New Sense of a Circle

Mamuka Meskhishvili

Abstract

New condition is found for the set of points in the plane, for which the locus is a circle.

It is proved: the locus of points, such that the sum of the \((2m)\)-th powers \(S_n^{(2m)}\) of the distances to the vertexes of fixed regular \(n\)-sided polygon is constant, is a circle if

\[
S_n^{(2m)} > nr^{2m}, \quad \text{where} \quad m = 1, 2, \ldots, n - 1
\]

and \(r\) is the distance from the center of the regular polygon to the vertex.

The radius \(\ell\) satisfies:

\[
S_n^{(2m)} = n \left[ (r^2 + \ell^2)^m + \sum_{k=1}^{[m/2]} \binom{m}{2k} (r^2 + \ell^2)^{m-2k} (r\ell)^{2k} \binom{2k}{k} \right].
\]

Key words and phrases. Locus, circle, center, regular polygon, vertex, constant sum of squares, constant sum of \(m\)-th powers, cosine sum, cosine power sum.

1 Introduction

A locus of points is the set of points, and only those points, that satisfies given conditions. A circle is usually defined as the locus of points (in the plane) at a given distance from a given point. This is well-known definition of a circle, but not only. It is known definition of a circle by using two fixed points – the locus of points, such that the sum of the squares of the distances to two distinct fixed points is constant, is a circle.

More generally, for any collection of \( n \) number of points \( P_i \), constants \( \lambda_i \) and \( S^{(2)}_n \), distances \( d(X, P_i) \) – the locus of points \( X \) such that

\[
\sum_{i=1}^{n} \lambda_i d^2(X, P_i) = S^{(2)}_n,
\]

is either

(a) a circle, a point or empty set if \( \sum_{i=1}^{n} \lambda_i \neq 0 \),

(b) a line, a plane or the empty set if \( \sum_{i=1}^{n} \lambda_i = 0 \).

Indeed, let \((a_i, b_i)\) be the coordinates of point \( P_i \) and \((x, y)\) the coordinates of point \( X \). Then the equation satisfied by \( X \) takes the form

\[
S^{(2)}_n = \sum_{i=1}^{n} \lambda_i ((x - a_i)^2 + (y - b_i)^2) =
\]

\[
= (x^2 + y^2) \sum_{i=1}^{n} \lambda_i - x \cdot 2 \sum_{i=1}^{n} \lambda_i a_i -
\]

\[
- y \cdot 2 \sum_{i=1}^{n} \lambda_i b_i + \sum_{i=1}^{n} \lambda_i (a_i^2 + b_i^2).
\]
If the coefficient of $x^2 + y^2$ is nonzero, then this equation determines either a circle, a point or the empty set and if it is zero, then the equation determines either a line, a plane, or the empty set [1].

In this article we consider under points $P_i$ – vertexes of a regular $n$-sided polygon $P_n$ and for coefficients

$$\lambda_i = 1, \ i = 1, 2, \ldots, n.$$ 

We start $m = 1$, i.e. we have the constant sum of the second powers of distances from point $X$ to the vertexes of regular $n$-sided polygon. In our notations – case $S_n^{(2)}$. The case of two points ($n = 2$) is well-known [2], thus we discuss $n > 2$.

2 Regular Polygon.
Constant Sum of 2nd Powers

Theorem 2.1. The locus of points, such that the sum of the second powers $S_n^{(2)}$ of the distances to the vertexes of fixed regular $n$-sided polygon is constant, is a circle if

$$S_n^{(2)} > nr^2,$$

where $r$ is the distance from the center of the regular polygon to the vertex. The center of the circle is at the center of the regular polygon and the radius is

$$\sqrt{\frac{S_n^{(2)}}{n} - r^2}.$$
If $S_n^{(2)} = nr^2$ the locus is a point – the center of polygon and if $S_n^{(2)} < nr^2$ it is the empty set.

Firstly discuss the regular polygon with even number of vertexes $2n$. Numerate vertexes as shown in Figure 1. Denote the distance from an arbitrary point $M$ to the vertex $i$ by $x_i$, respectively, $i = 1, \ldots, 2n$ and $OM = \ell$. In even case vertexes

$$1 \text{ and } 2n - 1 , \ldots, k \text{ and } 2n - k , \ldots, n - 1 \text{ and } n + 1$$

are symmetrical with respect to the line which passes through center 0 and vertex $2n$, as shown in Figure 1.
Calculate the square of distances in pairs

\[ x_1^2 \text{ and } x_{2n-1}^2, \ldots, x_k^2 \text{ and } x_{2n-k}^2, \ldots, x_{n-1}^2 \text{ and } x_{n+1}^2, \]
\[ x_n^2 \text{ and } x_{2n}^2. \]

To calculate angles, we use arrows directions (Figure 1) clockwise for 1, \ldots, n − 1 vertexes and counterclockwise for 2n − 1, \ldots, n + 1 vertexes;

\[ x_1^2 = r^2 + \ell^2 - 2r\ell \cos \left( \frac{360^\circ}{2n} - \alpha \right) \text{ and } \]
\[ x_{2n-1}^2 = r^2 + \ell^2 - 2r\ell \cos \left( \frac{360^\circ}{2n} + \alpha \right), \]
\[ \vdots \]
\[ x_k^2 = r^2 + \ell^2 - 2r\ell \cos \left( k \frac{360^\circ}{2n} - \alpha \right) \text{ and } \]
\[ x_{2n-k}^2 = r^2 + \ell^2 - 2r\ell \cos \left( k \frac{360^\circ}{2n} + \alpha \right), \]
\[ \vdots \]
\[ x_{n-1}^2 = r^2 + \ell^2 - 2r\ell \cos \left( (n-1) \frac{360^\circ}{2n} - \alpha \right) \text{ and } \]
\[ x_{n+1}^2 = r^2 + \ell^2 - 2r\ell \cos \left( (n-1) \frac{360^\circ}{2n} + \alpha \right), \]
\[ x_n^2 = r^2 + \ell^2 - 2r\ell \cos(180^\circ - \alpha) \text{ and } \]
\[ x_{2n}^2 = r^2 + \ell^2 - 2r\ell \cos \alpha. \]

