NONCOMMUTATIVE LR COEFFICIENTS AND CRYSTAL REFLECTION OPERATORS

E. RICHMOND AND V. TEWARI

Abstract. We relate noncommutative Littlewood-Richardson coefficients of Bessenrodt-Luoto-van Willigenburg to classical Littlewood-Richardson coefficients via crystal reflection operators. A key role is played by the combinatorics of frank words.

1. Introduction

Quasisymmetric Schur functions, introduced by Haglund-Luoto-Mason-van Willigenburg [14], form a prominent basis for the Hopf algebra of quasisymmetric functions denoted by QSym. The quasisymmetric Schur function indexed by the composition $\alpha$, denoted by $S_\alpha$, is obtained by summing monomials attached to semistandard composition tableaux of shape $\alpha$. This is reminiscent of the definition of Schur functions as sums of monomials corresponding to semistandard Young tableaux. As the name suggests, quasisymmetric Schur functions share many properties with classical Schur functions, and Mason’s map $\rho$ defined in [24] connects the combinatorics of composition tableaux to that of Young tableaux. Understanding analogues of Schur functions and their generalizations has long been a theme in algebraic combinatorics; see [1, 2, 3, 4, 5, 25, 28, 33] for recent work in this context.

The Hopf algebra of noncommutative symmetric functions, NSym, introduced in the seminal paper [12], is Hopf-dual to QSym as shown by Malvenuto-Reutenauer [23]. Bessenrodt-Luoto-van Willigenburg [6] studied the dual basis elements $s_\alpha$ corresponding to quasisymmetric Schur functions. The resulting functions are also indexed by compositions and are called noncommutative Schur functions. The inclusion of the Hopf algebra of symmetric functions Sym into QSym induces a projection $\chi : \text{NSym} \to \text{Sym}$. This projection maps noncommutative Schur functions to classical Schur functions, and justifies the name of the former. The structure constants $C_{\alpha\beta}^\gamma$ that arise in

$$s_\alpha \cdot s_\beta = \sum_{\gamma} C_{\alpha\beta}^\gamma s_\gamma \quad (1.1)$$

are called noncommutative Littlewood-Richardson (LR) coefficients. Noncommutative LR coefficients turn out to be nonnegative integers and furthermore, they refine the classical LR
coefficients $c_{\lambda \mu}^\nu$ that arise in the product of Schur functions
\begin{equation}
    s_\nu \cdot s_\mu = \sum_\lambda c_{\lambda \mu}^\nu s_\lambda.
\end{equation}
More precisely, suppose $\nu$ and $\mu$ are partitions that rearrange to compositions $\alpha$ and $\beta$ respectively. Applying $\chi$ to both sides in (1.1) and comparing the result with (1.2) implies
\begin{equation}
    c_{\nu \mu}^\lambda = \sum_\gamma C_{\alpha \beta}^\gamma
\end{equation}
where the sum on the right runs over all compositions $\gamma$ that rearrange to a fixed partition $\lambda$. Among the numerous combinatorial interpretations of $c_{\nu \mu}^\lambda$, the one we focus on states that $c_{\nu \mu}^\lambda$ counts the number of LR tableaux of shape $\lambda/\mu$ and content $\nu$. Our primary goal in this article is to understand the summands on the right hand side in (1.3) in terms of LR tableaux. To this end, crystal reflection operators are key.

To state our result, we introduce the necessary notation briefly. The reader is referred to Section 2 for details. Given a composition $\alpha$, we denote the partition underlying $\alpha$ by $\text{sort}(\alpha)$. Let $\text{LRT}(\lambda, \mu, \nu)$ be the set of LR tableaux of shape $\lambda/\mu$ and content $\nu$. Given a permutation $\sigma$, let $\text{LRT}^\sigma(\lambda, \mu, \nu)$ be the set of tableaux obtained by applying the crystal reflection operators corresponding to a reduced word of $\sigma$. Let $\alpha := \sigma \cdot \nu$, and let $\beta$ be any composition that satisfies $\text{sort}(\beta) = \mu$. On applying the map $\rho_{\beta}^{-1}$ (which sends Young tableaux to composition tableaux, [21, Chapter 4]) to elements in $\text{LRT}^\sigma(\lambda, \mu, \nu)$, we obtain the disjoint decomposition
\begin{equation}
    \text{LRT}^\sigma(\lambda, \mu, \nu) = \bigsqcup_\gamma X_{\alpha \beta}^\gamma,
\end{equation}
where $X_{\alpha \beta}^\gamma$ consists of all tableaux $T \in \text{LRT}^\sigma(\lambda, \mu, \nu)$ whose outer shape is given by the composition $\gamma$ under the map $\rho_{\beta}^{-1}$. Under this setup, our main theorem states the following.

**Theorem 1.1.** The noncommutative LR coefficient $C_{\alpha \beta}^\gamma$ equals the cardinality of $X_{\alpha \beta}^\gamma$.

The upshot of Theorem 1.1 is that starting from $\text{LRT}(\lambda, \mu, \nu)$, we can compute all noncommutative LR coefficients $C_{\alpha \beta}^\gamma$, where $\alpha$ dictates the choice of crystal reflections to be performed and $\beta$ determines the generalized $\rho$ map to be applied. We also interpret Theorem 1.1 in terms of chains in Young’s lattice indexed by certain frank words and obtain a rule for $C_{\alpha \beta}^\gamma$ involving box-adding operators on compositions. In the case where $\alpha$ is either a partition or reverse partition, our interpretations yield the two LR rules in [7].

**Outline of the article:** Section 2 sets up all the necessary combinatorial background. Section 3 describes our central result along with examples. In Section 4.1 we introduce frank words and describe the Lascoux-Schützenberger symmetric group action on frank words. Section 4.2 identifies LR tableaux to certain distinguished frank words, called compatible words, drawing upon work by Remmel-Shimozono [30]. Section 4.3 relates crystal reflections acting on LR tableaux to the symmetric group action on compatible words. Section 5
relates the results in Section 4 back to noncommutative LR coefficients. The key result in this section, which implies Theorem 1.1, is Proposition 5.3. We conclude our article with Corollary 5.4, which reinterprets our combinatorial interpretation for noncommutative LR coefficients in terms of box-adding operators on compositions.

2. Background

To keep our background section brief, we assume knowledge of combinatorial structures and algorithms arising in the well-studied theory of symmetric functions such as partitions, skew shapes, Young tableaux, Robinson-Schensted-Knuth insertion and jeu-de-taquin. The reader is referred to the standard texts [11, 22, 31, 34] for further information. Regarding notions relevant to the theory of quasisymmetric Schur functions, we adhere to the notation and conventions in [21]. We emphasize here that what we call quasisymmetric Schur functions in this article are the Young quasisymmetric Schur functions in [21]. We have made this choice so that the tableau objects that we consider in the quasisymmetric/noncommutative setting align with the more prevalent notion of Young tableaux rather than reverse tableaux.

