( G \in \mathcal{D}(\mathbb{K}_N) \), if \( r_N(G) \in \mathcal{D}^b(k_N) \), then \( G \in \mathcal{D}^b(\mathbb{K}_N) \). Hence \( Rf_* \) and \( Rf^! \) induce functors \( \mathcal{D}^b(\mathbb{K}_M) \to \mathcal{D}^b(\mathbb{K}_N) \) between the bounded categories. The case of \( f^{-1} \) is clear since it is an exact functor. To prove the existence of \( f^! \), right adjoint to \( Rf_! \), it is enough, by factorizing through the graph embedding, to consider the cases where \( f \) is an embedding or \( f \) is a submersion. The usual formulas work in our case. If \( f \) is an
embedding, then \( f^!(\cdot) = f^{-1}\hom^e(k_M, \cdot) \) is adjoint to \( Rf_* \). If \( f \) is a submersion, then \( f^!(\cdot) = f^{-1}(\cdot) \otimes^e \omega_{M|N} \). We also remark that \( f^{-1} \) and \( f^! \) commute with \( r_N \) and \( r_M \).

**Lemma 9.1.12.** Let \( f: M \to N \) be a morphism of manifolds. Then the functors \( Rf_* \), \( Rf! \), \( f^! \) and \( f^! \), between \( \text{D}^b(K_M) \) and \( \text{D}^b(K_N) \), preserve the categories \( \text{perf}(K_M) \) and \( \text{perf}(K_N) \). They induce pairs of adjoint functors (that we denote in the same way) between \( \text{D}^b_{/[1]}(k_M) \) and \( \text{D}^b_{/[1]}(k_N) \).

**Proof.** We only consider the case of \( Rf_* \), the other cases being similar. For \( F \in \text{D}^b(k_M) \) we have a natural morphism \( u: K_N \otimes_{K_N} Rf_* F \to Rf_*(K_M \otimes_{K_M} F) \). Since \( r_N(K_N) \simeq k_N^2 \) we see easily that \( r_N(u) \) is an isomorphism. Since \( r_N \) is conservative, \( u \) is an isomorphism and we obtain \( Rf_*(K_M \otimes_{K_M} F) \in \text{perf}(K_N) \). It follows as in (ii) of the proof of Lemma 9.1.3 that \( Rf_*(\text{perf}(K_M)) \subset \text{perf}(K_N) \), as required. \( \square \)

For \( F \in \text{D}^b_{/[1]}(k_M) \) and \( j: U \to M \) the inclusion of a locally closed subset, we use the standard notations \( F|_U = j^{-1}F \), \( F_U = Rj_*j^{-1}F \), \( R\Gamma_U(F) = Rj_*j^{-1}F \), \( R\Gamma(U; F) = R\Gamma(U)(F|_U) \in \text{D}^b_{/[1]}(k) \), where \( a_U \) is \( U \to \{\text{pt}\} \), and \( R\Gamma(U; F) = R\Gamma(U)(F|_U) \in \text{D}^b_{/[1]}(k) \). We have the same formulas as in \( \text{D}^b(k_M) \):

\[
F_U \simeq F \otimes^e k_U, \quad R\Gamma_U(F) \simeq \hom^e(k_U, F).
\]

We also define \( R\hom^e(F, G) = R\Gamma(M; \hom^e(F, G)) \in \text{D}^b_{/[1]}(k) \). The adjunctions \((a_M^{-1}, R\Gamma_M)\) and \((\otimes^e, \hom^e)\) give

\[
\hom_{\text{D}^b_{/[1]}(k_M)}(F, G) \simeq \hom_{\text{D}^b_{/[1]}(k)}(k, R\hom^e(F, G)) \simeq \hom_{\text{D}^b_{/[1]}(k_M)}(k, \hom^e(F, G)).
\]

Let \( N \) be a submanifold of \( M \). We recall that Sato’s microlocalization is a functor \( \mu_N: \text{D}^b(k_M) \to \text{D}^b(k_{T_N^*M}) \). It is defined by composing direct and inverse images functors and Lemma 9.1.12 implies that it induces functors, denoted in the same way:

\[
\mu_N: \text{D}^b(K_M) \to \text{D}^b(K_{T_N^*M}),
\]

\[
\mu_N: \text{D}^b_{/[1]}(k_M) \to \text{D}^b_{/[1]}(k_{T_N^*M}).
\]

**Definition 9.1.13.** Let \( q_1, q_2: M \times M \to M \) be the projections. We identify \( T^*_M(M \times M) \) with \( T^*M \) through the first projection. For \( F, G \in \text{D}^b_{/[1]}(k_M) \) we define as in (1.3.1)

\[
\mu hom^e(F, G) = \mu_{\Delta_M}(R\hom^e(q_1^{-1}F, q_2^!G)) \in \text{D}^b_{/[1]}(k_{T^*_M}).
\]

The following result follows from the analog one in \( \text{D}^b(k_M) \).
Lemma 9.1.14. Let \( \{F_i\}_{i \in I} \) a small family in \( \mathcal{D}^b(\mathbb{K}_M) \) satisfying the hypothesis of Lemma 9.1.13. Let \( f: M' \to M \) and \( g: M \to M'' \) be morphisms of manifolds and let \( G \in \mathcal{D}^b_{/[1]}(\mathbb{K}_M) \). Then we have canonical isomorphisms

\[
\begin{align*}
    f^{-1}(\bigoplus_{i \in I} Q_M(F_i)) &\simeq \bigoplus_{i \in I} f^{-1}Q_M(F_i), \\
    Rg_!(\bigoplus_{i \in I} Q_M(F_i)) &\simeq \bigoplus_{i \in I} Rg_!Q_M(F_i), \\
    (\bigoplus_{i \in I} Q_M(F_i)) \otimes_{\mathbb{K}_M} G &\simeq \bigoplus_{i \in I} (Q_M(F_i)) \otimes_{\mathbb{K}_M} G.
\end{align*}
\]

Lemma 9.1.15. Let \( U \) be an open subset of \( M \). Let \( F \in \mathcal{D}^b(\mathbb{K}_M) \) and \( F' \in \mathcal{D}^b(\mathbb{K}_U) \). We assume that there exists an isomorphism \( F|_U \simeq F' \) in \( \mathcal{D}^b_{/[1]}(\mathbb{K}_U) \). Then there exists \( F_1 \in \mathcal{D}^b(\mathbb{K}_M) \) such that \( F_1|_U \simeq F' \) in \( \mathcal{D}^b(\mathbb{K}_U) \) and \( F_1 \simeq F \) in \( \mathcal{D}^b_{/[1]}(\mathbb{K}_M) \).

Proof. We let \( j: U \to M \) be the inclusion and we set \( Z = M \setminus U \). Let \( u: F|_U \to F' \) be an isomorphism in \( \mathcal{D}^b_{/[1]}(\mathbb{K}_U) \). By Proposition 9.1.8 there exist \( n \in \mathbb{Z} \) and a morphism \( F[-n] \to F' \) in \( \mathcal{D}^b(\mathbb{K}_M) \) which represents \( u \). Defining \( P \) by the distinguished triangle \( F[-n] \to F' \to P \xrightarrow{+1} \) we have \( Q_U(P) \simeq 0 \). We apply \( j_! \) to this triangle and get (9.1.21) below; we also consider the excision triangle (9.1.20) and the triangle (9.1.22) built on the composition \( F_Z[-n-1] \to F_U[-n] \to j_!F' \):

\[
\begin{align*}
    (9.1.20) & \ 
    F_Z[-n-1] \xrightarrow{a} F_U[-n] \to F[-n] \xrightarrow{+1}, \\
    (9.1.21) & \ 
    F_U[-n] \xrightarrow{b} j_!F' \to j_!P \xrightarrow{+1}, \\
    (9.1.22) & \ 
    F_Z[-n-1] \xrightarrow{b\alpha a} j_!F' \to F_1 \xrightarrow{+1}.
\end{align*}
\]

Then the octahedron axiom gives the triangle \( F[-n] \to F_1 \to j_!P \xrightarrow{+1} \). We have \( Q_M(j_!P) \simeq j_!Q_M(P) \simeq 0 \), hence \( F_1 \simeq F[-n] \simeq F \) in \( \mathcal{D}^b_{/[1]}(\mathbb{K}_M) \). Applying \( j^{-1} \) to the triangle (9.1.22) gives \( F' \simeq F_1|_U \), as required. \( \square \)

Definition 9.1.16. For \( F \in \mathcal{D}^b_{/[1]}(\mathbb{K}_M) \) we define \( \text{supp}^{orb}(F) \subset M \) as the complement of the union of the open subsets \( U \subset M \) such that \( F|_U \simeq 0 \).

For an open subset \( U \subset M \) we have \( F|_U \simeq 0 \) in \( \mathcal{D}^b_{/[1]}(\mathbb{K}_U) \) if and only if \( F_U \simeq 0 \) in \( \mathcal{D}^b_{/[1]}(\mathbb{K}_M) \). By the Mayer-Vietoris triangle we deduce that, for a finite covering \( U = \bigcup_{i=1}^n U_i \), we have \( F|_U \simeq 0 \) if and only if \( F|_{U_i} \simeq 0 \) for all \( i \). For an increasing countable union \( U = \bigcup_{i=1}^\infty U_i \) we have the distinguished triangle \( \bigoplus_{i=1}^\infty \mathbb{K}_{U_i} \to \bigoplus_{i=1}^\infty \mathbb{K}_{U_i} \to \mathbb{K}_U \xrightarrow{+1} \) in
D(k_M). Applying F \otimes_{k_M} - we obtain a similar triangle

\[(9.1.23) \bigoplus_{i=1}^{\infty} F_{U_i} \to \bigoplus_{i=1}^{\infty} F_{U_i} \to F_U \xrightarrow{+1}
\]

and we deduce as in the finite case that F|_U \simeq 0 if F|_{U_i} \simeq 0 for all i.
We obtain finally, for any F \in D^b_{/[1]}(k_M),
\[(9.1.24) F|_{M\setminus supp_{orb}(F)} \simeq 0 \quad \text{and} \quad F \xrightarrow{\sim} F_{supp_{orb}(F)}.
\]

9.2. Microsupport in the triangulated orbit categories

We define the microsupport of objects of D^b_{/[1]}(k_M) and check that it satisfies the same properties as the usual microsupport.

We recall that the microsupport is invariant by restriction of scalars, that is, for F \in D(\mathbb{K}_M), we have SS(r_M(F)) = SS(F). We deduce that Theorem 1.2.11, about the microsupports of F \otimes G and R\text{Hom}(F,G), for F, G \in D(\mathbb{K}_M), is still true if we replace \otimes and R\text{Hom} by \otimes^e and R\text{Hom}^e, because of (9.1.7) and (9.1.12).

9.2.1. Definition and first properties. We define the microsupport SS^e_{orb}(F) of an object of F \in D^b_{/[1]}(k_M) from the microsupports of its representatives in D^b(\mathbb{K}_M). We prove in Proposition 9.2.3 that, for a given x_0 \in M and F \in D^b_{/[1]}(k_M), we can find a representative F' \in D^b(\mathbb{K}_M) with T^*_xM \cap SS(F') contained in an arbitrary neighborhood of T^*_xM \cap SS_{orb}(F).

**Definition 9.2.1.** Let F \in D^b_{/[1]}(k_M). We define SS_{orb}(F) \subset T^*M by SS_{orb}(F) = \bigcap_{F'} SS(F') where F' runs over the objects of D^b(\mathbb{K}_M) such that F' \simeq F in D^b_{/[1]}(k_M). We set SS_{orb}(F) = SS_{orb}(F) \cap T^*M.

We remark that SS_{orb}(F) is a closed conic subset of T^*M. We deduce from Lemma 9.1.15 that SS_{orb}(F) is a local notion, that is, for U \subset M open, we have
\[(9.2.1) SS_{orb}(F|_U) = SS_{orb}(F) \cap T^*U.
\]
In other words p = (x; \xi) \notin SS_{orb}(F) if and only if there exist a neighborhood U of x and F' \in D^b(\mathbb{K}_U) such that F'|_U \simeq F' in D^b_{/[1]}(k_U) and p \notin SS(F'). We also have supp_{orb}(F) = T^*_xM \cap SS_{orb}(F). Indeed we have T^*_xM \cap SS_{orb}(F) \subset supp_{orb}(F) by (9.2.1). Conversely, if (x; 0) \notin SS_{orb}(F), then F has a representative F' \in D^b(\mathbb{K}_M) such that (x; 0) \notin SS(F'). Hence F', and thus F, vanishes in some neighborhood of x.
Lemma 9.2.2. Let \( F \in D^b_{/|l|}(k_M) \) and \( F', F'' \in D^b(\mathbb{K}_M) \) such that \( Q_M(F') \simeq Q_M(F'') \simeq F \). Let \( x_0 \in M \) and let \( A \subset T^*_{x_0}M \) be an open contractible cone with a smooth boundary such that \( A \cap SS(F'') = \emptyset \). Let \( C \subset T^*_{x_0}M \) be a neighborhood of \( SS(F') \cap \partial A \). Then there exists \( G \in D^b(\mathbb{K}_M) \) such that \( Q_M(G) \simeq F \) and \( SS(G) \cap T^*_{x_0}M \subset (SS(F') \setminus A) \cup C \).

Proof. Let \( U \) be a chart around \( x_0 \) such that \( T^*U \simeq U \times T^*_xM \) and \( (U \times A) \cap SS(F'') = \emptyset \). We apply Proposition 3.3.2 with \( B = SS(F') \cap T^*_{x_0}M \) and \( B' = C \). We obtain a neighborhood \( W \) of \( x_0 \) and a functor \( R: D(\mathbb{K}_U) \to D(\mathbb{K}_W) \) together with a morphism of functors \( id \to R \). This functor \( R \) is a composition of usual sheaf operations and, by the results of the previous section, it induces a functor, also denoted \( R \), on \( D^b_{/|l|}(k_M) \). By (ii) of Proposition 3.3.2 we have \( F''|_W \simeq R(F'')|_W \). Hence \( F|_W \simeq R(F')|_W \) and it follows that \( Q_W(R(F')) \simeq F|_W \). By (i) of Proposition 3.3.2, the sheaf \( R(F') \), defined on \( W \), satisfies the conclusion of the lemma. By Lemma 9.1.15 we can extend \( R(F') \) into \( G \), defined on \( M \). \( \square \)

Proposition 9.2.3. Let \( F \in D^b_{/|l|}(k_M) \). Let \( x_0 \in M \) be given and let \( B \subset T^*_{x_0}M \) be a closed conic subset such that \( SS_{orb}^b(F) \cap B = \emptyset \). Then there exists \( F' \in D^b(\mathbb{K}_M) \) such that \( Q_M(F') \simeq F \) and \( SS(F') \cap B = \emptyset \).

Proof. (i) Let \( \Omega \subset T^*_{x_0}M \) be a conic neighborhood of \( A \) such that \( SS_{orb}^b(F) \cap \Omega = \emptyset \). We first prove the following claim, by induction on \( k \): for any compact submanifold \( S \) of \( \Omega/\mathbb{R}_{>0} \) of dimension \( k \), there exists \( F' \in D^b(\mathbb{K}_M) \) such that \( Q_M(F') \simeq F \) and \( (SS(F')/\mathbb{R}_{>0}) \cap S = \emptyset \).

(i-a) If \( k = 0 \), then \( S \) consists of finitely many points \( p_1, \ldots, p_N \). For each \( i = 1, \ldots, N \) there exists a neighborhood \( A_i \) of \( l_i = \mathbb{R}_{>0} \cdot p_i \) and \( F_i \) representing \( F \) such that \( SS(F_i) \cap A_i = \emptyset \). Now we find inductively \( F'_i \) representing \( F \) with a microsupport avoiding \( p_1, \ldots, p_i \) by applying Lemma 9.2.2 with \( F' = F'_i, F'' = F_i, A = A_i, C \) a neighborhood of \( \partial A_i \) not containing \( l_i \).

(i-b) We assume the claim is proved for \( k \). Let \( S \subset \Omega/\mathbb{R}_{>0} \) be of dimension \( k+1 \). For any \( p \in S \) we can find a small open convex smooth cone \( A \) around \( \mathbb{R}_{>0} \cdot p \) such that \( A \cap SS(F'') = \emptyset \) for some representative \( F'' \) of \( F \). We can find finitely many such cones \( A_1, \ldots, A_N \) such that \( S \) is covered by the \( A_i/\mathbb{R}_{>0} \)'s. We set \( S' = \bigcup_i S \cap (\partial A_i/\mathbb{R}_{>0}) \). The induction hypothesis gives \( F' \in D^b(\mathbb{K}_M) \) such that \( Q_M(F') \simeq F \) and \( (SS(F')/\mathbb{R}_{>0}) \cap S' = \emptyset \). Now we apply \( N \) times Lemma 9.2.2 by choosing \( A = A_i \) and \( C = \emptyset \).
Proposition 9.2.4. Let $F \to F' \to F'' \to +1$ be a distinguished triangle in $\mathbf{D}^b_{/\mathbb{K}(M)}$. Then $SS^{\text{orb}}(F'') \subset SS^{\text{orb}}(F') \cup SS^{\text{orb}}(F').$

Proof. Let $p = (x_0; \xi_0) \in T^* M$ be given. We assume that $p \not\in SS^{\text{orb}}(F') \cup SS^{\text{orb}}(F'')$. Let $u \colon F \to F'$ be the morphism of the triangle. By definition we can find $F_0, F'_0 \in \mathbf{D}^b_{/\mathbb{K}(M)}$ such that $Q_M(F_0) \simeq F, Q_M(F'_0) \simeq F'$ and $p \not\in SS(F_0), p \not\in SS(F'_0)$. By Proposition 9.1.8 there exist $n \in \mathbb{Z}$ and a morphism $u_0 \colon F_0[n] \to F'_0$ such that $Q_M(u_0) = u$. Then the cone of $u_0$, say $F''_0$, represents $F''$ and $p \not\in SS(F''_0)$ by the triangular inequality for the usual microsupport. The result follows.

9.2.2. Functorial behavior. We prove that $SS^{\text{orb}}(\cdot)$ satisfies the same properties as $SS(\cdot)$ with respect to the usual sheaf operations.

Proposition 9.2.5. Let $f \colon M \to N$ be a morphism of manifolds. Let $G \in \mathbf{D}^b_{/\mathbb{K}(N)}$. We assume that $f$ is non-characteristic for $SS^{\text{orb}}(G)$. Then $SS^{\text{orb}}(f^{-1}G) \cup SS^{\text{orb}}(f'^*G) \subset f_d f_{-1}SS^{\text{orb}}(G)$.

Proof. (i) The cases of $f^{-1}$ and $f'$ are similar and we only consider $f^{-1}$. We can write $f = p \circ i$ where $i \colon M \to M \times N$ is the graph embedding and $p \colon M \times N \to N$ is the projection. Since the result is compatible with the composition it is enough to consider the case of an embedding and a submersion separately:

(ii) We assume that $f$ is a submersion. Let $x \in M$ and set $y = f(x)$. Then

$$SS^{\text{orb}}(f^{-1}G) \cap T_x^* M = \bigcap_{F'} SS(F') \cap T_x^* M \subset \bigcap_{G'} SS(f^{-1}G') \cap T_x^* M,$$

where $F'$ runs over the objects of $\mathbf{D}^b_{/\mathbb{K}(M)}$ such that $F' \simeq f^{-1} G$ in $\mathbf{D}^b_{/\mathbb{K}(M)}$ and $G'$ over the objects of $\mathbf{D}^b_{/\mathbb{K}(N)}$ such that $G' \simeq G$ in $\mathbf{D}^b_{/\mathbb{K}(N)}$. Now the result follows from Theorem 1.2.7.

(iii) We assume that $f$ is an embedding. Let $(x_0; \xi_0) \in T^* M$ be such that $(x_0; \xi_0) \not\in f_d SS^{\text{orb}}(G) \cap T_{x_0}^* N$. Let $l$ be the half line $\mathbb{R}_{\geq 0} \cdot (x_0; \xi_0)$. Since $f$ is non-characteristic for $SS^{\text{orb}}(G)$, we have $f_{-1}(l) \cap SS^{\text{orb}}(G) \subset \{x_0\}$. By Proposition 9.2.3 there exist a neighborhood $V$ of $x_0$ and $G' \in \mathbf{D}^b_{/\mathbb{K}(V)}$ such that $G' \simeq G$ in $\mathbf{D}^b_{/\mathbb{K}(V)}$ and $f_{-1}(l) \cap SS(G') \subset \{x_0\}$.
\{x_0\}. Then \(f^{-1}G' \simeq f^{-1}G\) in \(\mathcal{D}^b_{/[1]}(k_{M'\times V})\) and \((x_0; \xi_0) \notin f_d(SS(G') \cap T_{x_0}^*N)\). This proves \((x_0; \xi_0) \notin SS^{orb}(f^{-1}G)\), hence the inclusion of the proposition. \(\Box\)

**Proposition 9.2.6.** Let \(f : M \rightarrow N\) be a morphism of manifolds. Let \(F \in \mathcal{D}^b_{/[1]}(k_M)\). We assume that \(f\) is proper on \(\text{supp}^{orb}(F)\). Then \(SS^{orb}(Rf_!F) \subset f_!f_d^{-1}SS^{orb}(F)\).

**Proof.** (i) As in the proof of Proposition 9.2.5 we can reduce the problem to the cases where \(f\) is an embedding or a projection. The case of an embedding is similar to the part (ii) of the proof of Proposition 9.2.5.

(ii) We assume now that \(M = M' \times N\) and \(f\) is the projection. Let \(q = (y; \eta) \in T^*N\) be such that \(q \notin f_dSS^{orb}(F)\). Let us prove that \(q \notin SS^{orb}(Rf_!F)\). Since \(f\) is proper on \(\text{supp}^{orb}(F)\), we can assume, up to restricting to a neighborhood of \(y\), that \(\text{supp}^{orb}(F) \subset C \times N\), for some compact set \(C \subset M'\). We can then find an open convex cone \(A\) in \(T_y^*N\) containing \(\eta\) and a neighborhood \(\Omega\) of \(C\), such that, for any \(x \in \Omega\) there exists \(G \in \mathcal{D}^b(k_M)\) representing \(F\) with \(SS(G) \cap (T_x^*M' \times A) = \emptyset\).

As in the proof of Lemma 9.2.2 we apply Proposition 3.3.2 to obtain two neighborhoods \(W \subset U\) of \(y\) in \(N\) and a functor \(R^+ : \mathcal{D}^b(k_{M'\times W}) \rightarrow \mathcal{D}^b(k_{M'\times V})\), of the form \(R^+(H) = K \circ H\), where \(K \in \mathcal{D}^b(k_W)\) is given by the proposition, which satisfies

(a) \(R^+\) induces a functor on \(\mathcal{D}^b_{/[1]}(k_{M'\times U})\),

(b) for \(G \in \mathcal{D}^b(k_{M'\times U})\) and \(x \in M'\) such that \(SS(G) \cap (T_x^*M' \times A) = \emptyset\) we have \(R^+(G) \simeq G|_W\) around \(\{x\} \times W\),

(c) for any \(G \in \mathcal{D}^b(k_{M'\times U})\) we have \(SS(R^+(G)) \cap (T_{x'}^*M' \times \{p\}) = \emptyset\).

Then (a) and (b) imply \(R^+(F) \simeq F|_W\). Now we choose a representative \(F' \in \mathcal{D}^b(k_M)\) of \(F\). Then \(R^+(F')\) is another representative of \(F\) and we deduce the result from the condition (c) and Proposition 9.2.3. \(\Box\)

**Proposition 9.2.7.** Let \(F, G \in \mathcal{D}^b_{/[1]}(k_M)\).

(i) We assume that \(SS^{orb}(F) \cap SS^{orb}(G)^a \subset T^*M\). Then \(SS^{orb}(F \otimes^\mathbb{L}_{k_M} G) \subset SS^{orb}(F) + SS^{orb}(G)\).

(ii) We assume that \(SS^{orb}(F) \cap SS^{orb}(G) \subset T^*M\). Then \(SS^{orb}(R\text{Hom}^\mathbb{L}(F, G)) \subset SS^{orb}(F)^a + SS^{orb}(G)\).

**Proof.** Let us prove (i). Let \(x_0 \in M\) and let \(A, B \subset T^*_{x_0}M\) be conic neighborhoods of \(SS^{orb}(F) \cap T^*_{x_0}M\), \(SS^{orb}(G) \cap T^*_{x_0}M\) such that \(A \cap B^a \subset \{x_0\}\). By Proposition 9.2.3 we can find representatives \(F', G' \in \mathcal{D}^b(k_M)\) of \(F, G\) such that \(SS(F') \cap T^*_{x_0}M \subset A\), \(SS(G') \cap T^*_{x_0}M \subset B\). Since microsupports are closed we have \(SS(F') \cap SS(G')^a \subset T^*_U\) for
some neighborhood $U$ of $x_0$. Then Theorem [1.2.11] gives $SS(F' \otimes_{k_M} C') \cap T_{x_0}^* M \subset A + B$. Since $A$ and $B$ are arbitrarily close to our microsupports we deduce (i). The proof of (ii) is the same. □

9.2.3. **Microsupport in the zero section.** In Proposition 9.2.10 we give a special case of Proposition 1.2.8 for $SS_{or}$.  

**Lemma 9.2.8.** Let $C = [a, b]^d$ be a compact cube in $\mathbb{R}^d$ and let $\{U_i\}_{i \in I}$ be a family of open subsets of $\mathbb{R}^d$ such that $C \subset \bigcup_{i \in I} U_i$. Then there exists a finite family of open subsets $\{V_n\}$, $n = 1, \ldots, N$, such that

(i) for each $n = 1, \ldots, N$ there exists $i \in I$ such that $V_n \subset U_i$,

(ii) $C \subset \bigcup_{n=1}^N V_n$,

(iii) $(\bigcup_{k=1}^n V_k) \cap V_{n+1}$ is contractible, for each $n = 1, \ldots, N - 1$.

**Proof.** For $x \in \mathbb{R}^d$ and $\varepsilon > 0$ we set $C^\varepsilon_x = x + ]-\varepsilon, \varepsilon[^d$. We can choose $\varepsilon > 0$ such that, for any $x \in C$, there exists $i \in I$ satisfying $C^\varepsilon_x \subset U_i$.

We let $x_n, n = 1, \ldots, N$, be the points of the lattice $C \cap (\varepsilon \mathbb{Z})^d$ ordered by the lexicographic order of their coordinates. Then the family $V_n = C^\varepsilon_{x_n}$, $n = 1, \ldots, N$, satisfies the required properties. □

**Lemma 9.2.9.** Let $M$ be a manifold and $U, V \subset M$ two open subsets. Let $F \in D^b_{/\{U\}}(k_M)$. We assume that $U \cap V$ is non empty and contractible and that there exist $A, A' \in \text{Mod}(k)$ such that $F|_U \simeq A_U$ and $F|_V \simeq A'_V$. Then $A \simeq A'$ and $F|_{U \cup V} \simeq A_{U \cup V}$.

**Proof.** We set $W = U \cap V$ and $X = U \cup V$. Taking the germs at some $x \in W$ gives $A \simeq A'$. The Mayer-Vietoris triangle yields in our case $A_W \xrightarrow{\text{u}} A_U \oplus A_V \xrightarrow{\text{v}} F_X \xrightarrow{+1}$, where $u$ is of the form $(1, v)$ for some isomorphism $v \in \text{Hom}_{D^b_{/\{U\}}(k_M)}(A_W, A_W)$. By Corollary 9.1.9 we have

$$\text{Hom}_{D^b_{/\{U\}}(k_M)}(A_V, A_V) \simeq \bigoplus_{i \in \mathbb{Z}} \text{Hom}_{D^b_{/\{U\}}(k_M)}(A_V, A_V[i])$$

$$\simeq \text{Hom}(A, A) \otimes \bigoplus_{i \in \mathbb{N}} H^i(V; k).$$

In the same way $\text{Hom}_{D^b_{/\{U\}}(k_M)}(A_W, A_W) \simeq \text{Hom}(A, A)$ since $W$ is contractible. Hence $v$ can be extended as an isomorphism to $V$ and we can define the commutative square (C) below:

$$\begin{array}{ccc}
A_W & \xrightarrow{(1, v)} & A_U \oplus A_V \xrightarrow{+1} F_X \\
\| & \| & \| \\
A_W & \xrightarrow{(1, 1)} & A_U \oplus A_V \xrightarrow{+1} A_X
\end{array}$$
We extend this square to an isomorphism of triangles and obtain $F_X \simeq A_X$, as required.

**Proposition 9.2.10.** Let $E = \mathbb{R}^d$ and $F \in \mathcal{D}^b_{/\{1\}}(k_E)$. We assume that $\text{SS}^{\text{orb}}(F) \subset T_E^*E$. Then there exists $A \in \text{Mod}(k)$ such that $F \simeq A_E$.

**Proof.** (i) By Proposition 9.2.3, for any $x \in E$ there exists a representative of $F$, say $F^x$, in $\mathcal{D}^b(\mathcal{K}_E)$ such that $\text{SS}(F^x) \cap T^*_xE \subset \{x\}$. Since microsupports are closed there exists an open neighborhood of $x$, say $U_x$, such that $\text{SS}(F^x) \cap \dot{T}^*_xU_x = \emptyset$, that is, $F^x|_{U_x}$ is constant. In other words, there exists $B^x \in \mathcal{D}^b(\mathcal{K})$ such that $F^x|_{U_x} \simeq B^x_{U_x}$. By Corollary 9.1.10 there exists $A^x \in \text{Mod}(k)$ such that $B^x \simeq A^x$ in $\mathcal{D}^b_{/\{1\}}(k_E)$ and we have $F|_{U_x} \simeq A^x_{U_x}$ in $\mathcal{D}^b_{/\{1\}}(k_{U_x})$.

(ii) We set $I_n = [-n, n]^d$ for $n \in \mathbb{N} \setminus \{0\}$. The family $\{U_x\}_{x \in \mathcal{V}}$ covers $\mathcal{V}$. Hence, by Lemmas 9.2.8 and 9.2.9 there exists $A \in \text{Mod}(k)$ such that $F_{I_n} \simeq A_{I_n}$ for all $n \in \mathbb{N} \setminus \{0\}$. We can assume that these isomorphisms are compatible with the morphisms $i_n: (\cdot)_{I_n} \to (\cdot)_{I_{n+1}}$. We obtain the commutative square (D) below between triangles deduced from (9.1.23)

\[
\begin{array}{ccc}
\oplus_n F_{I_n} & \xrightarrow{u} & \oplus_n F_{I_n} \\
| & | & | \\
\oplus_n A_{I_n} & \xrightarrow{u} & \oplus_n A_{I_n} \\
\end{array}
\]

\[
\begin{array}{ccc}
F & \xrightarrow{+1} & F \\
| & | & | \\
A_E & \xrightarrow{+1} & A_E \\
\end{array}
\]

where the $n^{th}$-component of $u$ is $\text{id} - i_n$. We extend this square to an isomorphism of triangles and we see that $F \simeq A_E$. □

**Part 10. The Kashiwara-Schapira stack**

Let $M$ be a manifold and $\Lambda$ a locally closed conic Lagrangian submanifold of $\dot{T}^*M$. In this part we define the Kashiwara-Schapira stack $\mu\text{Sh}(k_{\Lambda})$ and its orbit category version. It is obtained by quotienting the category of sheaves on $M$ by subcategories defined by microsupport conditions. These categories are introduced by Kashiwara-Schapira in [30]. For a subset $S$ of $\dot{T}^*M$ we denote by $\mathcal{D}^b(k_M; S)$ the quotient of $\mathcal{D}^b(k_M)$ by the subcategory of sheaves $F$ with $\text{SS}(F) \cap S = \emptyset$. Then $\mu\text{Sh}(k_{\Lambda})$ is the stack on $\Lambda$ associated with the prestack whose value over $\Lambda_0 \subset \Lambda$ is the subcategory of $\mathcal{D}^b(k_M; \Lambda_0)$ generated by the $F$ such that $\text{SS}(F) \cap \Lambda_0$ is open and closed in $\Lambda_0$ (in other words, near $\Lambda_0$ the microsupport of $F$ is contained in $\Lambda_0$). We remark that we loose the triangulated structure in the stackification process.

An important result of [30] says that the $\mathcal{H}om$ sheaf in $\mu\text{Sh}(k_{\Lambda})$ is given by $H^0\mu\text{hom}$ (see Corollary 10.1.5). It is then possible to describe
an object of $\mu \text{Sh}(k_\Lambda)$ by local data (see Remark 10.1.6). We check in Lemma 10.2.5 that, locally on $M$, there exists simple sheaves with microsupport $\Lambda$: if $B$ is a small ball in $M$ and $\Lambda$ is in generic position, there exist simple sheaves on $B$ with microsupport $\Lambda \cap T^*B$. We define two classes $\mu^{sh}_1(\Lambda) \in H^1(\Lambda; \mathbb{Z})$ and $\mu^{sh}_2(\Lambda) \in H^2(\Lambda; k^\times)$ which are obstructions for the existence of a global object of $\mu \text{Sh}(k_\Lambda)$ (that is, an object of $\mu \text{Sh}(k_\Lambda)(\Lambda)$). In the last two sections we make the link between these classes and the usual Maslov classes $\mu_1(\Lambda)$ and $\mu_2(\Lambda)$. In fact it would not be difficult to deduce $\mu^{sh}_1(\Lambda) = \mu_1(\Lambda)$ directly from Proposition 1.4.1 and the description of the Maslov class by Čech cohomology (for example in [23]). However the class $\mu_2(\Lambda)$ requires more work; we only prove the useful implication that the vanishing of $\mu^{sh}_2(\Lambda)$ implies the vanishing of $\mu_2(\Lambda)$.

When we work with sheaves of $k$-modules we only have the obstruction classes $\mu^{sh}_1(\Lambda)$ and $\mu^{sh}_2(\Lambda)$ for the existence of a global section of $\mu \text{Sh}(k_\Lambda)$. If we work with sheaves of spectra, there are infinitely many of them. Of course this requires to work with dg-categories or infinity categories (see [45, 46] or [36]). In this framework the stack $\mu \text{Sh}(k_\Lambda)$ has the structure of a stable category, like a category of sheaves (whereas the triangulated structures are not suited for stackification). This is explained in [25] where the higher classes $\mu^{sh}_i(\Lambda)$ are described (they do not coincide with the usual Maslov classes – see also [26]). In [3] it is proved that these classes vanish when $\Lambda$ is a Lagrangian immersion in $T^*M$ in the homotopy class of the base.

**Notation 10.0.1.** We follow the notations of [30, §7.5] with slight modifications. For a subset $S$ of $\dot{T}^*M$ we denote by $D^b_S(k_M)$ the full triangulated subcategory of $D^b(k_M)$ of the $F$ such that $\text{SS}(F) \subset S$. We denote by $D^b(k_M; S)$ the quotient of $D^b(k_M)$ by $D^b_{\dot{T}^*M \setminus S}(k_M)$. If $p \in \dot{T}^*M$, we write $D^b(k_M; p)$ for $D^b(k_M; \{p\})$. We denote by $D^b_{(S)}(k_M)$ the full triangulated subcategory of $D^b(k_M)$ of the $F$ for which there exists a neighborhood $\Omega$ of $S$ in $T^*M$ such that $\text{SS}(F) \cap \Omega \subset S$.

