SPATIAL REALIZATION OF A LIE ALGEBRA AND BAR CONSTRUCTION OF A GROUP

YVES FÉLIX AND DANIEL TANRÉ

ABSTRACT. We prove that the spatial realization of a rational complete Lie algebra $L$, concentrated in degree 0, is isomorphic to the simplicial Bar construction on the group, obtained from the Baker-Campbell-Hausdorff product on $L$.

INTRODUCTION

In [1], we construct a cosimplicial differential graded complete Lie algebra (henceforth cdgl) $(\mathfrak{L}_\bullet, d)$, in which $(\mathfrak{L}_1, d)$ is the Lawrence-Sullivan model of the interval introduced in [5]. As in the work of Sullivan ([7]) for differential commutative graded algebras, the existence of this cosimplicial object gives an adjoint pair of functors between the category cdgl of cdgl’s and the category Sset of simplicial sets, see [1] or [3]. In this work, we focus on one of them, the spatial realization functor,

$$\langle - \rangle : \text{cdgl} \to \text{Sset},$$

defined by $\langle L \rangle = \text{Hom}_{\text{cdgl}}(\mathfrak{L}_\bullet, L)$ for $L \in \text{cdgl}$. (Let us also notice that $\langle L \rangle$ is isomorphic to the nerve of $L$, a deformation retract of the Getzler-Hinich realization, see [2], [6].)

More precisely, we are interested in the realization $\langle L \rangle$ of a complete Lie algebra, $L$, concentrated in degree 0 and (thus) with the differential 0. In this case, a group structure can be defined on the set $L$ from the Baker-Campbell-Hausdorff formula. We denote by $\exp L$ this group. The main result of this work is

**Main Theorem.** Let $L$ be a complete differential graded Lie algebra, concentrated in degree 0. Then, its spatial realization $\langle L \rangle$ is isomorphic to the simplicial Bar construction on $\exp L$.

In Section 1, we recall basic background on cdgl and our construction $\mathfrak{L}_\bullet$. Section 2 consists of the proof of the Main theorem.

1. SOME REMINDERS

We first recall the construction of the cosimplicial cdgl $\mathfrak{L}_\bullet$. Let $V$ be a finite dimensional graded vector space. The completion of the free graded Lie algebra on $V$, $\mathbb{L}(V)$,
is the projective limit,
\[ \mathcal{L}(V) = \lim_{\to} \mathbb{L}(V)/\mathbb{L}^{\geq n}(V), \]
where \( \mathbb{L}^{\geq n}(V) \) is the ideal generated by the Lie brackets of length \( \geq n \). We call \( \mathcal{L}(V) \) the free complete graded Lie algebra on \( V \).

As graded Lie algebra, \( \mathfrak{L}_n \) is the free complete graded Lie algebra on the rational vector space generated by the elements \( a_{i_0 \ldots i_k} \) of degree \( |a_{i_0 \ldots i_k}| = k - 1 \), with \( 0 \leq i_0 < \cdots < i_k \leq n \). We denote by \(\operatorname{ad}_{a_{i_0 \ldots i_k}} \) the Lie derivation \([a_{i_0 \ldots i_k}, -]\). The cdgl \( \mathfrak{L}_n \) verifies the following properties.

- \( \mathfrak{L}_0 \) is the free cdgl on a Maurer-Cartan element \( a_0 \), that is:
  \[ \mathfrak{L}_0 = (L(a_0), d), \quad da_0 = -\frac{1}{2}[a_0, a_0]. \]

- \( \mathfrak{L}_1 = (\hat{\mathcal{L}}(a_0, a_1, a_{01}), d) \) is the Lawrence-Sullivan interval (see [5]), where \(a_0 \) and \( a_1 \) are Maurer-Cartan elements and
  \[ da_{01} = [a_{01}, a_1] + \frac{\operatorname{ad}_{a_{01}}}{e^{\operatorname{ad}_{a_{01}}} - 1}(a_1 - a_0). \]

- A model \( \mathfrak{L}_2 \) for the triangle has been described in [1] (see also [4]):
  \[ \mathfrak{L}_2 = (\hat{\mathcal{L}}(a_0, a_1, a_2, a_{01}, a_{02}, a_{12}, a_{0122}), d) \text{ with } d(a_{012}) = a_{01} * a_{12} * a_{02}^{-1} - [a_0, a_{012}]. \]
Here * denotes the Baker-Campbell-Hausdorff product defined for any pair of elements \( a, b \) of degree 0 by \( a * b = \log(\exp^a \exp^b) \).