2.1. Words. We denote the set of positive integers by \( \mathbb{Z}_+ \). Given \( n \in \mathbb{Z}_+ \), we define \([n] := \{1, \ldots, n\}\). Furthermore, we set \([0] = \emptyset\). Let \( \mathbb{Z}_+^n \) denote the set of all words in the alphabet \( \mathbb{Z}_+ \). Consider \( w = w_1 \ldots w_n \in \mathbb{Z}_+^n \). We call \( n \) the length of \( w \) and denoted it by \(|w|\). The word \( w_n \ldots w_1 \) is denoted by \( w^r \). We say that \( w \) is lattice if every prefix of \( w \) contains at least as many \( i \)'s as \( i+1 \)'s for all \( i \in \mathbb{Z}_+ \). We say that \( w \) is reverse-lattice if \( w^r \) is lattice. We call \( w \) a column word if \( w_1 > \cdots > w_n \). An ordered pair \((i, j)\) is said to be an inversion of \( w \) if \( w_i > w_j \) and \( 1 \leq i < j \leq n \). We denote the set of inversions of \( w \) by \( I(w) \). Note that there is a unique permutation \( \text{stan}(w) \in S_n \) such that \( I(\text{stan}(w)) = I(w) \). We call \( \text{stan}(w) \) the standardization of \( w \). We denote the longest word in \( S_n \) by \( w_0^{(n)} \), or simply by \( w_0 \) if \( n \) is clear from context. We let \( \sigma \in S_n \) act on a sequence \( \lambda = (\lambda_1, \ldots, \lambda_n) \) by \( \sigma \cdot \lambda = (\lambda_{\sigma^{-1}(1)}, \ldots, \lambda_{\sigma^{-1}(n)}) \). Note that this is a right action.

2.2. Compositions and partitions. A finite list of nonnegative integers \( \alpha = (\alpha_1, \ldots, \alpha_\ell) \) is called a weak composition. If \( \alpha_i > 0 \) for all \( 1 \leq i \leq \ell \), then \( \alpha \) is called a composition. If, in addition, we have \( \alpha_1 \geq \cdots \geq \alpha_\ell > 0 \), then \( \alpha \) is called a partition. Given \( \alpha = (\alpha_1, \ldots, \alpha_\ell) \) we call the \( \alpha_i \) the parts of \( \alpha \) and the sum of the \( \alpha_i \), denoted by \( |\alpha| \), is called the size of \( \alpha \). We denote the number of parts of \( \alpha \) by \( \ell(\alpha) \) and call it the length of \( \alpha \). The unique composition of length and size zero is denoted by \( \emptyset \). The partition obtained by sorting the parts of a composition \( \alpha \) in weakly decreasing order is denoted by \( \text{sort}(\alpha) \). We denote the composition \( (\alpha_\ell, \ldots, \alpha_1) \) by \( \alpha^r \). The composition diagram of \( \alpha = (\alpha_1, \ldots, \alpha_\ell) \) is the left-justified array of boxes with \( \alpha_i \) boxes in row \( i \) from the bottom. If \( \alpha \) is a partition, the composition diagram of \( \alpha \) coincides with the Young diagram of \( \alpha \) in the French convention. See Figure 1 for the composition diagram of \((2,1,3)\). Recall that compositions of \( n \) are in bijection with subsets of \([n−1]\) via the map that sends \( \alpha = (\alpha_1, \ldots, \alpha_\ell) \) to \( \text{set}(\alpha) := \{\alpha_1, \alpha_1+\alpha_2, \ldots, \alpha_1+\cdots+\alpha_{\ell−1}\} \). Finally, denote the transpose of a partition \( \lambda \) by \( \lambda^t \).
2.3. Young tableaux. A Young tableau $T$ of skew shape $\lambda/\mu$ is a filling of the boxes of $\lambda/\mu$ with positive integers so that the entries along the rows increase weakly read from left to right and entries along the columns increase strictly read from bottom to top. If the entries in $T$ are all distinct and belong to $|\lambda/\mu|$, then we say that $T$ is standard. We denote the set of Young tableaux of shape $\lambda/\mu$ by $YT(\lambda/\mu)$.

Given a word $w = w_1 \ldots w_n$, the Robinson-Schensted correspondence (via row insertion or column insertion) associates an ordered pair of Young tableaux $(P(w), Q(w))$ of the same shape. We call $P(w)$ (respectively $Q(w)$) the insertion tableau (respectively recording tableau). We call two words $w_1$ and $w_2$ Knuth-equivalent if $P(w_1) = P(w_2)$. The column reading word of $T \in YT(\lambda/\mu)$, denoted by $\text{crw}(T)$, is obtained by reading the entries of $T$ in every column from top to bottom starting from the left and going to the right. We declare tableaux $T_1$ and $T_2$ to be jdt-equivalent if their column reading words are Knuth-equivalent, that is, $P(\text{crw}(T_1)) = P(\text{crw}(T_2))$.

If $T$ is a Young tableau with maximal entry $m$, then the content of $T$, denoted by $\text{cont}(T)$, is the weak composition $(\alpha_1, \ldots, \alpha_m)$ where $\alpha_i$ for $1 \leq i \leq m$ counts the number of times $i$ appears in $T$. The standardization of $T$, denoted by $\text{stan}(T)$, is obtained by replacing the $\alpha_i$ entries in $T$ equal to $i$ by the integers $1 + \sum_{j=1}^{i-1} \alpha_j$ through $\sum_{j=1}^{i} \alpha_j$ from left to right. Thus, $\text{stan}(T)$ is standard and knowing $\text{cont}(T)$ allows us to recover $T$. We associate a word with $\text{stan}(T)$ by reading the entries from largest to smallest and noting the column in which they belong. We call this word the column growth word of $T$ and denote it by $\text{cgw}(T)$. For the tableau $T$ in Figure 2 we have $\text{cgw}(T) = 76564321531$. We extend the definition of column growth word to all tableaux by setting $\text{cgw}(T) := \text{cgw}(\text{stan}(T))$.

A descent of a standard Young tableau $T$ with $n$ boxes is an integer $i$ satisfying $1 \leq i \leq n - 1$ such that $i + 1$ occupies a row strictly above that occupied by $i$. The descent set of $T$ is the collection of descents of $T$, and the descent composition is the composition of $n$ corresponding to the descent set. The descent set of the standard Young tableau on the right in Figure 2 is $\{3, 8\}$. 

---

**Figure 1.** The composition diagram of $(2, 1, 3)$.

**Figure 2.** A Young tableau and its standardization.
2.4. **Composition Tableaux.** To define composition tableaux, we need an analogue of Young’s lattice. The **Young composition poset** \( L_c \) is the poset on compositions where the partial order \(<_c\) is obtained by taking the transitive closure of the cover relation \(\preceq_c\) defined next. Let \( \beta = (\beta_1, \ldots, \beta_m) \). Then \( \beta <_c \alpha \) if exactly one of the following conditions holds.

- \( \alpha = (\beta_1, \ldots, \beta_m, 1) \).
- \( \alpha = (\beta_1, \ldots, \beta_k + 1, \ldots, \beta_m) \) for some \( k \) where \( \beta_k \neq \beta_i \) for all \( i > k \).

The reader may check that, for instance, the compositions covering \( (2, 1, 3, 2) \) in \( L_c \) are \( (2, 1, 3, 2, 1), (2, 2, 3, 2), (2, 1, 3, 3) \) and \( (2, 1, 4, 2) \).