The quotient of a triangulated category by a triangulated subcategory is recalled in [30, §1.6]. In particular the objects of $D^b(k_M; S)$ are the same as $D^b(k_M)$. A morphism $u: F \to G$ in $D^b(k_M; S)$ is represented by a triple $(F', s, u')$ where $F' \in D^b(k_M)$ and $s, u'$ are morphisms

\begin{equation}
F \xleftarrow{s} F' \xrightarrow{u'} G
\end{equation}

such that the $L$ defined (up to isomorphism) by the distinguished triangle $F' \xrightarrow{s} F \to L \xrightarrow{+1}$ satisfies $\Omega \cap \text{SS}(L) = \emptyset$. Two such triples

\begin{equation}
F \xleftarrow{s} F' \xrightarrow{u'} G
\end{equation}

\begin{equation}
F \xleftarrow{s'} F' \xrightarrow{u'} G
\end{equation}

are called isomorphic if there exists an object $L' \in D^b(k_M; S)$ and a morphism $s'' \in D^b(k_M; S)$ such that $s''(F) \in L$ and $s''(F') \in L'$. This category is denoted by $D^b(k_M; S)$. We define $D^b(k_M; \dot{T}^*M \setminus S)$ similarly.
(\(F'_i, s_i, u'_i\)), \(i = 1, 2\), represent the same morphism if there exists a third triple \((F', s, u')\) and two morphisms \(v_i: F' \rightarrow F'_i\) such that \(s = s_i \circ v_i, i = 1, 2\), and \(u'_1 \circ v_1 = u'_2 \circ v_2\).

The notion of stack used here is that of “sheaf of categories”. We refer for example to [31, §19]. A prestack \(C\) on a topological space \(X\) consists of the data of a category \(C(U)\), for each open subset \(U\) of \(X\), restriction functors \(r_{V,U}: C(U) \rightarrow C(V)\), for \(V \subset U\), and isomorphisms of functors \(r_{W,V} \circ r_{V,U} \simeq r_{W,U}\), for \(W \subset V \subset U\), satisfying compatibility conditions.

A stack is a prestack satisfying some gluing conditions. In particular, if \(C\) is a stack and \(A, B \in C(U)\), then the presheaf \(V \mapsto \operatorname{Hom}_{C(V)}(A|_V, B|_V)\) is a sheaf on \(U\). Moreover, if \(U = \bigcup_{i \in I} U_i\) and \(A_i \in C(U_i)\) are given objects with compatible isomorphisms between their restrictions on the intersections \(U_i \cap U_j\), then these objects glue into an object of \(C(U)\).

For any given prestack we can construct its associated stack, similar to the associated sheaf of a presheaf.

10.1. Definition of the Kashiwara-Schapira stack

We use the categories associated with a subset of \(T^*M\) introduced in Notation [10.0.1]

**Definition 10.1.1.** Let \(\Lambda \subset T^*M\) be a locally closed conic subset. We define a prestack \(\mu \text{Sh}^0_\Lambda\) on \(\Lambda\) as follows. Over an open subset \(\Lambda_0\) of \(\Lambda\) the objects of \(\mu \text{Sh}^0_\Lambda(\Lambda_0)\) are those of \(D^b_{(\Lambda_0)}(k_M)\). For \(F, G \in \mu \text{Sh}^0_\Lambda(\Lambda_0)\) we set

\[
\operatorname{Hom}_{\mu \text{Sh}^0_\Lambda(\Lambda_0)}(F, G) := \operatorname{Hom}_{D^b(k_M;\Lambda_0)}(F, G).
\]

We define the Kashiwara-Schapira stack of \(\Lambda\) as the stack associated with \(\mu \text{Sh}^0_\Lambda\). We denote it by \(\mu \text{Sh}(k_{\Lambda_0})\) and, for \(\Lambda_0 \subset \Lambda\), we write \(\mu \text{Sh}(k_{\Lambda_0})\) instead of \(\mu \text{Sh}(k_{\Lambda_0})(\Lambda_0)\).

We denote by \(m_\Lambda: D^b_{(\Lambda)}(k_M) \rightarrow \mu \text{Sh}(k_{\Lambda_0})\) the obvious functor. However, for \(F \in D^b_{(\Lambda)}(k_M)\), we often write \(F\) instead of \(m_\Lambda(F)\) if there is no risk of ambiguity.

Several results in the next sections give links between \(\mu \text{Sh}(k_{\Lambda})\) and stacks of the following type.

**Definition 10.1.2.** Let \(X\) be a topological space. We let \(DL^0(k_X)\) be the subprestack of \(U \mapsto D^b(k_U), U\) open in \(X\), formed by the \(F \in D^b(k_U)\) with locally constant cohomologically sheaves. We let \(DL(k_X)\) be the stack associated with \(DL^0(k_X)\). We denote by \(\text{Loc}(k_X)\) the substack of \(\text{Mod}(k_X)\) formed by the locally constant sheaves.
We remark that $\mathcal{DL}(k_X)$ is only a stack of additive categories (the triangulated structure is of course lost in the “stackification”). However the cohomological functors $H^i: D^b(k_U) \to \text{Mod}(k_U)$ induce functors of stacks $H^i: \mathcal{DL}(k_X) \to \text{Loc}(k_X)$ and the natural embedding $\text{Mod}(k_U) \hookrightarrow D^b(k_U)$ induces $i: \text{Loc}(k_X) \to \mathcal{DL}(k_X)$. We have $H^0 \circ i \simeq \text{id}_{\text{Loc}(k_X)}$. Hence $i$ is faithful and $\text{Loc}(k_X)$ is a subcategory of $\mathcal{DL}(k_X)$.

**Link with microlocalization.** We recall now some results of [30] which explain the link between the localized categories $D^b(k_M; \Omega)$, for $\Omega \subset T^*M$, and the microlocalization, making these categories easier to describe.

First we recall some properties of the functor $\mu_{\text{hom}}$. For $U \subset M$ and $F, G \in D(k_U)$, the isomorphism $R\text{Hom}(F, G) \simeq R\pi_M^* \mu_{\text{hom}}(F, G)$ of (1.3.2) implies $\text{Hom}(F, G) \cong H^0(T^*U; \mu_{\text{hom}}(F, G))$; for $u: F \to G$ we denote by

\[(10.1.1) \quad u^\mu \in H^0(T^*U; \mu_{\text{hom}}(F, G))\]

the image of $u$ by this isomorphism (this notation has been introduced in (8.1.6)). For $F, G, H \in D^b(k_M)$ we have a composition morphism (see [30, Cor. 4.4.10])

\[(10.1.2) \quad \mu_{\text{hom}}(F, G) \overset{\cdot}{\otimes} \mu_{\text{hom}}(G, H) \to \mu_{\text{hom}}(F, H).\]

(With the notations of Definition 1.3.4, it is induced by a natural morphism $\mu_{\Delta_M}(A) \otimes \mu_{\Delta_M}(B) \to \mu_{\Delta_M}(A \overset{\cdot}{\otimes} B)$ and the composition morphism for $R\text{Hom}(q_2^{-1}F, q_1^{-1}G)$.)

**Notation 10.1.3.** For $F, G, H \in D^b(k_M)$, $\Omega \subset T^*M$ and sections of $\mu_{\text{hom}}(-, -)$, say $a \in H^i(\Omega; \mu_{\text{hom}}(F, G))$, $b \in H^j(\Omega; \mu_{\text{hom}}(G, H))$, we denote by

\[b \circ a \in H^{i+j}(\Omega; \mu_{\text{hom}}(F, H))\]

the image of $a \otimes b$ by the morphism induced by (10.1.2) on sections.

By construction $\circ$ is compatible with the usual composition morphism for $R\text{Hom}$ through the isomorphism (1.3.2): for $u: F \to G$, $v: G \to H$ we have $(v \circ u)^\mu = v^\mu \circ u^\mu$.

In the same way $\circ$ is also compatible with the functoriality of $\mu_{\text{hom}}$ as follows. A morphism $v: G \to H$ induces

\[(10.1.3) \quad \mu_{\text{hom}}(F, v): \mu_{\text{hom}}(F, G) \to \mu_{\text{hom}}(F, H)\]

and we have, for a section $a$ of $\mu_{\text{hom}}(F, G)$,

\[(10.1.4) \quad \mu_{\text{hom}}(F, v)(a) = v^\mu \circ a.\]
We come back to $D^b(k_M; \Omega)$. Let $u : F \to G$ be a morphism in $D^b(k_M; \Omega)$, represented by a triple $(F', s, u')$ as in (10.0.1). Let $L$ be defined (up to isomorphism) by the distinguished triangle $F' \xrightarrow{s} F \to L \to -1$ satisfies $\Omega \cap SS(L) = \emptyset$. By (1.3.6) we have $\mu hom(L, G)|_{\Omega} \simeq 0$ and $\mu hom(s, G)$ as in (10.1.5) gives an isomorphism

$$\mu hom(s, G) : \mu hom(F, G)|_{\Omega} \xrightarrow{\sim} \mu hom(F', G)|_{\Omega}.$$ 

Hence the triple $(F', s, u')$ yields a section $(\mu hom(s, G))^{-1}((u')^{\mu})$ of $H^0(\Omega; \mu hom(F, G))$. We can check that this section only depends on $u$ and not its representative $(F', s, u')$. Thus we obtain a well-defined morphism

$$(10.1.5) \quad \text{Hom}_{D^b(k_M; \Omega)}(F, G) \to H^0(\Omega; \mu hom(F, G)|_{\Omega}).$$

**Theorem 10.1.4** (Thm. 6.1.2 of [30]). If $\Omega = \{p\}$ for some $p \in T^*M$, then $(10.1.5)$ is an isomorphism.

It follows from Theorem (10.1.4) that the sheaf associated with $\Omega \mapsto \text{Hom}_{D^b(k_M; \Omega)}(F, G)$ is $H^0\mu hom(F, G)$, for given $F, G \in D^b(k_M)$. We obtain an alternative definition of $\mu Sh(k_{\Lambda})$:

**Corollary 10.1.5.** Let $\Lambda \subset T^*M$ be as in Definition (10.1.1). We define a prestack $\mu Sh^1_{\Lambda}$ on $\Lambda$ as follows. Over an open subset $\Lambda_0$ of $\Lambda$ the objects of $\mu Sh^1_{\Lambda}(\Lambda_0)$ are those of $D^b(\Lambda_0)(k_M)$. For $F, G \in \mu Sh^1_{\Lambda}(\Lambda_0)$ we set $\text{Hom}_{\mu Sh^1_{\Lambda}(\Lambda_0)}(F, G) := H^0(\Lambda_0; \mu hom(F, G)|_{\Lambda_0})$. The composition is induced by (10.1.2). Then, the natural functor of prestacks $\mu Sh^0_{\Lambda} \to \mu Sh^1_{\Lambda}$ induces an isomorphism on the associated stacks.

**Remark 10.1.6.** By Corollary 10.1.5 an object of $\mu Sh(k_{\Lambda})$ is determined by the data of an open covering $\{\Lambda_i\}_{i \in I}$ of $\Lambda$, objects $F_i \in D^b(\Lambda_i)(k_M)$, for any $i \in I$, and sections $u_{ij} \in H^0(\Lambda_{ij}; \mu hom(F_i, F_j)|_{\Lambda_{ij}})$, for any $i, j \in I$, such that

(i) $u_{ii}$ is induced by $id_{F_i}$, for any $i \in I$,

(ii) $u_{kj} \circ u_{ij} = u_{ki}$, for any $i, j, k \in I$.

For a complex of sheaves $A$, the sheaf associated with the presheaf $U \mapsto H^0(U; A)$ is $H^0A$. Hence, for $F, G \in D^b(\Lambda)(k_M)$, we find that the homomorphism sheaf $\text{Hom}_{\mu Sh(k_{\Lambda})}(m_{\Lambda}(F), m_{\Lambda}(G))$ is $H^0(\mu hom(F, G))|_{\Lambda}$. In particular, for an open subset $\Lambda_0 \subset \Lambda$,

$$(10.1.6) \quad \text{Hom}(m_{\Lambda}(F)|_{\Lambda_0}, m_{\Lambda}(G)|_{\Lambda_0}) \simeq H^0(\Lambda_0; H^0(\mu hom(F, G))).$$

**Remark 10.1.7.** We will only consider $\mu Sh(k_{\Lambda})$ when $\Lambda$ is conic Lagrangian submanifold of $T^*M$. In this case, for $F, G \in D^b_{(\Lambda)}(k_M)$ we
know by Corollary 1.3.7 that $\mu_{\hom}(F, G)$ has locally constant cohomology sheaves on $\Lambda$. Moreover, for a given $p = (x; \xi) \in \Lambda$ we have

$$\mu_{\hom}(F, G)_p \simeq \operatorname{RHom}((\Gamma_{\{\varphi_0 \geq 0\}}(F))_x, (\Gamma_{\{\varphi_0 \geq 0\}}(G))_x),$$

where $\varphi_0$ is such that $\Lambda$ and $\Lambda_{\varphi_0}$ intersect transversally at $p$ (see (1.4.6)). Hence, if $F$ and $G$ are pure along $\Lambda$, $\mu_{\hom}(F, G)$ is concentrated in one degree. In particular, the right hand side of (10.1.6) coincides with $H^0(\Lambda_0; \mu_{\hom}(F, G))$. If $F$ and $G$ are simple, then $\mu_{\hom}(F, G)$ is moreover of rank one.

**Remark 10.1.8.** For a conic subset $\Omega$ of $T^*M$, we recall that a morphism $a: F \to G$ in $\mathcal{D}(k_M)$ is an isomorphism on $\Omega$ if $\operatorname{SS}(C(a)) \cap \Omega = \emptyset$, where $C(a)$ is given by the distinguished triangle $F \xrightarrow{a} G \to C(a) \xrightarrow{+1}$. In particular $a$ induces an isomorphism in $\mathcal{D}^b(k_M; \Omega)$. We assume that $\Lambda$ is a conic Lagrangian submanifold and $F, G \in \mathcal{D}^b_\Lambda(k_M)$. Let $\Lambda_0$ be an open subset of $\Lambda$ and let $a: F \to G$ be an isomorphism on $\Lambda_0$. Then the morphism $m_{\Lambda}(a)|_{\Lambda_0}: m_{\Lambda}(F)|_{\Lambda_0} \to m_{\Lambda}(G)|_{\Lambda_0}$ is an isomorphism. It follows from Remark 10.1.7 that there exists $b \in H^0(\Lambda_0; H^0(\mu_{\hom}(G, F)))$ such that

$$a^\mu \circ b = \operatorname{id}_{F^\mu}, \quad b \circ a^\mu = \operatorname{id}_{F^\mu}.$$

The functor $\mu\operatorname{Sh}_\Lambda^{\text{opp}} \times \mu\operatorname{Sh}_\Lambda^\text{op} \to \mathcal{D}^b(k_\Lambda)$, $(F, G) \mapsto \mu_{\hom}(F, G)$ induces a functors of stacks

$$\mu_{\hom}: \mu\operatorname{Sh}(k_\Lambda)^{\text{opp}} \times \mu\operatorname{Sh}(k_\Lambda) \to \mathcal{D}L(k_\Lambda).$$

10.2. **Simple sheaves**

In this section we assume that $\Lambda$ is a locally closed conic Lagrangian submanifold of $\dot{T}^*M$. We have seen the notion of pure and simple sheaves along $\Lambda$ in Section 1.4. We give here some additional properties.

It is easy to describe the simple sheaves along a Lagrangian submanifold at a generic point. They are given in the following example.

**Example 10.2.1.** We consider the hypersurface $S = \mathbb{R}^{n-1} \times \{0\}$ in $M = \mathbb{R}^n$. We let $\Lambda = \{(x, 0; 0, \xi_n); \xi_n > 0\}$ be the “positive” half part of $T_{\Xi}^*M$. We set $Z = \mathbb{R}^{n-1} \times \mathbb{R}_{>0}$. The sheaf $k_Z$ is simple along $\Lambda$. More generally, by Example 1.2.9 the simple sheaves $F$ along $\Lambda$ fit in a distinguished triangle

$$E'_M \to k_Z[i] \to F \xrightarrow{+1},$$

for some integer $i$ and some $E' \in \mathcal{D}(k)$. Let $F \in \mathcal{D}^b_{\Lambda\cup T_{\Xi}^*M}(k_M)$. Then, there exists $L \in \mathcal{D}^b(k)$ such that the image of $F$ in the quotient category $\mathcal{D}^b(k_M; \dot{T}^*M)$ is isomorphic to $L_Z = L_M \otimes k_Z$. The pure sheaves
SHEAVES AND SYMPLECTIC GEOMETRY OF COTANGENT BUNDLES 113

correspond to the case where $L$ is concentrated in one degree and free. The simple sheaves correspond to the case where $L \simeq k[i]$ for some degree $i \in \mathbb{Z}$.

For any $p \in \Lambda$ we can find a homogeneous Hamiltonian isotopy that sends a neighborhood of $p$ in $\Lambda$ to the conormal bundle of a smooth hypersurface. Then Theorem 21.1.1 reduces the general case to Example 10.2.1 (since this is a local statement in $T^*M$ we can also use Theorem 7.2.1 of [30]). We deduce:

**Lemma 10.2.2.** Let $p = (x; \xi)$ be a given point of $\Lambda$. Then there exists a neighborhood $\Lambda_0$ of $p$ in $\Lambda$ such that

(i) there exists $F \in D^b_{(\Lambda_0)}(k_M)$ which is simple along $\Lambda_0$,

(ii) for any $G \in D^b_{(\Lambda_0)}(k_M)$ there exist a neighborhood $\Omega$ of $\Lambda_0$ in $T^*M$ and an isomorphism $F \otimes L_M \sim G$ in $D^b(k_M; \Omega)$, where $L \in D^b(k)$ is given by $L = \mu_{\text{hom}}(F, G)_p$.

**Definition 10.2.3.** Let $\Lambda \subset \check{T}^*M$ be a locally closed conic Lagrangian submanifold. We let $\mu\text{Sh}^p(k_\Lambda)$ (resp. $\mu\text{Sh}^s(k_\Lambda)$) be the substack of $\mu\text{Sh}(k_\Lambda)$ formed by the pure (resp. simple) sheaves along $\Lambda$.

Lemma 10.2.2 implies the following result.

**Proposition 10.2.4.** Let $\Lambda \subset \check{T}^*M$ be a locally closed conic Lagrangian submanifold. We assume that there exists a simple sheaf $F \in \mu\text{Sh}^s(k_\Lambda)$. Then the functor $\overline{\mu_{\text{hom}}}$ defined in (10.1.7) induces an equivalence of stacks

$$
\overline{\mu_{\text{hom}}}(F, \cdot): \mu\text{Sh}(k_\Lambda) \sim \mathcal{D}(k_\Lambda), \quad G \mapsto \overline{\mu_{\text{hom}}}(F, G).
$$

By Lemma 10.2.2 we can find a simple sheaf with microsupport $\Lambda$ locally around a given point $p \in \Lambda$. When $\Lambda$ is in a good position we can improve this result as follows.

**Lemma 10.2.5.** Let $M$ be a manifold and let $\Lambda \subset \check{T}^*M$ be a locally closed conic Lagrangian submanifold such that the projection $\Lambda / \mathbb{R}_{>0} \to M$ is finite. Let $p = (x; \xi) \in \Lambda$. Then there exist a neighborhood $U$ of $x$ and $F \in D^b(k_U)$ such that $\overline{\text{SS}}(F) \subset \Lambda \cap T^*U$ and $F$ is simple along $\Lambda \cap T^*U$.

**Proof.** (i) By hypothesis $\Lambda \cap T^*_x M$ consists of finitely many half-lines, say $\mathbb{R}_{>0} \cdot p_i$, with $p_i = (x; \xi_i)$, $i = 1, \ldots, n$. Up to a restriction to a neighborhood of $x$ we can assume that the $p_i$ belong to distinct connected components of $\Lambda$, say $\Lambda_i$, $i = 1, \ldots, n$. If $F_i$ is simple along $\Lambda_i$, then the direct sum $\bigoplus F_i$ is simple along $\Lambda$. Hence we can assume that $\Lambda \cap T^*_x M = \mathbb{R}_{>0} \cdot p$ for some $p = (x; \xi)$. 

(ii) By Lemma 10.2.2 there exists a neighborhood \( \Omega \) of \( p \) in \( T^*M \) and \( F_0 \in D^b(k_M) \) such that \( SS(F_0) \cap \Omega = \Lambda \) and \( F_0 \) is simple along \( \Lambda \) at \( p \). For a neighborhood \( W \) of \( x \) we choose a trivialization \( T^*W \simeq W \times T^*_xM \). We choose a small open cone \( C \subset T^*_xM \) containing \( \xi \). We set \( A = \mathbb{R}_{>0} \xi \) and \( A' = T^*_xM \setminus C \). By Proposition 3.3.1 applied to \( A, A' \), there exists a distinguished triangle \( F_1 \oplus F_2 \to F_0|_W \to L \xrightarrow{+1} \) in \( D(k_W) \), up to shrinking \( W \), where \( SS(F_1) = SS(F_0) \cap (W \times A) \), \( SS(F_2) = SS(F_0) \cap (W \times A') \) and \( L \) is constant. Then \( SS(F_1) = \Lambda \cap T^*W \) and \( F_1 \) is simple. We can set \( U = W \) and \( F = F_1 \). 

Now we check that the stalks of a simple sheaf at a generic point are of finite rank if they are of finite rank at some given point. We set

\[
Z_{\Lambda} = \{ x \in \hat{\pi}_M(\Lambda) ; \text{there exist a neighborhood } W \text{ of } x \text{ and a smooth hypersurface } S \subset W \text{ such that } \Lambda \cap T^*W \subset T^*_sW \}.
\]

The transversality theorem implies the following result.

**Lemma 10.2.6.** Let \( x, y \in M \setminus \hat{\pi}_M(\Lambda) \). Let \( I \) be an open interval containing \( 0 \) and \( 1 \). Then there exists a \( C^\infty \) embedding \( c: I \to M \) such that \( c(0) = x, c(1) = y \) and \( c([0,1]) \) only meets \( \hat{\pi}_M(\Lambda) \) at points of \( Z_{\Lambda} \), with a transverse intersection.

**Lemma 10.2.7.** We assume that \( M \) is connected. Let \( F \in D(k_M) \) be such that \( SS(F) \subset \Lambda \) and \( F \) is simple along \( \Lambda \). We set \( U = M \setminus \hat{\pi}_M(\Lambda) \). We assume that there exists \( x_0 \in U \) such that \( \bigoplus_{i \in \mathbb{Z}} H^i F_{x_0} \) is of finite rank over \( k \). Then \( \bigoplus_{i \in \mathbb{Z}} H^i F_x \) is of finite rank over \( k \), for all \( x \in U \).

**Proof.** Let \( x \in U \) and let \( I \) be an open interval containing \( 0 \) and \( 1 \). By Lemma 10.2.6 we can choose a \( C^\infty \) path \( \gamma: I \to M \) such that \( \gamma(0) = x_0, \gamma(1) = x \) and \( \gamma([0,1]) \) meets \( \hat{\pi}_M(\Lambda) \) at finitely many points, all contained in \( Z_{\Lambda} \) and with a transverse intersection. We denote these points by \( \gamma(t_i) \), where \( 0 < t_1 < \cdots < t_k < 1 \).

Since \( F \) is locally constant on \( U \), the stalk \( F_{\gamma(t)} \) is constant for \( t \in [t_i, t_{i+1}] \). Near a point \( x_i = \gamma(t_i) \) we have a hypersurface \( S \) of \( M \) such that \( \Lambda \) is half of \( T^*_S M \). By Example 10.2.1 there exists a distinguished triangle

\[
E'_M \to k_Z[i] \to F \xrightarrow{+1},
\]

where \( Z \) is one the closed half-spaces bounded by \( S, i \) is an integer and \( E' \) is an object of \( D(k) \). It follows that the stalks \( F_{\gamma(t_i-\varepsilon)} \) and \( F_{\gamma(t_i+\varepsilon)} \) differ by \( k[i] \) for \( \varepsilon > 0 \) small enough. The lemma follows.
10.3. Obstruction classes

There are two obstructions to the existence of a global simple object in $\mu \text{Sh}(k\Lambda)$ (by this we mean an object of $\mu \text{Sh}^s(k\Lambda)(\Lambda)$). They are classes in $\mu_1^{sh}(\Lambda) \in H^1(\Lambda; \mathbb{Z})$ and $\mu_2^{sh}(\Lambda) \in H^2(\Lambda; k^\times)$, where $k^\times$ is the group of units in $k$ (when $k = \mathbb{Z}/2\mathbb{Z}$ this last class is automatically zero). We will call them (sheafy) first and second Maslov classes. We will see in §10.6 that that the vanishing of $\mu_i^{sh}(\Lambda)$ implies the vanishing of the usual Maslov classes $\mu_i(\Lambda)$.

To define these classes we recall how we can describe an object of $\mu \text{Sh}^s(k\Lambda)(\Lambda)$. By Remark 10.1.6 a global simple object of $\mu \text{Sh}(k\Lambda)$ is determined by the data of an open covering $\{\Lambda_i\}_{i \in I}$ of $\Lambda$, objects $F_i \in \mathbb{D}^b_{(\Lambda_i)}(k_M)$, for all $i \in I$, which are simple along $\Lambda_i$, and sections $u_{ij} \in H^0(\Lambda_{ij}; \mu \text{hom}(F_i, F_j)|_{\Lambda_{ij}})$, for any $i, j \in I$, such that

(i) $u_{ij}$ is induced by $\text{id}_{F_i}$, for any $i \in I$,
(ii) $u_{kj} \circ u_{ij} = u_{ki}$, for any $i, j, k \in I$.

We try to find such a set of data. First we choose a covering $\{\Lambda_i\}_{i \in I}$ of $\Lambda$ by small open subsets. We assume that the $\Lambda_i$’s and all intersections $\Lambda_{ij}$, $\Lambda_{ijk}$ are contractible. We have seen in the previous section that, if the $\Lambda_i$’s are small enough, we can choose $F_i \in \mathbb{D}^b_{(\Lambda_i)}(k_M)$, for all $i \in I$, which are simple along $\Lambda_i$. Moreover, for each $i \in I$, if $F_i' \in \mathbb{D}^b_{(\Lambda_i)}(k_M)$ is another simple sheaf along $\Lambda_i$, we have $m_{\Lambda_i}(F_i') \simeq m_{\Lambda_i}(F_i)[d]$ for some shift $d$.

The sheaf $\mu \text{hom}(F_i, F_j)|_{\Lambda_{ij}}$ is constant on $\Lambda_{ij}$, free of rank one. Hence there exist isomorphisms $\varphi_{ji}: \mu \text{hom}(F_i, F_j)|_{\Lambda_{ij}} \simeq k_{\Lambda_{ij}}[d_{ij}]$, for some integers $d_{ij}$. They induce $\varphi_{ji} \in H^0(\Lambda_{ij}; \mu \text{hom}(F_i, F_j))[d_{ij}]$. In view of (10.1.6) the $\varphi_{ji}$’s give isomorphisms in $\mu \text{Sh}^s(k\Lambda)(\Lambda_{ij})$:

$$v_{ij}: m_{\Lambda_i}(F_i)|_{\Lambda_{ij}} \xrightarrow{\sim} m_{\Lambda_j}(F_j)|_{\Lambda_{ij}}[d_{ij}] .$$

We deduce that the Čech cochain $\{d_{ij}\}_{i, j \in I}$ is a cocycle and defines

$$\mu_i^{sh}(\Lambda) = \{[d_{ij}]\} \in H^1(\Lambda; \mathbb{Z}).$$

By the remark that $m_{\Lambda_i}(F_i)$ is well defined up to shift, this class only depends on $\Lambda$. If there exists a global simple object $\mathcal{F}$ in $\mu \text{Sh}(k\Lambda)$, for any coefficient ring $k$, then we can choose $F_i$’s which represent $\mathcal{F}|_{\Lambda_i}$ and this implies $d_{ij} = 0$ for all $i, j$ and thus $\mu_i^{sh}(\Lambda) = 0$.

Let us assume that $\mu_i^{sh}(\Lambda) = 0$. Then we can write $d_{ij} = d_j - d_i$ for some family of integers $d_i$, $i \in I$. We set $F_i' = F_i[d_i]$ and obtain isomorphisms

$$w_{ij}: m_{\Lambda_i}(F_i')|_{\Lambda_{ij}} \xrightarrow{\sim} m_{\Lambda_j}(F_j')|_{\Lambda_{ij}} .$$
For $i, j, k \in I$ we define an automorphism $c_{ijk}$ of $m_{\Lambda_i}(F'_i)|_{\Lambda_{ijk}}$ by $c_{ijk} = w_{ik} \circ w_{kj} \circ w_{ij}$. Since

$$\mathcal{H}om(m_{\Lambda_i}(F'_i), m_{\Lambda_i}(F'_i)) \simeq H^0 \mu hom(F'_i, F'_i) \simeq k_{\Lambda_i},$$

we can canonically identify the automorphisms group of $m_{\Lambda_i}(F'_i)|_{\Lambda_{ijk}}$ with $k^\times \subset H^0(\Lambda_{ijk}; k_{\Lambda_{ijk}}) \simeq k$. Hence the $c_{ijk}$'s give a Čech cochain with coefficient in $k^\times$. It is easy to see that it is a cocycle and defines

$$(10.3.2) \quad \mu^\text{sh}(\Lambda) = \{\{c_{ijk}\}\} \in H^2(\Lambda; k^\times).$$

The isomorphism $H^0 \mu hom(F'_i, F'_i) \simeq k_{\Lambda_i}$ also implies that $w_{ji}$ is well defined up to multiplication by a unit. It follows that $\mu^\text{sh}(\Lambda)$ only depends on $\Lambda$. If $\mu^\text{sh}(\Lambda) = 0$, then we can write $\{c_{ijk}\}$ as the boundary of a 2-cochain, say $\{b_{ij}\}$, with $b_{ij} \in k^\times$. Defining

$$w'_{ji} = b_{ji}^{-1}w_{ji} : m_{\Lambda_i}(F'_i)|_{\Lambda_{ij}} \simeq m_{\Lambda_j}(F'_j)|_{\Lambda_{ij}}$$

we have $w'_{ik} \circ w'_{kj} = w'_{ij}$ and the $m_{\Lambda_i}(F'_i)$ glue into a global simple object of $\mu \text{Sh}(k_{\Lambda_i})$.

### 10.4. The Kashiwara-Schapira stack for orbit categories

In this section we set $k = \mathbb{Z}/2\mathbb{Z}$. We have defined the usual sheaf operations for the triangulated orbit categories $D^b_{[1]}(k_M)$ and we can define a Kashiwara-Schapira stack in this situation. We give quickly the analogs of the results obtained in the previous sections.

For a subset $S$ of $T^*M$ we recalled in Notations [10.0.1] the categories $D^b_S(k_M)$, $D^b_\text{orb}(k_M)$ and $D^b_\text{orb}(k_M; S)$. We define $D^b_{[1], S}(k_M)$, $D^b_{[1], \text{orb}, S}(k_M)$ and $D^b_{[1], S}(k_M; S)$ in the same way, replacing $D^b$ by $D^b_{[1]}$ and SS by $\text{SS}^\text{orb}$.

Let $\Lambda \subset T^*M$ be a locally closed conic Lagrangian submanifold. We define a stack $\mu \text{Sh}^\text{orb}(k_{\Lambda})$ on $\Lambda$ as in Definition [10.1.1] again replacing $D^b$ by $D^b_{[1]}$. It comes with a functor $m_{\Lambda}^\text{orb} : D^b_{[1], \text{orb}, (\Lambda)}(k_M) \to \mu \text{Sh}^\text{orb}(k_{\Lambda})$.

We say that $F \in D^b_{[1]}(k_M)$ is simple along $\Lambda$ if $\text{SS}^\text{orb}(F) \cap T^*M \subset \Lambda$ and, for any $p \in \Lambda$, there exists $F' \in D^b(k_M)$ such that $t_M(F') \simeq F$ and $F'$ is simple along $\Lambda$ in a neighborhood of $p$. As in section [10.1] we can define the substack $\mu \text{Sh}^\text{orb, s}(k_{\Lambda})$ of $\mu \text{Sh}^\text{orb}(k_{\Lambda})$ associated with the simple sheaves. For $\Omega \subset T^*M$, we have a morphism similar to (10.1.3)

$$\text{Hom}_{D^b_{[1]}(k_M; \Omega)}(F, G) \to \text{Hom}_{D^b_{[1]}(k_{\Omega})}(k_{\Omega}, \mu \text{hom}^\text{c}(F, G)|_{\Omega})$$

and, as in Theorem [10.1.4] it is an isomorphism if $\Omega = \{p\}$ for some $p \in T^*M$.

We remark that Proposition [9.2.10] implies in particular that, if $B$ is homeomorphic to a ball and $L \in D^b_{[1]}(k_B)$ is locally of the form $k_U$, then there exists an isomorphism $u : L \simeq k_B$. Moreover
\[ \text{Hom}_{\mathcal{D}_{/\mathfrak{U}}(k_B)}(k_B, k_B) \simeq k \text{ (and } k = \mathbb{Z}/2\mathbb{Z}), \text{ hence } u \text{ is unique. For }
\]

Lemma 10.4.1. Let \( \Lambda \subset \tilde{T}^*M \) be a locally closed conic Lagrangian submanifold. We assume that \( \Lambda \) is contractible. Let \( F, F' \in \mathcal{D}_{/\mathfrak{U}}(k_M) \) be two simple sheaves along \( \Lambda \) and let \( \Omega \) be a neighborhood of \( \Lambda \) such that \( \text{SS}^{\text{orb}}(F) \cap \Omega = \text{SS}^{\text{orb}}(F') \cap \Omega = \Lambda \). Then we have a unique isomorphism \( \mu_{\text{hom}}^\varepsilon(F, F')|_{\Omega} \simeq k_\Lambda \) in \( \mathcal{D}_{/\mathfrak{U}}(k_\Omega) \).

By Lemma 10.4.1 there exists a unique simple sheaf in \( \mu_{\text{Sh}}^{\text{orb}}(k_{\Lambda_0}) \) for any contractible open subset \( \Lambda_0 \subset \Lambda \), up to a unique isomorphism. In other words \( \mu_{\text{Sh}}^{\text{orb}, s}(k_\Lambda) \) has locally a unique object with the identity as unique isomorphism. Hence gluing is trivial. Since \( \mu_{\text{Sh}}^{\text{orb}, s}(k_\Lambda) \) is a stack it follows that it has a unique global object.

We recall that \( \text{Loc}(k_X) \) is the substack of \( \text{Mod}(k_X) \) formed by the locally constant sheaves.

Definition 10.4.2. Let \( X \) be a manifold. We let \( \text{OL}^0(k_X) \) be the subprestack of \( U \mapsto \mathcal{D}_{/\mathfrak{U}}(k_U), \) \( U \) open in \( X \), formed by the \( F \in \mathcal{D}_{/\mathfrak{U}}(k_U) \) such that \( \text{SS}^{\text{orb}}(F) \subset T_U^*U \). We let \( \text{OL}(k_X) \) be the stack associated with \( \text{OL}^0(k_X) \).

By Proposition 9.2.10 the condition \( \text{SS}^{\text{orb}}(F) \subset T_U^*U \) is equivalent to: \( F \) is locally isomorphic to \( A_U \) for some \( A \in \text{Mod}(k) \). We recall the functors \( i_X^0 : \text{Mod}(k_X) \to \mathcal{D}_{/\mathfrak{U}}(k_X) \) and \( h_X^0 : \mathcal{D}_{/\mathfrak{U}}(k_X) \to \text{Mod}(k_X) \) defined before Corollary 9.1.10. They induce functors of stacks \( i_X : \text{Loc}(k_X) \to \text{OL}(k_X) \) and \( h_X : \text{OL}(k_X) \to \text{Loc}(k_X) \).

Lemma 10.4.3. The functors \( i_X \) and \( h_X \) are mutually inverse equivalences of stacks.

