Abstract. In this paper, we specify a set of optimal subspaces for $L_2$ approximation of three classes of functions in the Sobolev space $W_2^r$, defined on a segment and subject to certain boundary conditions. All of these subspaces are generated by equidistant shifts of a single function. In particular, we indicate optimal spline spaces of all degrees $d \geq r - 1$ with uniform knots.

1. Introduction

1.1. Notation. In what follows, $\mathbb{C}$, $\mathbb{R}$, $\mathbb{Z}$, $\mathbb{Z}_+$, $\mathbb{N}$ are the sets of complex, real, integer, nonnegative integer, and natural numbers, respectively; $[a : b] = [a, b] \cap \mathbb{Z}$. Unless otherwise follows from the context, all the functional spaces under consideration can be real or complex. If $p \in [1, +\infty)$, $L_p$ is the space of $2\pi$-periodic, measurable, and $p$-integrable functions; $L_p[a, b]$ is the space of measurable on $[a, b]$, $p$-integrable functions. The norms in these spaces are defined by

$$
\|f\|_p = \left( \int_{-\pi}^\pi |f|^p \right)^{1/p}, \quad \|f\|_{L_p[a, b]} = \left( \int_a^b |f|^p \right)^{1/p},
$$

respectively. Furthermore, $W_2^r[a, b]$ is the space of functions $f$ in $L_2[a, b]$ such that $f^{(r-1)}$ is absolutely continuous and $f^{(r)} \in L_2[a, b]$; the class $W_2^r$ of periodic functions is defined similarly.

The symbol $\langle \cdot, \cdot \rangle_H$ denotes the inner product in the Hilbert space $H$;

$$E(f, \mathcal{R})_p = \inf_{T \in \mathcal{R}} \|f - T\|_p$$

is best approximation of $f$ in $L_p$ by the set $\mathcal{R} \subset L_p$.

The Fourier coefficients of the function $f$ and the discrete Fourier transform of the finite sequence $\{\beta_k\}_{k=0}^{2n-1}$ are defined by the equalities

$$
c_k(f) = \frac{1}{2\pi} \int_{-\pi}^\pi f(t)e^{-ikt} \, dt, \quad \beta_k = \sum_{k=0}^{2n-1} \beta_k e^{-\frac{ikx}{n}}.
$$

The notation $f(x) \sim \sum_{k \in \mathbb{Z}} c_k e^{ikx}$ means that the series on the right-hand side is the Fourier series of $f$.

Key words and phrases. Spaces of shifts, splines, $n$-widths.

This work is supported by the Russian Science Foundation under grant No. 18-11-00055.
For $n \in \mathbb{N}$ and $\mu \in \mathbb{Z}_+$, let $S_{n,\mu}$ denote the $2n$-dimensional space of $2\pi$-periodic splines of degree $\mu$ and defect 1 with knots at the points $\frac{k\pi}{n}$, $k \in \mathbb{Z}$; $T_{2n-1}$ is the $(2n-1)$-dimensional space of trigonometric polynomials of degree at most $n-1$.

The symbols $f^e$ and $f^o$ denote the even and the odd parts of $f$, respectively, i.e.

$$f^e = \frac{f + f(-\cdot)}{2}, \quad f^o = \frac{f - f(-\cdot)}{2}.$$

Let $X$ be a normed linear space and $A$ a subset of $X$. The Kolmogorov $n$-width of $A$ in $X$ is given by

$$d_n(A; X) = \inf_{X_n} \sup_{x \in A} \inf_{y \in X_n} \|x - y\|_X,$$

where the external lower bound is taken over all subspaces $X_n$ of the space $X$, whose dimension does not exceed $n$.

1.2. An overview of the results. In [1], Floater and Sande studied the $L_2$ approximation of three classes of functions in $W^r_2(0, 1)$, defined by certain boundary conditions. With slightly different scaling (which we hereafter adhere to) these classes are given by

$$H^r_0 = \{u \in W^r_2(0, \pi): u^{(k)}(0) = u^{(k)}(\pi) = 0, \quad 0 \leq k < r, \quad k \text{ even}\},$$
$$H^r_1 = \{u \in W^r_2(0, \pi): u^{(k)}(0) = u^{(k)}(\pi) = 0, \quad 0 \leq k < r, \quad k \text{ odd}\},$$
$$H^r_2 = \{u \in W^r_2(0, \pi/2): u^{(k)}(0) = u^{(l)}\left(\frac{\pi}{2}\right) = 0, \quad 0 \leq k, l < r, \quad k \text{ even}, \quad l \text{ odd}\}.$$

The authors considered the function classes

$$A^r_0 = \{u \in H^r_0: \|u^{(r)}\|_{L^2[0, \pi]} \leq 1\}, \quad i = 0, 1,$$
$$A^r_2 = \{u \in H^r_2: \|u^{(r)}\|_{L^2[0, \pi/2]} \leq 1\}$$

and described the $n$-widths and certain optimal subspaces for $A^r_i$. Specifically, they showed that

$$d_n(A^r_0) = \frac{1}{(n+1)^r}, \quad d_n(A^r_1) = \frac{1}{n^r}, \quad d_n(A^r_2) = \frac{1}{(2n+1)^r},$$

and the spaces

$$\text{span} \{x \mapsto \sin kx\}_{k=1}^n, \quad \text{span} \{x \mapsto \cos kx\}_{k=0}^{n-1}, \quad \text{span} \{x \mapsto \sin(2k-1)x\}_{k=1}^n \quad (1)$$

are optimal $n$-dimensional spaces for, respectively, $A^r_0$, $A^r_1$, and $A^r_2$. The result for $A^r_1$ was proved by Kolmogorov [4]. In addition, the authors proved that the spaces $A^r_i$ admit optimal spline subspaces, which are defined as follows.