**Remark 2.1.** The definition of \( \preceq_c \) implies that \( \beta <_c \alpha \) if and only if for every \( \beta_i \geq \beta_j \) where \( i > j \) we have \( \alpha_i \geq \alpha_j \).

If \( \beta <_c \alpha \) and \( \beta \) is drawn in the bottom left corner of \( \alpha \), then the **skew composition shape** \( \alpha/\beta \) is defined to be the array of boxes that belong to \( \alpha \) but not to \( \beta \). We refer to \( \alpha \) and \( \beta \) as the **outer shape** and **inner shape** respectively. If the inner shape is \( \emptyset \), instead of writing \( \alpha/\emptyset \), we just write \( \alpha \) and refer to \( \alpha \) as a **straight shape**. The **size** of \( \alpha/\beta \), denoted by \( |\alpha/\beta| \), is \( |\alpha| - |\beta| \).

A **composition tableau** (abbreviated to CT) \( \tau \) of shape \( \alpha/\beta \) is a filling \( \tau : \alpha/\beta \to \mathbb{Z}_+ \) that satisfies the following conditions.

1. The entries in each row increase weakly from left to right.
2. The entries in the leftmost column increase strictly from bottom to top.
3. For any configuration in \( \tau \) of the type in Figure 3 if \( a \leq c \) then \( b < c \).

![Figure 3. A triple configuration.](image)

A composition tableau is **standard** if the filling \( \tau \) is a bijection between \( \alpha/\beta \) and \( |\alpha/\beta| \). We denote the set of CTs (respectively SCTs) of shape \( \alpha/\beta \) by CT\((\alpha/\beta)\) (respectively SCT\((\alpha/\beta)\)). Figure 4 depicts a tableau in CT\(((3,6,1,7)/(2,4))\) on the left, where the shaded boxes belong to the inner shape. The **column reading word** of \( \tau \in \text{CT}(\alpha/\beta) \), denoted by \( \text{crw}(\tau) \), is obtained by reading the entries in every column in decreasing order, starting from the leftmost column and going to the right.

Given a composition \( \alpha = (\alpha_1, \ldots, \alpha_k) \), the **canonical composition tableau** \( \tau_\alpha \) is constructed by filling the boxes in the \( i \)-th row of the composition diagram of \( \alpha \) with consecutive positive integers from \( 1 + \sum_{j=1}^{i-1} \alpha_j \) to \( \sum_{j=1}^{i} \alpha_j \) from left to right, for \( 1 \leq i \leq k \). Figure 4 shows the canonical CT of shape \( (4, 2, 3, 1) \) on the right.
2.5. The \( \rho \) map. Next we discuss a crucial map that establishes the bridge between the combinatorics of composition tableaux and that of Young tableaux. Let \( \text{CT}(\alpha/\beta) \) denote the set of all CTs with inner shape \( \beta \) and \( \text{YT}(\lambda/\beta) \) denote the set of all YTs with inner shape \( \text{sort}(\beta) \). Then the map \( \rho_\beta : \text{CT}(\alpha/\beta) \to \text{YT}(\lambda/\beta) \), which generalizes the map for semistandard skyline fillings [24] and is introduced in [21, Chapter 4], is defined as follows. Given \( \tau \in \text{CT}(\alpha/\beta) \), obtain \( \rho_\beta(\tau) \) by writing the entries in each column in increasing order from bottom to top and bottom-justifying these new columns on the inner shape \( \text{sort}(\beta) \), which might be empty.

The inverse map \( \rho_\beta^{-1} : \text{YT}(\lambda/\beta) \to \text{CT}(\alpha/\beta) \) is also straightforward to define. Given \( T \in \text{YT}(\lambda/\beta) \),

1. take the set of \( i \) entries in the leftmost column of \( T \) and write them in increasing order in rows \( \ell(\beta) + 1, 2, \ldots, \ell(\beta) + i \) above the inner shape \( \beta \) in the first column to form the leftmost column of \( \tau \),
2. take the set of entries in column 2 in increasing order and place them in the row with the largest index so that either
   - the box to the immediate left of the number being placed is filled and the row entries weakly increase when read from left to right, or
   - the box to the immediate left of the number being placed belongs to the inner shape,
3. repeat the previous step with the set of entries in column \( k \) for \( k = 3, \ldots, m \) where \( m \) is the largest part of \( \text{sort}(\beta) \).

In the case \( \beta = \emptyset \), the map \( \rho_\beta \) is Mason’s shift map [24] (also known as the \( \rho \) map), and we set \( \rho := \rho_\emptyset \). The reader may verify that the Young tableau \( T \) on the left in Figure 2 maps to the composition tableau on the left in Figure 4 under \( \rho_\beta^{-1} \).

Remark 2.2. In view of the map \( \rho_\beta \), all combinatorial notions discussed in the context of Young tableaux are inherited by composition tableaux, and we refrain from discussing all except one. Given \( \tau \in \text{CT}(\alpha/\beta) \), its rectification, denoted by \( \text{rect}(\tau) \), is defined to be \( \rho^{-1}(\text{rect}(\rho_\beta(\tau))) \). We make note of one important consequence: Let \( \mu \) be a partition, and \( \beta^{(1)}, \beta^{(2)} \) be compositions such that \( \text{sort}(\beta^{(i)}) = \mu \) for \( i = 1, 2 \). Given \( T \in \text{YT}(\lambda/\mu) \), let \( \tau_i = \rho^{-1}_{\beta^{(i)}}(T) \) for \( i = 1, 2 \). As \( \text{crw}(\tau_1) = \text{crw}(\tau_2) \), we infer that \( \text{rect}(\tau_1) = \text{rect}(\tau_2) \).
2.6. Classical and noncommutative LR coefficients. We refer the reader to \[12, 21, 13\] for background on noncommutative symmetric functions and quasisymmetric functions. Recall that the classical LR rule provides a combinatorial way to compute the structure coefficients $c^\lambda_{\nu\mu}$ in

$$s_\nu s_\mu = \sum_{\lambda \vdash |\mu|+|\nu|} c^\lambda_{\nu\mu} s_\lambda.$$ 

These same structure coefficients also arise in the expansion of the skew Schur function $s_{\lambda/\mu}$. The LR rule was stated by Littlewood-Richardson \[19\] in 1934, and the first rigorous proofs were obtained by Thomas \[37\] and Schützenberger \[32\] four decades later. We call $T \in YT(\lambda/\mu)$ a Littlewood-Richardson tableau (henceforth LR tableau) if $\text{cont}(T)$ is a partition and $\text{crw}(T)$ is reverse lattice. The set of LR tableaux of shape $\lambda/\mu$ and content $\nu$ is denoted by $\text{LRT}(\lambda, \mu, \nu)$. The classical LR coefficient $c^\lambda_{\nu\mu}$ equals $|\text{LRT}(\lambda, \mu, \nu)|$. Figure 5 depicts the LR tableaux that contribute to $c^{(7,6,4,3,2)}_{(4,3,1)(6,4,4)}$. For various interesting combinatorial interpretations of LR coefficients, the reader is referred to \[18, 10\]. For a Hopf-algebraic perspective, see \[15\], and for a beautiful unifying polytopal perspective, see \[26\].