Summarize each pair:
\[ x_1^2 + x_{2n-1}^2 = 2(r^2 + \ell^2) - 2r\ell \cdot 2 \cos \alpha \cdot \cos \frac{360^\circ}{2n}, \]
\[ \vdots \]
\[ x_k^2 + x_{2n-k}^2 = 2(r^2 + \ell^2) - 2r\ell \cdot 2 \cos \alpha \cdot \cos \frac{k \cdot 360^\circ}{2n}, \]
\[ \vdots \]
\[ x_{n-1}^2 + x_{n+1}^2 = 2(r^2 + \ell^2) - 2r\ell \cdot 2 \cos \alpha \cdot \cos \left( (n-1) \frac{360^\circ}{2n} \right), \]
\[ x_n^2 + x_{2n}^2 = 2(r^2 + \ell^2) - 2r\ell \cdot 2 \cos 90^\circ \cdot \cos(90^\circ - \alpha) = 2(r^2 + \ell^2). \]

There are \( n \) pairs, so total sum is

\[ S_{2n}^{(2)} = \sum_{i=1}^{2n} x_i^2 = \]
\[ = 2n(r^2 + \ell^2) - 4r\ell \cos \alpha \sum_{k=1}^{n-1} \cos \left( k \cdot \frac{360^\circ}{2n} \right). \]

\[ \sum_{k=1}^{n-1} \cos \left( k \cdot \frac{360^\circ}{2n} \right) = \sum_{k=1}^{n-1} \cos \left( k \cdot \frac{180^\circ}{n} \right) = \]
\[ = \cos \frac{180^\circ}{n} + \cos 2 \frac{180^\circ}{n} + \cdots + \cos(n-2) \frac{180^\circ}{n} + \cos(n-1) \frac{180^\circ}{n}. \]

After grouping
\[
\sum_{k=1}^{n-1} \cos \left( \frac{k \cdot 180^\circ}{n} \right) = \\
= \cos \left( \frac{180^\circ}{n} \right) + \cos \left( \frac{(n-1) \cdot 180^\circ}{n} \right) + \cos \left( \frac{2 \cdot 180^\circ}{n} \right) + \cos \left( \frac{(n-2) \cdot 180^\circ}{n} \right) + \cdots + \\
= \cos \left( \frac{180^\circ}{n} \right) + \cos \left( 180^\circ - \frac{180^\circ}{n} \right) + \cos \left( \frac{2 \cdot 180^\circ}{n} \right) + \\
\quad + \cos \left( \frac{180^\circ - 2 \cdot 180^\circ}{n} \right) + \cdots = 0,
\]

since each pair is 0.

**Note.** If \( n \) is odd we have \( \frac{n-1}{2} \) pairs, but if \( n \) is even \( \frac{n}{2} - 1 \) pairs (whose sums are 0) and one more alone term \( \cos \left( \frac{n \cdot 180^\circ}{2n} \right) \), which itself is 0. So we prove

\[
\sum_{k=1}^{n-1} \cos \left( \frac{k \cdot 180^\circ}{n} \right) = 0,
\]

and from that it follows

\[
S_n^{(2)} = \sum_{i=1}^{2n} x_i^2 = 2n(r^2 + \ell^2).
\]

Now discuss the case, when the number of vertexes of a regular polygon is odd \(- 2n + 1\).

Numerate vertexes as shown in Figure 2. As in even case vertexes

1 and \( 2n \), \ldots, \( k \) and \( 2n + 1 - k \), \ldots, \( n \) and \( n + 1 \)
are symmetrical with respect to the line which passes through center 0 and vertex $2n + 1$, as shown in Figure 2.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure2.png}
\caption{Figure 2.}
\end{figure}

Calculate the square of distances in pairs –

\[ x_1^2, \quad x_{2n}^2, \ldots, \quad x_k^2, \quad x_{2n+1-k}^2, \ldots, \quad x_n^2 \quad \text{and} \quad x_{n+1}^2. \]

Only $x_{2n+1}^2$ – square of distance remains single. To calculate the angles, we use arrows directions (Figure 2) clockwise for vertexes $1, \ldots, n$ and counterclockwise for vertexes $2n, \ldots, n + 1$;

\[ x_1^2 = r^2 + \ell^2 - 2rl \cos \left( \frac{360^\circ}{2n+1} - \alpha \right) \quad \text{and} \quad x_{2n}^2 = r^2 + \ell^2 - 2rl \cos \left( \frac{360^\circ}{2n+1} + \alpha \right), \]

\[ \vdots \]
\[ x_k^2 = r^2 + \ell^2 - 2r\ell \cos \left( k \frac{360^\circ}{2n+1} - \alpha \right) \text{ and} \]
\[ x_{2n+1-k}^2 = r^2 + \ell^2 - 2r\ell \cos \left( k \frac{360^\circ}{2n+1} + \alpha \right), \]
\[ : \]
\[ x_n^2 = r^2 + \ell^2 - 2r\ell \cos \left( n \frac{360^\circ}{2n+1} - \alpha \right) \text{ and} \]
\[ x_{2n+1}^2 = r^2 + \ell^2 - 2r\ell \cos \left( n \frac{360^\circ}{2n+1} + \alpha \right), \]
\[ x_{2n+1}^2 = r^2 + \ell^2 - 2r\ell \cos \alpha. \]

There are \( n \) pairs, so total sum is

\[ S_{2n+1}^{(2)} = \sum_{i=1}^{2n+1} x_i^2 = \]
\[ = (2n + 1)(r^2 + \ell^2) - 2r\ell \cos \alpha - \]
\[ - 2r\ell \sum_{k=1}^{n} \left( \cos \left( k \frac{360^\circ}{2n+1} - \alpha \right) + \cos \left( k \frac{360^\circ}{2n+1} + \alpha \right) \right) = \]
\[ = (2n + 1)(r^2 + \ell^2) - 2r\ell \cos \alpha - \]
\[ - 2r\ell \sum_{k=1}^{n} 2 \cos \alpha \cdot \cos \left( k \frac{360^\circ}{2n+1} \right) = \]
\[ = (2n + 1)(r^2 + \ell^2) - \]
\[ - 2r\ell \cos \alpha \left( 1 + 2 \sum_{k=1}^{n} \left( \cos k \frac{360^\circ}{2n+1} \right) \right). \]
Each addend of the sum
\[ \sum_{k=1}^{n} \cos k \frac{360^\circ}{2n + 1}, \]
multiply by
\[ 2 \sin \frac{180^\circ}{2n + 1}, \]
and then use trigonometric identity
\[ 2 \sin C \cdot \cos D = \sin(C + D) - \sin(D - C) \]
we get
\[ 2 \sin \frac{180^\circ}{2n + 1} \left( \cos \frac{2 \cdot 180^\circ}{2n + 1} + \cos \frac{2 \cdot 180^\circ}{2n + 1} + \right. \]
\[ + \cos \frac{3 \cdot 180^\circ}{2n + 1} + \cdots + \]
\[ \left. + \cos(n - 1) \frac{2 \cdot 180^\circ}{2n + 1} + \cos n \frac{2 \cdot 180^\circ}{2n + 1} \right) = \]
\[
\begin{align*}
&= \sin \frac{3 \cdot 180^\circ}{2n+1} - \sin \frac{180^\circ}{2n+1} + \\
&+ \sin \frac{5 \cdot 180^\circ}{2n+1} - \sin \frac{3 \cdot 180^\circ}{2n+1} + \\
&+ \sin \frac{7 \cdot 180^\circ}{2n+1} - \sin \frac{5 \cdot 180^\circ}{2n+1} + \\
&\quad \vdots \\
&+ \sin \frac{(2n-1) \cdot 180^\circ}{2n+1} - \sin \frac{(2n-3) \cdot 180^\circ}{2n+1} + \\
&+ \sin \frac{(2n+1) \cdot 180^\circ}{2n+1} - \sin \frac{(2n-1) \cdot 180^\circ}{2n+1} = \\
&= \sin \frac{(2n+1) \cdot 180^\circ}{2n+1} - \sin \frac{180^\circ}{2n+1} = -\sin \frac{180^\circ}{2n+1}.
\end{align*}
\]