Proof. We have seen in Corollary 9.1.10 that \( h_X \circ i_X \simeq \text{id}_{\text{Loc}(k_X)} \). Hence it is enough to see that \( i_X \) is locally an equivalence, that is, essentially surjective and fully faithful. Let \( U \subset X \) be an open subset homeomorphic to a ball. By Proposition 9.2.10 the functor \( i_U \) is essentially surjective and, for \( F, G \in \text{Loc}(k_U) \), Corollary 9.1.9 gives
\[
\text{Hom}_{\mathcal{D}_{/\mathfrak{U}}(k_U)}(i_U(F), i_U(G)) \simeq \bigoplus_{n \in \mathbb{Z}} \text{Hom}_{\mathcal{D}_{/\mathfrak{U}}(k_U)}(F[-n], G)
\]
\[
\simeq \text{Hom}_{\text{Loc}(k_U)}(F, G),
\]
which proves that \( i_U \) is fully faithful. \( \square \)

As we remarked after Lemma 10.4.1 \( \mu_{\text{Sh}}^{\text{orb}, s}(k_\Lambda) \) has a unique global object. As in 10.1.7 the functor \( \mu_{\text{hom}}^\varepsilon \) induces a functors of stacks \( \mu_{\text{hom}}^\varepsilon : (\mu_{\text{Sh}}^{\text{orb}}(k_\Lambda))^{\text{opp}} \times \mu_{\text{Sh}}^{\text{orb}}(k_\Lambda) \to \text{OL}(k_\Lambda) \simeq \text{Loc}(k_\Lambda) \).
We have an analog of Proposition 10.2.4 in the orbit category case.

**Proposition 10.4.4.** The stack $\mu \text{Sh}^{\text{orb}, s}(k_\Lambda)$ has a unique object, say $\mathcal{F}_0$, defined over $\Lambda$. Moreover the functor $\mu \text{hom}^s(\mathcal{F}_0, -)$ induces an equivalence of stacks $\mu \text{Sh}^{\text{orb}}(k_\Lambda) \sim \text{Loc}(k_\Lambda)$.

## 10.5. Microlocal germs

In this section and the next one we see the link between the classes $\mu_1^{sh}(\Lambda) \in H^1(\Lambda; \mathbb{Z})$ and $\mu_2^{sh}(\Lambda) \in H^2(\Lambda; \mathbb{k}^\times)$ introduced in §10.3 and the usual Maslov classes $\mu_1(\Lambda)$, $\mu_2(\Lambda)$ of $\Lambda$. We only prove the useful implication that the vanishing of $\mu_1^{sh}(\Lambda)$ implies the vanishing of $\mu_1(\Lambda)$.

In the definition of the microsupport of a sheaf $F$ we consider whether some local cohomology group vanishes, namely $(R\Gamma_{\{x; \phi(x) \geq \phi(x_0)\}}(F))_{x_0}$ for some function $\phi$. A natural question is then how this group depends on $\phi$ and not only on $x_0 = d\phi(x_0)$. In general it really depends on $\phi$, but it is proved in Proposition 7.5.3 of [30] that it is independent of $\phi$ (up to a shift $d_\phi$) if we assume that $\Lambda = \text{SS}(F)$ is a Lagrangian submanifold near $(x_0; \xi_0)$ and that $\Gamma_{d_\phi}$ is transverse to $\Lambda$ at $(x_0; \xi_0)$. Moreover the shift $d_\phi$ is related with the Maslov index of the three Lagrangian subspaces of $T_{(x_0; \xi_0)} T^*M$ given by $\lambda = T_{(x_0; \xi_0)} \Lambda$, $\lambda = T_{(x_0; \xi_0)} \Gamma_{d_\phi}$ and $\lambda_0 = T_{(x_0; \xi_0)} (\pi^{-1}(x_0))$. In particular $(R\Gamma_{\{x; \phi(x) \geq \phi(x_0)\}}(F))_{x_0}$ only depends on $\lambda_\phi$ which is a Lagrangian subspace of $T_{(x_0; \xi_0)} T^*M$ transverse both to $\lambda$ and $\lambda_0$. In this section we precise a little bit this result and prove that there exists a locally constant sheaf on the open subset of the Lagrangian Grassmannian of $\Lambda \times_{T^*M} TT^*M$ whose stalks at $\lambda_\phi$ is $(R\Gamma_{\{x; \phi(x) \geq \phi(x_0)\}}(F))_{x_0}$. We will also see that it has a non trivial monodromy.

We first introduce some notations. In this section $M$ is a manifold of dimension $n$ and $\Lambda$ is a locally closed conic Lagrangian submanifold of $T^*M$. We recall the notations (14.2): for a given point $p = (x; \xi) \in \Lambda$ we have the following Lagrangian subspaces of $T_p(T^*M)$

$$\lambda_0(p) = T_p(T^*_x M), \quad \lambda_\Lambda(p) = T_p \Lambda.$$ 

We let

$$(10.5.1) \quad \sigma_{T^*M} : \mathcal{L}_M \to T^*M, \quad \sigma_{T^*M}^0 : \mathcal{L}_M^0 \to T^*M$$

be respectively the fiber bundle of Lagrangian Grassmannian of $T^*M$ and the subbundle whose fiber over $p \in T^*M$ is the set of Lagrangian subspaces of $T_p T^*M$ which are transverse to $\lambda_0(p)$. Then $\mathcal{L}_M^0$ is an open subset of $\mathcal{L}_M$. For a given $p \in T^*M$ we set $V = T_{\pi_M(p)} M$ and we
identify $T_pT^*M$ with $V \times V^*$. We use coordinates $(\nu; \eta)$ on $T_pT^*M$. Then we can see that any $l \in (L^0_M)_p$ is of the form

$$l = \{(\nu; \eta) \in T_pT^*M; \; \eta = A \cdot \nu\},$$

where $A: V \to V^*$ is a symmetric matrix. This identifies the fiber $(L^0_M)_p$ with the space of $n \times n$-symmetric matrices.

For a function $\varphi$ defined on a product $X \times Y$ and for a given $x \in X$ we use the general notation $\varphi_x = \varphi|_{\{x\}\times Y}$.

**Lemma 10.5.1.** There exists a function $\psi: L^0_M \times M \to \mathbb{R}$ of class $C^\infty$ such that, for any $l \in L^0_M$ with $\sigma_{T^*M}(l) = (x; \xi)$,

$$\psi_l(x) = 0, \quad d\psi_l(x) = \xi, \quad \lambda_{\psi_l}(\sigma_{T^*M}(l)) = l.$$ 

**Proof.** (i) We first assume that $M$ is the vector space $V = \mathbb{R}^n$. We identify $T^*M$ and $M \times V^*$. For $p = (x; \xi) \in M \times V^*$ the fiber $(L^0_M)_p$ is identified with the space of quadratic forms on $V$ through (10.5.2). For $l \in (L^0_M)_p$ we let $q_l$ be the corresponding quadratic form. Now we define $\psi_0$ by

$$\psi_0(l, y) = \langle y - x; \xi \rangle + \frac{1}{2} q_l(y - x), \quad \text{where } (x; \xi) = \sigma^0_{T^*M}(l).$$

We can check that $\psi_0$ satisfies the conclusion of the lemma.

(ii) In general we choose an embedding $i: M \hookrightarrow \mathbb{R}^N$. For a given $p' = (x; \xi') \in M \times_{\mathbb{R}^N} T^*\mathbb{R}^N$ the subspace $T_{p'}(M \times_{\mathbb{R}^N} T^*\mathbb{R}^N)$ of $T_{p'}T^*\mathbb{R}^N$ is coisotropic. The symplectic reduction of $T_{p'}T^*\mathbb{R}^N$ by $T_{p'}(M \times_{\mathbb{R}^N} T^*\mathbb{R}^N)$ is canonically identified with $T_{p'}T^*M$, where $p = i_d(p')$. The symplectic reduction sends Lagrangian subspaces to Lagrangian subspaces and we deduce a map, say $r_{p'}: L_{\mathbb{R}^N,p'} \to L_{M,p'}$. The restriction of $r_{p'}$ to the set of Lagrangian subspaces which are transverse to $T_{p'}(M \times_{\mathbb{R}^N} T^*\mathbb{R}^N)$ is an actual morphism of manifolds. In particular it induces a morphism $r^0_{p'}: L^0_{\mathbb{R}^N,p'} \to L^0_{M,p'}$. We can see that $r^0_{p'}$ is onto and is a submersion. When $p'$ runs over $M \times_{\mathbb{R}^N} T^*\mathbb{R}^N$ we obtain a surjective morphism of bundles, say $r$:

$$L^0_{\mathbb{R}^N|_{M\times_{\mathbb{R}^N} T^*\mathbb{R}^N}} \overset{r}{\longrightarrow} L^0_M \quad \downarrow \quad \downarrow$$

$$M \times_{\mathbb{R}^N} T^*\mathbb{R}^N \overset{i_d}{\longrightarrow} T^*M.$$

We can see that $r$ is a fiber bundle, with fiber an affine space. Hence we can find a section, say $j: L^0_M \to L^0_{\mathbb{R}^N}$. For $(l, x) \in L^0_M \times M$ we set $\psi(l, x) = \psi_0(j(l), i(x))$, where $\psi_0$ is defined in (i). Then $\psi$ satisfies the conclusion of the lemma. \qed
We come back to the Lagrangian submanifold $\Lambda$ of $\hat{T}^*M$. We let

\begin{equation}
U_{\Lambda} \subset \mathcal{L}_M^0|_{\Lambda}
\end{equation}

be the subset of $\mathcal{L}_M^0|_{\Lambda}$ consisting of Lagrangian subspaces of $T_pT^*M$ which are transverse to $\lambda_{\Lambda}(p)$. We define $\sigma_{\Lambda} = \sigma_{T^*M|_{U_{\Lambda}}}$, $\tau_{M} = \pi_M|_{\Lambda}\circ\sigma_{\Lambda}$ and $i_{\Lambda}: U_{\Lambda} \hookrightarrow U_{\Lambda} \times M$, $l \mapsto (l, \tau_{M}(l))$:

\[
\begin{array}{ccc}
U_{\Lambda} & \xrightarrow{\sigma_{\Lambda}} & \Lambda \\
\downarrow i_{\Lambda} & & \downarrow \pi_{M|_{\Lambda}} \\
U_{\Lambda} \times M & \xrightarrow{q_{2}} & M.
\end{array}
\]

We note that $U_{\Lambda}$ is not a fiber bundle over $\Lambda$ but only an open subset of $\mathcal{L}_M^0|_{\Lambda}$. However, for a given $p \in \Lambda$, we will use the notation $U_{\Lambda,p} = \sigma_{\Lambda}^{-1}(p)$.

**Definition 10.5.2.** Let $\psi: \mathcal{L}_M^0 \times M \to \mathbb{R}$ be a function satisfying the conclusions of Lemma 10.5.1 and let $\varphi: U_{\Lambda} \times M \to \mathbb{R}$ be its restriction to $U_{\Lambda} \times M$. For $F \in \mathcal{D}^{b}_{(\Lambda)}(k_{M})$ we define $m_{\varphi}(F) \in \mathcal{D}^{b}(k_{U_{\Lambda}})$ by

\[
m_{\varphi}(F) = i_{\Lambda}^{-1}(R\Gamma_{\varphi^{-1}(0,\infty)}(q_{2}^{-1}F)),
\]

where $q_{2}: U_{\Lambda} \times M \to M$ is the projection.

**Proposition 10.5.3.** Let $F \in \mathcal{D}^{b}_{(\Lambda)}(k_{M})$. Let $\varphi: U_{\Lambda} \times M \to \mathbb{R}$ be as in Definition 10.5.2. Then the object $m_{\varphi}(F) \in \mathcal{D}^{b}(k_{U_{\Lambda}})$ has locally constant cohomology sheaves and its stalks are

\[(m_{\varphi}(F))_{l} \simeq (R\Gamma_{\varphi^{-1}(0,\infty)}(F))_{x},\]

for any $l \in U_{\Lambda}$ and $x = \tau_{M}(l)$.

**Proof.** (i) We first prove that $m_{\varphi}(F)$ is locally constant. For this we give another expression of $m_{\varphi}(F)$. We define $G \in \mathcal{D}^{b}(k_{T^*M(U_{\Lambda} \times M)})$ by $G = \mu_{\text{hom}}(k_{\varphi^{-1}(0,\infty)}, q_{2}^{-1}F)$. We define $I_{\Lambda} = \text{im}(i_{\Lambda}) \subset U_{\Lambda} \times M$ and $J_{\Lambda} \subset \hat{T}^*(U_{\Lambda} \times M)$, $J_{\Lambda} = \{(l, x; 0, \lambda \xi); (x; \xi) = \sigma_{\Lambda}(l), \lambda > 0\}$. We remark that $J_{\Lambda}$ is a fiber bundle over $I_{\Lambda}$ with fiber $\mathbb{R}_{\geq 0}$. We prove in (ii) and (iii) below that there exists a neighborhood $V$ of $I_{\Lambda}$ in $U_{\Lambda} \times M$ such that

\begin{enumerate}
\item[(a)] $\text{supp}(G) \cap \hat{T}^*V \subset J_{\Lambda}$,
\item[(b)] $\text{SS}(G|_{\hat{T}^*V}) \subset T_{l_{\Lambda}}^*(U_{\Lambda} \times M)$,
\item[(c)] $(R\Gamma_{\varphi^{-1}(0,\infty)}(q_{2}^{-1}F))_{I_{\Lambda}} \simeq R\hat{\pi}_{V*}(G|_{\hat{T}^*V})$.
\end{enumerate}

By Proposition 10.2.8 the properties (a-b) imply that $G|_{\hat{T}^*V}$ has support $J_{\Lambda}$ and is locally constant along $J_{\Lambda}$. Since $J_{\Lambda}$ is a fiber bundle over $I_{\Lambda}$, we deduce by (c) that $(R\Gamma_{\varphi^{-1}(0,\infty)}(q_{2}^{-1}F))_{I_{\Lambda}}$ is locally constant on $I_{\Lambda}$, hence $m_{\varphi}(F)$ is locally constant on $U_{\Lambda}$. 

(ii) We prove (i-a) and (i-b). We have defined \( \Lambda_\varphi \) and we also set \( \Lambda'_\varphi = \{(l, x; \lambda \cdot d\varphi(l, x)); (l, x) \in U_\Lambda \times M, \lambda > 0, \varphi(l, x) = 0\} \).

By Example 1.2.2 (iii) we have \( \mathcal{SS}(k_{\varphi^{-1}(0, +\infty)}) = \Lambda'_\varphi \). We also have \( \Lambda'_\varphi \cap (T^*_{U_\Lambda} U_\Lambda \times \Lambda) = J_\Lambda \) and this gives (i-a). We now prove that this intersection is clean. By Lemma 10.5.5 below this will prove (i-b).

Inside \( T^*(U_\Lambda \times M) \) we have three submanifolds \( \Lambda_\varphi : = \Gamma_{d\varphi}, \Xi = T^*_{U_\Lambda} U_\Lambda \times \Lambda \) and \( Z = (\varphi \circ \hat{\pi}_{U_\Lambda \times M})^{-1}(0) \). Then \( \Lambda_\varphi \) and \( \Xi \) are transverse. The hypothesis on \( \varphi \) implies that \( \Lambda_\varphi \) and \( \Xi \) are also transverse in some neighborhood \( \Omega \) of \( Z \) and \( \Lambda_\varphi \cap \Xi \cap \Omega \subset Z \). Hence the intersection of \( \Lambda_\varphi \cap Z \) with \( \Xi \) is clean. Now \( \Lambda'_\varphi = \mathbb{R}_{>0} \cdot (\Lambda_\varphi \cap Z) \) and it follows that the intersection of \( \Lambda'_\varphi \) with \( \Xi \) is clean, as required.

(iii) Now we prove the claim (c) of (i) and deduce that \( m(\varphi(F)) \) is locally constant. Sato’s triangle \((1.3.5)\) gives

\[
(D'(k_{\varphi^{-1}(0, +\infty)}) \otimes q_2^{-1}F)_{I\Lambda} \rightarrow (R\Gamma_{\varphi^{-1}(0, +\infty)}(q_2^{-1}F))_{I\Lambda} \rightarrow R\pi_{U_\Lambda \times M}^{-1}(G)_{I\Lambda} \xrightarrow{\sim} .
\]

By definition \( d\varphi \) does not vanish in a neighborhood of \( I_\Lambda \). Hence \( \varphi^{-1}(0) \) is a smooth hypersurface near \( I_\Lambda \) and \( D'(k_{\varphi^{-1}(0, +\infty)}) \simeq k_{\varphi^{-1}(0, +\infty)} \).

Since \( I_\Lambda \subset \varphi^{-1}(0) \), the first term of the above triangle is zero. By (i-a) the support of \( R\pi_{V \times \gamma}(G_{|T\gamma}) \) is already contained in \( I_\Lambda \). So we can forget the subscript \( I_\Lambda \) in the third term and we obtain (i-c).

(iv) We prove the last assertion of the proposition. Let \( l_0 \in U_\Lambda \) be given and \( (x_0; \xi_0) = \sigma(l_0) \). Since \( \Lambda'_\varphi \) is transverse to \( \Lambda \) at \( (x; \xi) = \sigma(l) \), by Lemma 10.5.6 below we can find neighborhoods \( U \) of \( l_0 \) and \( W \) of \( x_0 \) and a homogeneous Hamiltonian isotopy of \( T^*W \) parameterized by \( U \), say \( \Psi : U \times T^*W \rightarrow T^*W \), such that \( \Psi(l)(\Lambda_\varphi) \cap T^*W = \Lambda \cap T^*W \) and \( \Psi(l)(\Lambda'_\varphi) \cap T^*W = \Lambda'_\varphi \cap T^*W \), for all \( l \in U \). In other words, setting \( \Lambda_+ = \Lambda'_\varphi \cup (T_0^*U \times \Lambda) \) and \( \Lambda^+_l = \Lambda'_\varphi \cup \Lambda \) we have \( \Psi_l(\Lambda^+_l) = \Lambda^+_l \).

Since \( k_{\varphi^{-1}(0, +\infty)} \) and \( q_2^{-1}F \) belong to \( D_{\Lambda^+_l}(k_{U \times W}) \), we deduce, by Proposition 2.2.3 (ii)

\[
R\text{Hom}(k_{\varphi^{-1}(0, +\infty)}, q_2^{-1}F)|_{\{l_0\} \times W} \simeq R\text{Hom}(k_{\varphi^{-1}(0, +\infty)}|_{\{l_0\} \times W}, q_2^{-1}F|_{\{l_0\} \times W}) \simeq R\text{Hom}(k_{\varphi^{-1}(0, +\infty)}, F)|_W.
\]

Taking the germs at \( x_0 \in W \) we obtain the required isomorphism. \( \square \)

Let \( X \) be a manifold and \( Y, Z \) two submanifolds of \( X \). We recall that \( Y \) and \( Z \) have a clean intersection if \( W = Y \cap Z \) is a submanifold of \( X \).
and $TW = TY \cap TZ$. This means that we can find local coordinates $(x, y, z, w)$ such that $Y = \{z = w = 0\}$ and $Z = \{x = y = 0\}$. Using these coordinates the following lemma is easy.

**Lemma 10.5.4.** Let $X$ be a manifold and $Y, Z$ two submanifolds of $X$ which have a clean intersection. We set $W = Y \cap Z$. Then $C(Y, Z) = W \times_X TY + W \times_X TZ$.

**Lemma 10.5.5.** Let $X$ be a manifold and $\Lambda_1, \Lambda_2$ be two Lagrangian submanifolds of $\dot{T}^*X$. Let $F_1 \in \mathcal{D}_b(\Lambda_1)(k_X)$ and $F_2 \in \mathcal{D}_b(\Lambda_2)(k_X)$. We assume that $\Lambda_1$ and $\Lambda_2$ have a clean intersection and we set $\Xi = \Lambda_1 \cap \Lambda_2$. Then there exists a neighborhood $U$ of $\Xi$ in $T^*X$ such that $SS(\mu \text{hom}(F_1, F_2)|_U) \subset T^*_\Xi T^*X$, that is, $\mu \text{hom}(F_1, F_2)|_U$ is supported on $\Xi$ and has locally constant cohomology sheaves on $\Xi$.

**Proof.** We have $SS(\mu \text{hom}(F_1, F_2)) \subset -H^{-1}(C(SS(F_2), SS(F_1)))$ by the bound (1.3.7). Let $U_i$ be a neighborhood of $\Lambda_i$ such that $SS(F_i) \cap U_i \subset \Lambda_i$, $i = 1, 2$. Then $U = U_1 \cap U_2$ is a neighborhood of $\Xi$ and we have $-H^{-1}(C(SS(F_2), SS(F_1))) \cap T^*U \subset -H^{-1}(C(\Lambda_2, \Lambda_1))$.

Since $\Lambda_i$ is Lagrangian we have $-H^{-1}(T\Lambda_i) = T^*_\Lambda_i T^*X$, for $i = 1, 2$. In particular $-H^{-1}(\Xi \times_{T^*X} T\Lambda_i) \subset T^*_\Xi T^*X$ and the result follows from Lemma 10.5.4.

**Lemma 10.5.6.** Let $B$, be a neighborhood of $0$ in $\mathbb{R}^N$. Let $\varphi : B \times \mathbb{R}^n \to \mathbb{R}$ be a family of functions.

(i) We assume that $\Gamma_{d\varphi_0}$ is transverse to the zero-section $0_{\mathbb{R}^n}$ of $T^*\mathbb{R}^n$ and $\Gamma_{d\varphi_0} \cap 0_{\mathbb{R}^n} = \{0\}$. Then there exist neighborhoods $B'$ of $0$ in $\mathbb{R}^N$ and $V$ of $0$ in $\mathbb{R}^n$ and a family of Hamiltonian isotopies of $T^*\mathbb{R}^n$ parameterized by $B'$, say $\Psi : B' \times T^*\mathbb{R}^n \to T^*\mathbb{R}^n$, such that $\Psi_b(0_{\mathbb{R}^n}) = 0_{\mathbb{R}^n}$ and $\Psi_b(\Gamma_{d\varphi_0}) \cap T^*V = \Gamma_{d\varphi_b} \cap T^*V$, for all $b \in B'$.

(ii) Let $\Lambda \subset T^*\mathbb{R}^n$ be a closed conic Lagrangian submanifold. We assume that $\Gamma_{d\varphi_0}$ is transverse to $\Lambda$ with $\Gamma_{d\varphi_0} \cap \Lambda = \{(0; \xi_0)\}$, $\Gamma_{d\varphi_0} \cap \Lambda = \{(x_b; \xi_b)\}$ and $\varphi_b(x_b) = 0$. Then there exist neighborhoods $B'$ of $0$ in $\mathbb{R}^N$ and $V$ of $0$ in $\mathbb{R}^n$ and a family of homogeneous Hamiltonian isotopies of $T^*\mathbb{R}^n$ parameterized by $B'$, say $\Psi : B' \times T^*\mathbb{R}^n \to T^*\mathbb{R}^n$, such that $\Psi_b(\Lambda) = \Lambda$ and $\Psi_b(\Lambda'_b) = \Lambda'_b$, for all $b \in B'$, where $\Lambda'_b = \{(x; \lambda \cdot d\varphi_b(x)) ; \lambda > 0, \varphi_b(x) = 0\}$.

**Proof.** (i) The transversality hypothesis implies that $d\varphi_b$ viewed as a function from $\mathbb{R}^n$ to $(\mathbb{R}^n)^*$ is invertible near $0$, for $b$ small enough. We set $\theta_b = (d\varphi_b)^{-1}$ and view $\theta_b$ as a 1-form on $(\mathbb{R}^n)^*$ defined in some neighborhood of $0$. Since the graph of $\theta_b$ is Lagrangian, it is a closed 1-form and we can write $\theta_b = dh_b$ near $0$. We consider $h_b(\xi)$ as a Hamiltonian function on $T^*\mathbb{R}^n$. By construction its Hamiltonian vector...
field is \( X_{h_b}(x; \xi) = \sum_i (\theta_b)_i(\xi) \partial_{x_i} \) and the time 1 of its flow satisfies \( \phi_{h_b}^1(\{0\} \times (\mathbb{R}^n)^*) = \Gamma_{d\varphi_b} \) near 0. Moreover \( \phi_{h_b}'(\mathbb{R}^n \times \{0\}) \subset \mathbb{R}^n \times \{0\} \). Now we set \( \Psi_b = \phi_{h_b}^1 \circ (\phi_{h_b}^1)^{-1} \).

(ii) We can find a homogeneous Hamiltonian isotopy \( \Phi \) arbitrarily close to \( \text{id} \) and a neighborhood \( W \) of \( \Phi(0; \xi_0) \) such that \( T^*W \cap \Phi(\Lambda) \) is half of the conormal bundle of a smooth hypersurface \( X \) and \( T^*W \cap \Phi(\Gamma_{d\varphi_b}) \) is still the graph of a function for \( b \) close enough to 0. We take coordinates on \( W \) such that \( X = \mathbb{R}^{n-1} \times \{0\} \), \( \Phi(0; \xi_0) = (0, 0; 0, 1) \) and we write \( \Phi(x_b; \xi_b) = (y_b, 0; 0, \eta_b) \). Then \( \Phi(\Lambda'_b) \) is the conormal bundle of a hypersurface which is the graph of a function \( \phi'_b: \mathbb{R}^{n-1} \to \mathbb{R} \). Moreover \( \Gamma_{d\varphi'_b} \) is transverse to \( 0_{\mathbb{R}^{n-1}} \). Part (i) of the proof gives a family \( \Psi' \) of Hamiltonian isotopies of \( T^*\mathbb{R}^{n-1} \) such that \( \Psi'_b(0_{\mathbb{R}^{n-1}}) = 0_{\mathbb{R}^{n-1}} \) and \( \Psi'_b(\Gamma_{d\varphi'_b}) \cap T^*V = \Gamma_{d\varphi'_b} \cap T^*V \). We lift \( \Psi' \) into a family \( \Psi'' \) of homogeneous Hamiltonian isotopies of \( \hat{T}^*\mathbb{R}^n \) and we set \( \Psi_b = \Phi^{-1} \circ \Psi'' \circ \Phi \). \( \square \)

**Remark 10.5.7.** For \( F \in D^b_{(\Lambda)}(k_M) \) we remark that \( m_\varphi(F) \simeq 0 \) if \( \text{SS}(F) \cap \Lambda = \emptyset \). Hence \( m_\varphi \) factorizes through \( D^b_{(\Lambda)}(k_M; \Omega) \) if \( \Omega \cap \Lambda = \emptyset \). Passing to the associated stacks it induces a functor from \( \mu \text{Sh}(k_\Lambda) \) to \( \text{DL}(k_\Lambda) \).

### 10.6. Monodromy morphism

For \( F \in D^b_{(\Lambda)}(k_M) \) we know that \( m_\Lambda(F) \) is a locally constant object on \( U_\Lambda \). Here we describe the monodromy of its restriction to a fiber \( U_{\Lambda,p} \) of \( \sigma_\Lambda: U_\Lambda \to \Lambda \).

We first recall well-known results on locally constant sheaves and introduce some notations. Let \( X \) be a manifold and \( L \in D^b(k_X) \) such that \( \text{SS}(L) \subset T^*_X X \), that is, \( L \) has locally constant cohomology sheaves. Then any path \( \gamma: [0, 1] \to X \) induces an isomorphism

\[
M_\gamma(L): L_{\gamma(0)} \xrightarrow{\sim} \mathcal{R}^\Gamma([0, 1]; \gamma^{-1}L) \xrightarrow{\sim} L_{\gamma(1)}.
\]

Moreover, \( M_\gamma(L) \) only depends on the homotopy class of \( \gamma \) with fixed ends. We will use the notation \( M_{[\gamma]}(L) := M_\gamma(L) \), where \( [\gamma] \) is the class of \( \gamma \). For another path \( \gamma': [0, 1] \to X \) such that \( \gamma'(0) = \gamma(1) \), we have \( M_{\gamma'; \gamma}(L) = M_{\gamma'}(L) \circ M_\gamma(L) \). In particular, if we fix a base point \( x_0 \in X \), we obtain the monodromy morphism

\[
M(L): \pi_1(X; x_0) \to \text{Iso}(L_{x_0})
\]

\[
\gamma \mapsto M_\gamma(L),
\]

where \( \text{Iso}(L_{x_0}) \) is the group of isomorphisms of \( L_{x_0} \) in \( D^b(k) \).
Now we go back to the situation of section 10.5. For a given \( p \in \Lambda \) we set \( U_{\Lambda, p} = \sigma_\Lambda^{-1}(p) \). This is the open subset of Lagrangian Grassmannian manifold \( \mathcal{L}(T_pT^*M) \) formed by the Lagrangian subspaces of \( T_pA \) which are transverse to \( \lambda_0(p) \) and \( \lambda_\Lambda(p) \). Let us describe its connected components and their Poincaré groups.

Let \((V, \omega)\) be a symplectic vector space of dimension \( 2n \). Let \( l_1, l_2 \) be two Lagrangian subspaces. We can assume that \( V = \mathbb{R}^{2n} \) with \( \omega = \sum e_i \wedge f_i \) in the canonical base \((e_1, \ldots, e_n, f_1, \ldots, f_n)\) and \( l_1 = \langle e_1, \ldots, e_n \rangle, l_2 = \langle e_1, \ldots, e_k, f_{k+1}, \ldots, f_n \rangle \). Let \( U(l_1) \subset \mathcal{L}(V) \) be the open subset of Lagrangian subspaces which are transverse to \( l_1 \). Then \( U(l_1) \) is diffeomorphic to \( \text{Sym}_n \), the space of symmetric matrices of size \( n \times n \), through \( M \mapsto l_M := \{(My, y); y = (y_1, \ldots, y_n)\} \). Writing \( M = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \), with \( A \) of size \( k \times k \), we see that \( l_M \) is also transverse to \( l_2 \) if and only if \( C \) is invertible. Hence \( U(l_1) \cap U(l_2) \) is diffeomorphic to \( \mathbb{R}^d \times \text{Sym}^{0, k}_n \) where \( d \) is some integer and \( \text{Sym}^{0, k}_n \) is the subset of invertible matrices in \( \text{Sym}^{0, k}_n \).

Let us recall the topology of \( \text{Sym}^{p, q}_n \) the subset of \( \text{Sym}_n \) of matrices with \( p \) positive eigenvalues and \( q \) negative eigenvalues, \( p + q = n \). The action of \( \text{SL}_n \) on \( \text{Sym}^{p, q}_n \), \( A \cdot M = AMA \), gives \( \text{Sym}^{p, q}_n \cong \text{SL}_n / \text{SO}(p, q) \). In particular \( \text{Sym}^{p, q}_n \) is connected. Now a maximal compact subgroup of \( \text{SO}(p, q) \) is \( K = S(O(p) \times O(q)) \) and \( \text{SO}(p, q) \) is diffeomorphic to \( K \times \mathbb{R}^d \) for some \( d \). We deduce an exact sequence of fundamental groups:

\[ \pi_1(K) \rightarrow \pi_1(\text{SL}_n) \rightarrow \pi_1(\text{Sym}^{p, q}_n) \rightarrow \pi_0(K) \rightarrow \pi_0(\text{SL}_n) = \{1\} \]

We recall that \( \pi_1(\text{SO}(n)) = \pi_1(\text{SL}_n) = \mathbb{Z} \) for \( n = 2 \) and \( = \mathbb{Z}/2\mathbb{Z} \) for \( n \geq 2 \). We will only need the case where \( n \) is big. In particular we can assume \( n \geq 3 \) and \( p \) or \( q \geq 2 \). Since \( K \) contains \( \text{SO}(p) \times \text{SO}(q) \) it follows that the map \( \pi_1(K) \rightarrow \pi_1(\text{SL}_n) \) is surjective. Hence \( \pi_1(\text{Sym}^{p, q}_n) \cong \pi_0(K) \). If \( p \) and \( q \) are both \( \geq 1 \), then \( O(p) \times O(q) \) has four components and \( \pi_0(S(O(p) \times O(q))) = \mathbb{Z}/2\mathbb{Z} \). If \( p \) or \( q \) vanishes, then \( \text{SO}(p, q) = \text{SO}(n) \) and \( \text{Sym}^{p, q}_n \) is contractible. In conclusion, for \( n \geq 3 \) we have \( \pi_1(\text{Sym}^{p, q}_n) \cong \mathbb{Z}/2\mathbb{Z} \) if \( p \neq 0 \) and \( q \neq 0 \) and \( \pi_1(\text{Sym}^{p, q}_n) \cong 0 \) if \( p = 0 \) or \( q = 0 \).

Let us write down the above results for \( U_{\Lambda, p} = \sigma_\Lambda^{-1}(p) \). We set \( n = \dim M \) and \( k = \dim(\lambda_0(p) \cap \lambda_\Lambda(p)) \). We assume \( n - k \geq 3 \). Then \( U_{\Lambda, p} \) is topologically equivalent to \( \text{Sym}^{0, k}_n = \bigsqcup_{p=0}^{n-k} \text{Sym}^{p, n-k-p}_n \), which has \( n-k+1 \) components, two of them being contractible and the other ones having \( \pi_1 = \mathbb{Z}/2\mathbb{Z} \).

The inertia index \( \tau_{T_pT^*M} \) introduced in (1.4.3) gives a function on \( \tau_p: U_{\Lambda, p} \rightarrow \mathbb{Z}, \quad l \mapsto \tau_{T_pT^*M}(\lambda_0(p), \lambda_\Lambda(p), l) \).
which is constant on each component of $U_{\Lambda,p}$. In the coordinates chosen above for $l_1$, $l_2$ and with $l = l_M$, $M = \begin{pmatrix} A & B \\ tB & C \end{pmatrix}$ we can see that $\tau_p(l_M) = \text{sgn}(C)$, using Lemma A.3.3 of [30]. Since $C$ is an invertible symmetric matrix of size $(n - k)$, we obtain that the values of $\tau_p$ are \{-n+k, -n+k+2, \ldots, n-k\}. Hence $\tau_p$ distinguishes the components of $U_{\Lambda,p}$ and we can index them as follows:

\begin{equation}
(10.6.3) \quad U^i_{\Lambda,p} \text{ is the connected component of } U_{\Lambda,p} \text{ where } \tau_p = i.
\end{equation}

We have to be careful that the components of $U_{\Lambda}$ cannot be indexed in this way: the function $\tau_p$ is locally constant on $U_{\Lambda,p}$ but the function $l \mapsto \tau(l) = \tau_{\Lambda}(\sigma(l))(l)$ is not locally constant on $U_{\Lambda}$. For example, when $\dim(\Lambda(p) \cap \Lambda_{\Lambda}(p))$ changes by 1 (which happens when $p$ moves from a generic point to a cusp), the parity of the possible values of $\tau_p$ also changes. However we have the following result.

**Lemma 10.6.1.** The function $\delta: U_{\Lambda} \times U_{\Lambda} \to \mathbb{Z}$, $(l, l') \mapsto \tau_p(l) - \tau_p(l')$, where $p = \sigma(l) = \sigma(l')$, is locally constant on $U_{\Lambda} \times U_{\Lambda}$.

**Proof.** We recall that $\tau$ satisfies a cocycle relation (see for example [30], Thm A.3.2) $\tau(l_1, l_2, l_3) - \tau(l_2, l_3, l_4) + \tau(l_3, l_4, l_1) - \tau(l_4, l_1, l_2) = 0$ and that $\tau(l_1, l_2, l_3)$ is constant when $(l_1, l_2, l_3)$ moves but the dimensions of $l_1 \cap l_2$, $l_1 \cap l_3$, $l_2 \cap l_3$ do not change.