Let $\tau = (\tau_1, \ldots, \tau_m)$ be a knot vector such that $0 < \tau_1 < \ldots < \tau_m < P_1$, where $P_1 = P_2 = \pi$ and $P_2 = \pi/2$. Denote by $S_{d, \tau, i}$ the space of splines of degree $d$ and defect 1 on $[0, P_1]$ and consider its $n$-dimensional subspaces defined by

$$S_{d, 0} = \{s \in S_{d, \tau_0, 0}: s^{(k)}(0) = s^{(k)}(\pi) = 0, \quad 0 \leq k \leq d, \quad k \text{ even}\},$$
$$S_{d, 1} = \{s \in S_{d, \tau_1, 1}: s^{(k)}(0) = s^{(k)}(\pi) = 0, \quad 0 \leq k \leq d, \quad k \text{ odd}\},$$
$$S_{d, 2} = \{s \in S_{d, \tau_2, 2}: s^{(k)}(0) = s^{(l)}\left(\frac{\pi}{2}\right) = 0, \quad 0 \leq k, l \leq d, \quad k \text{ even}, \quad l \text{ odd}\},$$
where the knot vectors \( \tau_i \) for \( i = 0, 1, 2 \) are given as

\[
\tau_0 = \begin{cases} 
\left\{ \frac{k\pi}{n+1} \right\}_{k=1}^n, & d \text{ odd}, \\
\left\{ \frac{k\pi}{n+1} + \frac{\pi}{2 \alpha + 1} \right\}_{k=0}^n, & d \text{ even},
\end{cases}
\]

\[
\tau_1 = \begin{cases} 
\left\{ \frac{k\pi}{n} + \frac{\pi}{2\alpha} \right\}_{k=0}^{n-1}, & d \text{ odd}, \\
\left\{ \frac{k\pi}{n} \right\}_{k=1}^n, & d \text{ even},
\end{cases}
\]

\[
\tau_2 = \begin{cases} 
\left\{ \frac{k\pi}{2n+1} + \frac{\pi}{2(2n+1)} \right\}_{k=0}^{n-1}, & d \text{ even}, \\
\left\{ \frac{k\pi}{2n+1} \right\}_{k=1}^n, & d \text{ odd}.
\end{cases}
\]

It was proved in [1] that for any \( d \geq r - 1 \) the spline spaces \( S_{d,i} \) are optimal \( n \)-dimensional spaces for the set \( A^r_i \), \( i = 0, 1, 2 \).

As we can see, all the spaces \( S_{d,i} \) have equidistant knots, but the form of the knot vector is determined by the degree \( d \). In this paper, we show that the classes \( A^r_i \) admit optimal spline subspaces with both types of knots indicated in the definition of \( \tau_i \) independently of the degree. Of course, boundary conditions should be relaxed or some extra conditions should be added in the remaining cases to ensure the dimension to equal \( n \).

Our technique consists in the following. In [8], we studied the periodic case and found a wide set of optimal subspaces generated by shifts of a single function, including spline spaces. The conditions of optimality in the periodic case were formulated in terms of Fourier coefficients of a function mentioned. Now we reduce the problems for functions defined on \( \mathbb{R} \) to similar problems for periodic functions and, using the results of [8], specify a set of optimal subspaces in the nonperiodic situation.

2. Spaces of shifts

For \( n \in \mathbb{N} \) and \( B \in L_1 \), let \( S_{B,n} \) be the space of functions \( s \) defined on \( \mathbb{R} \) and representable in the form

\[
s(x) = \sum_{j=0}^{2n-1} \beta_j B \left( x - \frac{j\pi}{n} \right), \tag{2}
\]

and \( S^x_{B,n} \) be the space of functions in \( S_{B,n} \) that can be represented as (2) with the additional condition

\[
\sum_{j=0}^{2n-1} (-1)^j \beta_j = 0. \tag{3}
\]

Substituting the Fourier series expansion of \( B \) into (2), we obtain

\[
s(x) \sim \sum_{j=0}^{2n-1} \beta_j \sum_{l \in \mathbb{Z}} c_l(B) e^{ij\lambda} = \sum_{l \in \mathbb{Z}} c_l(B) \tilde{\beta}_l e^{ij\lambda} \sim \sum_{l=0}^{2n-1} \tilde{\beta}_l \Phi_{B,l}(x),
\]

where

\[
\Phi_{B,l}(x) = \sum_{j=0}^{2n-1} \beta_j e^{i\frac{j\pi}{n}} B \left( x - \frac{j\pi}{n} \right) \sim \sum_{l=2n}^{2n} c_l e^{i(l+2n\nu)\lambda x}.
\]

Clearly, \( \Phi_{B,l} = \Phi_{B,l+2n} \) and condition (3) is equivalent to \( \tilde{\beta}_n = 0 \). Thus, the spaces \( S_{B,n} \) and \( S^x_{B,n} \) coincide with linear spans of the sets \( \{ \Phi_{B,l}\}_{l=0}^{2n-1} \) (or, equivalently, \( \{ \Phi_{B,l}\}_{l=1}^{n-1} \)) and \( \{ \Phi_{B,l}\}_{l=1}^{n-1} \). For \( m \in [1 : n] \), denote by \( S^m_{B,n,m} \) the linear span of the set \( \{ \Phi_{B,l}\}_{l=1}^{m-1} \).
Note that the functions $\Phi_{B,l}$ are orthogonal: $\langle \Phi_{B,l}, \Phi_{B,j} \rangle_{L^2} = 0$ for $l \neq j$ and

$$\frac{1}{2\pi} \| \Phi_{B,l} \|_2^2 = D_{B,l} = D_{B,n,l} = \sum_{\nu \in \mathbb{Z}} |c_{l+2\nu l}(B)|^2.$$