So,
\[
\sum_{k=1}^{n} \cos k \cdot \frac{360^\circ}{2n+1} = -\frac{1}{2}.
\]

and in odd case we obtain
\[
S_{2n+1}^{(2)} = \sum_{i=1}^{2n+1} x_i^2 = (2n + 1)(r^2 + \ell^2).
\]

Summarize even and odd cases. For an arbitrary number \( n \), we have:
\[
S_n^{(2)} = n(r^2 + \ell^2),
\]

which finally proves the Theorem \ref{thm:main}.
3 Regular Triangle.
Constant Sum of 4th Powers

The sum of the fourth powers of the distances to the vertexes is:

\[ S_3^{(4)} = \sum_{i=1}^{3} x_i^4 = \]

\[ = (r^2 + \ell^2 - 2r\ell \cos \alpha)^2 + (r^2 + \ell^2 - 2r\ell \cos(120^\circ - \alpha))^2 + \]

\[ + (r^2 + \ell^2 - 2r\ell \cos(120^\circ + \alpha))^2. \]

Introduce new notations

\[ A = r^2 + \ell^2 \quad \text{and} \quad B = 2r\ell; \]

\[ S_3^{(4)} = (A - B \cos \alpha)^2 + (A - B \cos(120^\circ - \alpha))^2 + \]

\[ + (A - B \cos(120^\circ + \alpha))^2 = \]

\[ = 3A^2 - 2AB(\cos \alpha + \cos(120^\circ - \alpha) + \cos(120^\circ + \alpha)) + \]

\[ + B^2(\cos^2 \alpha + \cos^2(120^\circ - \alpha) + \cos^2(120^\circ + \alpha)); \]

\[ \cos \alpha + \cos(120^\circ - \alpha) + \cos(120^\circ + \alpha) = \]

\[ = \cos \alpha + 2 \cos 120^\circ \cos \alpha = 0, \]

\[ \cos^2 \alpha + \cos^2(120^\circ - \alpha) + \cos^2(120^\circ + \alpha) = \]

\[ = \frac{1}{2} \left( 3 + \cos 2\alpha + \cos(240^\circ - 2\alpha) + \cos(240^\circ + 2\alpha) \right) = \]
\[
= \frac{3}{2} + \frac{1}{2} \left( \cos 2\alpha + \cos (120^\circ + 2\alpha) + \cos (120^\circ - 2\alpha) \right) = \frac{3}{2}.
\]

So,
\[
S_3^{(4)} = 3A^2 + \frac{3}{2}B^2 = 3(r^4 + \ell^4 + 4r^2\ell^2).
\]

The sum \(S_3^{(4)}\) does not contain \(\alpha\), i.e. this expression does not depend on direction \(OM\) and only depends on length \(-OM\).

Since the triangle is fixed \(r\) is constant and this expression is increasing under \(\ell\) \((\ell > 0)\), so obtained relation is one to one:
\[
S_3^{(4)} = \text{const} \iff \ell = \text{const}.
\]

We proved

**Theorem 3.1.** The locus of points, such that the sum of the fourth powers \(S_3^{(4)}\) of the distances to the vertexes of fixed regular triangle is constant, is a circle if
\[
S_3^{(4)} > 3r^4,
\]

where \(r\) is the distance from the center of the regular triangle to the vertex. The center of the circle is at the center of the regular triangle and the radius \(\ell\) satisfies the following condition:
\[
S_3^{(4)} = 3 \left[ (r^2 + \ell^2)^2 + 2(r\ell)^2 \right].
\]

If \(S_3^{(4)} = 3r^4\) the locus is a point – the center of the regular triangle and if \(S_3^{(4)} < 3r^4\) it is the empty set.
Note. The sum of the sixth powers $S_3^{(6)}$ contains $\alpha$, so in this case the locus is not a circle.

4 Square.
Constant Sum of 4th and 6th Powers

$$S_4^{(4)} = (A - B \cos \alpha)^2 + (A - B \cos(90^\circ - \alpha))^2 +$$
$$+ (A - B \cos(180^\circ - \alpha))^2 + (A - B \cos(90^\circ + \alpha))^2 =$$
$$= 4A^2 - 2AB(\cos \alpha + \cos(90^\circ - \alpha) +$$
$$+ \cos(180^\circ - \alpha) + \cos(90^\circ + \alpha)) +$$
$$+ B^2(\cos^2 \alpha + \cos^2(90^\circ - \alpha) +$$
$$+ \cos^2(180^\circ - \alpha) + \cos^2(90^\circ + \alpha));$$

$$\cos \alpha + \cos(90^\circ - \alpha) + \cos(180^\circ - \alpha) + \cos(90^\circ + \alpha) =$$
$$= 2 \cos 90^\circ \cdot \cos(90^\circ - \alpha) + 2 \cos 90^\circ \cdot \cos \alpha = 0,$$

$$\cos^2 \alpha + \cos^2(90^\circ - \alpha) + \cos^2(180^\circ - \alpha) + \cos^2(90^\circ + \alpha) =$$
$$= \frac{1}{2} \left(4 + \cos 2\alpha + \cos(180^\circ - 2\alpha) +$$
$$+ \cos(360^\circ - 2\alpha) + \cos(180^\circ + 2\alpha)\right) = 2,$$

$$S_4^{(4)} = 4A^2 + 2B^2 = 4r^4 + \ell^4 + 4r^2\ell^2.$$
Theorem 4.1. The locus of points, such that the sum of the fourth powers \( S_4^{(4)} \) of the distances to the vertexes of fixed square is constant, is a circle if

\[
S_4^{(4)} > 4r^4,
\]

where \( r \) is the distance from the center of the square to the vertex. The center of the circle is at the center of the square and the radius \( \ell \) satisfying the following condition:

\[
S_4^{(4)} = 4 \left[ (r^2 + \ell)^2 + 2(r\ell)^2 \right].
\]

If \( S_4^{(4)} = 4r^4 \) the locus is a point – the center of the square and if \( S_4^{(4)} < 4r^4 \) it is the empty set.