The function $\delta$ is locally constant on $U_{\Lambda,p} \times U_{\Lambda,p}$ for a given $p$ because so are $\tau_p(l)$ and $\tau_p(l')$. When $p$ moves we choose a local trivialization of $T^*M$ and we consider $l$, $l'$, $\lambda_0(p)$, $\lambda_{\Lambda}(p)$ as subspaces of a fixed symplectic space. Then $\tau_p(l) - \tau_p(l') = \tau(l, l', \lambda_0(p)) - \tau(l, l', \lambda_{\Lambda}(p))$ is constant for $l, l'$ fixed and $\lambda_0(p)$, $\lambda_{\Lambda}(p)$ remaining transverse to $l, l'$. □

**Proposition 10.6.2.** Let $F \in D^b_{(\Lambda)}(k)$. Let $p \in \Lambda$ and let $U^i_{\Lambda,p}$, $U^j_{\Lambda,p}$ be two components of $U_{\Lambda,p}$ (see (10.6.3)). Then

(a) for $l \in U^i_{\Lambda,p}$, $l' \in U^j_{\Lambda,p}$ we have $m_{\Lambda}(F)_l \simeq m_{\Lambda}(F)_{l'}[i - j]/2$,

(b) if $\pi_1(U^j_{\Lambda,p}) = \mathbb{Z}/2\mathbb{Z}$, the monodromy of $m_{\Lambda}(F)|_{U^i_{\Lambda,p}}$ along the non trivial loop is the multiplication by $-1$.

**Proof.** The point (a) is already proved in [30] and stated here as Proposition 10.4.1. It will be recovered in the course of the proof of (b).

(i) Since $m_{\Lambda}(F)$ is locally constant on $U_{\Lambda}$ and $j - i$ is well-defined in a neighborhood of $U^i_{\Lambda,p} \times U^j_{\Lambda,p}$ by Lemma 10.6.1 we can assume for the proof of (a) that $p$ is a generic point of $\Lambda$. This also works for the proof of (b) since any loop in $U^i_{\Lambda,p}$ can be deformed into a loop in a nearby fiber $U^i_{\Lambda,q}$.
Hence we assume that $\Lambda = T^*_N M$ in a neighborhood of $p$, for some submanifold $N \subset M$. By Lemma \[0.2.2\] there exists a neighborhood $\Omega$ of $p$ in $T^* M$ such that $F$ is isomorphic to $L_N$ in $D^b(k_M; \Omega)$, for some $L \in D^b(k)$. Hence $m_{\Lambda}(F) \cong m_{\Lambda}(\mathcal{Z}_N) \otimes_{\mathbb{Z}} L$ and we can assume that $k = \mathbb{Z}$ and $F = \mathbb{Z}_N$.

(ii) We take coordinates $(x_1, \ldots, x_n)$ so that $N = \{x_1 = \cdots = x_k = 0\}$ and $p = (0; 1, 0)$. We identify $(\mathcal{L}^0_M)_p$ with a space of matrices as in \[0.5.2\]. Then $U_{\Lambda,p}$ is the space of symmetric matrices $A$ such that $\det(A_k) \neq 0$, where $A_k$ is the matrix obtained from $A$ by deleting the $k$ first lines and columns. The component $U^i_{\Lambda,p}$ is defined by $\text{sgn}(A_k) = i$. We can choose a base point $B \in U^i_{\Lambda,p}$ represented by a diagonal matrix $B$ with entries $0$, $1$ or $0$’s, with entries $0$’s, $1$’s and $\alpha$’s. We have $\alpha - \beta = i$, hence $2\alpha = i + n - k$. Since $\pi_1(U^i_{\Lambda,q}) \neq 0$ we also have $\alpha, \beta \geq 1$.

We choose $a, b$ such that $B_{aa} = 1$ and $B_{bb} = -1$. For $\theta \in [0, 2\pi]$, we define the matrix $B(\theta)$ which is equal to $B$ except

$$
\begin{pmatrix}
B_{aa}(\theta) & B_{ab}(\theta) \\
B_{ba}(\theta) & B_{bb}(\theta)
\end{pmatrix} = \begin{pmatrix}
\cos(\theta) & \sin(\theta) \\
\sin(\theta) & -\cos(\theta)
\end{pmatrix}.
$$

Then $\gamma: \theta \mapsto B(\theta)$ defines a non trivial loop in $U^i_{\Lambda,p}$ and we want to prove that the monodromy of $m_{\Lambda}(\mathbb{Z}_N)$ around $\gamma$ is the multiplication by $-1$. Since $m_{\Lambda}(\mathbb{Z}_N)$ has stalk $\mathbb{Z}$ up to some shift, we only have to check that this monodromy is not trivial.

(iii) We define $\varphi: [0, 2\pi] \times M \to \mathbb{R}$ by $\varphi(\theta, x) = x_1 + x \cdot B(\theta)^t x$. Then $C_\theta = \{\varphi_\theta \geq 0\} \cap N$ is a quadratic cone and the pair $(N, C_\theta)$ is homotopically equivalent to the pair $(N, V_\theta)$, where $V_\theta$ is the subspace

$$
V_\theta = \langle e_\theta, e_p; p = k + 1, \ldots, k + \alpha, p \neq a \rangle,
$$

of dimension $\alpha$ with $e_\theta = (0, \cos(\theta)_{a \choose 2}, 0, \sin(\theta)_{a \choose 2}, 0)$ and $e_p = (0, 1, 0)$. The stalk of $m_{\Lambda}(\mathbb{Z}_N)$ at $B(\theta) \in U^i_{\Lambda,p}$ is

$$
m_{\Lambda}(\mathbb{Z}_N)_{B(\theta)} \cong \text{R} \Gamma_{\{\varphi_\theta \geq 0\}}(\mathbb{Z}_N) \cong (H^{n-k-\alpha}_{V_\theta}(\mathbb{Z}_N))_0[k + \alpha - n]
$$

and the data of a non zero germ $s_\theta \in m_{\Lambda}(\mathbb{Z}_N)_{B(\theta)}$ is equivalent to a choice of relative orientation of $V_\theta$. In particular a non zero section of $m_{\Lambda}(\mathbb{Z}_N)$ defined on some neighborhood of $\gamma$ would induce relative orientations of all $V_\theta$ together for $\theta \in [0, 2\pi]$, which is impossible. Hence the monodromy of $m_{\Lambda}(\mathbb{Z}_N)$ is not $1$, which proves (b).

The part (a) follows from the fact that $m_{\Lambda}(\mathbb{Z}_N)_{B(\theta)}$ is concentrated in cohomological degree $k + \alpha - n = i/2 + (k - n)/2$. \qed
Let $M$ be a manifold and $L \subset T^*M$ a closed Lagrangian submanifold. We set $\mathcal{L} = \mathcal{L}_M|_L$. We have already defined the Gauss map $g: L \to \mathcal{L}$ as $g(p) = \lambda_\Lambda(p)$. We have also considered the tangent to the vertical fiber and we see it now as a map $v: L \to \mathcal{L}$, $p \mapsto \lambda_0(p)$. We can define the same maps after stabilisation. For an integer $N$ we let $V_N$ be the symplectic vector space $V_N = \mathbb{C}^N$ and we let $l_0^N = \mathbb{R}^N$, $l_1^N = i\mathbb{R}^N$ be two Lagrangian subspaces. We define $\mathcal{L}_N \to L$ the fiber bundle whose fiber at $p \in L$ is $\mathcal{L}(T_pT^*M \oplus V_N)$. We extend $g$ and $v$ into two sections $g_N, v_N: L \to \mathcal{L}_N$ defined by $g_N(p) = \lambda_\Lambda(p) \oplus l_1^N$ and $v_N(p) = \lambda_0(p) \oplus l_0^N$. Actually for $N$ big enough $\mathcal{L}_N$ is trivial and, taking the limit for $N \to \infty$, it gives the trivial bundle over $L$ with fiber $U/O = \lim_{\to k} U(k)/O(k)$. Then $g_\infty$ and $v_\infty$ are maps from $L$ to $U/O$. The Maslov classes of $L$ are the obstructions to find a homotopy of maps between $g_\infty$ and $v_\infty$. The $i^{th}$-class $\mu_i$ belongs to $H^i(L; \pi_{i+1}(U/O))$.

Let us assume that $L$ has a triangulation and denote by $S_k(L)$ the $k$-skeleton of $L$. Then $\mu_i = 0$ for $i = 1, \ldots, k$, if and only if there exists a homotopy between $g_\infty|_{S_k}$ and $v_\infty|_{S_k}$.

The question of finding an isotopy between $g$ and $v$ is related to finding a section of the map $U_L \to L$, where $L$ is the open subset of $\mathcal{L}_M|_L$ introduced in (10.5.3). Indeed, for $p \in L$ and $l \in U_{L,p}$ the open subset $U(l)$ of $\mathcal{L}_{M,p}$ consisting of Lagrangian subspaces transverse to $l$ is an affine chart of $\mathcal{L}_{M,p}$ isomorphic to a space of symmetric matrices. It has a natural structure of affine space. Since $g(p)$ and $v(p)$ belong to $U(l)$, we obtain an isotopy $h_t: t \mapsto tg(p) + (1 - t)v(p)$, $t \in [0, 1]$. Hence any section of the map $\sigma: U_L \to L$ over a subset $S$ of $L$ gives an isotopy between $g|_S$ and $v|_S$.

For an integer $N$ we set $\Xi_N = \check{\mathcal{L}}_{\mathbb{R}^N} \mathbb{R}^{N+1}$ and $\xi_N = (0, 0; 0, 1) \in \Xi_N$. For $F \in D(k_M)$ we consider $F \boxtimes k_{\mathbb{R}^N} \in D(k_M^{\times \mathbb{R}^{N+1}})$. Since $F \boxtimes k_{\mathbb{R}^N} \simeq i_*p^{-1}F$, where $p: M \times \mathbb{R}^N \to M$ is the projection and $i: M \times \mathbb{R}^N \to M \times \mathbb{R}^{N+1}$ the inclusion, we have $SS(F \boxtimes k_{\mathbb{R}^N}) = SS(F) \times \Xi_N$. If $SS(F) = \Lambda$, then $SS(F \boxtimes k_{\mathbb{R}^N})$ contains $\Lambda \times \Xi_N$ as an open set and $\Lambda \times \Xi_N$ is a neighborhood of $\Lambda \simeq \Lambda \times \{\xi_N\}$ which retracts to $\Lambda$. We can identify $\mathcal{L}(M \times \mathbb{R}^N)|_{\Lambda \times \{\xi_N\}}$ with the Lagrangian Grassmannian $\mathcal{L}_N$ of the stabilisation of $T^*M$ introduced above.

Summing up the discussion we obtain the following result. We assume that $\Lambda$ is triangulated. If the map $\sigma: U_{\Lambda \times \Xi_N} \to \Lambda \times \Xi_N$ has a section over the $k$-skeleton of $\Lambda \times \{\xi_N\}$, then $\mu_i(\Lambda) = 0$ for $i \leq k$.

**Corollary 10.6.3.** Let $\Lambda \subset T^*M$ be a closed conic Lagrangian submanifold. We assume that there exists $F \in \mu_\text{Sh}(k_{\Lambda})(\Lambda)$ which is simple along $\Lambda$. Then $\mu_1(\Lambda) = 0$. If, moreover $k = \mathbb{Z}$, then $\mu_2(\Lambda) = 0$. 
Proof. (i) We choose a triangulation of $\Lambda$. By the discussion before the corollary it is enough to prove that, for $N$ big enough, the map $\sigma: U_{\Lambda \times \Xi N} \to \Lambda \times \Xi N$ has a section over the $k$-skeleton of $\Lambda \times \{\xi_N\}$, for $k = 1, 2$.

We consider the connected components of $U_{\Lambda \times \Xi N}|_{\Lambda \times \{\xi\}}$, that we denote by $U^N_a$, $a \in A_N$. We let $U_a$, $a \in A$, be the connected components of $U_{\Lambda}$. To prove the vanishing of $\mu_1$ it is enough to see that there exists $N$ and $U^N_a$ such that $\sigma|_{U^N_a}: U^N_a \to \Lambda$ is surjective with connected fibers (then it is possible to find a section on the 1-skeleton).

(ii) By Remark 10.5.7 we can define $m_\Lambda(\mathcal{F}) \in DL(\mathbf{k}_\Lambda)$. Since $\mathcal{F}$ is simple, $m_\Lambda(\mathcal{F})$ is (locally) concentrated in one degree with germs $\mathbf{k}$ in this degree. Hence, for any $a \in A$ there exists $d_a \in \mathbb{Z}$ such that $m_\Lambda(F)|_{U^N_a[d_a]}$ is locally constant with germs $\mathbf{k}$.

Let $a, a' \in A$ and $p \in \Lambda$. We recall that the connected components of $U_{\Lambda, p}$ are distinguished by the inertia index and that we denote by $U^i_{\Lambda, p}$ the component with index $i$. We assume that $U^i_{\Lambda, p}$ is a component of $U_a \cap U_{\Lambda, p}$ and $U^i_{\Lambda, p}$ is a component of $U_a' \cap U_{\Lambda, p}$. By Proposition 10.6.2 (a) this implies $i - i' = 2(d_a - d_{a'})$. We thus obtain

(ii-a) $U_a$ cannot intersect $U_{\Lambda, p}$ in more than one connected component,

(ii-b) if $d_a = d_{a'}$ and $\sigma(U_a) \cap \sigma(U_{a'}) \neq \emptyset$, then $U_a = U_{a'}$.

Applying (ii-a) to $\mathcal{F} \boxtimes \mathbf{k}_{R N}$ we obtain that $\sigma|_{U^N_a}$ has connected fibers, for any component $U^N_a$ introduced in (i).

(iii) We denote by $V^N_b$, $b \in B_N$, the components of $U_{\Xi N}$ and by $d^N_b$ the cohomological degree such that $m_{\Xi N}(\mathbf{k}_{R N})$ has germs $\mathbf{k}$ in degree $d^N_b$. We can see directly on the formula of Proposition 10.5.3 that $d^N_b$ takes the values $0, 1, \ldots, N$ (more precisely $H^*_M(\mathbf{k}_{R N})$ is concentrated in degree $N - i$ when $f(x) = x_{N+1} + q(x_1, \ldots, x_N)$ and $q$ is a non degenerate quadratic form with $i$ negative eigenvalues). We can then identify $B_N$ with $\{0, \ldots, N\}$ and we get $d^N_b = b$.

We remark that the product of two Lagrangian subspaces gives a natural inclusion of $U_A \times U_{\Xi N}$ in $U_{\Lambda \times \Xi N}$. For $a \in A$ and $b \in B_N$ the component $U^N_c$ containing $U_a \times V^N_b$ satisfies $d_c = d_a + b$.

We set $d' = \max\{d_a; a \in A\}$, $d'' = \min\{d_a; a \in A\}$ and we choose $N$ bigger than $d' - d''$. For $a \in A$ we let $U^N_{c(a)}$, $c(a) \in A_N$, be the component which contains $U_a \times V^N_{d' - a}$. Then $d_{c(a)} = d'$, for all $a \in A$. Since $\sigma(U^N_{c(a)})$ contains $\sigma(U_a)$, the open subsets $\sigma(U^N_{c(a)})$ cover $\Lambda$. By (ii-b) we deduce that these components $U^N_{c(a)}$ are in fact a single component.

By the final remark of (i) this proves that $\mu_1 = 0$. 
Now we assume $k = \mathbb{Z}$ and prove $\mu_2 = 0$. Let us denote by $U_0^N$ the component of $U_{\Lambda \times \mathbb{Z}}|_{\Lambda \times \{1\}}$ found in (iii). Hence $\sigma|_{U_0^N} : U_0^N \to \Lambda$ is surjective with connected fibers. We recall that the components of $U_{\Lambda, p}$ have fundamental group $\mathbb{Z}$ if $\pi$ is small enough so that $\text{index}$. Hence, up to taking the product of $U_0^N$ by $V_1^2$ (the component of $U_{\mathbb{Z}}$ with index 1 – see (iii)), we can assume that the fibers of $\sigma|_{U_0^N}$ have fundamental group $\mathbb{Z}/2\mathbb{Z}$.

Let us recall how $\mu_2$ is defined. We assume that our triangulation is small enough so that $\pi_1(\sigma^{-1}(T)) = \pi_1(\sigma^{-1}(p)) = \mathbb{Z}/2\mathbb{Z}$ for any triangle $T$ and $p \in T$. We choose a section of $\sigma$ on the 1-skeleton, say $i : S_1(\Lambda) \to U_0^N$. Then $\mu_2$ is the obstruction to extend it to the 2-skeleton and is defined as follows. The boundary of each triangle $T$ gives a loop $i(\partial T)$ in $\pi_1(T)$, hence an element $c(T) \in \pi_1(\sigma^{-1}(T)) = \mathbb{Z}/2\mathbb{Z}$. Then $i$ can be extended to the 2-skeleton if and only if the chain $c : T \mapsto c(T)$ vanishes. It is easy to see that $c$ is a cocycle and, by definition $\mu_2 = [c]$. If $[c] = 0$, we write $c = \partial b$ where $b$ is a 1-chain and we can modify $i$ by $b$ and obtain a new section $i' : S_1(\Lambda) \to U_0^N$ which can be extended to $S_2(\Lambda)$.

Now we see how we can use our sheaf to define $i$ such that the chain $c$ vanishes. By Proposition 10.6.2(b) the sheaf $G = m_{\Lambda \times \mathbb{Z}}(\mathcal{F} \boxtimes \mathbb{Z}_{\mathbb{R}^N})$ is locally constant with germs $\mathbb{Z}$ and its restriction to the fibers has monodromy $-1$. We first define $i$ on $S_0(\Lambda)$ arbitrarily. For each $p \in S_0(\Lambda)$ we also choose a generator $u_p$ of $G_{i(p)} \simeq \mathbb{Z}$. We have two such generators $u_p$ and $-u_p$.

Let $E \subset S_1(\Lambda)$ be an edge with boundaries $p, p'$. The fundamental group of $\sigma^{-1}(E)$ is $\pi_1(\sigma^{-1}(E)) = \mathbb{Z}/2\mathbb{Z}$. Hence we have two sections $j, j'$ of $\sigma$ over $E$ up to homotopy such that $j(p) = j'(p) = i(p)$ and $j(\gamma) = j'(\gamma) = i(\gamma)$. Then $j^{-1}(G)$ is a constant sheaf on $E$ and we have a canonical isomorphism

$$a_j : G_{i(p)} \simeq (j^{-1}G)_p \xleftarrow{} \Gamma(E; j^{-1}G) \xrightarrow{} (j^{-1}G)_{p'} \simeq G_{i(p')}$$

and a similar one $a_{j'}$. Since $G$ has monodromy $-1$, we have $a_j = -a_{j'}$. Hence we can choose one section $j$ or $j'$, that we call $i$, such that $a_i(u_p) = u_{p'}$.

We do this for all edges and we obtain $i : S_1(\Lambda) \to U_0^N$. With this definition the monodromy of $G$ along $i(\partial T)$ is 1, for any triangle $T$. Using again $\pi_1(\sigma^{-1}(T)) = \mathbb{Z}/2\mathbb{Z}$ and the fact that $G$ has monodromy $-1$ along the non trivial loop, we deduce that $i(\partial T)$ is a trivial loop. Hence we can extend $i$ to $S_2(\Lambda)$. This proves $\mu_2 = 0$. 

□
Part 11. Convolution and microlocalization

Let \( N \) be a manifold and \( \Lambda \subset T^*N \) a locally closed conic Lagrangian submanifold. As explained in Remark 10.1.6 the objects of \( \mu \text{Sh}^*(k_{\Lambda}) \) are described by simple sheaves along a covering, \( F_i \in D^b(\Lambda_i)(k_N) \), and gluing “isomorphisms” \( u_ji \in H^0(\Lambda_j; \mu \text{hom}(F_i, F_j)|_{\Lambda_{ji}}) \). For a given object of \( \mu \text{Sh}^*(k_{\Lambda}) \) we want to find a representative in \( D^b(\Lambda)(k_N) \), or better, \( D^b(k_N) \). For this we would like to glue the \( F_i \)'s in the category \( D^b(k_N) \) instead of \( \mu \text{Sh}^*(k_{\Lambda}) \). A first step for this is to find other representatives of the \( m_{\Lambda_i}(F_i) \)'s for which the \( u_{ji} \) arise from morphisms in \( D^b(k_N) \). In this part we introduce a functor, \( \Psi \), which gives an answer to this question (see Proposition 11.3.5 below). This functor is a variation on Tamarkin’s projector of \( \S.3.5 \). To define \( \Psi \) we need to choose a direction on \( N \) and we assume that \( N \) is decomposed \( N = M \times \mathbb{R} \). For an open subset \( U \) of \( N \) we define \( \Psi_U: D(k_U) \to D(k_U|_{[0, +\infty[}) \) with the following properties: setting \( \Psi_U^e(F) = \Psi_U(F)|_{U \times \{ \varepsilon \}} \) for \( \varepsilon > 0 \), we have, for \( F, G \in D(k_U) \), \( H^0(\dot{\mu} \text{hom}(F, G)) \approx \lim_{\varepsilon \to 0} \text{Hom}(\Psi_U^e(F)|_V, \Psi_U^e(G)|_V) \), where \( V \) is a relatively compact open subset of \( U \).

The property (iv) will be used in the next part to glue representatives of objects of \( \mu \text{Sh}^*(k_{\Lambda}) \) as follows. For \( W \subset M \times \mathbb{R} \) we set \( \Lambda_W = \Lambda \cap T^*W \). We are given \( F \in \mu \text{Sh}^*(k_{\Lambda})(\Lambda_W) \), a covering \( W = W_1 \cup W_2 \) and \( F_i \in D(k_{W_i}) \) representing \( F|_{\Lambda_{W_i}} \). We set \( U = W_1 \cap W_2 \). We then have isomorphisms \( m_{\Lambda_U}(F_1|_U) \approx F|_{\Lambda_U} \approx m_{\Lambda_U}(F_2|_U) \), hence a section of \( H^0(\dot{\mu} \text{hom}(F_1, F_2)) \) over \( T^*U \). Using the property (iv) we deduce an isomorphism \( F_1|_U \approx F_2|_U \) and we can glue \( F_1 \) and \( F_2 \) into a representative of \( F \) over \( W \).

With this procedure we can construct sheaves representing objects of \( \mu \text{Sh}^*(k_{\Lambda})(\Lambda_0) \) when \( \Lambda_0 \subset \Lambda \) is of the type \( \Lambda \cap T^*W_i \), \( W_i \) open in \( M \times \mathbb{R} \). Unfortunately we will need to consider more general open subsets \( \Lambda_0 \) in \( \{12\} \). Our \( \Lambda_0 \) will not be a union of subsets \( \Lambda \cap T^*W_i \), but only a union of connected components of \( \Lambda \cap T^*W_i \). This means that \( \pi_{M \times \mathbb{R}}(\partial \Lambda_0) \) is a priori non empty. Let \( p = (x; \xi) \in \partial \Lambda_0 \), \( \Xi \) a neighborhood of \( p \) in \( \Lambda \) and \( U = \pi_{M \times \mathbb{R}}(\Xi) \), \( V = \pi_{M \times \mathbb{R}}(\Xi \cap \Lambda_0) \). Near \( x \) we will have to consider sheaves of the form \( R\Gamma_V(F) \) with \( F \in D(k_U) \), \( SS(F) = \Xi \). For sheaves of this kind the above
We introduce some notations. We set for short $\mathbb{R}_{>0} = [0, +\infty]$ and $\mathbb{R}_{\geq 0} = [0, +\infty[$. We usually endow the factor $\mathbb{R}$ in $M \times \mathbb{R}$ with the coordinate $t$. We will need an extra parameter, usually denoted $u$, running over $\mathbb{R}_{\geq 0}$ or $\mathbb{R}_{>0}$. The associated coordinates in the cotangent bundles are $(t; \tau)$ for $T^*\mathbb{R}$ and $(u; \tau)$ for $T^*\mathbb{R}_{>0}$. We set $T^*_{\tau \geq 0}\mathbb{R} = \{(t, \tau) \in T^*\mathbb{R}; \tau \geq 0\}$ and we define $T^*_{\tau > 0}\mathbb{R}$ similarly. For a manifold $M$ and an open subset $U \subset M \times \mathbb{R}$ we define

\begin{align}
T^*_{\tau \geq 0}U &= (T^*M \times T^*_{\tau \geq 0}\mathbb{R}) \cap T^*U, \quad T^*_{\tau \leq 0}U = (T^*_{\tau \geq 0}U)^a, \\
T^*_{\tau > 0}U &= (T^*M \times T^*_{\tau > 0}\mathbb{R}) \cap T^*U, \quad T^*_{\tau < 0}U = (T^*_{\tau > 0}U)^a.
\end{align}

**Definition 11.0.1.** Let $U$ be an open subset of $M \times \mathbb{R}$. We let $D^b_{\tau > 0}(k_U)$ (resp. $D^b_{\tau \geq 0}(k_U)$) be the full subcategory of $D^b(k_U)$ of sheaves $F$ satisfying $SS(F) \subset T^*_{\tau > 0}U$ (resp. $SS(F) \subset T^*_{\tau \geq 0}U$).

11.1. The functor $\Psi$

The convolution product is a variant of the “composition of kernels” considered in [30] (denoted by $\circ$ – see (1.5.1)). It is used in [33] to study the localization of $D^b(k_{M \times \mathbb{R}})$ by the objects with microsupport in $T^*_{\tau \leq 0}(M \times \mathbb{R})$, in a framework similar to the present one. Namely, Tamarkin proves that the functor $F \mapsto k_{M \times [0, +\infty[} \ast F$ is a projector from $D^b(k_{M \times \mathbb{R}})$ to the left orthogonal of the subcategory $D^b_{T^*_{\tau \leq 0}(M \times \mathbb{R})}(k_{M \times \mathbb{R}})$ of objects with microsupport in $T^*_{\tau \leq 0}(M \times \mathbb{R})$ (see [22] for a survey). We will use a variant of Tamarkin’s definition.

We will use the product $\ast$ in the following special situation. We define the subsets of $\mathbb{R} \times \mathbb{R}_{>0}$:

\begin{align}
\gamma &= \{(t, u); 0 \leq t < u\}, \\
\lambda_0 &= \{0\} \times \mathbb{R}_{>0}, \quad \lambda_1 = \{(t, u) \in \mathbb{R} \times \mathbb{R}_{>0}; t = u\}.
\end{align}

**Definition 11.1.1.** Let $M$ be a manifold and let $U \subset M \times \mathbb{R}$ be the an open subset. We define $U_\gamma \subset M \times \mathbb{R} \times \mathbb{R}_{>0}$ by

\[ U_\gamma = \{(x, t, u) \in M \times \mathbb{R} \times \mathbb{R}_{>0}; \{x\} \times [t - u, t] \subset U\}. \]
For $F \in D^b(k_{U'})$ and $G \in D^b(k_{\mathbb{R} \times \mathbb{R} > 0})$ with supp$(G) \subset \overline{\gamma}$, we define $G \star F \in D^b(k_{U''})$ by

\[(11.1.2) \quad G \star F = (R s'_1(F \boxtimes G))|_{U''},\]

where $s: U \times \mathbb{R} \times \mathbb{R} > 0 \to M \times \mathbb{R} \times \mathbb{R} > 0$ is the sum $s(x, t_1, t_2, u) = (x, t_1 + t_2, u)$. We define the functor $\Psi_{U'}: D^b(k_{U'}) \to D^b(k_{U''})$ by

\[(11.1.3) \quad \Psi_{U'}(F) = k_\gamma \star F = (R s'_1(F \boxtimes k_{(x, u); 0 \leq t < u}))|_{U''}.\]

**Remark 11.1.2.** (i) We see easily on the definition of $U_\gamma$ that, for any submanifold $M'$ of $M$, we have $U_\gamma \cap (M' \times \mathbb{R} \times \mathbb{R} > 0) = (U \cap (M' \times \mathbb{R}))_\gamma$. For a disjoint union $U = \bigsqcup_{i \in I} U_i$ we also have $U_\gamma = \bigsqcup_{i \in I} U_i\gamma$. Hence we can reduce the description of $U_\gamma$ to the case where $M$ is a point and $U = [a, b]$ is an interval of $\mathbb{R}$. Then we have

\[(11.1.4) \quad ([a, b])_\gamma = \{(t, u) \in \mathbb{R} \times \mathbb{R} > 0; a + u < t < b\}.\]

(ii) We have $s^{-1}(U_\gamma) \cap (M \times \mathbb{R} \times \overline{\gamma}) \subset U \times \overline{\gamma}$. Since supp$(G) \subset \overline{\gamma}$, it follows that we also have $G \star F = (R s'_1(F' \boxtimes G))|_{U''}$ where $F' \in D^b(k_{M \times \mathbb{R}})$ is any object such that $F'|_U = F$ and $s': M \times \mathbb{R}^2 \times \mathbb{R} > 0 \to M \times \mathbb{R} \times \mathbb{R} > 0$ is the sum.

(iii) For the same reason the restriction of $s$ to $s^{-1}(U_\gamma) \cap (M \times \mathbb{R} \times \overline{\gamma})$ is a proper map. Hence we can replace $R s_i$ by $R s_*$ in (11.1.2).

We define the projections

\[(11.1.5) \quad q: M \times \mathbb{R} \times \mathbb{R} > 0 \to M \times \mathbb{R}, \quad (x, t, u) \mapsto (x, t),\]

\[r: M \times \mathbb{R} \times \mathbb{R} > 0 \to M \times \mathbb{R}, \quad (x, t, u) \mapsto (x, t - u)\]

and we denote by $q_U, r_U: U_\gamma \to U$ the restrictions of $q, r$ to $U_\gamma$. Using the notations (11.1.1) we have $k_{\lambda_0} \star F \simeq q_U^{-1}(F)$ and $k_{\lambda_1} \star F \simeq r_U^{-1}(F)$, for any $F \in D^b(k_{U'})$. The closed inclusions $\lambda_0 \subset \gamma$, $\lambda_1 \subset \overline{\gamma}$ and $\lambda_1 \subset \overline{\gamma} \setminus \lambda_0$ give excision distinguished triangles

$$k_{\text{Int}((\gamma))} \xrightarrow{b'} k_\gamma \xrightarrow{a} k_{\lambda_0} \xrightarrow{+1}, \quad k_{\lambda_1}[-1] \xrightarrow{b} k_\gamma \to k_{\overline{\gamma}} \xrightarrow{+1},$$

and we have $b = b' \circ b'$. The convolution $- \star F$ turns the morphisms $a, b, b'$ into morphisms of functors:

\[(11.1.6) \quad \alpha(F): \Psi_U(F) \to q_U^{-1}(F), \quad \beta(F): r_U^{-1}(F)[-1] \to \Psi_U(F),\]
and \( \beta'(F) : r_U^{-1}(F)[-1] \to k_{\int(\gamma)} \star F \), \( \beta''(F) : k_{\int(\gamma)} \star F \to \Psi_U(F) \). We have \( \beta(F) = \beta''(F) \circ \beta'(F) \) and two distinguished triangles

\[
\begin{align*}
(11.1.7) \\ k_{\int(\gamma)} \star F & \xrightarrow{\beta''(F)} \Psi_U(F) \xrightarrow{\alpha(F)} q_U^{-1}(F) \xrightarrow{\beta'(F)} r_U^{-1}(F)[{-1}] \\
(11.1.8) \\ r_U^{-1}(F)[{-1}] & \xrightarrow{\beta'(F)} k_{\int(\gamma)} \star F \to k_{\gamma} \star F \xrightarrow{\alpha(F)} q_U^{-1}(F) \xrightarrow{\beta''(F)} r_U^{-1}(F)[{-1}].
\end{align*}
\]

**Lemma 11.1.3.** For \( F \in D^b_{r \geq 0}(k_U) \) the morphism \( \beta'(F) \) is an isomorphism and \( (11.1.7) \) gives the distinguished triangle

\[
(11.1.9) r_U^{-1}(F)[{-1}] \xrightarrow{\beta'(F)} k_{\int(\gamma)} \star F \xrightarrow{\alpha(F)} q_U^{-1}(F) \xrightarrow{\beta''(F)} r_U^{-1}(F)[{-1}].
\]

**Proof.** Since \( \beta(F) = \beta''(F) \circ \beta'(F) \) the second part of the lemma follows from the claim that \( \beta'(F) \) is an isomorphism. In view of \( (11.1.8) \) we only have to prove that \( k_{\gamma} \star F \simeq 0 \).

For \( x \in M \) and \( u > 0 \) we define \( i_{(x,u)} : \mathbb{R} \to M \times \mathbb{R} \times \mathbb{R}_{>0}, t \mapsto (x, t, u) \). It is enough to see that \( i_{(x,u)}^{-1}(k_{\gamma} \star F) \simeq 0 \), for all \( (x, u) \). By the base change formula we have \( i_{(x,u)}^{-1}(k_{\gamma} \star F) \simeq k_{[0,u]} \star F \) and we conclude with Lemma 11.1.4 below. \( \square \)

**Lemma 11.1.4.** Let \( a < b \in \mathbb{R} \) and let \( F \in D^b_{r \geq 0}(k_\mathbb{R}) \). Then \( k_{[a,b]} \star F \simeq 0 \).

**Proof.** By the definition of \( k_{[a,b]} \star F \) its germs at some \( x \in \mathbb{R} \) are

\[
(k_{[a,b]} \star F)_x \simeq R\Gamma_c(s^{-1}(x); (F \boxtimes k_{[a,b]})(s^{-1}(x))) \\
\simeq R\Gamma_c(\mathbb{R}; F \boxtimes k_{[x-b,x-a]}).
\]

The excision triangle applied to the inclusion \( \{x - a\} \subset [x - b, x - a] \) shows that \( (k_{[a,b]} \star F)_x \) is the cone of the restriction morphism \( R\Gamma([x - b, x - a]; F) \to F_{x-a} \), which is an isomorphism by the hypothesis on \( \text{SS}(F) \) and by Corollary 1.2.11. Hence \( (k_{[a,b]} \star F)_x \) vanishes for all \( x \in \mathbb{R} \) and this proves the lemma. \( \square \)

Let \( V \) be an open subset of \( U \). Let \( N \) be a submanifold of \( M \) and \( U'' = U \cap (N \times \mathbb{R}) \). We have

\[
\begin{align*}
(11.1.10) \\ \Psi_V(F|_V) & \simeq (\Psi_U(F)|_{V'_n}), \\
(11.1.11) \\ \Psi_{U''}(F|_{U''}) & \simeq (\Psi_U(F)|_{U''_n}),
\end{align*}
\]

where the first isomorphism follows from supports estimates as in Remark 11.1.2 (ii) and the second one follows from the base change formula.

In the next lemma we use an analog of the convolution for sets. For \( A \subset M \times \mathbb{R} \) and \( B \subset \mathbb{R} \times \mathbb{R}_{>0} \) we define \( B \star A \subset M \times \mathbb{R} \times \mathbb{R}_{>0} \) by

\[
(11.1.12) B \star A = s(A \times B),
\]
where \( s: U \times \mathbb{R} \times \mathbb{R}_{>0} \to M \times \mathbb{R} \times \mathbb{R}_{>0} \) is the sum as Definition \[11.1.1\]

**Lemma 11.1.5.** Let \( F \in D^b(k_U) \) and let \( V \subset U \) be an open subset. We assume that

\[
F|_{V \cap \{(x)\times \mathbb{R}\}} \text{ is locally constant, for any } x \in M.
\]

Then \( \Psi_U(F)|_{V \gamma} \simeq 0 \). As a special case, if \( SS(F|_V) \subset T^*_V V \), then \( \Psi_U(F)|_{V \gamma} \simeq 0 \). In particular \( \text{supp}(\Psi_U(F)) \subset (\gamma \star \hat{\pi}_U(\text{SS}(F))) \cap U_\gamma \).