The linear independence of the sets $\{ B(\cdots - \frac{j\pi}{n}) \}_{j=0}^{n-1}$ and $\{ B(\cdots - \frac{j\pi}{n}) \}_{j=1-n}^{n-1}$ is equivalent to the fact that the functions $\Phi_{B,l}$ are nonzero for $l \in [1-n:n]$ and $l \in [1-n:n-1]$, respectively. In this case, the systems $\{ \Phi_{B,l} \}_{l=1-n}^{n-1}$ and $\{ \Phi_{B,l} \}_{l=1-n}^{n-1}$ form orthogonal bases in the spaces $S_{B,n}$ and $S_{B,n}^\times$. Orthonormal bases are constituted by the functions $\frac{1}{\sqrt{2\pi D_{B,l}}} \Phi_{B,l}$.

When $B$ is the Dirichlet kernel

$$D_{n-1}(t) = \sum_{k=1-n}^{n-1} e^{ikt},$$

we have $S_{B,n} = S_{B,n}^\times = T_{2n-1}$, $S_{B,n,m} = T_{2m-1}$, $\Phi_{B,n} = 0$, and for $|l| < n$, the functions $\Phi_{B,l}$ are ordinary exponents.

If $B$ is the $B$-spline

$$B_{n,\mu}(t) = \sum_{k=\mathbb{Z}} \left( \frac{e^{ikt} - 1}{i\frac{\pi}{n}} \right)^{\mu+1} e^{ikt}, \quad \mu \in \mathbb{Z}_+$$

(henceforth, the fraction is assumed to equal 1 whenever $k = 0$), we find that $S_{B,n}$ is the space of splines $S_{n,\mu}$. The functions

$$\Phi_{B_{n,\mu},l}(x) = \left( \frac{e^{i\frac{\pi l}{n}} - 1}{i\frac{\pi}{n}} \right)^{\mu+1} \sum_{\nu \in \mathbb{Z}} e^{i(l+2\nu n)x} (l+2\nu)^{\mu+1},$$

which form an orthogonal basis in this space, are called exponential splines (by convention, we have $\Phi_{B_{n,\mu},0}(x) = 1$). The linear span of the system $\{ \Phi_{B_{n,\mu},l} \}_{l=1-n}^{n-1}$ is denoted by $S_{n,\mu}^\times$.

In more general nonperiodic situation exponential splines were introduced by Schoenberg; the basics of the theory and historical remarks can be found in [5]. The orthogonality of periodic exponential splines was noted by many authors; apparently, the earliest studies on this topic were [2, 3]. The spaces $S_{n,\mu}^\times$ and $S_{B,n}$ were considered by Vinogradov [6, 7].

The following lemma describes symmetry properties of spaces of shifts in terms of Fourier coefficients.

**Lemma 1.** Let $n, m \in \mathbb{N}$, $m \leq n$, and $B \in L^1$. Then the following statements are equivalent.

1. The inclusion $s \in S_{B,n,m}^\times$ implies $s(-\cdot) \in S_{B,n,m}^\times$.
2. For any $l \in [0 : m-1]$, there exists $c_l \in \mathbb{C} \setminus \{0\}$ such that $\gamma_0 \in \{-1,1\}$ and $c_{-1-2nk}(B) = \gamma_l c_{l+2nk}(B)$ for all $k \in \mathbb{Z}$.

Moreover, if $\gamma_0 = -1$, then $c_0(B) = 0$.

**Proof.** The first statement means that $\Phi_{B,l}(-\cdot) \in S_{B,n,m}^\times$ for all $l \in [1-m : m-1]$. Replacing $l$ with $-l$ for convenience, rewrite the inclusion as

$$\Phi_{B,-l}(-x) = \sum_{j=1-m}^{m-1} \gamma_j \Phi_{B,j}(x)$$

for some $\gamma_j$. Since $\Phi_{B,j}$ is orthogonal to $\Phi_{B,-l}(-\cdot)$ for $j \neq l$, we have

$$\Phi_{B,-l}(-x) = \gamma_l \Phi_{B,l}(x).$$
Equating the Fourier coefficients, we get (4). Replacing \( l \) with \(-l\) and \( k \) with \(-k\), we also have \( c_{l+2nk}(B) = \gamma_{-l}c_{-l-2nk}(B) \). If \( \gamma_l = 0 \) for some \( l \), then \( c_{l+2nk}(B) = c_{-l-2nk}(B) = 0 \) and the equalities are trivially satisfied with an arbitrary \( \gamma_l \). So, we can take \( \gamma_l \neq 0 \).

On the other hand, if (4) is valid for a number \( l \) with \( \gamma_l \neq 0 \), it is also valid for a number \(-l\) with \( \frac{1}{\gamma_l} \). So, it is sufficient to consider \( l \in [0 : m - 1] \).