The sum of sixth powers:

\[
S_4^{(6)} = (A - B \cos \alpha)^3 + (A - B \cos(90^\circ - \alpha))^3 +
\]

\[
+ (A - B \cos(180^\circ - \alpha))^3 + (A - B \cos(90^\circ + \alpha))^3 =
\]

\[
= 4A^3 - 3A^2B \left( \cos \alpha + \cos(90^\circ - \alpha) +
\right.
\]

\[
+ \cos(180^\circ - \alpha) + \cos(90^\circ + \alpha) \left. \right) +
\]

\[
+ 3AB^2 \left( \cos^2 \alpha + \cos^2(90^\circ - \alpha) +
\right.
\]

\[
+ \cos^2(180^\circ - \alpha) + \cos^2(90^\circ + \alpha) \left. \right) -
\]

\[
- B^3 \left( \cos^3 \alpha + \cos^3(90^\circ - \alpha) +
\right.
\]

\[
+ \cos^3(180^\circ - \alpha) + \cos^3(90^\circ + \alpha) \right),
\]

16
\[
\cos^3 \alpha + \cos^3 (90^\circ - \alpha) + \cos^3 (180^\circ - \alpha) + \cos^3 (90^\circ + \alpha) = \\
= \cos^3 \alpha + \cos^3 (90^\circ - \alpha) - \cos^3 \alpha - \cos^3 (90^\circ - \alpha) = 0.
\]

So,

\[S_4^{(6)} = 4A^3 + 3AB^2 \cdot 2 = 4(r^2 + \ell^2)(r^4 + \ell^4 + 8r^2\ell^2).\]

For fixed \(r\), obtained expression is increasing under variable \(\ell \ (\ell > 0)\), so it is one to one relation between the sum of the sixth powers \(S_4^{(6)}\) and \(\ell\):

\[S_4^{(6)} = \text{const} \iff \ell = \text{const}.\]

**Theorem 4.2.** The locus of points, such that the sum of the sixth powers \(S_4^{(6)}\) of the distances to the vertexes of fixed square is constant, is a circle if

\[S_4^{(6)} > 4r^6,\]

where \(r\) is the distance from the center of the square to the vertex. The center of the circle is at the center of the square and the radius \(\ell\) satisfying the following condition:

\[S_4^{(6)} = 4\left[(r^2 + \ell^2)^3 + 6(r^2 + \ell^2)(r\ell)^2\right].\]

If \(S_4^{(6)} = 4r^6\) the locus is a point – the center of the square and if \(S_4^{(6)} < 4r^6\) it is the empty set.

**Note.** The sum of the eighth powers – \(S_4^{(8)}\) contains \(\alpha\), so in this case the locus is not a circle.
5 Regular Pentagon.
Constant Sum of 4th, 6th and 8th Powers

\[ S_5^{(4)} = (r^2 + \ell^2 - 2r\ell \cos \alpha)^2 + (r^2 + \ell^2 - 2r\ell \cos(72^\circ - \alpha))^2 + \]
\[ + (r^2 + \ell^2 - 2r\ell \cos(144^\circ - \alpha))^2 + \]
\[ + (r^2 + \ell^2 - 2r\ell \cos(144^\circ + \alpha))^2 + \]
\[ + (r^2 + \ell^2 - 2r\ell \cos(72^\circ + \alpha))^2 = \]
\[ = (A - B \cos \alpha)^2 + (A - B \cos(72^\circ - \alpha))^2 + \]
\[ + (A - B \cos(144^\circ - \alpha))^2 + \]
\[ + (A - B \cos(144^\circ + \alpha))^2 + (A - B \cos(72^\circ + \alpha))^2 = \]
\[ = 5A^2 - 2AB \left( \cos \alpha + \cos(72^\circ - \alpha) + \cos(144^\circ - \alpha) + \cos(144^\circ + \alpha) + \cos(72^\circ + \alpha) \right) + \]
\[ + B^2 \left( \cos^2 \alpha + \cos^2(72^\circ - \alpha) + \cos^2(144^\circ - \alpha) + \cos^2(144^\circ + \alpha) + \cos^2(72^\circ + \alpha) \right). \]

\[
\cos \alpha + \cos(72^\circ - \alpha) + \cos(144^\circ - \alpha) + \cos(144^\circ + \alpha) + \\
+ \cos(72^\circ + \alpha) = \cos \alpha + 2 \cos \alpha \cdot 72^\circ + 2 \cos \alpha \cdot \cos 144^\circ = \\
= \cos \alpha \left( 1 + 2(\cos 72^\circ + \cos 144^\circ) \right). \]

Indeed,
$$\sin 18^\circ = \frac{\sqrt{5} - 1}{4},$$

$$\cos 72^\circ + \cos 144^\circ = \sin 18^\circ - \cos 36^\circ =$$

$$= \sin 18^\circ - 1(1 - 2 \sin^2 18^\circ) =$$

$$= \frac{\sqrt{5} - 1}{4} - 1 + \frac{(\sqrt{5} - 1)^2}{2} = -\frac{1}{2},$$

i.e.

$$\cos \alpha + \cos(72^\circ - \alpha) + \cos(144^\circ - \alpha) +$$

$$+ \cos(144^\circ + \alpha) + \cos(72^\circ + \alpha) = 0.$$

Calculate the sum of the second powers:

$$\cos^2 \alpha + \cos^2(72^\circ - \alpha) + \cos^2(144^\circ - \alpha) +$$

$$+ \cos^2(144^\circ + \alpha) + \cos^2(72^\circ + \alpha) =$$

$$= \frac{1}{2} \left( 5 + \cos 2\alpha + \cos(144^\circ - 2\alpha) + \cos(144^\circ + 2\alpha) +$$

$$+ \cos(288^\circ - 2\alpha) + \cos(288^\circ + 2\alpha) \right) =$$

$$= \frac{1}{2} \left( 5 + \cos 2\alpha + \cos(144^\circ - 2\alpha) + \cos(144^\circ + 2\alpha) +$$

$$+ \cos(72^\circ + 2\alpha) + \cos(72^\circ - 2\alpha) \right) = \frac{5}{2}.$$
So,

\[ S_5^{(4)} = 5A^2 + \frac{5}{2}B^2 = \]
\[ = 5(r^2 + \ell^2)^2 + 10r^2\ell^2 = 5(r^4 + \ell^4 + 4r^2\ell^2). \]