![LR Tableaux](image)

**Figure 5.** The three LR tableaux contributing to $c^{(7,6,4,3,2)}_{(4,3,1)(6,4,4)}$.

To describe the noncommutative LR rule, we need noncommutative analogues of Schur functions or, equivalently, quasisymmetric analogues of skew Schur functions. Following \[21, Proposition 5.2.6\], we define the *skew quasisymmetric Schur function* indexed by $\alpha//\beta$ to be

$$S_{\alpha//\beta} := \sum_{\tau \in CT(\alpha//\beta)} x^{\text{cont}(\tau)}.$$ 

In (2.1), $\text{cont}(\tau)$ refers to the content of $\tau$ and $x^{\text{cont}(\tau)} := x_{1}^{\alpha_1} \cdots x_{m}^{\alpha_m}$ where $m$ is the largest entry in $\tau$ and $(\alpha_1, \ldots, \alpha_m) = \text{cont}(\tau)$. If $\beta = \emptyset$ in (2.1), instead of writing $S_{\alpha//\emptyset}$, we write $S_\alpha$ and call this the *quasisymmetric Schur function* indexed by $\alpha$. Additionally, we set $S_\emptyset = 1$.

The noncommutative Schur functions are defined indirectly \[21, Definition 5.6.1\] as elements of the basis in NSym dual to the basis of quasisymmetric Schur functions in QSym. We state the LR rule for noncommutative Schur functions, equivalent to \[21, Theorem 5.6.2\].

**Theorem 2.3.** Let $\alpha, \beta$ be compositions. Then

$$s_\alpha s_\beta = \sum_{\gamma \vdash |\alpha|+|\beta|} C_{\alpha\beta}^\gamma s_\gamma,$$ 

where $C_{\alpha\beta}^\gamma$ are the classical LR coefficients.
where \( C^\gamma_{\alpha\beta} \) is the number of SCTs of shape \( \gamma \parallel \beta \) that rectify to \( \tau_\alpha \).

As alluded to in the introduction, one of our primary motivations for this article is a description for noncommutative LR coefficients involving LR tableaux. In particular, we seek an appropriate analogue to LR tableaux in the context of composition tableaux.

2.7. Crystal reflection operators and LR tableaux. For an in-depth exposition on crystal bases and their relevance in algebraic combinatorics and representation theory, we refer the reader to [8]. We proceed to describe crystal reflection operators as they are pertinent for our purposes.

Given a positive integer \( i \), we define the crystal reflection operator \( s_i \) acting on the set of Young tableaux as follows. Let \( T \in YT(\lambda/\mu) \), and let \( w = w_1 \ldots w_n := \text{crw}(T) \). Scan \( w \) from left to right and pair each \( i + 1 \) with the closest unpaired \( i \) that follows. If no further pairing is possible, change all unpaired \( i \)'s to \( i + 1 \)'s or vice versa depending on whether the number of \( i \)'s is greater than the number of \( i + 1 \)'s or not. Say the new word obtained via this procedure is \( w' \). Define \( s_i(T) \) to be the unique YT of shape \( \lambda/\mu \) such that \( \text{crw}(s_i(T)) = w' \).

Lascoux-Schützenberger [16] (see also [29, Proposition 9] and [17, Section 3]) proved that the operators \( s_i \) define an action of the (infinite) symmetric group on \( YT(\lambda/\mu) \) by establishing the following relations.

\[
s_i^2 = Id,
\]
\[
s_is_j = s_js_i \text{ if } |i - j| > 1,
\]
\[
s_is_{i+1}s_i = s_{i+1}s_is_{i+1}.
\]

These relations imply that \( \sigma(T) \) is well defined for any permutation \( \sigma \). In particular, to compute \( \sigma(T) \), let \( s_{i_1} \cdots s_{i_k} \) be any reduced word for \( \sigma \) and compute \( s_{i_1} \cdots s_{i_k}(T) \).

For \( \sigma \in S_{\ell(\nu)} \), define
\[
\text{LRT}^\sigma(\lambda, \mu, \nu) := \{ \sigma(T) \mid T \in \text{LRT}(\lambda, \mu, \nu) \}.
\]

Since crystal reflection operators define an \( S_{\ell(\nu)} \)-action, we have
\[
| \text{LRT}^\sigma(\lambda, \mu, \nu) | = | \text{LRT}(\lambda, \mu, \nu) | = c^\lambda_{\nu\mu},
\]
for all permutations \( \sigma \in S_{\ell(\nu)} \). Figure 6 shows all tableaux in \( \text{LRT}^\sigma(\lambda, \mu, \nu) \) where \( \lambda = (7, 6, 4, 3, 2) \), \( \mu = (6, 4, 4) \), \( \nu = (4, 3, 1) \) and \( \sigma = s_1s_2 \). The tableaux in \( \text{LRT}(\lambda, \mu, \nu) \) are shown in Figure 5. Note that all tableaux in Figure 6 have content \( (1, 4, 3) = \sigma \cdot (4, 3, 1) \).

![Figure 6. Crystal reflection corresponding to \( s_1s_2 \) on the tableaux in Figure 5.](image-url)
It transpires that even though the elements in $LRT^\sigma(\lambda, \mu, \nu)$ for an arbitrary permutation $\sigma$ shed no further light on classical LR coefficients, they do carry crucial information as far as computing noncommutative LR coefficients is concerned. To motivate our upcoming results and to establish a connection with Theorem 2.3, we invite the reader to check that for all tableaux $T$ in Figure 6, we have that $\rho^{-1}(\text{rect}(T))$ is the CT in Figure 7. Note that this CT is the unique CT with shape and content equaling $(1, 4, 3)$. Equivalently, we could say that $\rho^{-1}(\text{rect(\text{stan}(T)))}$ is the canonical CT of shape $(1, 4, 3)$.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure7.png}
\caption{The rectification of all tableaux in Figure 6.}
\end{figure}

In Section 4, we establish this property in general by employing various properties of frank words and their relation to jeu-de-taquin. Prior to that, we describe our main result and illustrate it with examples.

3. Main result

Our first main result provides a combinatorial description for $C^\gamma_{\alpha\beta}$ using crystal reflection operators. We state here the main theorem and provide a proof which assumes results we establish in Section 4.