**Proof.** We set \( V_x = V \cap \{(x) \times \mathbb{R}\} \). Then \( V_\gamma = \bigcup_{x \in M(V_x)} \gamma \) and we have to prove \( \Psi_U(F)|_{V \gamma} \simeq 0 \), for all \( x \in M \). By \[11.1.11\] we have \( \Psi_U(F)|_{(V_x) \gamma} \simeq \Psi_{V_x}(F|_{V_x}). \) The set \( V_x \) is a disjoint union of open intervals of \( \mathbb{R} \) and \( F|_{V_x} \) is constant on each of these intervals. A direct computation gives \( \Psi_{V_x}(F|_{V_x}) \simeq 0 \) and we obtain the result. \( \square \)

**Lemma 11.1.6.** Let \( F \in D^b(k_U) \).

(i) We have \( Rq_{U!} q_U^1(F) \hom Rr_{U!}(\Psi_U(F)) \simeq 0 \).

(ii) If \( F \in D^b_{\geq 0}(k_U) \), then \( Rq_{U!} r_U^{-1}(F) \) satisfies \[11.1.13\] (with \( V = U \)). In particular \( \Psi_U(Rq_{U!} r_U^{-1}(F)) \simeq 0 \).

(iii) We assume that \( U = M \times \mathbb{R} \), that \( F \in D^b_{\geq 0}(k_U) \) and that \( \text{supp}(F) \subset M \times [a, +\infty[ \) for some \( a \in \mathbb{R} \). Then \( Rq_{U!} r_U^{-1}(F) \simeq 0 \).

**Proof.** (i) The first morphism is the adjunction for \( (Rq_{U!}, q_U^1) \). It is an isomorphism because the fibers of \( q_U \) are intervals. Let us prove the second isomorphism. By the base change formula (see \[11.1.11\]) we may as well assume that \( M \) is a point. Then \( U \) is an open subset of \( \mathbb{R} \) and we can restrict to one component of \( U \). Hence we assume \( U \) is an interval. We define \( r': \mathbb{R}_2 \times \mathbb{R}_0 \to \mathbb{R}_2, (t_1, t_2, u) \mapsto (t_1, t_2 - u) \) and \( s': \mathbb{R}_2 \to \mathbb{R}, (t_1, t_2) \mapsto (t_1 + t_2) \). We have the commutative diagram

\[
\begin{array}{ccc}
\mathbb{R}_2 \times \mathbb{R}_0 & \xrightarrow{r'} & \mathbb{R}_2 \\
\downarrow{s} & & \downarrow{s'} \\
\mathbb{R} \times \mathbb{R}_0 & \xrightarrow{r} & \mathbb{R}.
\end{array}
\]

We let \( j: U \to \mathbb{R} \) be the inclusion and we set \( F' = j_! F \). Then \( \Psi_U(F) \simeq (k_\gamma \star F'|_{U \gamma}) \) and we have

\[
Rr_{U!}(\Psi_U(F)) \simeq R_{U!}((Rs_1(F' \boxtimes k_\gamma)|_{U \gamma})
\simeq R(r \circ s)_!((F' \boxtimes k_{\mathbb{R} \times \mathbb{R}_0}) \otimes k_{q_2^{-1} \gamma \cap s^{-1} U_\gamma})
\simeq R(s' \circ r')_!(r'^{-1}(F' \boxtimes k_\mathbb{R}) \otimes k_{q_2^{-1} \gamma \cap s^{-1} U_\gamma})
\simeq Rs'_!(F' \boxtimes k_\mathbb{R}) \otimes Rr'_!(k_{q_2^{-1} \gamma \cap s^{-1} U_\gamma}).
\]
Hence it is enough to prove that $\text{R}r'_U(\mathbf{k}_{\gamma; n-1}^\ast \tau) \simeq 0$. We write $U = ]a, b[$. Then we have $U_\gamma = \{(t, u) \in \mathbb{R} \times \mathbb{R}_{>0}; a + u < t < b\}$. For any $(t_1, t_2) \in \mathbb{R}^2$ the fiber $r^{-1}(t_1, t_2) \cap (q_2^{-1} \gamma \cap s^{-1} U_\gamma)$ is identified with

$$\{ u > 0; (t_1, t_2 + u, u) \in q_2^{-1} \gamma \cap s^{-1} U_\gamma \}$$

$$\{ u > 0; 0 \leq t_2 + u < u \text{ and } (t_1 + t_2 + u, u) \in U_\gamma \}$$

$$\{ u > 0; -t_2 \leq u \text{ and } u < b - t_1 - t_2 \},$$

where we assume $t_2 < 0$ and $a < t_1 + t_2$ (otherwise the fiber is empty).

Since $-t_2 > 0$ we see that the fiber is either empty or a half closed interval. This implies $\text{R}r'_U(\mathbf{k}_{\gamma; n-1}^\ast \tau) \simeq 0$, as required.

(ii) We choose $x \in M$ and we set $U_x = U \cap \{x\} \times \mathbb{R}$. By the base change formula we have $(\text{R}q_U \text{r}^{-1}_U(F))|_{U_x} \simeq \text{R}q_{U_x} \text{r}^{-1}_U(F|_{U_x})$. Hence we can assume that $M$ is a point and that $U$ is an interval, say $U = ]a, b[$.

By Example 1.2.2(i), to prove that $\text{R}r'_U(F)$ is constant it is enough to see that its microsupport is contained in the zero section.

We let $j: U \to \mathbb{R}$ be the inclusion and we set for short $q = q_\mathbb{R}, r = r_\mathbb{R}: \mathbb{R}^2 \to \mathbb{R}$. We set $F' = Rj_* F$. Then we have $\text{R}q_U \text{r}^{-1}_U(F) \simeq (\text{R}q_U j_* F'|_{U_x})|_U$.

We have $(\text{R}1_{-\infty, a} F))_a \simeq 0$ and we can deduce that $\text{SS}(F') \cap T_{\tau \geq 0}^* \mathbb{R} \subset T_{T_{\tau \geq 0}^* \mathbb{R}}$. Hence $\text{SS}(F') \cap T_{\tau \geq 0}^* \mathbb{R} \subset T_{T_{\tau \geq 0}^* \mathbb{R}}$. By Theorem 1.2.7 and Proposition 1.2.3 we obtain successively, with coordinates $(t, u; \tau, v)$ on $T^* \mathbb{R}^2$,

$$\text{SS}(r^{-1} F'|_{U \times \mathbb{R}}) \subset \{(\tau, -\tau); \tau \geq 0\},$$

$$\text{SS}(r^{-1} (F' \otimes \mathbf{k}_{\mathbb{R} \times \mathbb{R}_{>0}})|_{U \times \mathbb{R}}) \subset \{(\tau, -\tau + v); \tau \geq 0, v \leq 0\},$$

$$\text{SS}(\text{R}q_U \text{r}^{-1}_U(F)) \subset \{\tau = 0\},$$

which proves that $\text{R}q_U \text{r}^{-1}_U(F)$ is constant.

(iii) By (ii) $\text{R}q_U \text{r}^{-1}_U(F)$ is constant on the fibers $\{x\} \times \mathbb{R}$ for all $x \in M$.

By the hypothesis its restriction to $M \times \{a - 1\}$ vanishes. Hence it is zero. \hfill \Box

Lemma 11.1.7. We let $j: U \times \mathbb{R}_{>0} \to U \times \mathbb{R}$ be the inclusion. We set $A = (U \times \{0\}) \times \mathbb{R} \times T^*(U \times \mathbb{R})$. Let $F \in \mathcal{D}_{\tau \geq 0}(\mathbf{k}_U)$.

Then

$$\text{SS}(\Psi_U(F)) \subset q_a^{-1}(\text{SS}(F)) \cup r d_{\tau}^{-1}(\text{SS}(F)),$$

$$\text{SS}(Rj_! \Psi_U(F)) \cap A \subset \{(x, t, 0; \xi, \tau, v);$$

$$\quad (x, t; \xi, \tau) \in \text{SS}(F), -\tau \leq v \leq 0\}.$$
Proof. (i) The first inclusion follows from the triangle \([11.1.9]\) and the triangular inequality for the microsupport. To prove the second inclusion we consider \(\gamma\) as a subset of \(\mathbb{R}^2\) rather than \(\mathbb{R} \times \mathbb{R}_{\geq 0}\). We also consider the sum \(s, (x, t_1, t_2, u) \mapsto (x, t_1 + t_2, u)\), as a map from \(U \times \mathbb{R}^3\) to \(M \times \mathbb{R}^2\). Then by the base change formula we have \(R_{j!}\Psi_U(F) \simeq R_{\mathcal{S}}(F \boxtimes k_\gamma)\).

Setting \(V = (U \times ]-\infty, 0]) \cup U_\gamma\) we see that \(s\) is proper as a map from \(s^{-1}(V) \cap (U \times \overline{\tau})\) to \(V\). Hence we can use Proposition \([12.3]\) to bound SS(R\(_{\mathcal{S}}(F \boxtimes k_\gamma)|_V\)). We see that we only need to know SS(F \(\boxtimes k_\gamma\)) above \(U \times \mathbb{R} \times \{0\}\). Now SS(k\(_\gamma\)) \(\cap T^*_{t,0}\mathbb{R}^2\) is empty for \(t \neq 0\) and 

\[
\{-(\tau), \leq 0\} \cap \{u = 0\} \subset \{(x, t_1, 0, \xi, \tau_1, \tau_2, v): (x, t_1, \xi, \tau_1) \in \text{SS}(F), -\tau_2 \leq v \leq 0\}.
\]

We conclude with Proposition \([12.3]\).

(ii) We deduce \(R_{j!}\Psi_U(F) \simeq R_{j!}\Psi_U(F)\). Let us set \(Z = U \times ]-\infty, 0]\) and \(W = U \times \mathbb{R}_{\geq 0, +\infty}\). Then \(R_{j!}\Psi_U(F) \simeq R\Gamma_W(R_{j!}\Psi_U(F))\) and by the excision distinguished triangle, we are reduced to prove that \(R\Gamma_Z(R_{j!}\Psi_U(F)) \simeq 0\). Since the support of \(R_{j!}\Psi_U(F)\) is contained in \(W\), it is enough to prove \(R\Gamma_Z(R_{j!}\Psi_U(F))\) is empty for any \(z \in U \times \{0\}\). Going back to the definition of the microsupport, this follows from \(z; 0; 0; -1 \not\in \text{SS}(R_{j!}\Psi_U(F))\). \(\square\)

**Proposition 11.1.8.** Let \(F, G \in \mathcal{D}^b_{\tau \geq 0}(k_U)\). We set \(\Omega = T^*_{\tau > 0}U_\gamma\) for short. Then we have a natural decomposition

\[
\mu\text{hom}(\Psi_U(F), \Psi_U(G))|_\Omega \simeq \mu\text{hom}(q^{-1}_U(F), q^{-1}_U(G))|_\Omega
\]

\[
\oplus \mu\text{hom}(r^{-1}_U(F), r^{-1}_U(G))|_\Omega
\]

such that the corresponding projection from \(\mu\text{hom}(\Psi_U(F), \Psi_U(G))|_\Omega\) to \(\mu\text{hom}(q^{-1}_U(F), q^{-1}_U(G))|_\Omega\) is induced by \(\alpha(G)\) and \(\alpha(F)\) as follows:

\[
\mu\text{hom}(\Psi_U(F), \Psi_U(G))|_\Omega \overset{\alpha_1}{\rightarrow} \mu\text{hom}(\Psi_U(F), q^{-1}_U(G))|_\Omega
\]

\[
\alpha_2 \circ \mu\text{hom}(q^{-1}_U(F), q^{-1}_U(G))|_\Omega.
\]

Proof. (i) We set for short \(h(A) = \mu\text{hom}(\Psi_U(F), A)|_\Omega\) for a sheaf \(A\) on \(U_\gamma\). The triangle \((11.1.9)\) induces a distinguished triangle

\[
h(r^{-1}_U(G)|_{[-1]} \rightarrow h(\Psi_U(G)) \overset{\alpha_1}{\rightarrow} h(q^{-1}_U(G)) \overset{\alpha_2}{\rightarrow} h(r^{-1}_U(G))
\]

on \(\Omega\). We recall the bound supp \(\mu\text{hom}(F_1, F_2) \subset \text{SS}(F_1) \cap \text{SS}(F_2)\). By Theorem \([12.7]\) the microsupports of \(q^{-1}_U(G)\) and \(r^{-1}_U(F)\) are respectively contained in \(\{(x, t, u; \xi, \tau, 0)\}\) and \(\{(x, t, u; \xi, \tau, -\tau)\}\). Hence their intersection is contained in \(\{\tau = 0\}\). Since we work on \(\Omega = T^*_{\tau > 0}U_\gamma\) it follows that the supports of \(h(q^{-1}_U(G))\) and \(h(r^{-1}_U(G))\) are disjoint, hence that \(\gamma_1 = 0\). This proves that \(h(\Psi_U(G)) \simeq h(q^{-1}_U(G)) \oplus h(r^{-1}_U(G))\).
(ii) Now we check that \( \alpha_2 : \mu_{\text{hom}}(q_U^{-1}(F), q_U^{-1}(G))|_\Omega \to h(q_U^{-1}(G)) \) is an isomorphism. Using the triangle \([11.1.9]\) again, we see that the cone of \( \alpha_2 \) is \( \mu_{\text{hom}}(r_U^{-1}(F), q_U^{-1}(G))|_\Omega \) whose support is contained in \( \text{SS}(r_U^{-1}(F)) \cap \text{SS}(q_U^{-1}(G)) \). The same bound as in (i) shows that this set is contained in \( \{ \tau = 0 \} \) and does not meet \( \Omega \). Hence the cone of \( \alpha_2 \) vanishes and \( \alpha_2 \) is an isomorphism.

We obtain \( \mu_{\text{hom}}(r_U^{-1}(F), r_U^{-1}(G))|_\Omega \cong h(r_U^{-1}(G)) \) by swapping \( q_U \) and \( r_U \) in the previous argument. This concludes the proof of the proposition. \( \square \)

11.2. Adjunction properties

Let \( U \subset M \times \mathbb{R} \) be an open subset. We let \( D^{b,\text{ra}}_{\tau \geq 0}(k_{U^r}) \) be the full subcategory of \( D^b_{\tau \geq 0}(k_{U^r}) \) consisting of \( R \gamma \)-acyclic objects, that is, the objects \( G \) such that \( R \gamma G \simeq 0 \). This is a triangulated category. By Lemma \([11.1.6]\) (i) the functor \( \Psi_U \) takes values in \( D^{b,\text{ra}}_{\tau \geq 0}(k_{U^r}) \). Using Theorem \([12.1.3]\) for the embedding \( U^r \hookrightarrow U \times \mathbb{R} \) and Proposition \([12.2.3]\) we see that the functor \( Rq_{U^r} \) sends \( D^{b,\text{ra}}_{\tau \geq 0}(k_{U^r}) \) into \( D^{b,\text{ra}}_{\tau \geq 0}(k_U) \). Moreover the morphism of functors \( Rq_{U^r} \) sends \( D^{b,\text{ra}}_{\tau \geq 0}(k_{U^r}) \) into \( D^{b,\text{ra}}_{\tau \geq 0}(k_U) \).

\begin{equation}
\tag{11.2.1}
b_U(F) : Rq_{U^r}\Psi_U(F)[1] \to F, \quad \text{for all } F \in D^b_{\tau \geq 0}(k_{U^r}).
\end{equation}

**Lemma 11.2.1.** The functor \( Rq_{U^r}[1] : D^{b,\text{ra}}_{\tau \geq 0}(k_{U^r}) \to D^{b,\text{ra}}_{\tau \geq 0}(k_U) \) is left adjoint to \( \Psi_U : D^b_{\tau \geq 0}(k_U) \to D^{b,\text{ra}}_{\tau \geq 0}(k_{U^r}) \). In particular we have an adjunction morphism

\begin{equation}
\tag{11.2.2}
b'_U(G) : G \to \Psi_U Rq_{U^r}(G)[1], \quad \text{for all } G \in D^{b,\text{ra}}_{\tau \geq 0}(k_{U^r}).
\end{equation}

**Proof.** Since \( D^b_{\tau \geq 0}(k_U) \) and \( D^{b,\text{ra}}_{\tau \geq 0}(k_{U^r}) \) are full subcategories of \( D^b(k_U) \) and \( D^{b,\text{ra}}(k_{U^r}) \), it is enough to prove

\begin{equation}
\tag{11.2.3}
\text{Hom}_{D^b(k_{U^r})}(G, \Psi_U(F)) \simeq \text{Hom}_{D^b(k_U)}(Rq_{U^r}G[1], F)
\end{equation}

for any \( F \in D^b_{\tau \geq 0}(k_U) \) and \( G \in D^{b,\text{ra}}_{\tau \geq 0}(k_{U^r}) \). Since \( r_U \) is a smooth map with fibers homeomorphic to \( \mathbb{R} \) we have a canonical isomorphism of functors \( r_U^! F \simeq r_U^{-1}[1] \); hence an adjunction \( (Rr_U^!, r_U^!)[1] \). The same holds for \( q_U \). Applying \( \text{RHom}(G, \cdot) \) to \([11.1.9]\) we obtain the distinguished triangle

\[
\text{RHom}(G, r_U^{-1}F[1]) \to \text{RHom}(G, \Psi_U(F)) \to \text{RHom}(G, q_U^{-1}F) \xrightarrow{\simeq} .
\]

The adjunction \( (Rr_U^!, r_U^!)[1] \) and the hypothesis \( G \in D^{b,\text{ra}}_{\tau \geq 0}(k_{U^r}) \) give \( \text{RHom}(G, r_U^{-1}F[1]) \simeq 0 \). We deduce

\[
\text{RHom}(G, \Psi_U(F)) \xrightarrow{\simeq} \text{RHom}(G, q_U^{-1}F) \simeq \text{RHom}(Rq_{U^r}G[1], F),
\]
which implies (11.2.3).

Lemma 11.2.2. Let $F \in D^b_{\geq 0}(k_U)$. Then the morphisms $\Psi_U(b_U(F))$ and $b'_U(\Psi_U(F))$ are mutually inverse isomorphisms:

\[
\Psi_U(b_U(F)) : \Psi_U Rq_U \Psi_U(F)[1] \xrightarrow{\sim} \Psi_U(F),
\]

\[
b'_U(\Psi_U(F)) : \Psi_U(F) \xrightarrow{\sim} \Psi_U Rq_U \Psi_U(F)[1].
\]

Proof. (i) We prove the first isomorphism. We apply $Rq_U[1]$ to the distinguished triangle (11.1.9). Since $q_U$ has fibers isomorphic to $\mathbb{R}$ the adjunction morphism $Rq_U q_U^{-1}(F) \to F$ is an isomorphism and we obtain the distinguished triangle:

\[
L \to Rq_U \Psi_U(F)[1] \xrightarrow{b_U(F)} F \xrightarrow{+1},
\]

where $L = Rq_U r_U^{-1}(F)$. By Lemma 11.1.6 (ii) we have $\Psi_U(L) \simeq 0$. Hence applying $\Psi_U$ to (11.2.4) gives the lemma.

(ii) The composition $\Psi_U(b_U(F)) \circ b'_U(\Psi_U(F))$ is the identity morphism of $\Psi_U(F)$, by general properties of adjunctions. Hence the lemma follows from (i).

Proposition 11.2.3. We assume that $U = M \times \mathbb{R}$, that $F \in D^b_{\geq 0}(k_U)$ and that $\text{supp}(F) \subset M \times [a, +\infty[$ for some $a \in \mathbb{R}$. Then the adjunction morphism $b_U(F) : Rq_U \Psi_U(F)[1] \to F$ of (11.2.1) is an isomorphism and for any $G \in D^b_{\geq 0}(k_U)$ we have

\[
\text{Hom}(F, G) \xrightarrow{\sim} \text{Hom}(\Psi_U(F), \Psi_U(G)).
\]

Proof. By Lemma 11.1.6 (i) and (iii) we have $Rq_U q_U^{-1}(F) \xrightarrow{\sim} F$ and $Rq_U r_U^{-1}(F) \simeq 0$. Hence the first part follows from the distinguished triangle (11.1.9). Then the second part is given by the adjunction $(Rq_U, \Psi_U)$ of Lemma 11.2.1.

11.3. Link with microlocalization

In this section we prove Proposition 11.3.5 below which says that the space of homomorphisms from $\Psi_U(F)$ to $\Psi_U(G)$ is isomorphic to the sections of $\mu\text{hom}(F, G)$ outside the zero section. We first deduce from Proposition 11.1.8 a morphism from $\mu\text{hom}(\Psi_U(F), \Psi_U(G))$ to $\mu\text{hom}(F, G)$. Then we use “boundary values” of sheaves on $U$, in the following sense. Let $U \subset M \times \mathbb{R}$ and $V \subset M \times \mathbb{R} \times \mathbb{R}_{\geq 0}$ be open subsets satisfying

\[
i(U) \cup j(V) \text{ is open in } M \times \mathbb{R} \times \mathbb{R}_{\geq 0},
\]
where \( i, j \) are the natural inclusions

\[
\begin{align*}
i & : U \to M \times \mathbb{R} \times \mathbb{R}_{\geq 0}, \quad (x, t) \mapsto (x, t, 0), \\
j & : U \times \mathbb{R}_{>0} \to M \times \mathbb{R} \times \mathbb{R}_{\geq 0}, \quad (x, t, u) \mapsto (x, t, u).
\end{align*}
\]

Then, for \( G \in \mathcal{D}^b(\mathbf{k}_U) \), its boundary value is \( i^{-1}Rj_*(G) \in \mathcal{D}^b(\mathbf{k}_U) \).

Let \( \pi^{>0}_U : T^*_U \to U \) be the projection. Proposition 11.1.8 yields a morphism, for \( F, G \in \mathcal{D}^b_{T^*_U}(\mathbf{k}_U) \),

\[
R\mathbf{H}om(\Psi(U), \Psi(U,G)) \to R\pi^{>0}_{U_{\gamma,T}}(\mu_{\mathbf{hom}}(q^{-1}_U(F), q^{-1}_U(G))|_{T^*_U})
\]

which can be written as the composition

\[
R\mathbf{H}om(\Psi(U), \Psi(U,G)) \to R\mathbf{H}om(\Psi(U), q^{-1}_U(G)) \simeq R\pi^{>0}_{U_{\gamma,T}}(\mu_{\mathbf{hom}}(\Psi(U), q^{-1}_U(G))|_{T^*_U})
\]

\[
\simeq R\pi^{>0}_{U_{\gamma,T}}(\mu_{\mathbf{hom}}(q^{-1}_U(F), q^{-1}_U(G))|_{T^*_U})
\]

where the first line is induced by \( \alpha(G) : \Psi(U,G) \to q^{-1}_U(G) \), the second line is (11.3.2), the third line is the restriction to \( T^*_U \), and the fourth line is given by Proposition 11.1.8. Now it is easy to describe the boundary value of the right hand side of (11.3.3).

**Lemma 11.3.1.** For \( F, G, H \in \mathcal{D}(\mathbf{k}_U) \) and \( F \in \mathcal{D}^b(\mathbf{k}_{T^*_U}) \) we have natural isomorphisms

\[
\mu_{\mathbf{hom}}(q^{-1}_U(F), q^{-1}_U(G)) \simeq q^{-1}_{U,d_1}q^{-1}_{U,\pi}\mu_{\mathbf{hom}}(F, G),
\]

\[
R\pi^{>0}_{U_{\gamma,T}}((q^{-1}_{U,d_1}q^{-1}_{U,\pi}(\mathcal{F})|_{T^*_U}) \simeq q^{-1}_{U,d_1}R\pi^{>0}_{U_{\gamma,T}}(\mathcal{F}|_{T^*_U}),
\]

\[
i^{-1}Rj_*q^{-1}_UH \simeq H
\]

which induce

\[
i^{-1}Rj_*R\pi^{>0}_{U_{\gamma,T}}(\mu_{\mathbf{hom}}(q^{-1}_U(F), q^{-1}_U(G))|_{T^*_U}) \simeq R\pi^{>0}_{U_{\gamma,T}}(\mu_{\mathbf{hom}}(F, G)|_{T^*_U}).
\]

**Proof.** (i) The behaviour of \( \mu_{\mathbf{hom}} \) under an inverse image by a submersion is described in [30, Prop. 4.4.7] and gives in our case the isomorphism (11.3.6).

(ii) We remark that \( q_{U,d_1} = q_{U,d_*} \), since \( q_{U,d} \) is an embedding, and \( q^{-1}_U \simeq q^{-1}_U, q^{-1}_{U,\pi} \simeq q^{-1}_{U,\pi} \), since \( q_U \) is a projection. Now (11.3.7) follows from the base change formula.
(iii) We have \( i^{-1}R_jq_U^1H \simeq i^{-1}R\Gamma_{U \times \mathbb{R}^+, q_{1}^{-1}H} \), where \( q_1: U \times \mathbb{R} \to U \) is the projection. Since \( SS(\mathbb{k}_{U \times \mathbb{R}_+}) \subset T^*_U \times T^*\mathbb{R} \), Theorem \[1.2.11\] gives
\[
R\Gamma_{U \times \mathbb{R}_+}(q_{1}^{-1}H) \simeq R\mathcal{H}om(\mathbb{k}_{U \times \mathbb{R}_+}, q_{1}^{-1}H) \simeq \mathbb{k}_{U \times \mathbb{R}_+} \otimes q_{1}^{-1}H
\]
and we obtain \( i^{-1}R_jq_U^1H \simeq i^{-1}(\mathbb{k}_{U \times \mathbb{R}_+} \otimes q_{1}^{-1}H) \simeq H \). \( \square \)

**Definition 11.3.2.** For \( F, G \in \mathcal{D}^b_{\tau \geq 0}(\mathbb{k}_U) \) we define the morphism (functorial in \( F \) and \( G \))
\[
b(F, G): i^{-1}R_jR\mathcal{H}om(\Psi_U(F), \Psi_U(G)) \to R\pi_{U+}^0(\mu\mathcal{H}om(F, G)_{|T_{\tau > 0}U})
\]
as the composition of \[11.3.3\] and \[11.3.9\].

We prove below that \( b(F, G) \) is an isomorphism if \( G \in \mathcal{D}^b_{\tau \geq 0}(\mathbb{k}_U) \).

We need some remarks on the \( \mu\mathcal{H}om \) functor. We will use Sato’s distinguished triangle \[1.3.4\] and introduce the following notation.

**Notation 11.3.3.** Let \( X \) be a manifold. Let \( q_{X,1}, q_{X,2}: X \times X \to X \) be the projections and \( \delta_X: X \to X \times X \) the diagonal embedding. Let \( F, F' \in \mathcal{D}^b(\mathbb{k}_X) \). We set
\[
(11.3.10) \quad \mathcal{H}om'(F, F') := \delta_X^{-1}R\mathcal{H}om(q_{X,2}^{-1}F, q_{X,1}^{-1}F').
\]

Then Sato’s distinguished triangle becomes, for \( F, F' \in \mathcal{D}^b(\mathbb{k}_X) \),
\[
\mathcal{H}om'(F, F') \to R\mathcal{H}om(F, F')
\]
(11.3.11)
\[
\to R\pi_{U+}(\mu\mathcal{H}om(F, F')_{|T_{\tau > 0}}) \xrightarrow{+1}.
\]

**Lemma 11.3.4.** (i) Let \( f: X \to Y \) be a morphism of manifolds. Let \( F, F' \in \mathcal{D}^b(\mathbb{k}_Y) \) such that \( f \) is non-characteristic for \( SS(F) \) and \( SS(F') \). Then
\[
f^{-1}\mathcal{H}om'(F, F') \xrightarrow{\sim} \mathcal{H}om'(f^{-1}F, f^{-1}F').
\]

(ii) For \( F, F' \in \mathcal{D}^b(\mathbb{k}_X) \) we have \( SS(\mathcal{H}om'(F, F')) \subset SS(F)^a \oplus SS(F') \).

**Proof.** (i) We use the notations of Notation \[11.3.3\]. We set
\[
G = R\mathcal{H}om(q_{Y,2}^{-1}F, q_{Y,1}^{-1}F').
\]
Then \( SS(q_{Y,1}^{-1}F') \) and \( SS(G) \subset SS(F)^a \times SS(F') \) are non-characteristic for \( f \times f \). By Theorem \[1.2.7\] we deduce
\[
(f \times f)^{-1}q_{Y,1}^{-1}F' \simeq (f \times f)^{-1}q_{Y,1}^{-1}F' \otimes \omega_{X \times X | Y \times Y},
\]
\[
(f \times f)^{-1}G \simeq (f \times f)^{-1}G \otimes \omega_{X \times X | Y \times Y}^{-1}.
\]
Let us prove that the cone of (11.3.5) is isomorphic to $R\mathcal{O}$ by Lemma 11.1.6. We have $R\mathcal{O}$. By the microsupport, we remark as in (i) that the right-hand side runs over the open neighborhoods of $(x,t)$ in $U$. Hence $A \simeq 0$, as required.

(ii) Now we prove that (11.3.5) is an isomorphism. Using the hypothesis on the microsupport, we remark as in (i) that the right-hand side of (11.3.5) is isomorphic to $R\mathcal{O}(\mu hom(U(F), q_U^{-1}(G))|_{T_{>0}} U)$. Hence the cone of (11.3.5) is $B := i^{-1}Rj_*\mu hom'(U(F), q_U^{-1}(G))$, by the triangle (11.3.11). Let us prove that $B$ vanishes.

Proposition 11.3.5. Let $F, G \in D_{\tau \geq 0}(k_U)$. If $SS(F) \cap SS(G)$ is contained in $\{\tau > 0\}$, then we have

$$R\hat{\pi}_U, (\mu hom(F,G)|_{\hat{T}_U}) \simeq R\pi U, (\mu hom(F,G)|_{T_{>0}U})$$

and the morphism $b(F,G)$ of Definition 11.3.3 is an isomorphism.

Proof. (i) We recall that $supp \mu hom(F_1, F_2) \subset SS(F_1) \cap SS(F_2)$. Hence the hypothesis implies that $\mu hom(F,G)|_{T_{>0}U}$ is supported in $T_{>0}U$ and this gives the first isomorphism. To see that $b(F,G)$ is an isomorphism, we prove in (ii) below that the morphism (11.3.4), say $u$, induces an isomorphism $i^{-1}Rj_*(u)$, and in (iii) that (11.3.5) is an isomorphism.

(ii) Let us prove that $i^{-1}Rj_*(u)$ is an isomorphism. By the distinguished triangle (11.1.9) its cone is $A = i^{-1}Rj_*R\mathcal{O}(\Psi_U(F), r_U^{-1}(G))$ and we have to prove the vanishing of $A$. For a given $(x,t) \in U$ and $k \in \mathbb{Z}$ we have

$$H^k(A)(x,t) \simeq \lim_{W} \hom(\Psi_U(F)|_W, r_U^{-1}(G)|_W[k]),$$

where $W$ runs over the open subsets of $M \times \mathbb{R} \times R_{>0}$ such that $W$ is a neighborhood of $(x,t,0)$ in $U \times [0, +\infty[$. We may take $W = V_\gamma$, where $V$ runs over the open neighborhoods of $(x,t)$ in $U$. By (11.1.10) we have $\Psi_U(F)|_{V_\gamma} \simeq \Psi_V(F)|_{V}$. We also have $r_U^{-1}(G)|_{V_\gamma} \simeq r_V^{-1}(G)|_{V}$. Since $r_V^{-1} \simeq r_V^{-1}[1]$, the adjunction $(Rr_V^{-1}, r_V)$ gives

$$\hom(\Psi_V(F)|_{V}, r_V^{-1}(G)|_{V}[k]) \simeq \hom(Rr_V, \Psi_V(F)|_{V}, G|_{V}[k-1]).$$

By Lemma (11.1.6) we have $Rr_V, \Psi_V(F)|_{V} \simeq 0$ and we deduce the vanishing of (11.3.12) for all $(x,t) \in U$. Hence $A \simeq 0$, as required.

(iii) Now we prove that (11.3.5) is an isomorphism. Using the hypothesis on the microsupport, we remark as in (i) that the right-hand side of (11.3.5) is isomorphic to $R\hat{\pi}_U, (\mu hom(U(F), q_U^{-1}(G))|_{T_{>0}U})$. Hence the cone of (11.3.5) is $B := i^{-1}Rj_*\mu hom'(U(F), q_U^{-1}(G))$, by the triangle (11.3.11). Let us prove that $B$ vanishes.
Let \( p_U : U \times \mathbb{R} \to U \) be the projection. We set \( U_+ = U \times \mathbb{R}_{>0} \) and \( C = \mathcal{H}om'(Rj_*\Psi_U(F), p_U^{-1}(G)) \). Then

\[
Rj_*\mathcal{H}om'(\Psi_U(F), q_U^{-1}(G)) \simeq \Gamma_{U_+}C.
\]

By Lemma 11.1.7 we have \( SS(Rk^!(11.4.1) \mathcal{H}om'(\Psi_U(F), q_U^{-1}(G))) \simeq \mathcal{H}om'(\Psi_U(F), q_U^{-1}(G)) \). Since \( SS(k_{U_+}) = T^\tau_{\mathbb{R}}U \times \{v < 0\} \), we deduce \( \Gamma_{U_+}C \simeq D'(k_{U_+}) \otimes C \simeq C_{U_+} \) by Theorem 11.2.11. In particular \( B \simeq i^{-1}C \).

We have seen that \( i \) is non-characteristic for \( SS(Rj_*\Psi_U(F)) \) and \( SS(p_U^{-1}(G)) \). Since \( i^{-1}(Rj_*\Psi_U(F)) = 0 \), Lemma 11.3.4 gives \( i^{-1}C \simeq 0 \), as required.

\[\Box\]

11.4. Doubled sheaves

The isomorphism of Proposition 11.3.5 will be used mainly when \( SS(F) = SS(G) = \Lambda \) is a smooth Lagrangian submanifold of \( T^\tau_{>0}(M \times \mathbb{R}) \). In this case \( \mu \mathcal{H}om(F,G)|_{T^\tau_{>0}(M \times \mathbb{R})} \) is a locally constant sheaf on \( \Lambda \).

Unfortunately we will also need to consider the case where \( F \) and \( G \) have microsupport \( \Lambda \) only in a neighborhood of some open subset \( \Lambda_0 \) of \( \Lambda \). To easily handle this case we actually assume that \( \Lambda_0 \) is locally of the form \( \Lambda \cap T^\tau(U \times I) \), for some open set \( U \) of \( M \) and some open interval \( I \) of \( \mathbb{R} \), and that \( F \) (and \( G \) as well) is locally of the form \( \Gamma_{U_+}F' \) for some \( F' \) with \( SS(F') \subset \Lambda \). In the proof of Theorem 11.2.11 below we will glue such sheaves \( F \) or, rather, their images \( \Psi(F) \). For this reason we define a subcategory of \( D(k_{\Lambda_0 \times \mathbb{R}_{>0}}) \) of sheaves which are locally of the form \( \Psi(\Gamma_{U_+}F') \). We then give the analog of Proposition 11.3.5 for this subcategory (see Proposition 11.4.7 below).

For a family of subsets \( U_a, a \in A \), of some set \( E \) and for \( B \subset A \) we set \( U_B = \bigcap_{a \in B} U_a \) and \( U^B = \bigcup_{a \in B} U_a \).