**Theorem 5.1.** The locus of points, such that the sum of the fourth powers \( S_5^{(4)} \) of the distances to the vertexes of fixed regular pentagon is constant, is a circle if

\[ S_5^{(4)} > 5r^4, \]

where \( r \) is the distance from the center of the regular pentagon to the vertex. The center of the circle is at the center of the regular pentagon and the radius \( \ell \) satisfies the following condition:

\[ S_5^{(4)} = 5\left[(r^2 + \ell^2)^2 + 2(r\ell)^2\right]. \]

If \( S_5^{(4)} = 5r^4 \) the locus is a point – the center of the pentagon and if \( S_5^{(4)} < 5r^4 \) it is the empty set.
\[ S_5^{(6)} = (A - B \cos \alpha)^3 + (A - B \cos(72^\circ - \alpha))^3 + \]
\[ + (A - B \cos(144^\circ - \alpha))^3 + (A - B \cos(144^\circ + \alpha))^3 + \]
\[ + (A - B \cos(72^\circ + \alpha))^3 = \]
\[ = A^3 - 3A^2B \cos \alpha + 3AB^2 \cos^2 \alpha - B^3 \cos^3 \alpha + \]
\[ + A^3 - 3A^2B \cos(72^\circ - \alpha) + 3AB^2 \cos^2(72^\circ - \alpha) - \]
\[ - B^3 \cos^3(72^\circ - \alpha) + \]
\[ + A^3 - 3A^2B \cos(144^\circ - \alpha) + 3AB^2 \cos^2(144^\circ - \alpha) - \]
\[ - B^3 \cos^3(144^\circ - \alpha) + \]
\[ + A^3 - 3A^2B \cos(144^\circ + \alpha) + 3AB^2 \cos^2(144^\circ + \alpha) - \]
\[ - B^3 \cos^3(144^\circ + \alpha) + \]
\[ + A^3 - 3A^2B \cos(72^\circ + \alpha) + 3AB^2 \cos^2(72^\circ + \alpha) - \]
\[ - B^3 \cos^3(72^\circ + \alpha) = \]
\[ = 5A^3 - 3A^2B \left( \cos \alpha + \cos(72^\circ - \alpha) + \cos(144^\circ - \alpha) + \right. \]
\[ + \cos(144^\circ + \alpha) + \cos(72^\circ + \alpha) \right) + \]
\[ + 3AB^2 \left( \cos^2 \alpha + \cos^2(72^\circ - \alpha) + \cos^2(144^\circ - \alpha) + \right. \]
\[ + \cos^2(144^\circ + \alpha) + \cos^2(72^\circ + \alpha) \right) - \]
\[ - B^3 \left( \cos^3 \alpha + \cos^3(72^\circ - \alpha) + \cos^3(144^\circ - \alpha) + \right. \]
\[ + \cos^3(144^\circ + \alpha) + \cos^3(72^\circ + \alpha) \right). \]
From the preceding part we know the values of the sums of the first and the second powers. Calculate the sum of the third powers:

\[
\cos^3 \alpha + \cos^3 (72^\circ - \alpha) + \cos^3 (144^\circ - \alpha) + \\
+ \cos^3 (144^\circ + \alpha) + \cos^3 (72^\circ + \alpha) = \\
= \frac{1}{4} \left( 3 \cos \alpha + \cos 3\alpha + \\
+ 3 \cos (72^\circ - \alpha) + \cos (216^\circ - 3\alpha) + \\
+ 3 \cos (144^\circ - \alpha) + \cos (432^\circ - 3\alpha) + \\
+ 3 \cos (144^\circ + \alpha) + \cos (432^\circ + 3\alpha) + \\
+ 3 \cos (72^\circ + \alpha) + \cos (216^\circ + 3\alpha) \right) = \\
= \frac{1}{4} \left( 3 \left( \cos \alpha + \cos (72^\circ - \alpha) + \cos (144^\circ - \alpha) + \\
+ \cos (144^\circ + \alpha) + \cos (72^\circ + \alpha) \right) + \\
+ \cos 3\alpha + \cos (216^\circ - 3\alpha) + \cos (432^\circ - 3\alpha) + \\
+ 3 \cos (432^\circ + 3\alpha) + \cos (216^\circ + 3\alpha) \right) = \\
= \frac{1}{4} \left( \cos 3\alpha + \cos (144^\circ + 3\alpha) + \cos (72^\circ - 3\alpha) + \\
+ \cos (72^\circ + 3\alpha) + \cos (144^\circ - 3\alpha) \right) = 0.
\]

So,
Theorem 5.2. The locus of points, such that the sum of the sixth powers \( S_5^{(6)} \) of the distances to the vertexes of fixed regular pentagon is constant, is a circle if

\[
S_5^{(6)} > 5r^6,
\]

where \( r \) is the distance from the center of the regular pentagon to the vertex. The center of the circle is at the center of the regular pentagon and the radius \( \ell \) satisfies the following condition:

\[
S_5^{(6)} = 5\left[(r^2 + \ell^2)^3 + 6(r^2 + \ell^2)(r\ell)^2\right].
\]

If \( S_5^{(6)} = 5r^6 \) the locus is a point – the center of the regular pentagon and if \( S_5^{(6)} < 5r^6 \) it is the empty set.

\[
S_5^{(8)} = (A - B \cos \alpha)^4 + (A - B \cos(72^\circ - \alpha))^4 +
\]
\[
+ (A - B \cos(144^\circ - \alpha))^4 + (A - B \cos(144^\circ + \alpha))^4 +
\]
\[
+ (A - B \cos(72^\circ + \alpha))^4 =
\]
\[= A^4 - 4A^3B \cos \alpha + 6A^2B^2 \cos^2 \alpha -
\]
\[- 4AB^3 \cos^3 \alpha + B^4 \cos^4 \alpha + \cdots =
\]
\[= 5A^4 - 4A^3B \left( \cos \alpha + \cos(72^\circ - \alpha) + \cos(144^\circ - \alpha) +
\right.
\]
\[+ \cos(144^\circ + \alpha) + \cos(72^\circ + \alpha) \right) +
\]
\[+ 6A^2B^2 \left( \cos^2 \alpha + \cos^2(72^\circ - \alpha) + \cos^2(144^\circ - \alpha) +
\right.
\]
\[+ \cos^2(144^\circ + \alpha) + \cos^2(72^\circ + \alpha) \right) -
\]
\[- 4AB^3 \left( \cos^3 \alpha + \cos^3(72^\circ - \alpha) + \cos^3(144^\circ - \alpha) +
\right.
\]
\[+ \cos^3(144^\circ + \alpha) + \cos^3(72^\circ + \alpha) \right) +
\]
\[+ B^4 \left( \cos^4 \alpha + \cos^4(72^\circ - \alpha) + \cos^4(144^\circ - \alpha) +
\right.
\]
\[+ \cos^4(144^\circ + \alpha) + \cos^4(72^\circ + \alpha) \right).
\]