**Theorem 3.1.** Let $\alpha$, $\beta$ and $\gamma$ be compositions such that $|\beta| + |\alpha| = |\gamma|$. Let $(\lambda, \mu, \nu)$ be the triple $(\text{sort}(\gamma), \text{sort}(\beta), \text{sort}(\alpha))$. If $\sigma \in \mathfrak{S}_{\ell(\nu)}$ is a permutation such that $\alpha = \sigma \cdot \nu$, then

$$C^\gamma_{\alpha\beta} = |\{T \in LRT^\sigma(\lambda, \mu, \nu) \mid \text{shape}(\rho^{-1}_\beta(T)) = \gamma/\beta\}|$$

**Proof.** Let $(\lambda, \mu, \nu)$ be as in the statement of the theorem. Recall from (1.3) in the introduction that

$$c^\lambda_{\nu\mu} = \sum_{\text{sort}(\delta) = \lambda} C^\delta_{\alpha\beta},$$

where we work with the convention that $C^\delta_{\alpha\beta} = 0$ if $\delta$ does not lie above $\beta$ in $L_c$. Given $\gamma$ such that $\text{sort}(\gamma) = \lambda$, define

$$X_\gamma := \{T \in LRT^\sigma(\lambda, \mu, \nu) \mid \text{shape}(\rho^{-1}_\beta(\text{stan}(T))) = \gamma\}.$$

By Proposition 5.3, we have that $|X_\gamma| \leq C^\gamma_{\alpha\beta}$. On the other hand, from (3.1) and the fact that $\text{shape}(\rho^{-1}_\beta(\text{stan}(T))) = \text{shape}(\rho^{-1}_\beta(T))$ for all Young tableaux $T$ with inner shape $\mu$, we infer that

$$|\text{LRT}^\sigma(\lambda, \mu, \nu)| = \sum_{\text{sort}(\delta) = \lambda} |X_\delta|.$$
Thus, we must have $|X_\gamma| = C^\gamma_{\alpha\beta}$. □

Theorem 3.1 gives us a way to compute $C^\gamma_{\alpha\beta}$ using crystal reflections and the generalized $\rho$ map provided we know LRT$(\lambda, \mu, \nu)$. We discuss an example next to illustrate Theorem 3.1.

In (3.4), we depict $\rho_{(1,2)}^{-1}(1,2) \circ s_1(T)$ for the $T$ in LRT$((5, 3, 2), (2, 1), (4, 2, 1))$. By considering the shapes of resulting CTs, we infer that $C^{(3,5,2)}_{(2,4,1)(1,2)} = 1$ and $C^{(2,5,3)}_{(2,4,1)(1,2)} = 1$.

On the other hand, if we compute $\rho_{(2,1)}^{-1}(2,1) \circ s_1(T)$ for the same LR tableaux, then we obtain the two CTs in (3.5). We conclude that $C^{(3,5,2)}_{(2,4,1)(2,1)} = 1$ and $C^{(5,2,3)}_{(2,4,1)(2,1)} = 1$.

4. Frank words and LR tableaux

In order to prove Theorem 3.1 we need to understand the rectification of tableaux in LRT$^\sigma(\lambda, \mu, \nu)$ followed by an application of the generalized $\rho$ map. To this end, we study various aspects of column growth words of these tableaux. In particular, we identify these words as certain frank words that satisfy an additional compatibility condition. This characterization eventually allows us to connect LRT$^\sigma(\lambda, \mu, \nu)$ to the computation of noncommutative LR coefficients.

4.1. A symmetric group action on frank words. Frank words were introduced by Lascoux-Schützenberger [17] in their investigation of key polynomials. Subsequently, Reiner and Shimozono [27] studied the combinatorics of frank words in depth in the context of a flagged Littlewood-Richardson rule, and we follow their exposition as far as notions in this section are concerned.
Given a nonempty word \( w \in \mathbb{Z}_+^* \), consider its factorization \( w^{(1)}w^{(2)} \cdots w^{(m)} \) where each \( w^{(i)} \) is a maximal column word (necessarily nonempty). We call \( w \) an \( m \)-column word. Define the column form of \( w \) to be the composition \( \text{colform}(w) := (|w^{(1)}|, \ldots, |w^{(m)}|) \). We say that \( w \) is frank if \( P(w) \) is of shape \( \lambda \) where \( \lambda = \text{sort}(\text{colform}(w)) \). Given a composition \( \alpha \), denote the set of frank words \( w \) satisfying \( \text{colform}(w) = \alpha \) by \( \text{Frank}(\alpha) \).

Figure 8. The insertion tableau corresponding to \( w = \begin{array}{lll} 4 & 3 & 6 \\ 2 & 3 & 5 \\ 1 & 2 & 3 \end{array} \).

Let \( A \) denote the set of 2-column frank words. Consider \( w \in A \) and let \( \text{colform}(w) = (\beta_1, \beta_2) \). By [27, Appendix 2], we have that \( w \) may be identified as the column reading word of a tableau \( T \) of shape \( (\beta_1, \beta_2)^t \) if \( \beta_1 \geq \beta_2 \) or of a tableau \( T \) of shape \( (\beta_2, \beta_1)^t/(\beta_2 - \beta_1)^t \) if \( \beta_1 < \beta_2 \). If the former holds, define \( \iota(w) \) to be the column reading word of the unique tableau \( T' \) of shape \( (\beta_1, \beta_1)^t/(\beta_1 - \beta_2)^t \) that is jdt-equivalent to \( T \) (obtained by performing jeu-de-taquin slides within the rectangle \( (\beta_1, \beta_1)^t \)). If the latter holds, define \( \iota(w) \) to be the column reading word of the unique tableau \( T' \) of shape \( (\beta_2, \beta_1)^t \) that is jdt-equivalent to \( T \). Clearly, \( \iota \) is an involution on \( A \). Equally importantly, \( w \) and \( \iota(w) \) are Knuth-equivalent. For instance, jdt-equivalence of the tableaux in Figure 9 implies that \( \iota(\begin{array}{lll} 7 & 6 & 4 \\ 6 & 4 & 2 \\ 4 & 2 & 1 \\ 2 & 1 & 1 \end{array}) = \begin{array}{lll} 6 & 2 & 1 \\ 4 & 7 & 3 \\ 3 & 6 & 2 \\ 2 & 1 & 2 \end{array} \).

Figure 9. Establishing \( \iota(\begin{array}{lll} 7 & 6 & 4 \\ 6 & 4 & 2 \\ 4 & 2 & 1 \\ 2 & 1 & 1 \end{array}) = \begin{array}{lll} 6 & 2 & 1 \\ 4 & 7 & 3 \\ 3 & 6 & 2 \\ 2 & 1 & 2 \end{array} \) by jeu-de-taquin.
We employ the involution \( \iota \) to construct the desired symmetric group action. Let \( \lambda \) be a partition and let \( m := \ell(\lambda) \). Define

\[
\mathcal{F}_\lambda := \prod_{\text{sort}(\beta) = \lambda} \text{Frank}(\beta).
\]

Following [17], define an action of \( S_m \) on \( \mathcal{F}_\lambda \) by describing the action of the generator \( s_i \) for \( 1 \leq i \leq m - 1 \) as follows: Let \( w^{(1)} \ldots w^{(m)} \) be the maximal column word factorization of \( w \in \mathcal{F}_\lambda \). Let \( v^{(i)} v^{(i+1)} := \iota(w^{(i)} w^{(i+1)}) \) and define \( v = w^{(1)} \ldots w^{(i-1)} v^{(i)} v^{(i+1)} w^{(i+2)} \ldots w^{(m)} \). Observe that \( \text{sort}(\text{colform}(v)) = \lambda \). As \( v \) and \( w \) are Knuth-equivalent, we infer that \( v \in \mathcal{F}_\lambda \). We define \( v \) to be \( s_i(w) \). This given, we may now define \( \sigma(w) \) for any \( \sigma \in S_m \) by making a choice of reduced word for \( \sigma \).