Putting \( l = 0 \), we conclude that \( c_{-2nk}(B) = \gamma_0 c_{2nk}(B) \) for all \( k \). Replacing \( k \) by \(-k\), we also have \( c_{2nk}(B) = \gamma_0 c_{-2nk}(B) \). If \( c_{2nk}(B) = 0 \) for all \( k \), we can take \( \gamma_0 = 1 \). If \( c_{2nk}(B) \neq 0 \) for some \( k \), then \( c_{-2nk}(B) \neq 0 \) for the same \( k \), and so \( \gamma_0 = \pm 1 \). Obviously, \( \gamma_0 = -1 \) implies \( c_0(B) = 0 \).

Note that all even functions (and, in particular, the Dirichlet kernel) satisfy the second condition of Lemma 1 with \( \gamma_0 \) for all \( l \).

For the \( B \)-spline, we have \( \gamma_l = e^{-i\Phi_l(n+1)} \), and for the shifted \( B \)-spline \( \tilde{B}_{n,\mu} \), the identity \( c_k(\tilde{B}_{n,\mu}) = e^{-i\Phi_k(\mu+1)} \) yields \( \gamma_l = e^{-i\Phi_l(n+1)} \).

**Remark 1.** For \( l \in [1 : m - 1] \), we have \( \Phi_{B,-l} = \gamma_l \Phi_{B,l} \) and \( \Phi_{B,-l}^o = -\gamma_l \Phi_{B,l}^o \).

Therefore, the space \( S_{B,n,m}^\times \) can be represented as

\[
S_{B,n,m}^\times = \text{span} \{ \Phi_{B,0} \} \oplus \text{span} \{ \Phi_{B,l}^{m-1} \} \oplus \text{span} \{ \Phi_{B,l}^o \}_{l=1}^{m-1}.
\]

**Remark 2.** If \( s \in S_{B,n,m}^\times \), then \( s(\cdot + \pi) \in S_{B,n,m}^\times \) and, since \( \Phi_{B,l}(x + \pi) = (-1)^l \Phi_{B,l}(x) \), we have

\[
\Phi_{B,l}(\pi - x) = (-1)^l \Phi_{B,l}(x), \quad \Phi_{B,l}(\pi - x) = (-1)^l \Phi_{B,l}(x).
\]

3. Main Results

The following theorem was established in [8, Theorem 1].

**Theorem 1.** Let \( r, n, m \in \mathbb{N} \), \( m \leq n \), and \( B \in L_2 \). Then the following statements are equivalent.

1. For any function \( f \in W_2^{(r)} \), the following inequality holds:

\[
E(f, S_{B,n,m}^\times) \leq \frac{1}{m^r} \| f^{(r)} \|_2.
\]

2. The Fourier coefficients of \( B \) satisfy the conditions

\[
c_l(B) \neq 0 \quad \text{for all} \quad |l| \in [0 : m - 1],
\]

\[
c_{2\nu}(B) = 0 \quad \text{for all} \quad \nu \in \mathbb{Z} \setminus \{0\},
\]

\[
\sum_{|l| \in [0 : m - 1]} \left| \frac{c_{l+2nk}(B)}{(l+2nk)^{2r}} \right| \geq \frac{1}{m^{2r}} \quad \text{for all} \quad |k| \in [1 : m - 1].
\]

We need the following simple corollary of Theorem 1.

**Corollary 1.** Let \( r, n, m \in \mathbb{N} \), \( m \leq n \), and \( B \in L_2 \). Then the following statements are equivalent.

1. For any function \( f \in W_2^{(r)} \) such that \( c_0(f) = 0 \), the following inequality holds:

\[
E(f, S_{B,n,m}^\times) \leq \frac{1}{m^r} \| f^{(r)} \|_2.
\]

2. For all \( |l| \in [1 : m - 1] \), we have \( c_l(B) \neq 0 \) and

\[
\sum_{|k| \in [1 : m - 1]} \left| \frac{c_{l+2nk}(B)}{(l+2nk)^{2r}} \right| \geq \frac{1}{m^{2r}}.
\]
Proof. For \( g \in L_2 \), put \( g_0(x) = \sum_{\nu \in \mathbb{Z}} c_{2n\nu}(g)e^{i2n\nu x} \). Obviously, the inequality (6) on the whole class \( W_2^{(r)} \) is equivalent to the system

\[
E(f_0, S_{B_0,n,m}^x) \leq \frac{1}{m^r} \|f_0^{(r)}\|_2,
\]

\[
E(f - f_0, S_{B_0,n,m}^x) \leq \frac{1}{m^r} \|(f - f_0)^{(r)}\|_2.
\]

(1) \( \implies \) (2). Let \( \tilde{B} \in L_2 \) be such a function that \( c_0(\tilde{B}) = 1 \), \( c_{2n\nu}(\tilde{B}) = 0 \) for all \( \nu \in \mathbb{Z} \setminus \{0\} \), and \( c_k(\tilde{B}) = c_k(B) \) for \( k \neq 2n\nu \). For any \( f \in W_2^{(r)} \) we have

\[
E(f_0, S_{B_0,n,m}^x) \leq \|f_0 - c_0(f)\|_2 \leq \frac{1}{m^r} \|f_0^{(r)}\|_2,
\]

(8)

\[
E(f - f_0, S_{B_0,n,m}^x) \leq \frac{1}{m^r} \|(f - f_0)^{(r)}\|_2.
\]

(9)

Here (8) is trivial because \( S_{B_0,n,m}^x \) contains constants, while (9) holds due to assumption. So, (6) is valid. By Theorem 1, the Fourier coefficients of \( \tilde{B} \) satisfy its second assertion, so the same holds for \( c_k(B) \) when \( k \neq 2n\nu \).