Calculate the sum of the fourth powers:

\[\cos^4 \alpha + \cos^4(72^\circ - \alpha) + \cos^4(144^\circ - \alpha) +
\]
\[+ \cos^4(144^\circ + \alpha) + \cos^4(72^\circ + \alpha) =
\]
\[= \frac{1}{8} \left( \cos 4\alpha + 8 \cos^2 \alpha - 1 +
\right.
\]
\[+ \cos(288^\circ - 4\alpha) + 8 \cos^2(72^\circ - \alpha) - 1 +
\]
\[+ \cos(576^\circ - 4\alpha) + 8 \cos^2(144^\circ - \alpha) - 1 +
\]

24
\[ + \cos(576^\circ + 4\alpha) + 8 \cos^2(144^\circ + \alpha) - 1 + \\
+ \cos(288^\circ + 4\alpha) + 8 \cos^2(72^\circ + \alpha) - 1 ] = \\
\frac{1}{8} \left( -5 + 8 \left( \cos^2 \alpha + \cos^2(72^\circ - \alpha) + \\
+ \cos^2(144^\circ - \alpha) + \cos^2(144^\circ + \alpha) + \cos^2(72^\circ + \alpha) \right) + \\
+ \cos 4\alpha + \cos(288^\circ - 4\alpha) + \cos(576^\circ - 4\alpha) + \\
+ \cos(576^\circ + 4\alpha) + \cos(288^\circ + 4\alpha) \right) = \\
\frac{1}{8} \left( -5 + 8 \cdot \frac{5}{2} + \cos 4\alpha + \cos(72^\circ + 4\alpha) + \\
+ \cos(144^\circ + 4\alpha) + \cos(144^\circ - 4\alpha) + \cos(72^\circ - 4\alpha) \right) = \\
\frac{15}{8}, \\
S_5^{(8)} = 5A^4 + 6A^2B^2 \cdot \frac{5}{2} + B^4 \cdot \frac{15}{8} = \\
= 5(r^2 + \ell^2)^2(r^4 + \ell^4 + 14r^2\ell^2) + 30r^4\ell^4.

**Theorem 5.3.** The locus of points, such that the sum of the eighth powers \(S_5^{(8)}\) of the distances to the vertexes of fixed regular pentagon is constant, is a circle if 

\[ S_5^{(8)} > 5r^8, \]
where \( r \) is the distance from the center of the regular pentagon to the vertex. The center of the circle is at the center of the regular pentagon and the radius \( \ell \) satisfies the following condition:

\[
S_5^{(8)} = 5 \left[ (r^2 + \ell^2)^4 + 12(r^2 + \ell^2)^2(\ell r)^2 + 6(\ell r)^4 \right].
\]

If \( S_5^{(8)} = 5r^8 \) the locus is a point – the center of the regular pentagon and if \( S_5^{(8)} < 5r^8 \) it is the empty set.

Note. The sum of the tenth powers contains \( \alpha \), so the locus is not a circle.

6 Circle as Locus of Constant Sum of Powers

Summarize obtained results. If \( d(X, P_i) \) is the distance from \( X \) to the vertex \( P_i \) of the regular \( n \)-sided polygon and \( r \) is the distance from the center of the regular polygon to the vertex, we have:

\[
1. \left\{ X : \sum_{i=1}^{n} d^2(X, P_i) = S_n^{(2)} = \text{const} \right\} = \\
= \begin{cases} 
\text{circle,} & \text{if } S_n^{(2)} > nr^2 \\
\text{point,} & \text{if } S_n^{(2)} = nr^2 \\
\varnothing, & \text{if } S_n^{(2)} < nr^2
\end{cases}
\]
2. \( \{ X : \sum_{i=1}^{3} d^4(X, P_i) = S_3^{(4)} = const \} = \)
\[
= \begin{cases} 
\text{circle, if } S_3^{(4)} > 3r^4 \\
\text{point, if } S_3^{(4)} = 3r^4 \\
\emptyset, \text{ if } S_3^{(4)} < 3r^4
\end{cases}
\]

3. \( \{ X : \sum_{i=1}^{4} d^4(X, P_i) = S_4^{(4)} = const \} = \)
\[
= \begin{cases} 
\text{circle, if } S_4^{(4)} > 4r^4 \\
\text{point, if } S_4^{(4)} = 4r^4 \\
\emptyset, \text{ if } S_4^{(4)} < 4r^4
\end{cases}
\]

4. \( \{ X : \sum_{i=1}^{4} d^6(X, P_i) = S_4^{(6)} = const \} = \)
\[
= \begin{cases} 
\text{circle, if } S_4^{(6)} > 4r^6 \\
\text{point, if } S_4^{(6)} = 4r^6 \\
\emptyset, \text{ if } S_4^{(6)} < 4r^6
\end{cases}
\]
5. \( \left\{ X : \sum_{i=1}^{5} d^4(X, P_i) = S_{5}^{(4)} = const \right\} = \)

\[
= \begin{cases} 
\text{circle, if } S_{5}^{(4)} > 5r^4 \\
\text{point, if } S_{5}^{(4)} = 5r^4 \\
\emptyset, \text{ if } S_{5}^{(4)} < 5r^4
\end{cases}
\]

6. \( \left\{ X : \sum_{i=1}^{5} d^6(X, P_i) = S_{5}^{(6)} = const \right\} = \)

\[
= \begin{cases} 
\text{circle, if } S_{5}^{(6)} > 5r^6 \\
\text{point, if } S_{5}^{(6)} = 5r^6 \\
\emptyset, \text{ if } S_{5}^{(6)} < 5r^6
\end{cases}
\]

7. \( \left\{ X : \sum_{i=1}^{5} d^8(X, P_i) = S_{5}^{(8)} = const \right\} = \)

\[
= \begin{cases} 
\text{circle, if } S_{5}^{(8)} > 5r^8 \\
\text{point, if } S_{5}^{(8)} = 5r^8 \\
\emptyset, \text{ if } S_{5}^{(8)} < 5r^8
\end{cases}
\]

Now we are ready to state general hypothesis:
Hypothesis. The locus of points, such that the sum of the $(2m)$-th powers $S_n^{(2m)}$ of the distances to the vertexes of fixed regular $n$-sided polygon is constant, is a circle if

$$S_n^{(2m)} > nr^{2m}, \text{ where } m = 1, 2, \ldots, n - 1$$

and $r$ is the distance from the center of the regular polygon to the vertex. The center of the circle is at the center of the regular polygon.