4.2. \( \lambda/\mu \)-compatible frank words and LR tableaux.\footnote{Given partitions \( \lambda, \mu \) such that \( \mu \subseteq \lambda \) and a composition \( \alpha \), we say that \( w \in \text{Frank}(\alpha) \) is \( \lambda/\mu \)-\textit{compatible} if for every suffix \( w' \) of \( w \), we have that \( \text{cont}(w') + \mu' \) is a partition and that \( \text{cont}(w) + \mu' = \lambda' \). All this says is that \( w \in \text{Frank}(\alpha) \) is the column growth word of some tableau of shape \( \lambda/\mu \). Observe that we must have \( \alpha \vdash |\lambda| - |\mu| \). For instance, \( w = \begin{bmatrix} 621 & 76432 \end{bmatrix} \in \text{Frank}(\alpha) \) is \( \lambda/\mu \)-compatible for \( \lambda = (7, 6, 4, 2, 2) \), \( \mu = (5, 5, 2, 1) \), and \( \alpha = (3, 5) \). The reader can easily verify that \( w \) is the column growth word of the tableau in Figure 10.

Define

\[
\text{LRFrank}(\lambda, \mu, \alpha) := \{ w \in \text{Frank}(\alpha) \mid w \text{ is } \lambda/\mu\text{-compatible} \}.
\]

What is special about this subset of frank words with column form \( \alpha \)? There is an intimate link between LR tableaux and compatible words that we motivate by the following example. Consider \( \lambda = (7, 6, 4, 3, 2) \), \( \mu = (6, 4, 4) \) and \( \alpha = (3, 4, 1) \). The reader can verify that \( \text{LRFrank}(\lambda, \mu, \alpha) \) consists of \begin{bmatrix} 321 & 7621 & 5 \end{bmatrix} \begin{bmatrix} 621 & 76321 & 5 \end{bmatrix} \text{ and } \begin{bmatrix} 321 & 6521 & 7 \end{bmatrix} \text{ Remarkably, these words are precisely column growth words of tableaux in Figure 6. We make this connection precise.}

Given \( w \in \text{LRFrank}(\lambda, \mu, \alpha) \), let \( w^{(1)} \ldots w^{(m)} \) be its maximal column word factorization where \( m := \ell(\alpha) \). Construct a Young tableau \( \phi(w) \) of shape \( \lambda/\mu \) and content \( \alpha^c \) as follows: Let \( \lambda^{(0)} := \lambda \) and inductively define \( \lambda^{(i)} \) for \( 1 \leq i \leq m \) to be such that \( \lambda^{(i-1)}/\lambda^{(i)} \) is a horizontal strip with boxes in columns given by letters appearing in \( w^{(i)} \). Subsequently, fill the boxes of the horizontal strips \( \lambda^{(i-1)}/\lambda^{(i)} \) with \( m+1-i \) to obtain \( \phi(w) \). Note that \( \lambda^{(m)} \) is \( \mu \) and that \( \phi(w) \) does indeed belong to \( \text{YT}(\lambda/\mu) \). As an example, consider \( w = \begin{bmatrix} 621 & 76432 \end{bmatrix} \) which is \( \lambda/\mu \)-compatible for \( \lambda = (7, 6, 4, 2, 2) \) and \( \mu = (5, 5, 2, 1) \). The tableau \( \phi(w) \) is shown in Figure 10.

Define

\[
\text{LRFrankTab}(\lambda, \mu, \alpha) := \{ \phi(w) \mid w \in \text{LRFrank}(\lambda, \mu, \alpha) \}.
\]

Given a partition \( \lambda \), denote the skew shape obtained by a \( 180^\circ \) rotation by \( \text{rotate}(\lambda) \). Our next lemma establishes that \( \text{LRT}(\lambda, \mu, \nu) = \text{LRFrankTab}(\lambda, \mu, \nu^c) \).
Lemma 4.1. Let $\lambda, \mu$ and $\nu$ be partitions such that $\mu \subseteq \lambda$ and $|\nu| = |\lambda/\mu|$. We have

$$\text{LRT}(\lambda, \mu, \nu) = \text{LRFrankTab}(\lambda, \mu, \nu^r).$$

Proof. Let $w \in \text{LRFrank}(\lambda, \mu, \nu^r)$. As $\text{colform}(w) = \nu^r$ and $w$ is frank, we know that $w$ is the column reading word of a tableau of skew shape $\text{rotate}(\nu^r)$. It follows that $\phi(w) \in \text{LRT}(\lambda, \mu, \nu)$. This establishes $\text{LRFrankTab}(\lambda, \mu, \nu^r) \subseteq \text{LRT}(\lambda, \mu, \nu)$. The opposite inclusion relies on the fact that the column growth word of any $T \in \text{LRT}(\lambda, \mu, \nu)$ is the column reading word of a Young tableau of skew shape $\text{rotate}(\nu^r)$. □

Figure 11 depicts column growth words of tableaux in $\text{LRT}(\lambda, \mu, \nu)$ (shown in Figure 5) as column reading words of Young tableaux of skew shape $\text{rotate}(\nu^r)$ where $\lambda = (7, 6, 4, 3, 2)$, $\mu = (6, 4, 4)$ and $\nu = (4, 3, 1)$.

![Figure 10. The tableau $\phi(w)$ corresponding to 621 76432.](image)

4.3. Relating the two symmetric group actions. Our next lemma connects the action of crystal reflection operators on $\text{LRFrankTab}(\lambda, \mu, \alpha)$ to the symmetric group action on $\lambda/\mu$-compatible frank words in $\text{LRFrank}(\lambda, \mu, \alpha)$.

Lemma 4.2. Consider $w \in \text{LRFrank}(\lambda, \mu, \alpha)$ and $i$ satisfying $1 \leq i \leq \ell(\alpha) - 1$. We have that $s_i(\phi(w)) = \phi(s_{\ell(\alpha) - i}(w))$.

Proof. Without loss of generality, we may assume that $\alpha$ has two parts. Suppose $\alpha = (p, q) \models n$ Assume $w = w^{(1)}w^{(2)}$ where $|w^{(1)}| = p$ and $|w^{(2)}| = q$. We would like to establish that $s_i(\phi(w)) = \phi(s_{\ell(\alpha) - i}(w))$.

Assume $p < q$. Let $w^{(1)} = a_1 \ldots a_p$ and $w^{(2)} = b_1 \ldots b_q$. We have $a_1 > \cdots > a_p$ and $b_1 > \cdots > b_q$. As $w$ is frank, it is the column reading word of a Young tableau of skew shape $\text{rotate}((q, p)^t)$. Thus, $a_i \leq b_i$ for $1 \leq i \leq p$. 

![Figure 11. Column growth words of LR tableaux are frank words.](image)
Instead of computing $$\iota(w)$$ by way of rectifying the appropriate two-columned tableau, one may perform successive Schensted column insertions of the numbers $$a_p$$ down to $$a_1$$ starting from the single-columned tableau with column word $$w^{(2)}$$. See Figure 12 for an example. Compare with Figure 9 which established the same fact using jeu-de-taquin.