Definition 11.4.1. Let \( \Lambda \subset T^\tau_{>0}(M \times \mathbb{R}) \) be a conic Lagrangian submanifold such that \( \Lambda \cap \mathbb{R}_{>0} \) is compact, the map \( \Lambda / \mathbb{R}_{>0} \to M \) is finite. A finite family \( \mathcal{V} = \{V_a; a \in A\} \) of open subsets of \( M \times \mathbb{R} \) is said adapted to \( \Lambda \) if the following conditions hold:

(i) for each \( a \in A \) we have \( V_a = U_a \times I_a \) and \( \Lambda \cap T^\tau V_a \) is contained in \( \pi_{M \times \mathbb{R}}^{-1}(U_a \times K) \) for some compact interval \( K \) of \( I_a \),

(ii) for all \( B, B' \subset A \) we have \( D'(k_{V_B}) \simeq k_{V_{B'}} \) and, setting \( \Lambda_+ = \Lambda \cup 0_M \),

\[ (SS(k_{V_B}) \simeq SS(k_{V_{B'}})^a) \cap (\Lambda_+ \simeq \Lambda_+) \subset 0_{M \times \mathbb{R}}. \]

We first check that we have enough such adapted families.
Lemma 11.4.2. Let \( \Lambda \subset T_{r>0}^*(M \times \mathbb{R}) \) be a conic Lagrangian submanifold such that \( \Lambda / \mathbb{R}_{r>0} \) is compact and let \( \Lambda = \bigcup_{i \in I} \Lambda_i \) be a finite covering by conic open subsets. Then there exists a Hamiltonian isotopy \( \Psi_t \) as closed to \( \text{id} \) as desired, and a finite family \( \{ V_a; a \in A \} \) of open subsets of \( M \times \mathbb{R} \) which is adapted to \( \Lambda' = \Phi_1(\Lambda) \) such that each connected component of \( \Lambda' \cap T^*V_a \), for \( a \in A \), is contained in \( \Phi_1(\Lambda_i) \), for some \( i \in I \).

Proof. (i) We will use the following fact (See [30, Prop. 8.4.1]). Let \( N \) be a manifold and \( \Sigma = \{ \Sigma_j; j \in J \} \) a Whitney stratification of \( N \). We set \( \Lambda_{\Sigma} = \bigcup_{j \in J} T_{\Sigma_j}^*N \). We have \( \Lambda_{\Sigma} + \Lambda_{\Sigma} = \Lambda_{\Sigma} \) by the Whitney condition. Now any sheaf \( F \in \mathcal{D}(k_N) \) which is constructible with respect to \( \Sigma \) (which means that \( F|_{\Sigma_j} \) is locally constant of finite rank for each \( j \in J \)) satisfies \( \text{SS}(F) \subset \Lambda_{\Sigma} \). Indeed, using excision distinguished triangles like \( F_{\Sigma_j} \to F \to F_{S,\Sigma_j}^{|-1} \), where \( S = \text{supp}(F) \) and \( \Sigma_j \) is of maximal dimension in \( S \), and the triangular inequality for the microsupport, we reduce the question to the case where \( F \) is locally constant on one stratum. In this last case the result follows from Example 11.2.2(ii), Theorem 11.2.13 and the property \( \Lambda_{\Sigma} + \Lambda_{\Sigma} = \Lambda_{\Sigma} \).

(ii) We can find a small Hamiltonian isotopy \( \Phi \) and a Whitney stratification of \( M \times \mathbb{R} \), say \( \Sigma = \{ \Sigma_j; j \in J \} \), such that \( \Sigma \) is a refinement of the partition of the front \( Fr_\Lambda := \pi_{M \times \mathbb{R}}(\Phi_1(\Lambda)) \) given by the function \( x \mapsto \min\{\text{rank of } d\pi(\xi); \pi(\xi) = x\} \). Then \( \Phi_1(\Lambda) \subset \Lambda_{\Sigma} \). Hence to check (11.4.1) it is enough to see \( (SS(k_V^B) + SS(k_{V'}^B)^n) \cap \Lambda_{\Sigma} \subset M \times \mathbb{R} \).

(iii) We choose a finite covering of \( Fr_\Lambda \), say \( W_a \), \( a \in A \), such that \( W_a = U_a \times I_a \) as in (i) of Definition 11.4.1 and \( U_a = \{ f_a < 0 \} \) for a \( C^\infty \) function \( f_a : M \to \mathbb{R} \). We can even assume that there exists a compact interval \( K_a \subset I_a \) such that \( \Lambda' \cap T^*W_a \) is contained in \( \pi_{M \times \mathbb{R}}^{-1}(U_a \times K_a) \). Let \( \xi_a = \{ \varepsilon_a; a \in A \} \) be a family of negative numbers. We define \( W_{a;\varepsilon} = \{ f_a < \varepsilon_a \} \times I_a \) and, for \( B \subset A \), we set \( W_{a;\varepsilon}^B = \bigcup_{a \in B} W_{a;\varepsilon_a} \). We choose \( \delta > 0 \) such that \( Fr_\Lambda \subset \bigcup_{a \in A} W_{a;\varepsilon_a}^B \).

Let \( E \subset [-\delta,0[^A \) be the subset formed by the \( \varepsilon \) such that:

(a) the hypersurfaces \( X_{a;\varepsilon_a} = \{ f_a = \varepsilon_a \} \), \( a \in A \), are smooth and intersect transversely, in the sense that their union is locally diffeomorphic to the embedding of coordinates hyperplanes in \( \mathbb{R}^n \),

(b) for any \( B \subset A \), the manifold \( X_{B;\xi} = \bigcap_{a \in B} (X_{a;\xi_a} \times I_a) \) intersects each stratum \( \Sigma_j \) of \( \Sigma \) transversely.

By the transversality theorem \( E \) is dense in \( [-\delta,0[^A \). Hence we only have to prove that, for any \( \xi \in E \), the family \( V_a = W_{a;\xi_a} \), \( a \in A \), satisfies
the conclusion of the lemma. For \( \varepsilon \in E \) we set \( \Lambda_\varepsilon = \bigcup_{a \in A} T_{X_a, \varepsilon \in \partial I_a} (M \times \mathbb{R}) \) and \( Y = \bigcup_{a \in A} (X_{a, \varepsilon \in \partial I_a}) \). We remark that \( \Lambda_\Sigma \) does not meet \( \pi_{M \times \mathbb{R}}^{-1}(Y) \). We can find a stratification \( \Sigma' \) of \( (M \times \mathbb{R}) \setminus Y \) such that \( \Lambda_\varepsilon \subset \Lambda_\Sigma \). We have \( \Lambda_\varepsilon \cap \Lambda_\varepsilon = \Lambda_\varepsilon \) and \( \Lambda_\varepsilon \cap \Lambda_\varepsilon \subset 0_{M \times \mathbb{R}} \). For \( B \subset A \) the open set \( W^B \cap ((M \times \mathbb{R}) \setminus Y) \) is constructible with respect to \( \Sigma' \) and we deduce \( \text{SS}(k_{W^B}) \subset \Lambda_\varepsilon \), away from \( Y \). The result follows. \[ \square \]

**Definition 11.4.3.** Let \( \Lambda \) and \( \mathcal{V} = \{V_a; a \in A\} \) be as in Definition 11.4.1. We set \( S_\Lambda = \oplus_{M \times \mathbb{R}}(\Lambda) \). Let \( V \subset M \times \mathbb{R} \) be an open subset. We denote by \( \mathcal{D}^{bd}_{A,V}(k_V) \) the subcategory of \( \mathcal{D}(k_{V \times \mathbb{R} > 0}) \) formed by the \( G \) such that there exists \( \varepsilon > 0 \) for which

(i) \( \text{supp}(G) \cap (V \times [0, \varepsilon[) \subset S_\Lambda \),

(ii) any point of \( V \) has a neighborhood \( W \) such that \( \Lambda \cap T^*W \) has finitely many connected components, say \( \Lambda_i, i \in I \), and for each \( i \in I \) there exist \( A_i \subset A \) and \( F_i \in \mathcal{D}_A(k_V) \) such that

\[
G|_{W^\varepsilon} \simeq \bigoplus_{i \in I} \Psi_W(\text{RG}_{V,A_i}(F_i))|_{W^\varepsilon},
\]

where \( W^\varepsilon = W \cap \cap (V \times [0, \varepsilon[) \) and \( V^{A_i} = \bigcup_{a \in A_i} V_a \).

**Lemma 11.4.4.** Let \( \Lambda \) and \( \mathcal{V} = \{V_a; a \in A\} \) be as in Definition 11.4.1. Let \( W \) be an open subset of \( M \times \mathbb{R} \) and let \( \Lambda_1 \) be a connected component of \( \Lambda \cap T^*W \). Let \( F \in \mathcal{D}_{A_1}(k_W) \) and \( B \subset A_1 \) be given. Then

(i) \( \text{SS}(\text{RG}_{V,B}(F)) \cap \Lambda \subset \Lambda_1 \cap T^*\mathbb{R}^B \),

(ii) there exists a neighborhood \( \Omega \) of \( \Lambda_1 \cap T^*\mathbb{R}^B \) in \( T^*W \) such that \( \text{SS}(\text{RG}_{V,B}(F)) \cap \Omega \subset \Lambda_1 \cap T^*\mathbb{R}^B \),

(iii) for \( \varepsilon > 0 \) we have \( \Psi_W(\text{RG}_{V,B}(F))|_{W^\varepsilon} \simeq \text{RG}_{V,B}(F)_{|0,\varepsilon]} \Psi_W(F) \),

(iv) for any \( G \in \mathcal{D}^{bd}_{A,V}(k_W) \) we have

\[
i^{-1}\text{Rj}_{*}\mathcal{R}\text{Hom}(G, \Psi_W(\text{RG}_{V,B}(F)))
\]

\[
\simeq \text{RG}_{V,B}(i^{-1}\text{Rj}_{*}\mathcal{R}\text{Hom}(G, \Psi_W(F)))
\]

**Proof.** (i)-(ii) We remark that (11.4.1) implies \( \text{SS}(k_{V,B}) \cap \Lambda = \emptyset \). Hence \( \text{SS}(\text{RG}_{V,B}(F)) \subset \text{SS}(k_{V,B})_{|0,\varepsilon]} + \Lambda_1 \) by Theorem 1.2.11. Then (11.4.1) again implies (i) and (ii).

(iii) For a submersion \( f \) the sheaf \( f^{-1}\text{R}\text{Hom}(H, H') \) is isomorphic to \( \mathcal{R}\text{Hom}(f^{-1}H, f^{-1}H') \). For \( H = k_{V,B} \) we obtain \( f^{-1}(\text{RG}_{V,B}F) \simeq \text{RG}_{f^{-1}(V,B)}(f^{-1}F) \). Using this isomorphism with \( f = q \) or \( r \) and the distinguished triangle (11.1.9) we deduce (iii).

(iv-a) The isomorphism (iv) is local on \( W \) and we can shrink \( W \) if necessary. Since \( G \in \mathcal{D}^{bd}_{A,V}(k_W) \) we can thus assume \( G = \Psi_W(\text{RG}_{V,B}(F)) \),
for some $B' \subset A$ and $F' \in D_A(k_W)$. We will prove

$$i^{-1}R_j^*R \mathcal{H}om(\Psi_W(R \Gamma_{V'B'}(F')), \Psi_W(R \Gamma_{VB}(F)))$$

$$\simeq R \Gamma_{V'B' \cap VB}(i^{-1}R_j^*R \mathcal{H}om(\Psi_W(F'), \Psi_W(F))).$$

(11.4.4)

This implies (11.4.3): use (11.4.4) as it is stated and also in the case where $V'B' = W$, together with $R \Gamma_{V'B'}(-) \simeq R \Gamma_{VB}(R \Gamma_{V'B'}(-))$.

Let us set $J = ]0, \varepsilon[, J' = ]-\varepsilon, \varepsilon[$. By (11.4.4) and Theorem 1.2.11 we have $R \Gamma_{V'B'}(F') \simeq (F')_{V'B'}$. We also have as in (iii) $\Psi_W((F')_{V'B'}) \simeq \Psi_W(F')_{V'B'}$. We set $H = R \mathcal{H}om(\Psi_W(F'), \Psi_W(F))$. Using the isomorphism $R \mathcal{H}om((-)_{Z'}, R \Gamma_{Z'}(-)) \simeq R \Gamma_{Z' \cap Z}R \mathcal{H}om(-,-)$, we deduce that the left hand side of (11.4.4) is

$$i^{-1}R_j^*R \Gamma_{(V'B' \cap VB) \times J}(H) \simeq i^{-1}R \Gamma_{(V'B' \cap VB) \times J}(R_j^*H)$$

and we are reduced to prove

$$i^{-1}R \Gamma_{(V'B' \cap VB) \times J}(R_j^*H) \simeq R \Gamma_{V'B' \cap VB}(i^{-1}R_j^*H).$$

For this it is enough to check

$$SS(k_{V'B' \cap VB}) \times 0_{J'} \cap SS(R_j^*(H)) = \emptyset,$$

$$SS(k_{V'B' \cap VB}) \cap SS(i^{-1}R_j^*(H)) = \emptyset.$$  

(11.4.5)

Indeed, (11.4.5), (11.4.4) and Theorem 1.2.11 imply the isomorphisms

$$R \Gamma_{(V'B' \cap VB) \times J}(R_j^*H) \simeq D'(k_{(V'B' \cap VB) \times J'}) \overset{\mathbb{L}}{\otimes} R_j^*H$$

$$\simeq q^{-1}D'(k_{V'B' \cap VB}) \overset{\mathbb{L}}{\otimes} R_j^*H,$$

$$R \Gamma_{V'B' \cap VB}(i^{-1}R_j^*H) \simeq D'(k_{V'B' \cap VB}) \overset{\mathbb{L}}{\otimes} i^{-1}R_j^*H.$$  

We then use the commutation of $i^{-1}$ with the tensor product.

(iv-b) Let us prove (11.4.5). Proposition 1.1.1(g) gives

$$R_j^*H \simeq R \mathcal{H}om(R_j^*\Psi_W(F'), R_j^*\Psi_W(F)).$$

For $F'' \in D(k_W)$ Lemma 11.1.7 says $R_j^*\Psi_W(F'') \simeq R_j^*\Psi_W(F''')$ and gives a bound for $SS(R_j^*\Psi_W(F'''))$. We deduce the following less precise bound which is easier to handle. For $S \subset T^*W$ and $\varepsilon > 0$ we define $N_{\varepsilon}(S) = \bigcup_{c \in [0, \varepsilon]} T_c(S)$ where $T_c$ is the vertical translation $T_c(x, t; \xi, \tau) = (x, t + c \xi, \tau)$. Lemma 11.1.7 implies, for $J' = ]-\varepsilon, \varepsilon[$,

$$SS(R_j^*\Psi_W(F''))_{|_{W \times J'}} \subset N_{\varepsilon}(SS(F''')) \times T^*J'.$$

By (11.4.4) and Theorem 1.2.11 we deduce

$$SS(R_j^*(H)) \subset N_{\varepsilon}(\Lambda_+ \oplus \Lambda_+) \times T^*J'.$$  

(11.4.6)
Finally we remark \( SS(\kappa q) \). When we take the inverse image by \( i \) in \((11.4.6)\) we can assume \( \varepsilon \) as small as we want and Theorem 11.2.7 gives
\[(11.4.7) \quad SS(i^{-1}R_j(H)) \subset \Lambda^\varepsilon \subset \Lambda^+.\]

Finally we remark \( SS(\kappa_{V\rightarrow B}^q) \subset SS(\kappa_V^q \cap \kappa_{V\rightarrow B}^a) \). Now we deduce the relations \((11.4.3)\) from \((11.4.6)\) (taking \( \varepsilon \) as small as required), \((11.4.7)\) and \((11.4.1)\). \( \square \)

For a subset \( \Xi \) of \( T^*(M \times \mathbb{R}) \) we introduce the notations \( \Xi^q = q_d q^{-1}_\pi(\Xi), \Xi^r = r_d r^{-1}_\pi(\Xi) \) and
\[\Xi^{q,\varepsilon} = \Xi^q \cap T^*(M \times \mathbb{R} \times ]0,\varepsilon[), \quad \Xi^{r,\varepsilon} = \Xi^r \cap T^*(M \times \mathbb{R} \times ]0,\varepsilon[).\]

We remark that \( \Xi^{q,\varepsilon} \) is diffeomorphic to \( \Xi \times ]0,\varepsilon[ \).

We will state the analog of Proposition 11.3.5 for \( \Lambda \). For \( G, G' \in \mathbb{D}^{dbl}_{\Lambda}(k_V) \), there exists a sheaf \( \mu hom^{dbl}(G, G') \) in \( \mathbb{D}(k) \) such that
\[\mu hom(G, G')|_{\Lambda^{\varepsilon}} \simeq p_\Lambda^{-1}(\mu hom^{dbl}(G, G')) \]
where \( p_\Lambda: \Lambda^{q,\varepsilon} \rightarrow \Lambda \) is the projection.

\[\text{Proof.}\] The objects of \( \mathbb{D}^{dbl}_{\Lambda}(k_V) \) are locally of the form \( \Psi_W(F) \) for \( W \subset V \) small enough and some \( F \in \mathbb{D}(k_W) \). Then Proposition 11.1.8 implies that the restriction of \( \mu hom(G, G')|_{\Lambda^{\varepsilon}} \) to \( W \times ]0,\varepsilon[ \) is of the form \( \mu hom(q_W^{-1}(F), q_W^{-1}(F')) \simeq q_W^{-1}_\pi \mu hom(F, F') \). In particular \( \mu hom(G, G')|_{\Lambda^{\varepsilon}} \) is constant on the fibers of the projection \( p_\Lambda \). Hence it is the inverse image of some sheaf \( \mu hom^{dbl}(G, G') \) by \( p_\Lambda \) (and we have \( \mu hom^{dbl}(G, G') = R p_\Lambda(\mu hom(G, G')|_{\Lambda^{\varepsilon}})) \). \( \square \)

The following result follows easily from the definition of \( \mathbb{D}^{dbl}_{\Lambda}(k_V) \) and Lemma 11.4.4 (ii).

**Lemma 11.4.6.** For \( G \in \mathbb{D}^{dbl}_{\Lambda}(k_V) \) there exists a unique open subset \( \Lambda_0 \subset \Lambda \cap T^*V \), that we denote \( SS^{dbl}(G) \), such that

1. for any open subset \( W \subset V \) where a decomposition \((11.4.2)\) holds we have \( \Lambda_0 = \bigcup_{i \in I} \Lambda_i \cap T^*V_{\Lambda_i} \) (with the notations of Definition \((11.4.3)\)).
2. for \( \varepsilon > 0 \) small enough we have \( SS(G) \cap \Lambda^{q,\varepsilon} = \Lambda_0^{q,\varepsilon} \),
(iii) there exists a neighborhood $\Omega$ of $\Lambda_0^{q,\varepsilon}$ in $T^* (V \times ]0,\varepsilon[)$ such that $\mathrm{SS}(G) \cap \Omega \subset \Lambda_0^{q,\varepsilon}$.

Let $\pi, \pi_{\Lambda_0^{q,\varepsilon}}, \pi_{\Lambda}$ be the projections from $T^* (V \times ]0,\varepsilon[)$, $\Lambda_0^{q,\varepsilon}$, $\Lambda$ respectively to $V \times ]0,\varepsilon[$ or $V$. Let $G, G' \in \mathcal{D}_{A,\Lambda}^{\ddbl}(k_V)$ and set $\Lambda_0 = \mathrm{SS}^{\ddbl}(G)$, $\Lambda'_0 = \mathrm{SS}^{\ddbl}(G')$. Lemma 11.4.6 implies that $\mu \operatorname{hom}^{\ddbl}(G, G')$ has support in $\Lambda_0 \cap \Lambda'$. Since $\Lambda'_0$ is open we have a natural morphism $(-) \to \Gamma G'_0 (-)$ and we deduce the following sequence of morphisms

$$
\mathcal{RHom}(G, G')|_{V \times ]0,\varepsilon[} \cong \mathcal{R}\pi_* \mu \operatorname{hom}(G, G')
\to \mathcal{R}(\pi_{A,\varepsilon})_* (\mu \operatorname{hom}(G, G')|_{A,\varepsilon})
\cong q_{V}^{-1} \mathcal{R}(\pi_{A})_* \mu \operatorname{hom}^{\ddbl}(G, G')
\to q_{V}^{-1} \mathcal{R}(\pi_{A})_* \Gamma G'_0 \mu \operatorname{hom}^{\ddbl}(G, G').
$$

We apply the functor $i^{-1} \mathcal{R}j_*$ to this sequence and we obtain a version of the morphism $b(F, G)$ of Definition 11.3.2 for $\mathcal{D}_{A,\Lambda}^{\ddbl}(k_V)$:

$$
b'(G, G') : i^{-1} \mathcal{R}j_* \mathcal{RHom}(G, G')
\to \mathcal{R}(\pi_{A})_* \Gamma G'_0 \mu \operatorname{hom}^{\ddbl}(G, G'),
$$

where $\Lambda'_0 = \mathrm{SS}^{\ddbl}(G')$. The Proposition 11.3.5 generalizes to this setting as follows.

**Proposition 11.4.7.** Let $G, G' \in \mathcal{D}_{A,\Lambda}^{\ddbl}(k_V)$. Then the morphism $b'(G, G')$ in (11.4.8) is an isomorphism.

**Proof.** Since the statement is local on $V$ we may as well assume that $G$ and $G'$ are decomposed as in (11.4.2) and it is enough to consider one summand in their decompositions. Hence we can assume that $G = \Psi_W (\Gamma V_B (F_0))$ and $G' = \Psi_W (\Gamma V_{B'} (F'_0))$ for some open subset $W \subset V$, $F_0, F'_0 \in \mathcal{D}_{A} (k_W)$ and $B, B' \subset A$. By Lemma 11.4.4 the left hand side of (11.4.8) becomes

$$
i^{-1} \mathcal{R}j_* \mathcal{RHom}(\Psi_W (\Gamma V_B (F_0)), \Psi_W (\Gamma V_{B'} (F'_0)))
\cong \Gamma V_{B'} (i^{-1} \mathcal{R}j_* \mathcal{RHom}(\Psi_W (\Gamma V_B (F_0)), \Psi_W (F'_0))).$$

We have $\mu \operatorname{hom}^{\ddbl}(G, G') \cong \mu \operatorname{hom}(\Gamma V_B (F_0), \Gamma V_{B'} (F'_0))|_{\Lambda}$ by Proposition 11.1.8. Let us set $\Lambda' = \mathrm{SS}(F'_0)$. We have $\mathrm{SS}^{\ddbl}(G') = \Lambda' \cap T^* V_{B'}$ and the right hand side of (11.4.8) becomes

$$
\Gamma G'_0 \mathcal{R}(\pi_{A})_* \mu \operatorname{hom}^{\ddbl}(\Gamma V_B (F_0), \Gamma V_{B'} (F'_0))
\cong \mathcal{R}(\pi_{A})_* \Gamma T^* V_{B'} \mu \operatorname{hom}(\Gamma V_B (F_0), F'_0)
\cong \mathcal{R}(\pi_{A})_* \Gamma V_{B'} (\mathcal{R}(\pi_{A})_* (\mu \operatorname{hom}(\Gamma V_B (F_0), F'_0)),$
where the first isomorphism follows from $\mathbb{R}\Gamma_{\mathcal{N} \cap T^*V''} \simeq \mathbb{R}\Gamma_{\Lambda'} \mathbb{R}\Gamma_{T^*V''}$ and the fact that $\mathbb{R}\Gamma_{U}(H)$ only depends on $H|_{U}$ when $U$ is open (here $U = T^*V''$) and the second isomorphism follows from the inclusion $\text{supp}(\mu_{\text{hom}}(H, F'_0)) \subset \Lambda'$, whatever $H$. Since $\text{SS}(F'_0) \subset \{ \tau > 0 \}$ we can apply Proposition [11.3.5] with $F = \mathbb{R}\Gamma_{V'}(F_0)$, $G = F'_0$ and the result follows.

**Corollary 11.4.8.** Let $G \in D_{\Lambda, \mathbb{N}}^{\text{dbl}}(k_V)$ and $\Lambda_0 = SS_{\text{dbl}}^{\text{dbl}}(G) \subset T^*V$ (see Lemma [11.4.6]). Let $\Lambda_0 = \Lambda_1 \cup \Lambda_2$ be a decomposition of $\Lambda_0$ where $\Lambda_1$ and $\Lambda_2$ are unions of connected components of $\Lambda_0$. Let $V' \subset V$ be a relatively compact open subset. Then there exists a decomposition $G|_{V'} \simeq G_1 \oplus G_2$ in $D_{\Lambda, \mathbb{N}}^{\text{dbl}}(k_V)$ such that $SS^{\text{dbl}}_{\text{dbl}}(G_i) = \Lambda_i \cap T^*V'$, $i = 1, 2$.

**Proof.** (i) By Proposition [11.4.7] we have

$$H^0(V; i^{-1}\mathbb{R}j_!\mathbb{R}\text{Hom}(G, G)) \simeq H^0(\Lambda; \mu_{\text{hom}}^{\text{dbl}}(G, G)). \tag{11.4.9}$$

The identity induces a section $\text{id}_G$ of the left hand side of (11.4.9) and we let $\mu_{\text{id}}^G$ be the corresponding section of $\mu_{\text{hom}}^{\text{dbl}}(G, G)$. In the case $G = G'$ the definition of $\mu_{\text{hom}}^{\text{dbl}}(G, G')$ gives $\mu_{\text{hom}}^{\text{dbl}}(G, G) \simeq \mathbb{R}\Gamma_{\Lambda_0} \mu_{\text{hom}}^{\text{dbl}}(G, G)$. Since $\Lambda_0$ is split into two open and closed subsets we obtain

$$H^0(\Lambda; \mu_{\text{hom}}^{\text{dbl}}(G, G)) \simeq \bigoplus_{i=1,2} H^0(\Lambda_i; \mu_{\text{hom}}^{\text{dbl}}(G, G))$$

and we write $\mu_{\text{id}}^G = e_1 + e_2$ according to this decomposition. Since $\Lambda_1$ and $\Lambda_2$ are disjoint we have $e_1 e_2 = e_2 e_1 = 0$. Hence $e_1$ and $e_2$ are orthogonal idempotents. By (11.4.9) again we deduce a decomposition $\mu_{\text{id}}_G = f_1 + f_2$ where $f_1$ and $f_2$ are also orthogonal idempotents.

(ii) We can find $f'_1, f'_2$ in $H^0(V^+; \mathbb{R}\text{Hom}(G, G))$ which represent $f_1, f_2$, for some open subset $V^+$ of $V \times \mathbb{R}_{>0}$ such that $V \times \{0\} \cup V^+$ is a neighborhood of $V \times \{0\}$. Up to shrinking $V^+$ we can also assume that $f'_1, f'_2$ are orthogonal idempotents (using (11.4.9) again). By [8] we deduce a corresponding decomposition $G_{V^+} \simeq G_1 \oplus G_2$ in $D(k_{V^+})$.

(iii) It remains to check that $G_i \in D_{\Lambda_i, \mathbb{N}}^{\text{dbl}}(k_V)$ and $SS_{\text{dbl}}^{\text{dbl}}(G_i) = \Lambda_i \cap T^*V'$. For this we use the local decomposition (11.4.2) of $G$ over a subset $W \times ]0, \varepsilon[$. We define $G'_1$ (resp. $G'_2$) to be the sum of the summands in (11.4.2) indexed by the $j \in I$ so that $\Lambda_j \cap T^*V_{A_j}$ is contained in $\Lambda_1$ (resp. $\Lambda_2$). This gives another decomposition of $G$ and corresponding idempotents $f''_1, f''_2$. Since $SS(G'_i)$ contains $\Lambda_i$ the section of $\mu_{\text{hom}}^{\text{dbl}}(G, G)$ associated with $f''_i$ by (11.4.9) must be $e_i$. We deduce $f'' = f_i'$ and then $G'_i \simeq G_i|_{W \times ]0, \varepsilon[}$, which proves the result. \(\square\)
Part 12. Quantization

The main result of this part is that, for any global object $\mathcal{F}$ of the Kashiwara-Schapira stack $\mu\text{Sh}(k_\Lambda)$, there exists $F \in \text{D}(k_{M \times \mathbb{R}})$ with $\text{SS}(F) = \Lambda$ which represents $\mathcal{F}$, when $\Lambda$ is the conification of a compact exact Lagrangian submanifold of $T^*M$ (see (12.0.1) below). This recover a result of Viterbo in [51] who proves the existence of such a sheaf using Floer theory (the proof of [51] was sketched in [50] in 2011).

We first consider a compact Legendrian submanifold of $J^1M$, or equivalently, a closed conic Lagrangian submanifold $\Lambda$ of $T^*_{\tau>0}(M \times \mathbb{R})$ such that $\Lambda/\mathbb{R}_{>0}$ is compact. We apply the procedure sketched in the introduction of Part 11 and we prove that any object $\mathcal{F} \in \mu\text{Sh}(k_\Lambda)$, or $\mathcal{F} \in \mu\text{Sh}^{\text{orb}}(k_\Lambda)$, is represented by some $F \in \text{D}(k_{M \times \mathbb{R}})$, or $F \in \text{D}_{/\mu}^!(k_{M \times \mathbb{R}})$, such that $\text{SS}(F) = \Lambda \sqcup T_\varepsilon(\Lambda)$ for $\varepsilon > 0$ small, where $T_\varepsilon$ is the translation along the factor $\mathbb{R}$.

Then, assuming that $\Lambda/\mathbb{R}_{>0}$ has no Reeb chord we will prove that there exists a representative $F \in \text{D}(k_{M \times \mathbb{R}})$ such that $\text{SS}(F) = \Lambda$. We recall that “having no Reeb chord” means that $\rho_M: T^*_{\tau>0}(M \times \mathbb{R}) \to T^*M, (x,t;\xi,\tau) \mapsto (x;\xi/\tau)$, induces an injection $\Lambda/\mathbb{R}_{>0} \hookrightarrow T^*M$. The image $\tilde{\Lambda} = \rho_M(\Lambda)$ is then a compact exact Lagrangian submanifold of $T^*M$ in the sense that $\alpha_M|_{\tilde{\Lambda}}$ is exact. The link between $\Lambda$ and $\tilde{\Lambda}$ is given by

$$(12.0.1) \quad \Lambda = \{(x,t;\xi,\tau); \tau > 0, (x;\xi/\tau) \in \tilde{\Lambda}, t = -f(x;\xi/\tau)\},$$

where $f$ is a primitive of $\alpha_M|_{\tilde{\Lambda}}$.

In Section 12.4 we see that, for two sheaves $F, G \in \text{D}(k_{M \times \mathbb{R}})$ with microsupport $\Lambda$, we have $\text{RHom}(F,G) \simeq \text{R}\Gamma(\Lambda; \mu\text{hom}(F,G))$. We also prove $\text{RHom}(F,G) \simeq \text{RHom}(F_+,G_+)$, where $F_+ = F|_{M \times \{t\}}$ for any $t \gg 0$. This will be used in Part 13 to prove that $\Lambda$ is homotopically equivalent to $M$.

Now we introduce some notations. We first remark that, by Theorem 2.1.1 we can as well move $\Lambda$ by any contact isotopy of $J^1M$ and assume from the beginning that it satisfies any generic hypothesis. In particular we can assume that the map $\Lambda/\mathbb{R}_{>0} \to M$ is finite and that there exists an adapted family $\mathcal{V} = \{V_a; a \in A\}$ in the sense of Definition 11.4.1. We let $A_b, b \in B_a$, be the family of components of $\Lambda \cap T^*V_a$. We set $B = \bigsqcup_{a \in A} B_a$ and we let $\sigma: B \to A$ be the obvious map. Hence $\Lambda_b$ is a component of $\Lambda \cap T^*V_{\sigma(b)}$.

For an open subset $V \subset M \times \mathbb{R}$ we have introduced the subcategory $\text{D}_{/\mu}^{\text{dbl}}(k_{V})$ of $\text{D}(k_{M \times \mathbb{R}_{>0}})$ in Definition 11.4.3. For $G \in \text{D}_{/\mu}^{\text{dbl}}(k_{V})$ we have defined $\text{SS}^{\text{dbl}}(G)$ in Lemma 11.4.6. It is an open subset of $\Lambda \cap T^*V$.
of the form \((\bigcup_{b \in B'} \Lambda_b) \cap T^*V\) for some \(B' \subset B\). We choose \(B' \subset B\) and set \(\Lambda_0 = \bigcup_{b \in B'} \Lambda_b\). We define \(D_{\Lambda_0,V}^{dbl}(k_V)\) as the full subcategory of \(D_{A,V}^{dbl}(k_V)\) formed by the \(G\) with \(\text{SS}^{dbl}(G) = \Lambda_0 \cap T^*V\). By (ii) of Lemma 11.4.6 for \(G \in D_{\Lambda_0,V}^{dbl}(k_V)\) there exists \(\epsilon > 0\) such that \(G|_{V \times [0,\epsilon[}\) belongs to \(D_{(\Lambda_0^\epsilon)}^{b,k}(k_V|_{X \times [0,\epsilon[})\). Since \(\Lambda_0^\epsilon\) is diffeomorphic to \(\Lambda_0 \times [0,\epsilon[\), the categories \(\mu \text{Sh}(k_{\Lambda_0})\) and \(\mu \text{Sh}(k_{\Lambda_0^\epsilon})\) are equivalent. Hence the functor \(m_{\Lambda}: D_{(\Lambda)}^{b,k}(k_V) \to \mu \text{Sh}(k_{\Lambda_0\cap T^*V})\) extends naturally as

\[
m_{\Lambda_0}^{dbl}: D_{\Lambda_0,V}^{dbl}(k_V) \to \mu \text{Sh}(k_{\Lambda_0\cap T^*V}).
\]

The same definitions make sense for the orbit category. We define the subcategory \(D_{/[1],\Lambda_0,V}^{dbl}(k_V)\) of \(D_{/[1],(k_V \times \mathbb{R})}^{dbl}\) as in Definition 11.4.3 replacing everywhere \(D(k_X)\) by \(D_{/[1]}(k_X)\). We also define \(D_{/[1],\Lambda_0,V}^{dbl}(k_V)\) as above and a functor

\[
m_{\Lambda_0}^{dbl}: D_{/[1],\Lambda_0,V}^{dbl}(k_V) \to \mu \text{Sh}^{\text{orb}}(k_{\Lambda_0\cap T^*V}).
\]

In Theorems 12.1.1 and 12.2.2 we see that the functors \(m_{\Lambda_0}^{dbl}\) and \(m_{\Lambda_0}^{dbl}\) are essentially surjective. The microsupport of an object of \(D_{\Lambda,V}^{dbl}(k_V)\) is made of two copies of \(\Lambda\). In the Corollaries 12.3.3 and 12.3.4 we see that, if we have no Reeb chords, we can translate one copy of \(\Lambda\) vertically using a Hamiltonian isotopy and obtain an object of \(D_{\Lambda}(k_{M \times \mathbb{R}})\) from a given one in \(D_{\Lambda_0,V}^{dbl}(k_{M \times \mathbb{R}})\). In \(\Sigma\) we see a relation between objects of \(D_{\Lambda}(k_{M \times \mathbb{R}})\), their restrictions to \(M \times \{t_0\}, t_0 \gg 0\), and their microlocalizations; in particular we see that \(F \mapsto F|_{M \times \{t_0\}}\) induces an equivalence of categories between sheaves on \(M \times \mathbb{R}\) with microsupport \(\Lambda\) and vanishing on \(M \times \{t\}, t \ll 0\), and locally constant sheaves on \(M\).