(2) \( \implies \) (1). Let \( f \in W_2^{(r)} \), \( c_0(f) = 0 \). Define \( \tilde{B} \) as above. Then, by Theorem 1, (6) holds for \( \tilde{B} \). By (8) and (9), it also holds for \( B \). \( \square \)

Consider the following functional classes:

\[
\tilde{H}_0^r = \{u \in W_2^{(r)} : u \text{ is odd}\},
\]

\[
\tilde{H}_1^r = \{u \in W_2^{(r)} : u \text{ is even}\},
\]

\[
\tilde{H}_2^r = \{u \in W_2^{(r)} : u \text{ is odd, } u \left(\cdot + \frac{\pi}{2}\right) \text{ is even}\}.
\]

Evidently, every function \( u \in \tilde{H}_r^r \) belongs to \( H_r^r \). Conversely, according to the boundary conditions in the definition of the classes \( H_r^r \), the \( 2\pi \)-periodization of the odd extension of \( u \in H_0^r \) to the interval \([-\pi, 0]\) belongs to \( \tilde{H}_0^r \). Similarly, the \( 2\pi \)-periodization of the even extension of \( u \in H_1^r \) to the interval \([-\pi, 0]\) is in \( \tilde{H}_1^r \).

Consecutively extending \( u \in H_0^r \) to an even (with respect to \( \pi/2 \)) function on \([0, \pi]\) and to an odd function on \([-\pi, \pi]\), after \( 2\pi \)-periodization we get a function belonging to \( \tilde{H}_2^r \).

Therefore, putting

\[
\tilde{A}_i^r = \{u \in \tilde{H}_i^r : \|u^{(r)}\|_2 \leq 1\}, \quad i = 0, 1, 2,
\]

we derive

\[
d_n(\tilde{A}_0^r; L_2) = d_n(A_0^r; L_2[0, \pi]) = \frac{1}{(n + 1)^r},
\]

\[
d_n(\tilde{A}_1^r; L_2) = d_n(A_1^r; L_2[0, \pi]) = \frac{1}{n^r},
\]

\[
d_n(\tilde{A}_2^r; L_2) = d_n(A_2^r; L_2\left[0, \frac{\pi}{2}\right]) = \frac{1}{(2n + 1)^r}.
\]

Thus, we can reduce problems for nonperiodic classes to those for periodic classes and apply Theorem 1. We will formulate our results for periodic classes (denoted with tildes).
Remark 3. Let $S$ be a closed subspace of $L_2$ such that the condition $s \in S$ implies $s(-\cdot) \in S$. Then an element of best approximation of any function $u \in \tilde{H}_0^r$ in $L_2$ by the space $S$ is odd. Indeed, if $\|u - s\|_2 = \inf_{T \in S} \|f - T\|_2$, we can write

$$\|u - s\|_2 \leq \left\| u - \frac{s - s(-\cdot)}{2} \right\|_2 = \left\| u - s + \frac{u + s(-\cdot)}{2} \right\|_2 = \frac{1}{2} (\|u - s\|_2 + \|u(-\cdot) - s(-\cdot)\|_2) = \|u - s\|_2.$$  

This means that all the inequalities in this chain turn into equalities. In particular, we have $\|u - s\|_2 = \|u - s^o\|_2$. By the uniqueness of an element of best approximation in $L_2$, we conclude that $s$ is odd.

For the same reason, an element of best approximation of any function $u \in \tilde{H}_0^r$ by the space $S$ is even. If, in addition, the space $S$ is invariant under the shift by $\pi$, an element of best approximation of any $u \in \tilde{H}_0^r$ by the space $S$ possesses the same symmetry properties as the function $u$ itself.

Consider the following $m$-dimensional spaces:

$$\tilde{S}_{B,n,m}^0 = \text{span} \{ \Phi_{B,l}^o \}_{l=1}^m \quad \text{for} \quad m + 1 \leq n,$$

$$\tilde{S}_{B,n,m}^1 = \text{span} \{ \Phi_{B,l}^e \} \oplus \text{span} \{ \Phi_{B,l}^o \}_{l=1}^{m-1} \quad \text{for} \quad m \leq n,$$

$$\tilde{S}_{B,n,m}^2 = \text{span} \{ \Phi_{B,l}^o \}_{l=1}^{2m-1} \quad \text{for} \quad 2m + 1 \leq n.$$

In the following three theorems we give sufficient conditions of extremality of these spaces.

**Theorem 2.** Let $r, n, m \in \mathbb{N}$, $m + 1 \leq n$, and suppose that the Fourier coefficients of a function $B \in L_2$ satisfy the following conditions.

1. For any $l \in [1 : m]$ there exists $\gamma_l \in \mathbb{C} \setminus \{0\}$ such that for all $k \in \mathbb{Z}$

$$c_{l-2nk}(B) = \gamma_l c_{l+2nk}(B).$$

2. For all $\nu \in \mathbb{N}$, $\varepsilon_{2m\nu}(B) = c_{-2m\nu}(B)$.

3. For all $l \in [1 : m]$, we have $c_l(B) \neq 0$ and

$$\sum_{k \in \mathbb{Z}} \frac{|c_{l+2nk}(B)|^2}{(l+2nk)^2} = \frac{1}{(m+1)^2} \geq 0.$$  

Then for any $u \in \tilde{H}_0^r$,

$$E(u, \tilde{S}_{B,n,m}^0)_{L_2} \leq \frac{1}{(m+1)^2} \|u(r)\|_2. \tag{10}$$

**Proof.** Since every $u \in \tilde{H}_0^r$ has zero mean and $B$ satisfies the conditions of the second proposition of Corollary 1, we can write

$$E(u, \tilde{S}_{B,n,m+1}^o)_{L_2} \leq \frac{1}{(m+1)^2} \|u(r)\|_2. \tag{11}$$