2 \\
1 \\
\end{array} 
\]

**Figure 12.** Establishing that $$\iota([621\ 76432]) = 76421632$$ by column-inserting 1, 2, and 6 into the single-columned tableau with column reading word 76432. Blue boxes show the entries being inserted whereas red boxes contain the entries bumped.

During each intermediate step of this column-insertion procedure, the number $$a_i$$ being inserted into the current tableau bumps a distinct element from $$\{b_1, \ldots, b_q\}$$. Furthermore this bumped entry is guaranteed to be strictly greater than the entries in the second column in the current tableau. Therefore, the insertion tableau is completely determined by the entries that get bumped. More precisely, for $$i$$ from $$p$$ down to 1, define the integer $$m(i)$$ recursively as follows. We define $$m(p)$$ to be the largest integer $$j$$ such that $$a_p \leq b_j$$. Subsequently, for $$i = p - 1, \ldots, 1$$, define $$m(i)$$ to be the largest integer $$j$$ such that $$j < m(i + 1)$$ and $$a_i \leq b_j$$. Observe that in our Schensted column-insertion procedure, the entry $$a_i$$ bumps $$b_{m(i)}$$. Therefore, the set of entries that get bumped is $$\{b_{m(i)} \mid 1 \leq i \leq p\}$$. For the example in Figure 12, we have $$m(3) = 5$$, $$m(2) = 4$$ and $$m(1) = 2$$. Therefore the set of entries that get bumped is $$\{b_5, b_4, b_2\} = \{2, 3, 6\}$$.

Consider $$\text{crw}(\phi(w)) = u_1 \ldots u_n$$. The word $$v := v_1 \ldots v_n$$ obtained by recording the column to which each $$u_i$$ belongs gives us the weakly increasing arrangement of letters in $$w$$. Furthermore, for $$1 \leq i \leq p$$ (respectively $$1 \leq i \leq q$$) the letter in $$v$$ corresponding to the $$i$$th 2 (respectively 1) from the left in $$\text{crw}(\phi(w))$$ is equal to $$a_i$$ (respectively $$b_i$$). Recall that the crystal reflection operator $$s_1$$ acting on $$\phi(w)$$ begins by pairing each 2 in $$\text{crw}(\phi(w))$$ to the closest unpaired 1 to its right. Equivalently, in our current context, a 2 corresponding to $$a_i$$ for some $$1 \leq i \leq p$$ gets paired with the 1 in $$\text{crw}(\phi(w))$$ corresponding to $$b_{m(i)}$$. We infer that the unpaired 1s in $$\text{crw}(\phi(w))$$ correspond to those $$b_j$$ that are not bumped. These are precisely the $$b_j$$ that determine which 1s in $$\phi(w)$$ turn into 2s in computing $$s_1(\phi(w))$$. Thus we infer that $$s_1(\phi(w)) = \phi(\iota(w))$$. This establishes the claim in the case $$p < q$$. The case $$p \geq q$$ is similar and left to the reader. 

To illustrate the ideas in the preceding proof, Figure 13 depicts the action of $$s_1$$ on the tableau $$\phi(w)$$ from Figure 10 where $$w = [621\ 76432]$$. From Figure 12, we see that the entries that do not get bumped are $$\{4, 7\}$$. Also, note that $$\text{crw}(\phi(w)) = 22111211$$ where
the unpaired 1s are highlighted. In terms of the tableau $\phi(w)$, we see that the unpaired 1s belong to columns 4 and 7. The tableau on the right in Figure 13 is easily verified to be $\phi(\iota(w))$ as $\iota(w) = 76421632$.

**Figure 13.** Crystal reflection on $\phi(w)$ and its relation to the $\iota$ involution.

We are ready to give a precise relation between $\text{LRT}^\sigma(\lambda, \mu, \nu)$ and $\lambda/\mu$-compatible frank words with a certain column form that generalizes Lemma 4.1.

**Proposition 4.3.** Let $\lambda, \mu$ and $\nu$ be partitions such that $\mu \subseteq \lambda$ and $|\nu| = |\lambda/\mu|$. Let $w_0$ be the longest word in $S_{\ell(\nu)}$. For $\sigma \in S_{\ell(\nu)}$, we have

$$\text{LRT}^\sigma(\lambda, \mu, \nu) = \text{LRFrankTab}(\lambda, \mu, (w_0\sigma w_0) \cdot \nu^r).$$

**Proof.** Lemma 4.1 implies $\text{LRT}(\lambda, \mu, \nu) = \text{LRFrankTab}(\lambda, \mu, \nu^r)$. Consider $T \in \text{LRT}^\sigma(\lambda, \mu, \nu)$. We must have $T = \sigma(T')$ for a unique $T' \in \text{LRT}(\lambda, \mu, \nu)$, which in turn implies that $T = \sigma(\phi(w'))$ for a unique $w' \in \text{LRFrank}(\lambda, \mu, \nu^r)$. Lemma 4.2 implies that $T = \phi(w_0\sigma w_0(w'))$. As $\text{colform}(w_0\sigma w_0(w')) = (w_0\sigma w_0) \cdot \nu^r$, we conclude that

$$\text{LRT}^\sigma(\lambda, \mu, \nu) \subseteq \text{LRFrankTab}(\lambda, \mu, (w_0\sigma w_0) \cdot \nu^r).$$

A simple cardinality count implies this inclusion must be an equality. \qed

Proposition 4.3 states that elements of $\text{LRT}^\sigma(\lambda, \mu, \nu)$ are in bijection with $\lambda/\mu$-compatible frank words with column form $(w_0\sigma w_0) \cdot \nu^r$. As an example, consider $\text{LRT}^\sigma(\lambda, \mu, \nu)$ from Figure 6 where $\lambda = (7, 6, 4, 3, 2)$, $\mu = (6, 4, 4)$, $\nu = (4, 3, 1)$ and $\sigma = s_1s_2$. Note that the column growth words of these tableaux are indeed frank words with column form $(w_0s_1s_2w_0) \cdot (1, 3, 4) = (s_2s_1) \cdot (1, 3, 4) = (3, 4, 1)$. Figure 14 shows these frank words as column reading words of tableaux with column lengths 3, 4 and 1 read from left to right. We encourage the reader to obtain these tableaux by performing jeu-de-taquin slides to tableaux in Figure 11.

**Figure 14.** Column growth words of tableaux in Figure 6 are frank words.
5. NONCOMMUTATIVE LR COEFFICIENTS AND FRANK WORDS

Now that we understand tableaux in LRT$^\sigma(\lambda, \mu, \nu)$ as certain $\lambda/\mu$-compatible words with a prescribed column form, we are ready to establish the connection to noncommutative LR coefficients. We need some preliminary lemmas.

**Lemma 5.1.** For any Young tableau $T$, we have $\text{rect}(\text{stan}(T)) = \text{evac}(\text{Q}(\text{cgw}(T)))^t$.