12.1. Quantization for the Doubled Legendrian

We assume that the sets \(V_a\) are small enough so that, for each \(a \in A\), the intersection \(\Lambda \cap T^*V_a\) has finitely many connected components. We let \(\Lambda_b, b \in B_a\), be the family of components of \(\Lambda \cap T^*V_a\). We set \(B = \bigsqcup_{a \in A} B_a\) and we let \(\sigma: B \to A\) be the obvious map. Hence \(\Lambda_b\) is a component of \(\Lambda \cap T^*V_{\sigma(b)}\). We also assume that, for each \(b \in B, \Lambda_b\) is contractible and there exist a neighborhood \(V_b'\) of \(\overline{V_{\sigma(b)}}\) and \(F_b \in D(k_{V_b'})\) such that \(\text{SS}(F_b) \subset \Lambda \cap T^*V_b', F_b\) is simple and \(\text{SS}(F_b) \cap T^*V_{\sigma(b)} = \Lambda_b\).

**Theorem 12.1.1.** In the above setting let \(B'\) be a subset of \(B\) and set \(\Lambda_0 = \bigcup_{b \in B'} \Lambda_b\). Then, for any pure object \(F \in \mu \text{Sh}(k_{\Lambda_0})\) there exists \(F \in D_{\Lambda_0,V}^{dbl}(k_{M \times \mathbb{R}})\) such that \(m_{\Lambda_0}^{dbl}(F) \simeq F\).
Proof. (i) We proceed by induction on $|B'|$. Let $b \in B$. Since $\Lambda_b$ is contractible, the objects of $\mu\mathbf{Sh}(k_{\Lambda_b})$ are of the form $\mathfrak{m}_{\Lambda_b}(E_{V_b}^{1}) \otimes F_b$ for some $E \in D(k)$. By definition $F = \Psi_{\nu_{\sigma(b)}}(R\Gamma_{\nu_{\sigma(b)}}(E_{V_b}^{1}) \otimes F_b))$ belongs to $D^{\text{dgl}}_{\Lambda_b}(k_{M \times R})$ and satisfies $\mathfrak{m}^{\text{dgl}}_{\Lambda_b}(F) \simeq F$. This proves the case $B' = \{b\}$.

(ii) Now we write $B' = B'' \cup \{b\}$ and assume that the result holds for $B''$. We set $\Lambda_1 = \bigcup_{b \in B''} \Lambda_b$. We let $\Lambda'_b$ be the component of $\Lambda_1 \cap T^* V'_b$ containing $\Lambda_b$. We set $\Lambda'_0 = \Lambda_1 \cup \Lambda'_b$. Up to choosing a smaller set $V'_b$ we can assume that $\mathcal{F}$ extends as an object of $\mathcal{F} \in \mu\mathbf{Sh}(k_{\Lambda'_0})$.

(iii) By the induction hypothesis there exist $F_1 \in D^{\text{dgl}}_{\Lambda'_1}(k_{M \times R})$ and an isomorphism $\varphi_1 : \mathfrak{m}^{\text{dgl}}_{\Lambda'_1}(F_1) \simeq F|_{\Lambda_1}$. By (i) there also exist $G \simeq E_{V_b}^{1} \otimes F_b$ in $D(k_{V'_b})$ and an isomorphism $\varphi_2 : m_{\Lambda'_0}(G) \simeq F|_{\Lambda'_0}$. We set $\Xi = \Lambda_1 \cap \Lambda'_b$ and $u = \varphi_1^{-1} \circ \varphi_2 : m_{\Lambda'_0}(G)|_{\Xi} \simeq m^{\text{dgl}}_{\Lambda'_1}(F_1)|_{\Xi}$.

(iv) We set $\Lambda'_1 = \Lambda'_0 \cap \Lambda_1$ and $\Lambda''_1 = \Lambda'_0 \cap \Lambda_1 \setminus \Lambda'_1$. By Corollary 11.4.8 we can decompose $F_1|_{V'_b \times 0, \varepsilon} \simeq F'_1 \oplus F''_1$ such that $F'_1 \in D^{\text{dgl}}_{\Lambda'_1}(k_{V'_b})$ and $F''_1 \in D^{\text{dgl}}_{\Lambda''_1}(k_{V'_b})$. Then $m^{\text{dgl}}_{\Lambda'_1}(F_1)|_{\Xi} \simeq m^{\text{dgl}}_{\Lambda'_1}(F'_1) \oplus m^{\text{dgl}}_{\Lambda''_1}(F''_1)$ and the morphism $u$ of (iii) factorizes through $m^{\text{dgl}}_{\Lambda'_1}(F'_1)$ since the support of $m_{\Lambda'_0}(G)$ is contained in $\Lambda'_b$.

(v) We recall that the $\mathcal{H}_{\text{om}}$ sheaf in $\mu\mathbf{Sh}(k_{\Lambda_b})$ is induced by $\mathcal{H}^0 \mu\text{hom}$. Hence $u$ can be seen as an element of $\Gamma(\Xi; \mathcal{H}^0 \mu\text{hom}^{\text{dgl}}(\Psi_{V'_b}(G), F'_1)|_{\Xi})$. By the purity hypothesis $\mu\text{hom}^{\text{dgl}}(\Psi_{V'_b}(G), F'_1)|_{\Xi}$ is concentrated in degree 0 and $u$ can be seen as an element of $\mathcal{H}^0(\Xi; \mu\text{hom}^{\text{dgl}}(\Psi_{V'_b}(G), F'_1)|_{\Xi})$. By Proposition 11.4.7 we have

$$
\mathcal{H}^0(\Xi; \mu\text{hom}^{\text{dgl}}(\Psi_{V'_b}(G), F'_1)|_{\Xi}) \simeq \mathcal{H}^0(\Theta'_b; i^{-1}R\Delta_{\varepsilon}\mathcal{H}_{\text{om}}(\Psi_{V'_b}(G), F'_1)).
$$

Hence there exists $v : \Psi_{V'_b}(G) \rightarrow F'_1$ representing $u$ defined on some open subset $W$ of $V'_b \times 0, \varepsilon$ such that $V'_b \cup W$ is a neighborhood of $V'_b$. Up to shrinking $\varepsilon$ we can assume that $W$ contains $V_{\sigma(b)} \times 0, \varepsilon$.

(vi) We set for short $W_b = V_{\sigma(b)} \times 0, \varepsilon$. The morphism $v$ induces $v' : R\Gamma_{W_b}(\Psi_{M \times R}(G)) \rightarrow R\Gamma_{W_b}(\Psi_{M \times R}(F'_1)))$. We denote by $f$ the composition $F_1 \xrightarrow{g} R\Gamma_{W_b}(F_1) \xrightarrow{h} R\Gamma_{W_b}(F'_1)$ where $g$ is the natural morphism and $h$ is induced by the decomposition $F_1 |_{V'_b \times 0, \varepsilon} \simeq F'_1 \oplus F''_1$ in (iv).

Now we define $F \in D(k_{M \times R})$ by the distinguished triangle

$$(12.1.1) \quad F \rightarrow F_1 \oplus R\Gamma_{W_b}(\Psi_{M \times R}(G)) \xrightarrow{(f_{-1}, -v')} R\Gamma_{W_b}(F'_1) \xrightarrow{+1}. $$

Then $F \in D_{\Lambda_0}(k_{M \times R})$ and $m^{\text{dgl}}_{\Lambda_0}(F) \simeq F$. □
12.2. The triangulated orbit category case

We checked in Sections 9.1 and 9.2 that the results we used in the category $D^{b}(k_{M})$ have analogs in the category $D^{b}_{\text{tr}}(k_{M})$. In particular we have already defined a Kashiwara-Schapira stack $\mu \text{Sh}^{\text{orb}}(k_{\lambda})$ in this situation. However the proof of Theorem 12.1.1 does not work because we used the fact that some $\mu \text{hom}$ sheaf was concentrated in degree 0, which makes no sense in the orbit category. We can still prove the existence part of this theorem for the triangulated orbit category by gluing two sheaves obtained on two open subsets by Theorem 12.1.1. For this we first remark in Lemma 12.2.1 below that we can decompose $\Lambda$ in two open subsets with vanishing Maslov classes.

**Lemma 12.2.1.** Let $X$ be a manifold and let $c \in H^{1}(X; \mathbb{Z}_{X})$. Then there exists a map $f: X \to S^{1}$ of class $C^{\infty}$ such that $c = f^{*}(<\delta)$, where $\delta \in H^{1}(S^{1}; \mathbb{Z}_{S^{1}})$ is the canonical class. In particular, for any covering $S_{1} = I_{1} \cup I_{2}$ by two open intervals, the restrictions $c|_{f^{-1}(I_{i})} \in H^{1}(f^{-1}(I_{i}); \mathbb{Z}_{f^{-1}(I_{i})})$ vanish, for $i = 1, 2$.

**Proof.** Since $H^{1}(X; \mathbb{Z}_{X}) \to H^{1}(X; \mathbb{R}_{X})$ is injective, it is enough to prove the result for the image of $c$ in $H^{1}(X; \mathbb{R}_{X})$, which we represent by a 1-form $\alpha$. Let $r: X' \to X$ be the universal covering of $X$ and let $g: X' \to \mathbb{R}$ be a primitive of $r^{*}(\alpha)$. Then, for any $x_{1}, x_{2} \in X'$ such that $r(x_{1}) = r(x_{2})$ we have $g(x_{1}) - g(x_{2}) = \langle c, \gamma \rangle$, where $\gamma$ is the loop at $g(x_{1})$ determined by $x_{1}, x_{2}$. Hence $g(x_{1}) - g(x_{2})$ is an integer and $g$ descends to a map $f: X \to S^{1}$ which satisfies the conclusion of the lemma. □

For the next result the ring is $k = \mathbb{Z}/2\mathbb{Z}$.

**Theorem 12.2.2.** For any global object $\mathcal{F}$ of $\mu \text{Sh}^{\text{orb}}(k_{\lambda})$ there exists an object $F \in D^{\text{db}}_{\text{tr}}(k_{M \times \mathbb{R}})$ such that $\mathcal{W}_{\lambda}^{\text{db}}(F) \simeq \mathcal{F}$.

**Proof.** (i) By Proposition 10.4.3 $\mu \text{Sh}^{\text{orb}}(k_{\lambda})$ has a unique simple object, $\mathcal{F}_{0}$, and $\mathcal{F}$ is of the type $\mathcal{F} \simeq \mathcal{F}_{0} \otimes L$ for some $L \in \text{Loc}(k_{\lambda})$.

We let $\mu_{1}(\Lambda) \in H^{1}(\Lambda; \mathbb{Z}_{\Lambda})$ be the Maslov class of $\Lambda$. We choose $f: \Lambda \to S^{1}$ as in Lemma 12.2.1 and a covering $S_{1} = I_{+} \cup I_{-}$ by two open intervals. We set $\Lambda_{\pm} = f^{-1}(I_{\pm})$. Then $\mu_{1}(\Lambda)|_{\Lambda_{\pm}} = 0$ and the categories $\mu \text{Sh}(k_{\Lambda_{\pm}})$ have simple objects, say $\mathcal{F}_{0,\pm}$. Their images in $\mu \text{Sh}^{\text{orb}}(k_{\Lambda_{\pm}})$ are $\mathcal{F}_{0}|_{\Lambda_{\pm}}$ because $\mu \text{Sh}^{\text{orb}}(k_{\Lambda_{\pm}})$ has a unique simple object. The intersection $I_{+} \cap I_{-}$ is the union of two intervals, say $I_{a}, I_{b}$. We set $\Lambda_{a} = f^{-1}(I_{a})$, $\Lambda_{b} = f^{-1}(I_{b})$ and $\mathcal{F}_{0,a} = \mathcal{F}_{0,+}|_{\Lambda_{a}}$, $\mathcal{F}_{0,b} = \mathcal{F}_{0,+}|_{\Lambda_{b}}$. We remark that simple objects in $\mu \text{Sh}(k_{\Xi})$, for $\Xi$ open in $\Lambda$, with coefficients $k = \mathbb{Z}/2\mathbb{Z}$, are unique up to shift and up to a unique isomorphism.
Hence we have the following canonical isomorphisms

$\varphi^a_+ = \text{id}: F_{0,a} \sim \sim F_{0,|\Lambda_a|}$, $\varphi^b_+ = \text{id}: F_{0,b} \sim \sim F_{0,|\Lambda_b|}$,

$\varphi^a_- : F_{0,a} \sim \sim F_{0,-|d_a|}$, $\varphi^b_- : F_{0,b} \sim \sim F_{0,-|d_b|}$,

where $d_a, d_b \in \mathbb{Z}$ are locally constant functions on $\Lambda_a, \Lambda_b$. We set

$F_+ = F_{0,\pm} \otimes L$, $F_a = F_{0,a} \otimes L$, $F_b = F_{0,b} \otimes L$ and $\Phi^*_\pm = \varphi^*_\pm \otimes \text{id}_L$.

(ii) Up to shrinking $\Lambda_0$ and $\Lambda_1$ we can find a finite family $\mathcal{V} = \{V_a; a \in A\}$ of open subsets of $M \times \mathbb{R}$ which is adapted to $\Lambda$ such that $\Lambda_+$ and $\Lambda_-$ are of the form $\Lambda^B$ for some $B \subset A$.

By Theorem [12.1.1] there exist $F_\pm \in D^\mathcal{db}_{\Lambda \pm}(k_{M \times \mathbb{R}})$, $F_* \in D^\mathcal{db}_{\Lambda*}(k_{M \times \mathbb{R}})$, for $* = a, b$, such that $m^\mathcal{db}_\Lambda(F_\pm) \simeq F_\pm$ and $m^\mathcal{db}_\Lambda(F_*) \simeq F_*$. Moreover, by Proposition [11.4.7] we have morphisms $\Psi^+_\pm : F_\pm \to F_\pm$ and $\Psi^-_* : F_* \to F_-|d_*|$ representing $\Phi^*_\pm$. In $D^b_{/\mathcal{V}}(k_{M \times \mathbb{R}}|0,\mathcal{V})$ we have $F_- \simeq F_-|d_*|$ and we can define $F \in D^b_{/\mathcal{V}}(k_{M \times \mathbb{R}}|0,\mathcal{V})$ by the distinguished triangle

$$F_a \oplus F_b \xrightarrow{(\psi_a^\pm, \psi_b^\pm)} F_+ \oplus F_- \to F \xrightarrow{+1}.$$ 

Then $m^\mathcal{db}_\Lambda(F) \simeq F$. \hfill \qed

12.3. Translation of the microsupport

Now we assume that the Legendrian submanifold $\Lambda/\mathbb{R}_{>0}$ of $J^1M$ has no Reeb chord, that is, the map $T^*_\tau(M \times \mathbb{R}) \to T^*M$, $(x, t; \xi, \tau) \mapsto (x; \xi/\tau)$, induces an injection $\Lambda/\mathbb{R}_{>0} \hookrightarrow T^*M$ (see [12.0.1]).

For $u \in \mathbb{R}$ we define the translation $T_u : M \times \mathbb{R} \to M \times \mathbb{R}$, $(x, t) \mapsto (x, t + u)$. We denote by $T'_u : T^*(M \times \mathbb{R}) \to T^*(M \times \mathbb{R})$, $(x, t; \xi, \tau) \mapsto (x, t + u; \xi, \tau)$, the induced map on the cotangent bundle. We also introduce some notations, for $\Lambda \subset T^*_\tau(M \times \mathbb{R})$:

\begin{equation}
\Lambda_u = \Lambda \cup T'_u(\Lambda) \subset T^*_\tau(M \times \mathbb{R}), \quad \text{for } u > 0,
\end{equation}

\begin{equation}
\Lambda^+ = q_d q_\pi^{-1}(\Lambda) \cup r_d r_\pi^{-1}(\Lambda) \subset T^*_\tau(M \times \mathbb{R} \times \mathbb{R}_{>0}).
\end{equation}

We remark that $\Lambda^+$ is non-characteristic for the inclusions $i_u$, $u > 0$, and that $\Lambda_u = (i_u)_d((i_u)_\pi^{-1}(\Lambda^+))$.

**Lemma 12.3.1.** There exists $\phi : T^*(M \times \mathbb{R}) \times \mathbb{R}_{>0} \to \hat{T}^*(M \times \mathbb{R})$, a homogeneous Hamiltonian isotopy, such that $\phi_1 = \text{id}$ and, using the notations [11.5.5] and [12.3.1], we have $\Gamma_\phi \circ^{\alpha} \Lambda_1 = \Lambda^+$. In particular $\phi_u(\Lambda_1) = \Lambda_u$, for all $u > 0$.

**Proof.** (i) We set $I = \mathbb{R}_{>0}$. Since the map $(x, t; \xi, \tau) \mapsto (x; \xi/\tau)$ induces an injection $\Lambda/\mathbb{R}_{>0} \hookrightarrow T^*M$, the sets $\Lambda$ and $T'_u(\Lambda)$ are disjoint for all
Then $\Lambda^0$ and $\Lambda^1$ are disjoint and the projections $\Lambda^i/\mathbb{R}_{>0} \to I$ are proper for $i = 0, 1$. Hence we can find a conic neighborhood $\Omega$ of $\Lambda^0$ in $\hat{T}^*(M \times \mathbb{R}) \times I$ such that $\bar{\Omega} \cap \Lambda^0 = \emptyset$ and the projection $\bar{\Omega}/\mathbb{R}_{>0} \to I$ is proper, that is, $\bar{\Omega} \cap (\hat{T}^*(M \times \mathbb{R}) \times \{u\})$ is compact for all $u > 0$.

(ii) We choose a $C^\infty$-function $h: \hat{T}^*(M \times \mathbb{R}) \times I \to \mathbb{R}$ such that,

(a) $h_u := h|_{\hat{T}^*(M \times \mathbb{R}) \times \{u\}}$ is homogeneous of degree 1, for all $u \in I$,

(b) $h$ vanishes outside $\Omega$,

(c) there exists a neighborhood $\Omega'$ of $\Lambda^1$ such that $h(x, t; \xi, \tau) = -\tau$, for all $(x, t; \xi, \tau) \in \Omega'$.

By (a), (b) and the compactness of $(\bar{\Omega} \cap (\hat{T}^*(M \times \mathbb{R}) \times \{u\}))/\mathbb{R}_{>0}$, the Hamiltonian flow of $h$, say $\phi$, is defined on $I$ (the initial time here is $t_0 = 1$). Then $\phi_u$ is the identity map outside $\Omega$ for all $u \in I$ and $\phi_u(x, t; \xi, \tau) = (x, t + u - 1; \xi, \tau)$, for all $((x, t; \xi, \tau), u) \in \Omega'$. Since $\Lambda^0 \subset (\hat{T}^*(M \times \mathbb{R}) \setminus \Omega)$ and $\Lambda^1 \subset \Omega'$ the lemma follows. \hfill \Box

In our situation we reformulate Corollary \[2.1.4\] as follows.

**Corollary 12.3.2.** Let $\Lambda_u \subset T^*_{\tau>0}(M \times \mathbb{R})$, $u > 0$, and $\Lambda^+ \subset T^*_{\tau>0}(M \times \mathbb{R} \times \mathbb{R}_{>0})$ be the sets defined in \[12.3.1\]. Then we have:

(i) The inverse image functor induces an equivalence of categories

\[12.3.2\]

\[i_u^*: \mathcal{D}^b_{\Lambda^+}(\mathbb{K}_{M \times \mathbb{R} \times \mathbb{R}_{>0}}) \to \mathcal{D}^b_{\Lambda_u}(\mathbb{K}_{M \times \mathbb{R}}),\]

for any $u > 0$. In particular, for all $F, G \in \mathcal{D}^b_{\Lambda^+}(\mathbb{K}_{M \times \mathbb{R} \times \mathbb{R}_{>0}})$ we have

\[12.3.3\]

\[\text{RHom}(F, G) \cong \text{RHom}(F|_{M \times \mathbb{R} \times \{u\}}, G|_{M \times \mathbb{R} \times \{u\}}).\]

(ii) The restriction functor induces an equivalence of categories

\[12.3.4\]

\[\mathcal{D}^b_{\Lambda^+}(\mathbb{K}_{M \times \mathbb{R} \times \mathbb{R}_{>0}}) \to \mathcal{D}^b_{\Lambda^+}(\mathbb{K}_{M \times \mathbb{R} \times [0, u]}),\]

for any $u > 0$. In particular, for all $F, G \in \mathcal{D}^b_{\Lambda^+}(\mathbb{K}_{M \times \mathbb{R} \times \mathbb{R}_{>0}})$ we have

\[12.3.5\]

\[\text{RHom}(F, G) \cong \text{RHom}(F|_{M \times \mathbb{R} \times [0, u]}, G|_{M \times \mathbb{R} \times [0, u]}).\]

**Proof.** By Lemma \[12.3.1\] we can apply Corollary \[2.1.4\] with $A = \Lambda_0$, $A' = \Lambda^+$, $s = u$. We choose $0 < u < u'$. The corollary applied with
$I = \mathbb{R}_{>0}$ or $I = ]0, u'[ $ says that the functors $A$ and $B$ in the following diagram

$$
\begin{array}{ccc}
D_{\Lambda^+}^{\text{lb}}(k_{M \times \mathbb{R} \times \mathbb{R}_{>0}}) & \xrightarrow{R} & D_{\Lambda^+}^{\text{lb}}(k_{M \times \mathbb{R} \times ]0,u['}) \\
\downarrow A & & \downarrow B \\
D_{\Lambda_u}^{\text{lb}}(k_{M \times \mathbb{R}})
\end{array}
$$

are equivalences of categories. It follows that the restriction functor $R$ is an equivalence of categories. The functor $A$ is (12.3.2) and the functor $R$ is (12.3.4). This proves the corollary.  

**Corollary 12.3.3.** Let $\Lambda$ be a closed conic Lagrangian submanifold of $T^*_{r>0}(M \times \mathbb{R})$ coming from a compact exact submanifold of $T^*M$ as in (12.0.1). Then, for any pure object $\mathcal{F} \in \mu \text{Sh}(k_{\Lambda})$ there exists $F \in D_{\Lambda}(k_{M \times \mathbb{R}})$ such that $m_{\Lambda}(F) \simeq \mathcal{F}$.

**Proof.** By Theorem 12.1.1 there exists $F_0 \in D_{\Lambda_0}^{\text{dbl}}(k_{M \times \mathbb{R}})$ such that $m_{\Lambda_0}(F_0) \simeq \mathcal{F}$. By the definition of $D_{\Lambda_0}^{\text{dbl}}(k_{M \times \mathbb{R}})$ the restriction $F_1 = F_0|_{M \times \mathbb{R} \times ]0,u[}$ belongs to $D_{\Lambda_0^+}(k_{M \times \mathbb{R} \times ]0,u[})$ for $u > 0$ small enough. By the equivalence of categories (12.3.4) there exists $F_2 \in D_{\Lambda_0^+}(k_{M \times \mathbb{R} \times \mathbb{R}_{>0}})$ which extends $F_1$.

Since $\Lambda/\mathbb{R}_{>0}$ is compact we can choose $A > 0$ such that $\Lambda \subset T^*_{r>0}(M \times ]-A,A[)$. For $u \geq 2A + 1$ we have $\Lambda_u \subset T^*_{r>0}(M \times ]A + 1, +\infty[)$. We set $F_3 = (i_u^{-1}F_2)|_{M \times ]-\infty,-A+1[}$. Then $SS(F_3) = \Lambda$. We choose a diffeomorphism $f: ]-\infty,A+1[ \to \mathbb{R}$ such that $f$ is the identity map on $]0, A[$. Then $F = R(id_M \times f)_*F_3$ is the required sheaf.

The proofs given in this section work verbatim in the case of the orbit category and Theorem 12.2.2 gives the analog of Corollary 12.3.3.

**Corollary 12.3.4.** Let $\Lambda$ be as in Corollary 12.3.3. Then, for any $\mathcal{F} \in \mu \text{Sh}^{\text{orb}}(k_{\Lambda})$ there exists $F \in D_{\Lambda}(k_{M \times \mathbb{R}})$ such that $m_{\Lambda}(F) \simeq \mathcal{F}$.

**Corollary 12.3.5.** We keep the hypothesis of Corollary 12.3.3. Then for any $F_1, F_2 \in D_{\Lambda}^{b}(k_{M \times \mathbb{R}})$ we have isomorphisms

$$
\text{RHom}(F_1, F_2) \simeq \text{RHom}(q^{-1}F_1, r^{-1}F_2) \simeq \text{RHom}(F_1, T_{u*}F_2),
$$

for any $u \geq 0$.

**Proof.** Since $r$ is a submersion with fibers diffeomorphic to $\mathbb{R}_{>0}$ we have $\text{RHom}(F_1, F_2) \simeq \text{RHom}(r^{-1}F_1, r^{-1}F_2)$. Applying the functor $\text{RHom}(\cdot, r^{-1}F_2)$ to the triangle (11.1.9) we obtain the distinguished
By Lemma 11.1.6 (i) we have \( R\Psi_1(\Psi_M \times \mathbb{R}(F)) \simeq 0 \). Hence the third term in (12.3.6) vanishes and we obtain the first isomorphism of the corollary. The second one follows from (12.3.3) applied with \( F = q^{-1}F_1 \) and \( G = r^{-1}F_2 \).

### 12.4. Restriction at infinity

As in (12.3) we assume that \( \Lambda/\mathbb{R}_{>0} \) has no Reeb chord. Since \( \Lambda/\mathbb{R}_{>0} \) is compact we can choose \( A > 0 \) such that \( \Lambda \subset T_{>0}^r(M \times [-A, A]) \). Then, for any \( F \in \text{D}^b_\Lambda(k_M \times \mathbb{R}) \), the restrictions \( F|_{M \times [-\infty,-A]} \) and \( F|_{M \times [A,\infty]} \) have locally constant cohomology sheaves.

**Definition 12.4.1.** For \( F \in \text{D}^b_\Lambda(k_M \times \mathbb{R}) \) we let \( F_- , F_+ \in \text{D}^b(k_M) \) be the restrictions at infinity \( F_- = F|_{M \times \{-t\}} , \) \( F_+ = F|_{M \times \{t\}} \), for any \( t \in [A, \infty[ \). Then \( F_- , F_+ \) are indeed independent of \( t \in [A, \infty[ \) and have locally constant cohomology sheaves. We let \( \text{D}^b_{\Lambda,+}(k_M \times \mathbb{R}) \) be the full subcategory of \( \text{D}^b_\Lambda(k_M \times \mathbb{R}) \) consisting of the \( F \) such that \( F_- \simeq 0 \).

For \( F \in \text{D}^b_{\Lambda,+}(k_M \times \mathbb{R}) \) we have by definition

\[
F|_{M \times [A,\infty]} \simeq F_+ \boxtimes k|_{A,\infty} , \quad F|_{M \times [-\infty,-A]} \simeq 0 .
\]

**Lemma 12.4.2.** Let \( F \in \text{D}^b(k_M \times \mathbb{R}) \). We assume that there exists \( A > 0 \) such that \( \text{supp}(F) \subset M \times [-A, A] \). We also assume either \( \text{SS}(F) \subset T_{\gtrless 0}^r(M \times \mathbb{R}) \) or \( \text{SS}(F) \subset T_{\lesssim 0}^r(M \times \mathbb{R}) \). Let \( p_M : M \times \mathbb{R} \to M \) be the projection. Then \( R_{p_M}(F) \simeq R\Psi_{p_M^*}(F) \simeq 0 \).

**Proof.** By base change we may assume that \( M \) is a point. Then the result follows from Corollary 12.2.14 \( \Box \)

**Theorem 12.4.3.** Let \( F,F' \in \text{D}^b_{\Lambda,+}(k_M \times \mathbb{R}) \). We let \( F_+ , F'_+ \in \text{D}^b(k_M) \) be their restrictions to \( M \times \{t\} , t > 0 \), as in Definition 12.4.1. Then

\[
\text{RHom}(F,F') \simeq \text{RHom}(F_+,F'_+) .
\]

In particular the functor \( \text{D}^b_{\Lambda,+}(k_M \times \mathbb{R}) \to \text{D}^b(k_M) \) given by \( F \mapsto F_+ \) is fully faithful and we have: \( F \simeq F' \) if and only if \( F_+ \simeq F'_+ \).

As in the previous section the statement also holds in the case of the orbit category.
Proof. Let \( p_M : M \times \mathbb{R} \to M \) be the projection. Let us choose \( A > 0 \) so that (12.4.1) holds for \( F \) and \( F' \) and let \( u > 2A \). Hence \( \text{supp}(T_{u*}F') \subset M \times ]A, +\infty[ \) and we obtain, by Corollary 12.3.5 and by (12.4.1),

\[
R\text{Hom}(F, F') \simeq R\text{Hom}(p_M^{-1}(F_+), T_{u*}F') \\
\simeq R\text{Hom}(F_+, Rp_M^*T_{u*}F').
\]

(12.4.3)

Let us set

\[
G = (T_{u*}F') \otimes k_{M \times ]-\infty, A+u[}.
\]

Then \( \text{supp}(G) \subset [A, A + u] \) and \( SS(G) \subset T^*_{r \geq 0}(M \times \mathbb{R}) \) by Theorem 1.2.11. By Lemma 12.4.2 we obtain \( Rp_M^*(G) \simeq 0 \). By (12.4.1) again we have the distinguished triangle \( G \to T_{u*}F' \to F'_+ \otimes k_{[A+u, +\infty]} \xrightarrow{+1} \) and we deduce \( Rp_M^*T_{u*}F' \simeq Rp_M^*(F'_+ \otimes k_{[A+u, +\infty]}) \simeq F'_+ \). Hence (12.4.3) implies (12.4.2). \( \square \)

**Theorem 12.4.4.** Let \( F, F' \in D^b_{\Lambda^+}(k_{M \times \mathbb{R}}) \). Then we have an isomorphism

\[
R\text{Hom}(F, F') \xrightarrow{\sim} R\Gamma(\Lambda; \mu\text{hom}(F, F')).
\]

Its composition with (12.4.2) gives a canonical isomorphism

\[
R\text{Hom}(F_+, F'_+) \simeq R\Gamma(\Lambda; \mu\text{hom}(F, F')).
\]

As in the previous section the statement also holds in the case of the orbit category.

**Proof.** We recall the notation \( \Lambda^+ \subset T^*_{r > 0}(M \times \mathbb{R} \times \mathbb{R}_{>0}) \) of (12.3.1). By Lemma 11.1.7 \( \Psi_{M \times \mathbb{R}}(F) \) and \( \Psi_{M \times \mathbb{R}}(F') \) belong to \( D^b_{\Lambda^+}(k_{M \times \mathbb{R} \times \mathbb{R}_{>0}}) \). Using the isomorphism (12.3.5) and Proposition 11.3.5 we have, setting \( N_\varepsilon = M \times \mathbb{R} \times ]0, \varepsilon[ \),

\[
H^iR\Gamma(\Lambda; \mu\text{hom}(F, F')) \simeq \lim_{\varepsilon \to 0} H^iR\text{Hom}(\Psi_{M \times \mathbb{R}}(F)|_{N_\varepsilon}, \Psi_{M \times \mathbb{R}}(F')|_{N_\varepsilon})) \simeq H^iR\text{Hom}(F, F'),
\]

for any \( i \in \mathbb{Z} \). This implies (12.4.4). \( \square \)

**Remark 12.4.5.** We have recalled in (10.1.2) that \( \mu\text{hom} \) admits a composition morphism (denoted by \( \circ \) in Notation 10.1.3) compatible with the composition morphism for \( R\text{Hom} \). In particular the isomorphism (12.4.4) is compatible with the composition morphisms \( \circ \) and \( \circ \). Since (12.4.2) is clearly compatible with \( \circ \), we deduce that (12.4.5) also is compatible with \( \circ \) and \( \circ \).
Part 13. Exact Lagrangian submanifolds in cotangent bundles

In this part $M$ is a connected manifold and $\Lambda_0 \subset T^* M$ is a compact exact Lagrangian submanifold. We use the sheaves constructed in Corollary 12.3.3 and Theorems 12.4.3, 12.4.4 to recover some results on the topology of $\Lambda_0$, namely that the projection $\Lambda_0 \to M$ is a homotopy equivalence and that the first and second Maslov classes of $\Lambda_0$ vanish.

The fact that $\Lambda$ and $M$ have the same homology was proved by Fukaya, Seidel, Smith in [16] and also by Nadler in [37] using the Fukaya category of the cotangent bundle and assuming that the first Maslov class vanishes. The fact that the projection $\Lambda_0 \to M$ is a homotopy equivalence was proved by Abouzaid in [2], also assuming the vanishing of the Maslov class. Then Kragh in [34] proved that this vanishing holds.

Abouzaid and Kragh gave more precise results on the topology of $\Lambda$. In [4] they proved that the map $\Lambda_0 \to M$ is a simple homotopy equivalence and in [3] they proved a vanishing result for the higher Maslov classes (very roughly the images of the Maslov classes by the map $BO \to BH$ vanish, where $H$ is the group of homotopy equivalences of the sphere – this gives the vanishing of obstructions for the existence of a sheaf in spectra – see [26] [25]).

In the following we choose $f : \Lambda_0 \to \mathbb{R}$ such that $df = \alpha_M|_{\Lambda_0}$ and define as in (12.0.1)

$$\Lambda = \{(x, t; \xi, \tau); \tau > 0, (x; \xi/\tau) \in \Lambda_0, t = -f(x; \xi/\tau)\}.$$

We have $\Lambda/\mathbb{R}_{>0} = \Lambda_0$ and we work with $\Lambda$ instead of $\Lambda_0$.

13.1. Poincaré groups

We let $\pi_\Lambda : \Lambda \to M$ be the projection to the base and we denote by $\pi_1(\pi_\Lambda) : \pi_1(\Lambda) \to \pi_1(M)$ the induced morphism of Poincaré groups.

**Proposition 13.1.1.** The morphism $\pi_1(\pi_\Lambda) : \pi_1(\Lambda) \to \pi_1(M)$ is injective.

**Proof.** (i) We set $k = \mathbb{Z}/2\mathbb{Z}$ and $G = \pi_1(\Lambda)$. We let $\rho : G \to GL(k[G])$ be the regular representation of $G$. This means that $k[G]$ is the vector space with basis $\{e_g\}_{g \in G}$ and the action of $G$ is given by $g \cdot e_h = e_{gh}$, for all $g, h \in G$. We let $L_\rho$ be the local system on $\Lambda$ with stalks $k[G]$ corresponding to this representation $\rho$.

(ii) We recall some results of §10.4. The $\mathcal{H}om$ sheaf in $\mu \mathcal{Sh}^{\text{orb}}(k_\Lambda)$ is induced by $\underline{\mu \text{Hom}}$ through the equivalence $\mathcal{O} \Lambda \simeq \text{Loc}(k_\Lambda)$. By
Proposition 10.4.4 there exists a simple object $\mathcal{F}_0 \in \mu\text{Sh}^{\text{orb}}(k_\Lambda)$ and $\mathcal{H}om(\mathcal{F}_0, \cdot)$ gives an equivalence $\mu\text{Sh}^{\text{orb}}(k_\Lambda) \simeq \text{Loc}(k_\Lambda)$.