If $S_n^{(2m)} = nr^{2m}$ the locus is a point – the center of the polygon and if $S_n^{(2m)} < nr^{2m}$ it is the empty set.

Thus, for each even $(2m)$-th power, so that $m < n$:

$$\left\{ X : \sum_{i=1}^{n} d^{2m}(X, P_i) = S_n^{(2m)} = const \right\} =$$

$$= \begin{cases} 
\text{circle,} & \text{if } S_n^{(2m)} > nr^{2m} \\
\text{point,} & \text{if } S_n^{(2m)} = nr^{2m} \\
\emptyset, & \text{if } S_n^{(2m)} < nr^{2m} 
\end{cases}$$

To prove the hypothesis, first of all two lemmas must be proved.
7 Cosine Multiple Arguments
and Cosine Powers Sums

Lemma 7.1. For arbitrary positive integers \(m\) and \(n\), so that \(m < n\), the following condition

\[
\sum_{k=1}^{n} \cos \left( m \left( \alpha - (k - 1) \frac{360^\circ}{n} \right) \right) = 0
\]

is satisfied, where \(\alpha\) is an arbitrary angle.

Denote by

\[
P = e^{im\alpha} + e^{im(\alpha - \frac{360^\circ}{n})} + e^{im(\alpha - 2 \frac{360^\circ}{n})} + \ldots + e^{im(\alpha - (n - 1) \frac{360^\circ}{n})}.
\]

By using Euler’s formula

\[
e^{i\varphi} = \cos \varphi + i \sin \varphi
\]

real part of \(P\) is:

\[
\text{Re}(P) = \sum_{k=1}^{n} \cos \left( m \left( \alpha - (k - 1) \frac{360^\circ}{n} \right) \right).
\]

The formula of the sum of geometric progression gives:
\[ P = e^{im\alpha} \left( 1 + e^{-im\frac{360^\circ}{n}} + (e^{-im\frac{360^\circ}{n}})^2 + \cdots + (e^{-im\frac{360^\circ}{n}})^{n-1} \right) = \\
= e^{im\alpha} \frac{1 - (e^{-im\frac{360^\circ}{n}})^n}{1 - e^{-im\frac{360^\circ}{n}}}, \\
\]
e^{-im360^\circ} = \cos(-360^\circ m) + i(-360^\circ m) = 1.

Since \( m < n \), \( e^{-im\frac{360^\circ}{n}} \neq 1 \). So \( P = 0 \), i.e. \( \text{Re}(P) = 0 \) which proves the Lemma 7.1.

**Note.** If \( m = n \), the sum equals \( n \cos(n\alpha) \). The sum is not zero only in cases when \( m \) is multiple of \( n \). If \( m = pn \), the sum is \( n \cos(pn\alpha) \).

**Lemma 7.2.** For arbitrary positive integers \( m \) and \( n \), so that \( m < n \) and for an arbitrary angle \( \alpha \) the following conditions are satisfied:

if \( m \) is odd

\[
\sum_{k=1}^{n} \cos^m \left( \alpha - (k - 1) \frac{360^\circ}{n} \right) = 0;
\]

if \( m \) is even

\[
\sum_{k=1}^{n} \cos^m \left( \alpha - (k - 1) \frac{360^\circ}{n} \right) = n \frac{m^2}{m^2}.
\]
By using power-reduction formula for cosine, when \( m \) is odd:

\[
\cos^m \theta = \frac{2}{2^m} \sum_{k=0}^{m-1} \binom{m}{k} \cos\left((m - 2k)\theta\right),
\]

we have

\[
\sum_{k=1}^{n} \cos^m \left( \alpha - (k - 1) \frac{360^\circ}{n} \right) =
\]

\[
= \cos^m \alpha + \cos^m \left( \alpha - \frac{360^\circ}{n} \right) + \cdots + \cos^m \left( \alpha - (n - 1) \frac{360^\circ}{n} \right) =
\]

\[
= \frac{2}{2^m} \left[ \binom{m}{0} \cos m\alpha + \binom{m}{1} \cos(m - 2)\alpha + \cdots + \binom{m}{m-\frac{1}{2}} \cos \alpha +
\right.
\]

\[
+ \binom{m}{0} \cos m\left( \alpha - \frac{360^\circ}{n} \right) + \binom{m}{1} \cos(m - 2)\left( \alpha - \frac{360^\circ}{n} \right) + \cdots +
\]

\[
+ \binom{m}{m-\frac{1}{2}} \cos \left( \alpha - \frac{360^\circ}{n} \right) + \cdots +
\]

\[
+ \binom{m}{0} \cos m\left( \alpha -(n-1) \frac{360^\circ}{n} \right) + \binom{m}{1} \cos(m-2)\left( \alpha -(n-1) \frac{360^\circ}{n} \right) +
\]

\[
+ \cdots + \binom{m}{m-\frac{1}{2}} \cos \left( \alpha - (n - 1) \frac{360^\circ}{n} \right) \right] =
\]

32
\[
\begin{align*}
&= \frac{2}{2^m} \left[ \binom{m}{0} \left( \cos m\alpha + \cos m\left(\alpha - \frac{360^\circ}{n}\right) + \cdots + 
\right. \\
&\quad + \cos m\left(\alpha - (n - 1)\frac{360^\circ}{n}\right) \left. \right) + \\
&\quad + \binom{m}{1} \left( \cos(m-2)\alpha + \cos(m-2)\left(\alpha - \frac{360^\circ}{n}\right) + \cdots + 
\right. \\
&\quad + \cos(m-2)\left(\alpha - (n - 1)\frac{360^\circ}{n}\right) \left. \right) + \\
&\quad \vdots \\
&\quad + \binom{m}{\frac{m-1}{2}} \left( \cos \alpha + \cos \left(\alpha - \frac{360^\circ}{n}\right) + \cdots + 
\right. \\
&\quad + \cos \left(\alpha - (n - 1)\frac{360^\circ}{n}\right) \left. \right) \right].
\end{align*}
\]

Since \( m < n \), from the Lemma 7.1 follows – each sum equals zero, which proves the first part of the Lemma 7.2.