**Proof.** We sketch the proof and follow the exposition in [20]. Let $T' = \text{stan}(T)$ and suppose that $T$ has $n$ boxes. Consider the biword $[u \ v]$ where $u := u_1 \ldots u_n$ is the longest word in $S_n$ and $v := v_1 \ldots v_n$ is obtained by recording the column in $T'$ to which $u_i$ belongs. In other words, $v = \text{cgw}(T') = \text{cgw}(T)$. Consider biwords $[u' \ v']$ and $[u'' \ v'']$, where $u'$ (respectively $v''$) in the weakly increasing rearrangement of $u$ (respectively $v$) and $v'$ (respectively $u''$) is the rearrangement induced by the aforementioned sorting. Then we have that $v' = \text{cgw}(T')^r$ and $u'' = \text{crw}(T')$.

Note that $\text{rect}(\text{stan}(T)) = \text{rect}(T') = \text{P}(\text{crw}(T')) = \text{P}(u'')$. By [20, Proposition 5.3.9], this equals $\text{Q}(v')$ and by [34, Corollary A1.2.11] which relates reversal to evacuation, the claim now follows.

For the leftmost tableau $T$ in Figure 6, its standardization rectifies to the tableau in the middle in Figure 15. We have $\text{cgw}(T) = \begin{bmatrix} 321 & 7621 & 5 \end{bmatrix}$, and $\text{Q}(\text{cgw}(T))$ is shown on the right. We invite the reader to verify that $\text{evac}(\text{Q}(\text{cgw}(T)))$ is indeed the tableau in the middle upon transposing.

![Figure 15](image)

**Figure 15.** A demonstration of the claim $\text{rect}(\text{stan}(T)) = \text{evac}(\text{Q}(\text{cgw}(T)))^t$.

**Lemma 5.2.** Let $\alpha$ be a composition. There is a unique Young tableau $T$ of shape $\text{sort}(\alpha)$ and descent composition $\alpha$. Furthermore, this tableau satisfies $\rho^{-1}(T) = \tau_\alpha$.

**Proof.** Observe that the first column of $T$ when read from bottom to top is forced to be $1, 1 + \alpha_1, 1 + \alpha_1 + \alpha_2, \ldots, 1 + \sum_{j=1}^{\ell(\alpha)-1} \alpha_j$. The first claim follows easily from this observation, and our second claim follows from applying the map $\rho$ to the Young tableau $T$ obtained earlier. We leave the details to the interested reader.
We finally arrive at the key proposition that is utilized in the proof of our central result which is Theorem 3.1.

**Proposition 5.3.** If $T \in \text{LRT}^\sigma(\lambda, \mu, \nu)$, then $\text{rect}(\text{stan}(T)) = \rho(\tau_\alpha)$ where $\alpha = \sigma \cdot \nu$.

**Proof.** Throughout, assume that $\sigma \cdot \nu = \alpha$ and set $n := |\alpha|$. By Lemma 5.1 we have

\begin{equation}
\text{rect}(\text{stan}(T)) = \text{evac}(Q(\text{cgw}(T)))^t.
\end{equation}

Since $T \in \text{LRT}^\sigma(\lambda, \mu, \nu)$, Proposition 4.3 implies

\begin{equation}
\text{cgw}(T) \in \text{LRFrank}(\lambda, \mu, \alpha^t).
\end{equation}

Therefore, the shape underlying $Q(\text{cgw}(T))$ is $\text{sort}(\alpha)^t = \nu^t$. Using the preceding fact along with (5.1), we infer that $\text{rect}(\text{stan}(T))$ has shape $\nu$.

Note that the descent set of $\text{cgw}(T)$ is $\{n-i \mid i \in [n-1] \setminus \text{set}(\alpha)\}$, which therefore is also the descent set of $Q(\text{cgw}(T))$. It follows that the descent set of $\text{evac}(Q(\text{cgw}(T)))$ is $[n-1] \setminus \text{set}(\alpha)$, which in turn implies that the descent set of $\text{rect}(\text{stan}(T)) = \text{evac}(Q(\text{cgw}(T)))^t$ is $\text{set}(\alpha)$. Thus we have established that $\text{rect}(\text{stan}(T))$ has shape $\text{sort}(\alpha)$ and descent composition $\alpha$. Lemma 5.2 proves the proposition.

This also completes the proof of our main theorem. A remarkable aspect of Proposition 5.3 is that the symmetric group action on LR tableaux via crystal reflection operators translates to the usual permutation action on the parts of the shape underlying the rectification, after applying the $\rho$ map.

We briefly describe an equivalent interpretation that involves box-adding operators on compositions. By Proposition 4.3, we know that elements of $\text{LRT}^\sigma(\lambda, \mu, \nu)$ may be constructed by computing $\lambda/\mu$-compatible words $w$ satisfying $\text{colform}(w) = (w_0 \sigma w_0) \cdot \nu^t$, where $w_0$ is the longest word in $S_{\ell(\nu)}$. Equivalently, these words are exactly the column growth words of standardizations of tableaux in $\text{LRT}^\sigma(\lambda, \mu, \nu)$. Therefore, they may be identified with certain saturated chains in Young’s lattice from $\mu$ to $\lambda$. By applying the map $\rho_\mu$ where $\text{sort}(\beta) = \mu$, these chains may be interpreted as chains in $\mathcal{L}_c$ from $\beta$ to certain compositions $\gamma$ that satisfy $\text{sort}(\gamma) = \lambda$. Fixing a $\gamma$ and counting these chains allows us to compute $C_{\alpha,\beta}^{\gamma}$ where $\alpha = \sigma \cdot \nu$.

We make the preceding discussion precise by phrasing the result in the language of box-adding operators on compositions introduced in [36] following the seminal work of Fomin [9].

Given $i \geq 1$ and a composition $\alpha$ that has at least one part equaling $i-1$, we define $t_i(\alpha)$ to be the unique composition covering $\alpha$ in $\mathcal{L}_c$ where the new box occurs in the $i$-th column. Given a word $w = w_1 \ldots w_n$, define $t_w := t_{w_1} \cdots t_{w_n}$. We have the following corollary.

**Corollary 5.4.** Let $\alpha$, $\beta$ and $\gamma$ be compositions such that $|\beta| + |\alpha| = |\gamma|$. Let $(\lambda, \mu, \nu)$ be the triple $(\text{sort}(\gamma), \text{sort}(\beta), \text{sort}(\alpha))$. If $\sigma \in S_{\ell(\nu)}$ satisfies $\alpha = \sigma \cdot \nu$, then

\[ C_{\alpha,\beta}^{\gamma} = \{|w \in \text{LRFrank}(\lambda, \mu, (w_0 \sigma w_0) \cdot \nu^t) \mid t_w(\beta) = \gamma\}|. \]

The cases in Corollary 5.4 where $\sigma$ is either the identity permutation or the longest permutation in $S_{\ell(\nu)}$ correspond to left and right LR rules of [7]. We remark here that the two...
LR rules in [7] were proved by different approaches. Thus, not only does our Corollary 5.4 generalize these LR rules, it provides a uniform proof that works in all cases.

Acknowledgements

We are very grateful to Sami Assaf for suggesting that we study our noncommutative LR coefficients from a crystal perspective and for numerous helpful discussions. We are also thankful to Sara Billey and Steph van Willigenburg for various discussions.