By Lemma 1, the space $S_{B,n,m+1}^\times$ contains each function $s$ with its odd and even parts. Thus, an element of best approximation of $u \in \tilde{H}_0^r$ by the space $S_{B,n,m+1}^\times$ is odd. This implies that the space $S_{B,n,m+1}^\times$ on the left-hand side of (11) can be substituted for its subspace consisting of odd functions. Since $\Phi_{B,0}$ is even (by condition 2), it follows from decomposition (5) that the desired approximating subspace coincides with $S_{B,n,m}^0$. \hfill $\square$

**Theorem 3.** Let $r, n, m \in \mathbb{N}$, $m \leq n$, and suppose that the Fourier coefficients of a function $B \in L_2$ satisfy the following conditions.
For any \( u \in [1 : m - 1] \) there exists \( \gamma_l \in \mathbb{C} \setminus \{0\} \) such that for all \( k \in \mathbb{Z} \)
\[
c_{-1-2nk}(B) = \gamma_l c_{2nk}(B).
\]
(2) For all \( l \in [0 : m - 1] \), \( c_l(B) \neq 0 \).
(3) For all \( \nu \in \mathbb{Z} \setminus \{0\} \), \( c_{2\nu l}(B) = 0 \).
(4) For all \( l \in [1 : m - 1] \), we have
\[
\sum_{k \in \mathbb{Z}} \frac{|c_{1+2nk}(B)|^2}{(l+2nk)^2} \geq 0.
\]
Then for any \( u \in \tilde{H}_r^1 \),
\[
E(u, \tilde{S}_{B,n,m}^1) \leq \frac{1}{m^r} \|u(r)\|_2.
\]
\[
(12)
\]
**Proof.** Applying Theorem 1 to \( u \in \tilde{H}_r^1 \), we can write
\[
E(u, \tilde{S}_{B,n,m}^1) \leq \frac{1}{m^r} \|u(r)\|_2.
\]
Using the same argument as in the proof of Theorem 2, we conclude that the space \( \tilde{S}_{B,n,m}^r \) on the left-hand side of the last inequality can be substituted for the subspace of even functions, i.e. for \( \tilde{F}_{B,n,m} \).

**Theorem 4.** Let \( r, n, m \in \mathbb{N} \), \( 2m + 1 \leq n \), and suppose that the Fourier coefficients of a function \( B \in L_2 \) satisfy the following conditions.
(1) For any \( l \in [1 : 2m] \) there exists \( \gamma_l \in \mathbb{C} \setminus \{0\} \) such that for all \( k \in \mathbb{Z} \)
\[
c_{-1-2nk}(B) = \gamma_l c_{2nk}(B).
\]
(2) For all \( \nu \in \mathbb{N} \), \( c_{2\nu l}(B) = c_{-2\nu l}(B) \).
(3) For all \( l \in [1 : 2m] \), we have \( c_l(B) \neq 0 \) and
\[
\sum_{k \in \mathbb{Z}} \frac{|c_{1+2nk}(B)|^2}{(l+2nk)^2} \geq 0.
\]
Then for any \( u \in \tilde{H}_r^2 \),
\[
E(u, \tilde{S}_{B,n,m}^2) \leq \frac{1}{(2m+1)^r} \|u(r)\|_2.
\]
\[
(13)
\]
**Proof.** Because \( \tilde{H}_r^2 \) is a subspace of \( \tilde{F}_{B,n}^r \), by Theorem 2, for every \( u \in \tilde{H}_r^2 \), we have
\[
E(u, \tilde{S}_{B,n,2m}^2) \leq \frac{1}{(2m+1)^r} \|u(r)\|_2.
\]
Since \( u \) satisfies the equality \( u = u(\pi - \cdot) \), we can restrict the space \( \tilde{S}_{B,n,2m}^2 \) to a subspace of functions possessing this property. By Remark 2, we obtain that the desired subspace coincides with \( \tilde{S}_{B,n,m}^2 \).

**Remark 4.** It follows easily that under the assumptions of Theorem 4 the space \( \text{span}\{\Phi_{B,2l-1}\}_{l=1}^m \) is extremal for the set defined by interchanging the roles of \( k \) and \( l \) in \( \tilde{H}_r^2 \) (or, equivalently, the symmetry conditions in \( \tilde{H}_r^2 \)).

**Remark 5.** Note that the conditions of Theorems 2–4 are invariant under the shift of \( B \) by \( \frac{\pi}{2m} \).

**Remark 6.** Inequalities (10), (12) and (13) turn into equalities for the functions \( x \mapsto \sin(m+1)x \), \( x \mapsto \cos mx \) and \( x \mapsto \sin(2m+1)x \), respectively.

The estimates from Theorems 2–4 can be strengthened in a standard way by replacing their right-hand sides with best approximations.

