Recently, a distinct topological semimetal, nodal-net semimetal, has been identified by Wang et al. through ab initio calculations [1]. The authors claimed that a new body-centered tetragonal carbon allotrope with \textit{I4/mmm} symmetry, termed bct-C$_{40}$, can host this novel state exhibiting boxed-asterisk shaped nodal nets. In this Comment, however, we demonstrate that bct-C$_{40}$ is in fact a nodal surface semimetal, the concept of which has been proposed as early as 2016 [2,3].

In Fig. 3(a) of Ref. [1], the authors present the electronic band structure of bct-C$_{40}$ along the high-symmetry $k$-path of X-P-L-X-G-L-A-G-Z-A-X. Based on the six Dirac points and the crystal symmetry, they directly jump to the conclusion that bct-C$_{40}$ possesses two boxed-asterisk shaped nodal nets comprising six nodal lines which link nine special nodal points 0–8 [Fig. 3(c) in Ref.[1]]. From our careful re-calculations using the same code (VASP [4]) and computational details in Ref.[1], we obtain the same band structure and confirm that the position coordinates of 0, 1 and 2 nodes in Ref. [1] are indisputable. However, upon closer examination we find that the node (D$_{01}$) along the line of A-G not locates in the straight line of 0-1, and the node (D$_{02}$) along LX also not in 0-2 [Figs. 1(a-c)]. Thus, the shape formed by the...
nodes between 0 and any of the other eight nodal points (1~8) could not be a straight line as displayed in Figs. 3(c), 4(e) and 4(f) of Ref. [1]. Our further calculations of band structures in L-A-Z-G-L and L-P-X-G-L planes reveal that the Dirac nodes from 0 to 1 [Fig. 1(b)] and 0 to 2 [Fig. 1(c)] both form a wavy line.

FIG. 1 (a) The zone constructed by the high-symmetry points in the 3D BZ of bct-C\textsubscript{40}, in which K\textsubscript{1}, K\textsubscript{2}, K\textsubscript{3}, K\textsubscript{4} and K\textsubscript{5} are the midpoints of N-P, P-X, G-Z, N-K\textsubscript{3} and K\textsubscript{2}-K\textsubscript{4}, respectively; the nodes of 0, 1, 2, D\textsubscript{01}, and D\textsubscript{02} are labelled by blue symbols. Wavy lines (red) formed by nodes (b) between 0 and 1 in the L-A-Z-G-L plane, and (c) between 0 and 2 in the L-P-X-G-L plane. (d) Band structure of bct-C\textsubscript{40} along the \textit{k}-path of K\textsubscript{1}-K\textsubscript{5}. (e) 3D plot of the highest valence band and the lowest conduction band in the N-P-K\textsubscript{2}-K\textsubscript{4}-N plane. The found Dirac nodes in the plane are denoted by red line.

Additionally, the authors ignored a much more important question: whether there are any Dirac nodal points located inside the region surrounded by 0-1-2? To explore this aspect, we attempt to calculate the band structure of bct-C\textsubscript{40} along a linear \textit{k}-path,
$K_1$-$K_5$ [see Fig. 1(a)], which must passes through the region with 0-1-2 as the edge. As presented in Fig. 1(d), the valence and conduction bands linearly cross at the Fermi level, forming a new Dirac nodal point $D_g$ which not belongs to any line of the boxed-asterisk shaped nets in [1]. Based on this fact, then we perform the calculation of the 3D band structure in the N-P-K$_2$-K$_4$-N plane. The result shows that there are lots of other new nodal points locate in a quasi-line in the plane [Fig. 1(e)]. Evidently, all of these nodes also not belong to the boxed-asterisk shaped net.

**FIG. 2** (a) The two mirror symmetric nodal surfaces with high-symmetry points in the bulk BZ of bct-C$_{40}$. The enlarged (b) side and (c) top views of the above nodal surface.

To ascertain the actual situation of the nodal distribution in 3D momentum space of bct-C$_{40}$, we further calculate its band structure in the whole 3D BZ. The result demonstrates that the found nodes form two mirror symmetric nodal surfaces which span the entire BZ, as illustrated in Fig. 2(a). Zooming into the above nodal surface, we find that the surface is like a “basin” with a quasi-square wavy boundary [Fig. 2(b)]
and 2(c)]. Thus bct-C_{40} is actually just a new member of topological nodal surface semimetals [2,3], and the corresponding nodal surfaces should belong to “Class-I nodal surfaces” classified according to the different mechanisms of symmetric protection [5]. Although there only a few topological nodal surface semimetals have been predicted to date [2,3,5-7], the Dirac nodal surface state has been confirmed in quite recent experiment by angle-resolved photoemission spectroscopy [8].