We let $\mathcal{F}_\rho \in \mu\text{Sh}^{\text{orb}}(k_\Lambda)$ be the object associated with $\mathcal{L}_\rho$ by this equivalence. By Corollary 12.3.4, there exist $0, F_0, F_\rho \in D^b_{[1]}(k_{M \times \mathbb{R}})$ such that $\mathfrak{m}_\Lambda^{\text{orb}}(F_0) \simeq \mathcal{F}_0$ and $\mathfrak{m}_\Lambda^{\text{orb}}(F_\rho) \simeq \mathcal{F}_\rho$. Moreover $\mathfrak{h}om(F_0, F_\rho)$ is isomorphic to $\mu\text{hom}^{\mathfrak{e}}(F_0, F_\rho)|_\Lambda$. Hence $\mu\text{hom}^{\mathfrak{e}}(F_0, F_\rho)|_\Lambda \simeq \mathcal{L}_\rho$. We define $L_0, L_1 \in D^b_{[1]}(k_M)$ by $L_0 = F_0|_{M \times \{t\}}$ and $L_1 = F_\rho|_{M \times \{t\}}$ for $t \gg 0$. We let $p: M \times \mathbb{R} \to M$ be the projection and we set $F = F_0 \otimes^{\mathfrak{e}} p^{-1}L_1$ and $F' = F_\rho \otimes^{\mathfrak{e}} p^{-1}L_0$. Then $F|_{M \times \{t\}} \simeq L_0 \otimes^{\mathfrak{e}} L_1 \simeq F'|_{M \times \{t\}}$ for $t \gg 0$ and Theorem 12.4.3 (for the orbit category) implies

$$F_0 \otimes^{\mathfrak{e}} p^{-1}L_1 \simeq F_\rho \otimes^{\mathfrak{e}} p^{-1}L_0.$$  

(iii) For $i = 0, 1$ we set $L_i = h_M(L_i)$ (see Lemma 10.4.3); it is the sheaf on $M$ associated with the presheaf $U \mapsto \text{Hom}_{D^b_{[1]}(k_U)}(k_U, L_i)$. Then $L_0$ and $L_1$ are local systems on $M$. Applying $\mathfrak{m}_\Lambda^{\text{orb}}$ to (13.1.1) and the equivalence $\mu\text{Sh}^{\text{orb}}(k_\Lambda) \simeq \text{Loc}(k_\Lambda)$, we find $\pi_1^{-1}L_1 \simeq \mathcal{L}_\rho \otimes \pi_1^{-1}L_0$.

(iv) We let $\rho_0'$ and $\rho_1'$ be the representations of $\pi_1(M)$ corresponding to the local systems $L_0$ and $L_1$. They induce representations of $G = \pi_1(\Lambda)$, say $\rho_0''$ and $\rho_1''$, through the morphism $\pi_1(\Lambda)$. Then the result of (iii) gives the isomorphism of representations of $G$, $\rho_i'' \simeq \rho \otimes \rho_0''$. We restrict these representations to the subgroup $K = \ker(\pi_1(\Lambda))$ of $G$. Then $\rho_0''|_K$ and $\rho_1''|_K$ are trivial representations and we deduce that $\rho|_K$ also is trivial. Since $\rho$ is a faithful representation of $G$, this gives $K = \{1\}$, as required.

Let $r: M' \to M$ be a covering. The derivative of $r$ induces a covering $r': T^*M' \to T^*M$. We let $\Lambda_0'$ be a connected component of $r'^{-1}(\Lambda')$. Then $\Lambda_0' \to \Lambda$ is a covering and $\pi_1(\Lambda_0')$ is a subgroup of $\pi_1(\Lambda)$. We have the commutative diagram

$$\begin{array}{ccc}
\pi_1(\Lambda_0') & \longrightarrow & \pi_1(\Lambda) \\
\downarrow & & \downarrow \pi_1(\pi_\Lambda) \\
\pi_1(M') & \longrightarrow & \pi_1(M),
\end{array}$$  

where $\pi_1(\pi_\Lambda)$ is injective by Proposition 13.1.1. This implies that the morphism $\pi_1(\Lambda_0') \to \pi_1(M')$ is injective. In particular, if $M'$ is the universal cover of $M$, then $\pi_1(\Lambda_0')$ vanishes, that is, $\Lambda_0'$ is the universal cover of $\Lambda$.

We let $m_\Lambda: \pi_1(\Lambda) \to \mathbb{Z}$ be the group morphism induced by the Maslov class $\mu_1^h(\Lambda) \in H^1(\Lambda; \mathbb{Z}_\Lambda)$ introduced in 10.3. We remark that $m_\Lambda$ determines $\mu_1^h(\Lambda)$. 
Corollary 13.1.2. We assume that \( m_A \neq 0 \). Then there exist covering maps \( f : M_0 \to M_1, g : M_1 \to M \) where \( f \) is a cyclic cover of group \( \mathbb{Z} \) and closed conic connected Lagrangian submanifolds \( \Lambda_i \subset \hat{T}^*(M_i \times \mathbb{R}) \) for \( i = 0, 1 \), such that the derivatives of \( f \) and \( g \) induce a cyclic cover of group \( \mathbb{Z} \), \( \Lambda_0 \to \Lambda_1 \), and an isomorphism \( \Lambda_1 \simeq \Lambda \):

\[
\begin{array}{ccc}
\Lambda_0 & \xrightarrow{z} & \Lambda_1 \\
\downarrow & & \downarrow \\
M_0 & \xrightarrow{f} & M_1 \\
\downarrow & & \downarrow \\
M & \xrightarrow{g} & M.
\end{array}
\]

Moreover the isomorphism \( \Lambda_1 \simeq \Lambda \) identifies \( \mu^s_1(\Lambda_1) \) and \( \mu^s_1(\Lambda) \) and we have \( \mu^s_1(\Lambda_0) = 0 \).

Proof. We set \( K = \ker(m_A) \). Since \( m_A \neq 0 \) we have \( \pi_1(\Lambda)/K \simeq \mathbb{Z} \). We let \( M' \) be the universal cover of \( M \) and we define \( \Lambda'_0 \) as in the diagram (13.1.2). Hence \( \Lambda'_0 \) is the universal cover of \( \Lambda \). Since \( K \) and \( \pi_1(\Lambda) \) are subgroups of \( \pi_1(M) \) they act freely on \( M' \). These actions commute with their actions on \( \Lambda'_0 \) through the map \( \Lambda'_0 \to M \). We obtain the diagram of quotient manifolds

\[
\begin{array}{ccc}
\Lambda'_0 & \xrightarrow{f'} & \Lambda'_0/\pi_1(\Lambda) \\
\downarrow & & \downarrow \\
M' & \xrightarrow{f} & M'/\pi_1(\Lambda),
\end{array}
\]

where \( f' \) and \( f \) are covering maps with group \( \pi_1(\Lambda)/K \simeq \mathbb{Z} \). We set \( \Lambda_0 = \Lambda'_0/K, M_0 = M'/K, \Lambda_1 = \Lambda'_0/\pi_1(\Lambda) \) and \( M_1 = M'/\pi_1(\Lambda) \). Then \( \Lambda_1 \) is identified with \( \Lambda \) since it is the quotient of the universal cover of \( \Lambda \) by its Poincaré group. This gives the diagram (13.1.3). The claim on the Maslov classes follows easily. \( \Box \)

13.2. Vanishing of the Maslov class

By Corollary 10.6.3 the vanishing of \( \mu^s_1(\Lambda) \) implies the vanishing of the usual Maslov class \( \mu_1(L) \). We recall that \( m_A : \pi_1(\Lambda) \to \mathbb{Z} \) is the group morphism induced by \( \mu^s_1(\Lambda) \) and that \( m_A \) determines \( \mu^s_1(\Lambda) \).

Theorem 13.2.1. We have \( \mu_1(\Lambda) = 0 \).
The diagram (13.2.1) induces the isomorphisms\[ \pi_1(\Lambda_0) \to \pi_1(\Lambda) \xrightarrow{m_\Lambda} \mathbb{Z}. \]
The diagram (13.2.1) induces the isomorphisms\[ \pi_1(\Lambda)/\pi_1(\Lambda_0) \simeq \mathbb{Z} \simeq \pi_1(M)/\pi_3(M_0) \]
and we deduce that \( m \) factorizes through a morphism \( m: \pi_1(M) \to \mathbb{Z} \) such that \( \ker(m) \simeq \pi_1(M_0) \).

We let \( c \in H^1(M; \mathbb{Z}) \) be the cohomology class corresponding to \( m \).
Then \( \pi_1^*(c) \) is the Maslov class of \( \Lambda \) (viewed as a cohomology class) and \( f^*(c) = 0 \).

We will obtain a contradiction by constructing a quantization \( G \) of \( \Lambda_0 \) on \( M_0 \times \mathbb{R} \) with opposite properties: (i) \( G \) should be unbounded because of the non-vanishing of \( c \) and (ii) \( G \) could be bounded because \( G|_{M_0 \times \{t\}} \), \( t \gg 0 \), is a locally bounded locally constant object.

The construction of \( G \) consists in checking that Corollary 13.1.2 holds when we replace \( M \) by a cyclic cover.

(ii) By Lemma 12.2.1 there exist two open subsets \( U_1, U_2 \) of \( M \) such that \( U_1, U_2 \) and \( U_1 \cap U_2 \) have a finite number of connected components and the restrictions \( c|_{U_i} \in H^1(U_i; \mathbb{Z}) \) vanish, for \( i = 1, 2 \).
We can decompose \( U_1 \cap U_2 = V_+ \sqcup V_- \) into two disjoint open subsets such that \( c \) is represented by the Čech cocyle \( c_{12}: U_{12} \to \mathbb{Z} \) (\( c_{12} \) is a locally constant function) with values 0 on \( V_+ \) and \( d \) on \( V_- \), for some \( d \in \mathbb{Z} \). Since \( m_\Lambda \neq 0 \) we have \( d \neq 0 \).

We set \( \Lambda_i = \Lambda \cap T^*(U_i \times \mathbb{R}) \) for \( i = 1, 2 \).
By Theorem 12.1.1 and Proposition 11.4.7 there exist simple objects \( F_i \in D^k_{\Lambda_i}(\mathbb{K}_U \times \mathbb{R}) \) and isomorphisms \( \varphi_+: F_1|_{V_+ \times \mathbb{R}} \simeq F_2|_{V_+ \times \mathbb{R}} \) and \( \varphi_-: F_1|_{V_- \times \mathbb{R}} \simeq F_2|_{V_- \times \mathbb{R}}[d] \).

(iii) For \( n \in \mathbb{Z} \) we denote by \( \psi_n \) the action of \( n \) on \( M_0 \times \mathbb{R} \times \mathbb{R}_{>0} \). We set \( U_i' = f^{-1}(U_i \times \mathbb{R} \times \mathbb{R}_{>0}) \), \( i = 1, 2 \), and we decompose \( U_i' = \bigcup_{n \in \mathbb{Z}} U_i^n \) in such a way that \( f \) identifies each \( U_i^n \) with \( U_i \times \mathbb{R} \times \mathbb{R}_{>0} \) and \( U_i^n = \psi_n(U_i^0) \).
We can also assume that \( f \) identifies \( U_1^0 \cap U_2^0 \) with \( V_+ \times \mathbb{R} \times \mathbb{R}_{>0} \) and \( U_1^0 \cap U_2^0 \) with \( V_- \times \mathbb{R} \times \mathbb{R}_{>0} \).

We define \( G_i \) on \( U_i' \) by \( G_i|_{U_i^n} = (f^{-1}(F_i))[U_i^n][nd] \). Then the isomorphisms \( \varphi_\pm \) of (ii) induce an isomorphism \( \varphi: G_1|_{U_{12}'} \simeq G_2|_{U_{12}'} \).
We let \( j_1, j_2 \) be the inclusions of \( U_1', U_{12}' \) in \( M_0 \times \mathbb{R} \times \mathbb{R}_{>0} \). We define \( G' \in D(\mathbb{K}_{M_0 \times \mathbb{R} \times \mathbb{R}_{>0}}) \) by the distinguished triangle
\[ G' \to Rj_{1*}G_1 \oplus Rj_{2*}G_2 \xrightarrow{(\varphi,-\text{id})} Rj_{12*}(G_2|_{U_{12}'}) \xrightarrow{\pm 1}. \]
Then $G' \in \mathcal{D}^{bt}_{\Lambda_0}(k_{M_0 \times \mathbb{R}})$ and $G'$ is simple along $q_{d}q_{d}^{-1}(\Lambda_0) \cup r_{d}r_{d}^{-1}(\Lambda_0)$. By construction we also have isomorphisms $\psi_n^{-1}(G') \simeq G'[nd]$, for each $n \in \mathbb{Z}$.

(iv) We apply Lemma 12.3.1 to $\Lambda$ and we obtain a homogeneous Hamiltonian isotopy $\phi$ of $\mathcal{T}^*(M \times \mathbb{R})$ which keeps $\Lambda$ fixed and translates $T^*_{1}(\Lambda)$ vertically. Lifting $\phi$ to $\mathcal{T}^*(M_0 \times \mathbb{R})$ we see that $\Lambda_0$ satisfies the conclusions of Lemma 12.3.1. Hence we can apply Corollary 12.3.2 to $\Lambda_0$ and we deduce from the object $G' \in \mathcal{D}^{bt}_{\Lambda_0}(k_{M_0 \times \mathbb{R}})$ defined in (iii) an object $G \in \mathcal{D}_{\Lambda_0}(k_{M_0 \times \mathbb{R}})$ which is simple along $\Lambda_0$ and such that we have isomorphisms $\psi_n^{-1}(G) \simeq G'[nd]$, for each $n \in \mathbb{Z}$.

(v) We have $G|_{M_0 \times \{t\}} \simeq 0$ for $t \ll 0$ and we define $G_+ = G|_{M_0 \times \{t\}}$ for $t \gg 0$ as in Definition 12.4.1. Theorem 12.4.3 gives $\mathcal{R}Hom(G, G) \simeq \mathcal{R}Hom(G_+, G_+)$. Since $G \not\simeq 0$ it follows that $G_+ \not\simeq 0$. We also know that $G_+$ has locally constant cohomology sheaves. Since $M_0$ is connected the stalk $(G_+)_x$ is independent of $x \in M_0$. By Lemma 10.2.7 we also know that $(G_+)_x$ is finite. In particular $G_+$ is bounded in degrees.

The isomorphisms $\psi_n^{-1}(G) \simeq G'[nd]$ give $\psi_n^{-1}(G_+) \simeq G_+[nd]$, for all $n \in \mathbb{Z}$. Since $G_+$ is bounded and non zero, we obtain $d = 0$ but this contradicts the hypothesis $m_\Lambda \neq 0$.

\section{13.3. Restriction at infinity}

We recall the notation $\mathcal{D}^b_{\Lambda_0}(k_{M \times \mathbb{R}})$ of Definition 12.3.1 and $F_+ = F|_{M \times \{t_0\}}$ for $t_0 \gg 0$, for $F \in \mathcal{D}^b_{\Lambda_0}(k_{M \times \mathbb{R}})$.

\begin{proposition}
We assume that $k = \mathbb{Z}$ or $k$ is a finite field. Let $F \in \mathcal{D}^b_{\Lambda_0}(k_{M \times \mathbb{R}})$. We assume that $F$ is simple along $\Lambda$. Then $F_+$ is concentrated in one degree, say $i$, and $H^iF_+$ is a local system with stalks isomorphic to $k$.
\end{proposition}

\begin{proof}
(i) We first assume that $k$ is a finite field. Let us prove that $F_+$ is concentrated in one degree. Let $a \leq b$ be respectively the minimal and maximal integers $i$ such that $H^iF_+ \not\simeq 0$. By Lemma 10.2.7 the local systems $H^iF_+$ are of finite rank. Since $k$ is finite we can find a finite cover $r: M' \rightarrow M$ such that $r^{-1}(\mathcal{H}^iF_+)$ is trivial, for $i = a, b$. We set $F' = (r \times \text{id}_{\mathbb{R}})^{-1}F$ and $\Lambda' = d(r \times \text{id}_{\mathbb{R}})^{-1}(\Lambda)$. Then $r^{-1}(\mathcal{H}^iF_+) \simeq \mathcal{H}^iF'_+$, $F'$ is simple along $\Lambda'$ and we have $\muhom(F', F') \simeq k_{\Lambda'}$. Since $\Lambda'/\mathbb{R}_{>0}$ is compact, Theorem 12.4.3 gives

(13.3.1) $\mathcal{R}Hom(F'_+, F'_+) \simeq \mathcal{R}\Gamma(\Lambda'; k_{\Lambda'})$.

On the other hand the complex $G = \mathcal{R}Hom(F'_+, F'_+)$ is concentrated in degrees greater than $a - b$ and $H^{a-b}G \simeq \mathcal{H}om(H^{a-b}F'_+, H^bF'_+)$ is a non zero constant sheaf. Hence $H^{a-b}\mathcal{R}Hom(F'_+, F'_+)$ is non zero.
By (13.3.1) we deduce that $H^{a-b}\Gamma(\Lambda'; k_{\Lambda'})$ also is non zero, which implies $a - b \geq 0$. Hence $a = b$ and $F_+$ is concentrated in a single degree.

(ii) Now we prove that $H^a F_+$ is of rank one, that is, $H^a F'_+ \simeq k_{M'}$. There exists $d \geq 1$ such that $H^a F'_+ \simeq k^d_{M'}$. The isomorphism (13.3.1) gives in degree 0:

\[(13.3.2) \quad \text{Hom}(k^d, k^d) \simeq H^0(\Lambda'; k_{\Lambda'}).\]

By Remark (12.3.3) this isomorphism is compatible with the algebra structures of both terms. Let $I$ be the set of connected components of $\Lambda'$. We obtain $|I| = d^2$. The natural decomposition $H^0(\Lambda'; k_{\Lambda'}) \simeq \bigoplus_{i \in I} H^0(\Lambda'_i; k_{\Lambda'_i})$ gives an expression of the unit as a sum of orthogonal idempotents, $1 = \sum_{i \in I} e_i$, where $e_i$ is the projection $e_i : H^0(\Lambda'; k_{\Lambda'}) \to H^0(\Lambda'_i; k_{\Lambda'_i}), \quad i \in I$.

We let $m_i \in \text{Hom}(k^d, k^d) = \text{Mat}_{d \times d}(k)$ be the image of $e_i$ by (13.3.2). The relation $1 = \sum_{i \in I} e_i$ gives a decomposition of the identity matrix $I = \sum_{i \in I} m_i$ as a sum of $|I|$ non-zero orthogonal projections, that is, $m_i^2 = m_i$ and $m_i m_j = 0$, for $i \neq j$. We deduce that $|I| \leq d$, that is, $d^2 \leq d$. Hence $d = 1$, as claimed.

(iii) Now we assume that $k = \mathbb{Z}$. By Lemma (10.2.7) the stalks of $F_+$ are of finite rank over $\mathbb{Z}$. We recall that any object of $\mathcal{D}^b(\mathbb{Z})$ is the sum of its cohomology. Hence, for $z = (x, t), \ t \gg 0$, we can write $(F_+)_z = \bigoplus_{i = 0}^{b} M_i[-i]$, where the $M_i$’s are abelian groups of finite rank.

We first prove that the $M_i$’s are free. If this is not the case, there exist $i \in \mathbb{Z}$ and a prime $p$ such that $M_i$ has $p$-torsion. We set $G = F \otimes_{\mathbb{Z}} \mathbb{Z}/p\mathbb{Z}$. Then $G$ is simple along $\Lambda$ and $(G_+)_z \simeq (F_+)_z \otimes_{\mathbb{Z}} \mathbb{Z}/p\mathbb{Z}$. We have seen that $(G_+)_z$ is isomorphic to $\mathbb{Z}/p\mathbb{Z}[j]$ for some shift $j$. On the other hand $H^{-1}(M_i \otimes \mathbb{Z}/p\mathbb{Z})$ and $H^0(M_i \otimes \mathbb{Z}/p\mathbb{Z})$ are both non zero, since $M_i$ has $p$-torison. This gives a contradiction and proves that, for each $i$, we have $M_i \simeq \mathbb{Z}^{d_i}$, for some $d_i$.

We set $G = F \otimes_{\mathbb{Z}} \mathbb{Z}/2\mathbb{Z}$. We have again $(G_+)_z \simeq (F_+)_z \otimes_{\mathbb{Z}} \mathbb{Z}/2\mathbb{Z} \simeq \mathbb{Z}/2\mathbb{Z}[j]$. Hence $d_i = 0$ for all $i \neq j$ and $d_j = 1$, as claimed. \hfill $\Box$

**Corollary 13.3.2.** We assume that $k = \mathbb{Z}$ or $k$ is a finite field and that $\mu \text{Sh}(k_{\Lambda})$ has at least one global simple object. Then the projection $\Lambda \to M$ induces an isomorphism $\text{R}\Gamma(M; k_M) \cong \text{R}\Gamma(\Lambda; k_{\Lambda})$.

**Proof.** We choose a simple object $F \in \mu \text{Sh}(k_{\Lambda})$. By Corollary (12.3.3) there exists $F \in \mathcal{D}^b_{\Lambda, +}(k_{M \times \mathbb{R}})$ such that $m_\Lambda(F) \simeq F$. By Proposition (13.3.1) $F_+$ is concentrated in one degree, say $i$, and $H^i F_+$ is a
local system with stalks isomorphic to \( k \). Hence \( R\text{Hom}(F_+, F_+) \cong k_M \) and \( R\text{Hom}(F_+, F_+) \cong \Gamma_\Lambda(M; k_M) \). Since \( F \) is simple we also have \( \mu_\text{hom}(F, F)|_\Lambda \cong k_\Lambda \). By Theorem 12.4.4 we deduce an isomorphism

\[
(13.3.3) \quad \Gamma_\Lambda(M; k_M) \cong \Gamma_\Lambda(\Lambda; k_\Lambda).
\]

By construction (13.3.3) is given by taking the global sections in the bottom morphism of the commutative diagram:

\[
\begin{array}{ccc}
\mathbb{k}_{M \times \mathbb{R}} & \longrightarrow & R\hat{\pi}_*(\mathbb{k}_\Lambda) \\
\downarrow b & & \downarrow i \\
R\text{Hom}(F, F) & \cong & R\hat{\pi}_*(\mu_\text{hom}(F, F)|_\Lambda),
\end{array}
\]

where \( \pi = \pi_{M \times \mathbb{R}} \), \( b \) and \( c \) map the sections 1 to the identity morphisms. When taking global sections, \( b \) and \( c \) induce isomorphisms and \( a \) induces the natural morphism \( R\Gamma(M; k_M) \to R\Gamma(\Lambda; k_\Lambda) \) given by the projection of \( \Lambda \) to the base \( M \). The bottom horizontal arrow induces (13.3.3). This shows that (13.3.3) is indeed induced by the projection to the base.

\[\square\]

Remark 13.3.3. By Theorem 13.2.1 the first Maslov class of \( \Lambda \) vanishes. Hence, when \( k = \mathbb{Z}/2\mathbb{Z} \) the stack \( \mu\text{Sh}(k_M) \) has a global simple object and Corollary 13.3.2 applies: the projection \( \Lambda \to M \) induces an isomorphism

\[
R\Gamma(M; \mathbb{Z}/2\mathbb{Z}_M) \cong R\Gamma(\Lambda; \mathbb{Z}/2\mathbb{Z}_\Lambda).
\]

13.4. Vanishing of the second Maslov class

We have seen the class \( \mu_2^{sh}(\Lambda) \in H^2(\Lambda; k^\times) \) in (10.3). By Corollary 10.6.3 if \( k = \mathbb{Z} \), the vanishing of \( \mu_2^{sh}(\Lambda) \) implies the vanishing of the usual Maslov class \( \mu_2(L) \). Here we prove that \( \mu_2^{sh}(\Lambda) \in H^2(\Lambda; \mathbb{Z}/2\mathbb{Z}_\Lambda) \) vanishes. For this we will use Corollary 12.3.3 in the framework of twisted sheaves. Let \( c \in H^2(M; \mathbb{Z}/2\mathbb{Z}) \) be given and let \( \check{c} = \{c_{ijk}\} \), \( i, j, k \in I \), be a Čech cocycle representing \( c \) with respect to a finite covering \( \{U_i\}_{i \in I} \) of \( M \). We view \( \mathbb{Z}/2\mathbb{Z} \) as the multiplicative group \( \{\pm 1\} \) and \( c_{ijk} = \pm 1 \), for all \( i, j, k \).

Definition 13.4.1. A \( \check{c} \)-twisted sheaf \( F \) on \( M \) is the data of sheaves \( F_i \in \text{Mod}(k_{U_i}) \) and isomorphisms \( \varphi_{ij}: F_j|_{U_{ij}} \cong F_i|_{U_{ij}} \) satisfying the condition

\[
\varphi_{ij} \circ \varphi_{jk} = c_{ijk} \varphi_{ik}.
\]

The \( \check{c} \)-twisted sheaves form an abelian category that we denote by \( \text{Mod}(k_M^\check{c}) \). We denote by \( D^b(k_M^\check{c}) \) its derived category.
The prestack $U \mapsto \text{Mod}(k^U_{ij})$ is a stack which is locally equivalent to the stack of sheaves. The usual operations on sheaves extend to twisted sheaves. In particular if $c$ and $d$ are Čech cocycles on $M$ and $F \in \text{D}^b(k^c_M)$, $F' \in \text{D}^b(k^d_M)$, we have a tensor product $F \otimes F' \in \text{D}(k^{c+d}_M)$ and a homomorphism sheaf $R\text{Hom}(F, F') \in \text{D}(k^{c-d}_M)$. If $f: M \to N$ is a morphism of manifolds and $\tilde{d}$ is a Čech cocycle on $N$ with values in $\{\pm 1\}$, we have inverse images $f^{-1}, f': \text{D}^b(k^c_N) \to \text{D}^b(k^{f^{*}d}_M)$ and direct images $Rf_*, Rf!: \text{D}^b(k^{f^{*}d}_N) \to \text{D}^b(k^d_M)$ with the usual adjunction properties. The notion of microsupport also generalizes to the twisted case (since this is a local notion and twisted sheaves are locally equivalent to sheaves) with the same behaviour with respect to the sheaves operations.

We can define a Kashiwara-Schapira stack $\mu\text{Sh}(k^c_A)$ and formulate a version of Corollary 12.3.3 in this framework: for $F \in \mu\text{Sh}(k^c_A)$ there exists $F \in \text{D}^b(k^c_{M \times \mathbb{R}})$ such that $\text{SS}(F) = \Lambda$, $F|_{M \times \{t\}} \simeq 0$ for $t \ll 0$ and $m_\Lambda^{c}(F) \simeq F$.

**Proposition 13.4.2.** The class $\mu_2(\Lambda) \in H^2(\Lambda; \mathbb{Z}/2\mathbb{Z}_{\Lambda})$ is zero.

**Proof.** (i) By Corollary 13.3.2 and Remark 13.3.3 we have an isomorphism $H^2(M; \mathbb{Z}/2\mathbb{Z}_M) \simeq H^2(\Lambda; \mathbb{Z}/2\mathbb{Z}_{\Lambda})$. We let $c \in H^2(M; \mathbb{Z}/2\mathbb{Z}_M)$ be the inverse image of $\mu_2^{sh}(\Lambda)$ by this isomorphism and we choose a Čech cocycle $\tilde{c}$ representing $c$. Then the twisted Kashiwara-Schapira stack $\mu\text{Sh}(Z^c_\Lambda)$ has a simple global object and the twisted version of Corollary 12.3.3 gives $F \in \text{D}^b_{\Lambda,+}(Z^c_\Lambda \times \mathbb{R})$ which is simple along $\Lambda$. By Proposition 13.3.3 we have $F_+ \simeq L[d]$ where $L \in \text{Mod}(Z^c_\Lambda)$ is a twisted locally constant sheaf with stalks isomorphic to $\mathbb{Z}$ and $d$ is some integer.

(ii) Now we prove that the existence of $L \in \text{Mod}(Z^c_\Lambda)$ as in (i) implies that $\tilde{c}$ is a boundary, that is, $\mu_2^{sh}(\Lambda) = 0$. The cocycle $\tilde{c}$ is associated with a covering $\{U_i\}_{i \in I}$ of $M$. The object $L \in \text{Mod}(Z^c_M)$ is given by sheaves $L_i \in \text{Mod}(\mathbb{Z}_{U_i})$ and isomorphisms $\varphi_{ij}: L_j|_{U_{ij}} \simeq L_i|_{U_{ij}}$, for any $i, j \in I$, such that $\varphi_{ij} \circ \varphi_{jk} = c_{ijk} \varphi_{ik}$ for all $i, j, k \in I$. We can assume that $U_i$ is contractible and that $U_{ij}$ is connected for any $i, j \in I$. Since $L$ is locally constant, we can choose an isomorphism $\varphi_i: L_i|_{U_i} \simeq \mathbb{Z}_{U_i}$ for each $i \in I$. Then the composition $b_{ij} = \varphi_i \varphi_{ij} \varphi_{j}^{-1}$ is an isomorphism $\mathbb{Z} \simeq \mathbb{Z}$, that is, $b_{ij} = \pm 1$. We let $\bar{b}$ be the 1-cochain defined by $\{b_{ij}\}_{i, j \in I}$. Then the equality $\varphi_{ij} \circ \varphi_{jk} = c_{ijk} \varphi_{ik}$ says that $\tilde{c}$ is the boundary of $\bar{b}$, as required. \qed
13.5. Homotopy equivalence

Here we recover a result of \[2\] that the projection \(\pi_\Lambda : \Lambda \to M\) is a homotopy equivalence, that is, it induces an isomorphism of all fundamental groups. It is well known that this is equivalent to the following: \(\pi_1(\Lambda) \xrightarrow{\sim} \pi_1(M)\) and, for any local system \(L\) on \(M\), \(R\Gamma(M; L) \xrightarrow{\sim} R\Gamma(\Lambda; \pi_\Lambda^{-1}L)\).

We recall the subcategory \(D^b_{\Lambda,+}(k_{M \times R})\) of \(D^b_{\Lambda}(k_{M \times R})\) introduced in Definition 12.4.1. It consists of the locally constant sheaves. In particular the object \(L\) in (i) is unique up to a unique isomorphism.

Theorem 13.5.1. Let \(k\) be a ring with finite global dimension.

(i) There exists \(F \in D^b_{\Lambda,+}(k_{M \times R})\) such that \(F_+ \cong k_M\); it is a simple sheaf.

(ii) The functor \(G : \Lambda \to M\) induces an equivalence between \(D^b_{\Lambda,+}(k_{M \times R})\) and the subcategory of \(D^b(k_M)\) formed by the locally constant sheaves. In particular the object \(F\) in (i) is unique up to a unique isomorphism.

(iii) The projection \(\pi_\Lambda : \Lambda \to M\) induces an isomorphism in cohomology \(R\Gamma(M; k_M) \xrightarrow{\sim} R\Gamma(\Lambda; k_\Lambda)\).

(iv) More generally we have \(R\Gamma(M; L) \xrightarrow{\sim} R\Gamma(\Lambda; \pi_\Lambda^{-1}L)\) for any local system \(L\) on \(M\).

Proof. (i) We first assume that \(k = \mathbb{Z}\). By Theorem 13.2.1 and Proposition 13.4.2 we know that \(\mu_1(\Lambda) = 0\) and \(\mu_2(\Lambda) = 0\). By Corollary 12.3.3 there exists \(F^0 \in D^b_{\Lambda,+}(k_{M \times R})\) which is simple along \(\Lambda\). By Proposition 13.3.1 we have \(F^0 \cong L[d]\) where \(L \in \text{Mod}(k_M)\) is locally constant with stalks isomorphic to \(\mathbb{Z}\) and \(d\) is some integer. Let \(p : M \times \mathbb{R} \to M\) be the projection. Then \(F^1 = F^0 \otimes p^{-1}L^{d-1}[-d]\) satisfies the required properties. For a general ring \(k\) we set \(F = F^1 \otimes_{\mathbb{Z}_{M \times R}} k_{M \times R}\).

(ii) By Theorem 12.4.3 the functor \(G \mapsto G_+\) is fully faithful. Let \(L \in D^b(k_M)\) be a locally constant sheaf. Then \(F_+ \otimes L\) belongs to \(D^b_{\Lambda,+}(k_{M \times R})\) and we have \((F \otimes p^{-1}L)_+ \cong F_+ \otimes L \cong L\), which proves that \(G \mapsto G_+\) is essentially surjective.

(iii) follows from Corollary 13.3.2.

(iv) We apply Theorem 12.4.4 with \(F\) given by (i) and \(F' = F_+ \otimes L\). We have in this case \(F'_+ \cong F_+ \otimes L \cong L\), hence \(\mathcal{H}\text{om}(F_+, F'_+) \cong L\), and also \(\mu\text{hom}(F, F') \cong \mu\text{hom}(F, F) \otimes \pi_\Lambda^{-1}L \cong \pi_\Lambda^{-1}L\). The theorem then gives \(R\Gamma(M; L) \cong R\Gamma(\Lambda; \pi_\Lambda^{-1}L)\).  \(\square\)
Now we prove that $\pi_1(\Lambda) \to \pi_1(M)$ is an isomorphism. It is equivalent to show that the inverse image by $\pi_\Lambda$ induces an equivalence of categories $\text{Loc}(k_M) \xrightarrow{\sim} \text{Loc}(k_\Lambda)$, for some field $k$.

**Proposition 13.5.2.** Let $k$ be a field. Let $\pi_\Lambda: \Lambda \to M$ be the projection. Then the inverse image functor $\pi_\Lambda^{-1}: \text{Loc}(k_M) \to \text{Loc}(k_\Lambda)$ is an equivalence of categories.

*Proof.* (i) We first prove that $\pi_\Lambda^{-1}$ is fully faithful. Let $F \in D^b_{\text{Loc},+}(k_{M \times \mathbb{R}})$ be the simple object given by Theorem 13.5.1. Since $F$ is simple we have $\mu_{\text{hom}}(F, F)|_{\Lambda} \simeq k_\Lambda$ and we deduce, for $L, L' \in \text{Loc}(k_M)$,

$$\mu_{\text{hom}}(F \otimes p^{-1}L, F \otimes p^{-1}L') \simeq \mathcal{H}\text{om}(\pi_\Lambda^{-1}L, \pi_\Lambda^{-1}L'),$$

where $p: M \times \mathbb{R} \to M$ is the projection. Then the inverse image functor $\mu_{\text{hom}}(F, \cdot)$ induces an equivalence of categories.

(ii) We prove that $\pi_\Lambda^{-1}$ is essentially surjective. Let $L_1 \in \text{Loc}(k_\Lambda)$ be given. We recall that the functor $\mu_{\text{hom}}(F, \cdot)$ induces an equivalence $\mu_{\text{Sh}}(k_\Lambda) \xrightarrow{\sim} \text{Loc}(k_\Lambda)$ (see Proposition 13.2.3, where the induced functor is denoted $\mu_{\text{hom}}(F, \cdot)$). Hence there exists $\mathcal{L}_1 \in \mu_{\text{Sh}}(k_\Lambda)$ such that $\mu_{\text{hom}}(F, \mathcal{L}_1) \simeq \mathcal{L}$. By Corollary 13.3.3 there exists $F_1 \in D^b(k_{M \times \mathbb{R}})$ such that $\mathcal{m}_\Lambda(F_1) \simeq L_1$. Then we have $\mu_{\text{hom}}(F, F_1)|_{\Lambda} \simeq L_1$.

We set $L = (F_1)_+ \in D^b(k_M)$. Then $SS(L) = \emptyset$ and, since $F_+ \simeq k_M$, we also have $L \simeq (F \otimes p^{-1}L)_+$. Hence $(F_1)_+ \simeq (F \otimes p^{-1}L)_+$ and Theorem 12.4.5 gives $F_1 \simeq F \otimes p^{-1}L$. We deduce

$$\mu_{\text{hom}}(F, F_1)|_{\Lambda} \simeq \mu_{\text{hom}}(F, F \otimes p^{-1}L)|_{\Lambda} \simeq \pi_\Lambda^{-1}L.$$

Hence $L_1 \simeq \pi_\Lambda^{-1}L$. This proves that $L$ is concentrated in degree 0. Since $SS(L) = \emptyset$ we have $L \in \text{Loc}(k_M)$ and $L_1 \in \pi_\Lambda^{-1}(\text{Loc}(k_M))$. \hfill $\square$

**Corollary 13.5.3.** The projection $\Lambda \to M$ is a homotopy equivalence.

*Proof.* As already recalled this follows from Theorem 13.5.4(iv) and Proposition 13.5.2. \hfill $\square$