**Corollary 2.** Let \( B \in W^{(r)}_2 \) under the assumptions of Theorem 2.
(1) If \( r \) is even, then for any \( u \in \tilde{H}_1^r \),
\[
E(u, S_{B,n,m}^0) \leq \frac{1}{(m+1)^r} E(u^{(r)}, S_{B^{(r)},n,m}^0)\cdot
\]
(2) If \( r \) is odd, then for any \( u \in \tilde{H}_1^r \),
\[
E(u, S_{B,n,m}^0) \leq \frac{1}{(m+1)^r} E(u^{(r)}, \text{span} \{\Phi_{B^{(r)},l}^{(r)} \}_{l=1}^m)\.
\]

Proof. If \( r \) is even, denote by \( s \) an element of best approximation of the function \( u^{(r)} \) by the space \( S_{B^{(r)},n,m}^0 \). For odd \( r \), let \( s \) be an element of best approximation of \( u^{(r)} \) by the space \( \text{span} \{\Phi_{B^{(r)},l}^{(r)} \}_{l=1}^m \). Since \( c_0(s) = 0 \), the function \( s \) has \( 2\pi \)-periodic \( r \)th primitive, which we denote by \( s_r \). For any \( l \in [1 : m] \),
\[
(\Phi_{B,l}^{(r)}) = \begin{cases} 
\Phi_{B,n,m}^{(r)}, & r \text{ is even,} \\
\Phi_{B^{(r)},l}^{(r)}, & r \text{ is odd}
\end{cases}
\]

and hence \( s_r \in S_{B,n,m}^0 \). Applying Theorem 2 to the function \( u - s_r \), we obtain
\[
E(u, S_{B,n,m}^0) = E(u - s_r, S_{B,n,m}^0) \leq \frac{1}{(m+1)^r} \|u^{(r)} - s\|_2 = \\
= \begin{cases} 
\frac{1}{(m+1)^r} E(u^{(r)}, S_{B^{(r)},n,m}^0), & r \text{ is even,} \\
\frac{1}{(m+1)^r} E(u^{(r)}, \text{span} \{\Phi_{B^{(r)},l}^{(r)} \}_{l=1}^m), & r \text{ is odd.}
\end{cases}
\]

\( \Box \)

The proof of the two following statements goes exactly the same way as in Corollary 2 and therefore is omitted.

Corollary 3. Let \( B \in W_2^{(r)} \) under the assumptions of Theorem 3.

(1) If \( r \) is even, then for any \( u \in \tilde{H}_1^r \),
\[
E(u, S_{B,n,m}^1) \leq \frac{1}{m} E(u^{(r)}, \text{span} \{\Phi_{B^{(r)},l}^{(r)} \}_{l=1}^{m-1})\.
\]
(2) If \( r \) is odd, then for any \( u \in \tilde{H}_1^r \),
\[
E(u, S_{B,n,m}^1) \leq \frac{1}{m} E(u^{(r)}, S_{B^{(r)},n,m-1})\.
\]

Corollary 4. Let \( B \in W_2^{(r)} \) under the assumptions of Theorem 4.

(1) If \( r \) is even, then for any \( u \in \tilde{H}_2^r \),
\[
E(u, S_{B,n,m}^2) \leq \frac{1}{(2m+1)^r} E(u^{(r)}, S_{B^{(r)},n,m}^2)\.
\]
(2) If \( r \) is odd, then for any \( u \in \tilde{H}_2^r \),
\[
E(u, S_{B,n,m}^2) \leq \frac{1}{(2m+1)^r} E(u^{(r)}, \text{span} \{\Phi_{B^{(r)},2l-1}^{(r)} \}_{l=1}^m)\.
\]

4. Examples

In [8, Theorem 2], we specified an easily verifiable condition that is sufficient for the fulfilment of inequality (7) (and, therefore, of the corresponding conditions of Theorems 2–4). Namely, inequality (7) holds for all functions \( B \) possessing the property
\[
|l + 2nk|^{r-1}c_{l+2nk}(B) \leq |l|^{r}c_l(B) \quad \text{for all } |l| \in [1 : m - 1], k \in \mathbb{Z}.
\]
Among examples of functions $B$ satisfying this condition for all $m \leq n$ are the functions with coefficients of the form

$$c_k(B) = \left( \frac{\sin \frac{\pi}{n} k}{\frac{\pi}{n} k} \right)^{n+1} \eta_k, \quad \mu \in \mathbb{Z}_+, \mu + 1 \geq r,$$

where $|\eta_{2+\lambda k}| \leq |\eta_k|$ and $\eta \neq 0$ for $|l| < n$. For $\eta_k = 1$ we get the $B$-spline. If $\eta_k$ are the Fourier coefficients of the function $K \in L_1$, the function $B$ is the Steklov average of order $\mu + 1$ of $K$. For example, $K$ can be the Poisson kernel ($\eta_k = e^{-\alpha k^2}$, $\alpha > 0$), the heat kernel ($\eta_k = e^{-\alpha k^2}$, $\alpha > 0$), the kernels of some differential operators ($\eta_k = \frac{1}{P((k))}$, where $P$ is a polynomial with only real roots), and the generalized Bernoulli kernel ($\eta_k = |k|^{-s} e^{-i\beta \sign k}$, $s > 0$, $\beta \in \mathbb{R}$); in the latter two examples, $\eta_k$ is assumed to equal 1.

Taking the Dirichlet kernels of appropriate order as a function $B$ in Theorems 2–4, we get the optimal subspaces of trigonometric polynomials (1).

Now we describe spline spaces arising from Theorems 2–4 and show that the results of [1] follow from these theorems.

Recall that for a given space of periodic functions with appropriate symmetry conditions, we denote the space of their restrictions to $[0, \pi]$ or to $[0, \pi/2]$ by the same letter but without tilde.