When \( m \) is even power-reduction formula for cosine is:

\[
\cos^m \theta = \frac{1}{2^m} \binom{m}{m/2} + \frac{2}{2^m} \sum_{k=0}^{\frac{m-1}{2}} \binom{m}{k} \cos \left( (m - 2k)\theta \right).
\]

By using the same manner, as in preceding part the sum of the second addends gives zero, and because the number of the first addends is \( n \) total sum equals:
\( n \left( \frac{m}{2} \right) \),

which proves the Lemma 7.2.

8 General Theorem

**Theorem 8.1.** The locus of points, such that the sum of the 
\((2m)\)-th powers \(S_n^{(2m)}\) of distances to the vertexes of fixed regular 
\(n\)-sided polygon is constant, is a circle if

\[ S_n^{(2m)} > nr^{2m}, \text{ where } m = 1, 2, \ldots, n - 1 \]

and \(r\) is the distance from the center of the regular polygon to 
the vertex. The center of the circle is at the center of the regular 
polygon and the radius \(\ell\) satisfies the following condition:

\[ S_n^{(2m)} = n \left( \frac{m}{2} \right)^m + \sum_{k=1}^{\left\lfloor \frac{m}{2} \right\rfloor} \left( \frac{m}{2k} \right) \left( r^2 + \ell^2 \right)^{m-2k} (r\ell)^{2k} \binom{2k}{k}. \]

If \(S_n^{(2m)} = nr^{2m}\) the locus is a point – the center of the polygon 
and if \(S_n^{(2m)} < nr^{2m}\) the locus is the empty set.

For \((2m)\)-th power sum of the distances from an arbitrary point to the 
vertexes \(P_i\) of regular \(n\)-sided polygon, we have:
\[ S_n^{(2m)} = (A - B \cos \alpha)^m + \left( A - B \cos \left( \frac{360^\circ}{n} - \alpha \right) \right)^m + \\
+ \left( A - B \cos \left( 2 \cdot \frac{360^\circ}{n} - \alpha \right) \right)^m + \cdots + \\
+ \left( A - B \cos \left( (n - 1) \frac{360^\circ}{n} - \alpha \right) \right)^m = \\
= nA^m - \binom{m}{1} A^{m-1} B \left( \cos \alpha + \cos \left( \frac{360^\circ}{n} - \alpha \right) \right) + \cdots + \\
+ \cos \left( (n - 1) \frac{360^\circ}{n} - \alpha \right) + \\
+ \binom{m}{2} A^{m-2} B^2 \left( \cos^2 \alpha + \cos^2 \left( \frac{360^\circ}{n} - \alpha \right) \right) + \cdots + \\
+ \cos^2 \left( (n - 1) \frac{360^\circ}{n} - \alpha \right) - \\
- \binom{m}{3} A^{m-3} B^3 \left( \cos^3 \alpha + \cos^3 \left( \frac{360^\circ}{n} - \alpha \right) \right) + \cdots + \\
+ \cos^3 \left( (n - 1) \frac{360^\circ}{n} - \alpha \right) + \\
\vdots \\
\pm \binom{m}{m} B^m \left( \cos^m \alpha + \cos^m \left( \frac{360^\circ}{n} - \alpha \right) \right) + \cdots + \\
+ \cos^m \left( (n - 1) \frac{360^\circ}{n} - \alpha \right). \]
By using the Lemma 7.2 each sum with negative sign “−” is zero, because they contain odd powers and only sum with even powers remains.

If $m$ is even the sum is:

$$S^{(2m)}_n = nA^m +$$

$$+ \binom{m}{2} A^{m-2} B^2 \left( \cos^2 \alpha + \cos^2 \left( \frac{360^\circ}{n} - \alpha \right) \right) + \cdots +$$

$$+ \cos^2 \left( (n - 1) \frac{360^\circ}{n} - \alpha \right) +$$

$$\vdots$$

$$+ \binom{m}{m} B^m \left( \cos^m \alpha + \cos^m \left( \frac{360^\circ}{n} - \alpha \right) \right) + \cdots +$$

$$+ \cos^m \left( (n - 1) \frac{360^\circ}{n} - \alpha \right) =$$

$$= n \left( A^m + \sum_{k=1}^{\frac{m}{2}} \binom{m}{2k} A^{m-2k} B^{2k} \frac{1}{2^{2k}} \binom{2k}{k} \right).$$

If $m$ is odd the sum is

$$S^{(2m)}_n = nA^m +$$

$$+ \binom{m}{2} A^{m-2} B^2 \left( \cos^2 \alpha + \cos^2 \left( \frac{360^\circ}{n} - \alpha \right) \right) + \cdots +$$

$$+ \cos^2 \left( (n - 1) \frac{360^\circ}{n} - \alpha \right) + \cdots +$$

36
\begin{align*}
&+ \binom{m}{m-1} AB^{m-1} \left( \cos^{m-1} \alpha + \cos^{m-1} \left( \frac{360^\circ}{n} - \alpha \right) + \\
&\quad \quad \quad \quad \quad \quad + \cdots + \cos^{m-1} \left( (n-1) \frac{360^\circ}{n} - \alpha \right) \right) = \\
&= n \left( A^m + \sum_{k=1}^{\frac{m}{2}} \binom{m}{2k} A^{m-2k} B^{2k} \frac{1}{2^{2k}} \binom{2k}{k} \right).
\end{align*}

Using integer part, it is possible to write obtained results in one formula:

\begin{align*}
S_n^{(2m)} &= n \left( A^m + \sum_{k=1}^{\left\lfloor \frac{m}{2} \right\rfloor} \binom{m}{2k} A^{m-2k} B^{2k} \frac{1}{2^{2k}} \binom{2k}{k} \right),
\end{align*}

which proves the Theorem 8.1.

Thus, for each even \((2m)\)-th power \(m = 1, 2, \ldots, n - 1\):

\begin{align*}
\left\{ X : \sum_{i=1}^{n} d^{2m}(X, P_i) = S_n^{(2m)} = \text{const} \right\} &= \\
&= \begin{cases} 
\text{circle, if } S_n^{(2m)} > nr^{2m} \\
\text{point, if } S_n^{(2m)} = nr^{2m} \\
\emptyset, \text{ if } S_n^{(2m)} < nr^{2m}
\end{cases}
\end{align*}

In case of circle, the radius \(\ell\) satisfies:
\[ S_n^{(2m)} = n \left[ (r^2 + \ell^2)^m + \sum_{k=1}^{[m/2]} \binom{m}{2k} (r^2 + \ell^2)^{m-2k}(r\ell)^{2k} \binom{2k}{k} \right]. \]

What happens if we consider the sum of even powers more than \(2(n-1)\)? In these cases, cosine functions appear in the sum expressions (see note of Lemma 7.1), which proves that the locus is not a circle. But what kind of figures are there? The investigation of this subject is the aim of future studies.