1. Replace $n$ with $n + 1$ in Theorem 2 and take $m = n$, $B = B_{n+1,d}$. Then our space $S^0_{B,n+1,n}$ is the $n$-dimensional space of odd splines from $S^x_{B,n+1}$. Consider the space $Q_{d,1}$ of splines $s$ which have knots $\left\{ \frac{k\pi}{n+1} \right\}_{k=1}^n$ and satisfy the boundary conditions

$$s^{(k)}(0) = s^{(k)}(\pi) = 0, \quad 0 \leq k < d, \; k \text{ even.}$$

Its dimension equals $n$ for $d$ odd and equals $n + 1$ for $d$ even. So, for $d$ odd we have $S^0_{B,n+1,n} = Q_{d,1} = S_{d,0}$. For $d$ even, $S^0_{B,n+1,n}$ is an $n$-dimensional subspace of $Q_{d,1}$.

2. Replace $n$ with $n + 1$ in Theorem 2 and take $m = n$, $B = B_{n+1,d} \left( - \frac{\pi}{2(n+1)} \right)$. Then our space $S^0_{B,n+1,n}$ is the $n$-dimensional space of odd splines from $S^x_{B,n+1}$. Consider the space $Q_{d,2}$ of splines $s$ which have knots $\left\{ \frac{k\pi}{n+1} + \frac{\pi}{2(n+1)} \right\}_{k=0}^n$ and satisfy the boundary conditions

$$s^{(k)}(0) = s^{(k)}(\pi) = 0, \quad 0 \leq k < d, \; k \text{ even.}$$

Its dimension equals $n$ for $d$ even and equals $n + 1$ for $d$ odd. Note that 0 and $\pi$ are not the knots. So, for $d$ even we have $S^0_{B,n+1,n} = Q_{d,2} = S_{d,0}$. For $d$ odd, $S^0_{B,n+1,n}$ is an $n$-dimensional subspace of $Q_{d,2}$.

3. Take $m = n$, $B = B_{n,d}$ in Theorem 3. Then our space $\hat{S}^1_{B,n,n}$ is the $n$-dimensional space of even splines from $S^x_{B,n}$. Consider the space $Q_{d,3}$ of splines $s$ which have knots $\left\{ \frac{k\pi}{n} \right\}_{k=1}^{n-1}$ and satisfy the boundary conditions

$$s^{(k)}(0) = s^{(k)}(\pi) = 0, \quad 0 \leq k < d, \; k \text{ odd.}$$

Its dimension equals $n$ for $d$ even and equals $n + 1$ for $d$ odd. So, for $d$ even we have $S^1_{B,n,n} = Q_{d,3} = S_{d,1}$. For $d$ odd, $S^1_{B,n,n}$ is an $n$-dimensional subspace of $Q_{d,3}$.

4. Take $m = n$, $B = B_{n,d} \left( - \frac{\pi}{2n} \right)$ in Theorem 3. Then our space $\hat{S}^2_{B,n,n}$ is the $n$-dimensional space of even splines from $S^x_{B,n}$. Consider the space $Q_{d,4}$ of splines $s$ which have knots $\left\{ \frac{k\pi}{n} + \frac{\pi}{2n} \right\}_{k=0}^{n-1}$ and satisfy the boundary conditions

$$s^{(k)}(0) = s^{(k)}(\pi) = 0, \quad 0 \leq k < d, \; k \text{ odd.}$$
Its dimension equals \( n \) for \( d \) odd and equals \( n + 1 \) for \( d \) even. Note that 0 and \( \pi \) are not the knots. So, for \( d \) odd we have \( S_{B,n,n}^d = Q_{d,4} = S_{d,1} \). For \( d \) even, \( S_{B,n,n}^d \) is an \( n \)-dimensional subspace of \( Q_{d,4} \).

5. Replace \( n \) with \( 2n + 1 \) in Theorem 4 and take \( m = n, B = B_{2n+1,d} \). Consider the space \( Q_{d,5} \) of splines \( s \) which have knots \( \left\{ \frac{k\pi}{2n+1} \right\}_{k=1}^n \) and satisfy the boundary conditions

\[
s^{(k)}(0) = s^{(l)} \left( \frac{\pi}{2} \right) = 0, \quad 0 \leq k < d, \quad 0 \leq l \leq d, \quad k \text{ even, } l \text{ odd}.
\]

Its dimension equals \( n \) for \( d \) odd and equals \( n + 1 \) for \( d \) even. So, for \( d \) odd we have \( S_{B,2n+1,n}^2 = Q_{d,5} = S_{d,2} \). For \( d \) even, \( S_{B,2n+1,n}^2 \) is an \( n \)-dimensional subspace of \( Q_{d,5} \).

6. Replace \( n \) with \( 2n + 1 \) in Theorem 4 and take \( m = n, B = B_{2n+1,d} \left( \cdot - \frac{\pi}{2(2n+1)} \right) \). Consider the space \( Q_{d,6} \) of splines \( s \) which have knots \( \left\{ \frac{k\pi}{2n+1} + \frac{\pi}{2(2n+1)} \right\}_{k=0}^{n-1} \) and satisfy the boundary conditions

\[
s^{(k)}(0) = s^{(l)} \left( \frac{\pi}{2} \right) = 0, \quad 0 \leq k \leq d, \quad 0 \leq l < d, \quad k \text{ even, } l \text{ odd}.
\]

Its dimension equals \( n \) for \( d \) even and equals \( n + 1 \) for \( d \) odd. So, for \( d \) even we have \( S_{B,2n+1,n}^2 = Q_{d,6} = S_{d,2} \). For \( d \) odd, \( S_{B,2n+1,n}^2 \) is an \( n \)-dimensional subspace of \( Q_{d,6} \).

Taking other values of \( m \) and \( n \) and taking the \( B \)-spline (shifted or not) as a function \( B \) in Theorems 2–4 we get new families of optimal spline subspaces with equidistant knots.