Moreover these structures appear in each \( \mathfrak{L}_n \): each vertex \( a_r \) is a Maurer-Cartan element, each triple \( (a_r, a_s, a_{rs}) \) is a Lawrence-Sullivan interval and each family \( (a_r, a_s, a_{ts}, a_{rst}, a_{rstl}) \) is a triangle as above.

The family \( (\mathfrak{L}_n)_n \) forms a cosimplicial cdgl which allows the definition of the spatial realization of \( L \in \text{cdgl} \) by,
\[ \langle L \rangle := \text{Hom}_{\text{cdgl}}(\mathfrak{L}_*, L). \]
The cofaces \( \delta^i \) and the codegeneracies \( \sigma^i \) of the cosimplicial cdgl \( \mathfrak{L}_* \) are defined by
\[ \delta^i a_{i_0 \ldots i_p} = a_{j_0 \ldots j_p} \quad \text{with} \quad j_k = \begin{cases} i_k & \text{if } i_k < i, \\ i_k + 1 & \text{if } i_k \geq i, \end{cases} \quad (1.1) \]
\[ \sigma^i a_{i_0 \ldots i_p} = \begin{cases} 0 & \text{if } \{i, i + 1\} \subset \{i_0, \ldots, i_p\}, \\ a_{j_0 \ldots j_p} & \text{otherwise, with} \quad j_k = \begin{cases} i_k & \text{if } i_k \leq i, \\ i_k - 1 & \text{if } i_k > i. \end{cases} \quad (1.2) \]

2. PROOF OF THE MAIN THEOREM

The simplicial bar construction \( B_* G \) on a group \( G \), with rational coefficients, is the simplicial rational vector space with \( B_n G \) the \( \mathbb{Q} \)-vector space generated by the symbols \([g_1, \ldots, g_n], g_i \in G \). Its faces \( d_i \) and degeneracies \( s_i \) are defined as follows:
\[ d_0 [g_1, \ldots, g_n] = [g_2 \ldots g_n], \quad (2.1) \]
\[ d_i [g_1, \ldots, g_n] = [g_1, g_{i+1} \ldots, g_n], \quad \text{for } 0 < i < n, \]
\[ d_n [g_1, \ldots, g_n] = [g_1 \ldots g_{n-1}]. \]
The degeneracy $s_i$ consists to insert the identity $e$ in position $i$.

Let $L \in \mathbf{cdgl}$ be generated in degree 0 and $f : L_n \to L$ a morphism in $\mathbf{cdgl}$. For degree reasons, we have $f(a_{i_0} \ldots i_k) = 0$ if $k \neq 1$. Moreover, since $f$ commutes the differential, from the definition of the differential in $L_2$, we get

$$0 = df(a_{0rs}) = f(a_{0r}) * f(a_{rs}) * f(a_{0s})^{-1}.$$ 

Therefore, for any $r, s > 0$, we have

$$f(a_{rs}) = f(a_{0r})^{-1} * f(a_{0s}).$$

The map $f$ being entirely defined by its values on the $a_{0r}$, we have a bijection

$$\Phi : \text{Hom}_{\mathbf{cdgl}}(L_n, L) \to L^n,$$

defined by $f \mapsto (f(a_{01}), f(a_{02}), \ldots, f(a_{0n}))$.

We now determine the image of the faces and degeneracies on $\text{Hom}_{\mathbf{cdgl}}(L_\bullet, L)$, induced from (1.1) and (1.2). For the face operators, as only the elements $(a_{0r})$ play a role, it suffices to consider,

$$\delta^i(a_{0r}) = \begin{cases} a_{0r} & \text{if } r < i \\ a_{0,r+1} & \text{if } r \geq i \end{cases} \quad \text{for } i > 0, \quad \text{and } \delta^0(a_{0r}) = a_{1,r+1}.$$ 

Let $f : L_n \to L$ described by $(f(a_{01}), \ldots, f(a_{0n}))$. Then $d_0 f = f \circ \delta^0 : L_{n-1} \to L$ is described by

$$d_0(f(a_{01}), \ldots, f(a_{0(n-1)})) = (f \circ \delta^0(a_{01}), \ldots, f \circ \delta^0(a_{0(n-1)})) = (f(a_{12}), \ldots, f(a_{1n})) = (f(a_{01})^{-1} * f(a_{02}), \ldots, f(a_{01})^{-1} * f(a_{0n})).$$

Therefore, the face operator $d_0$ on $L^\bullet$, induced from $\Phi$, is

$$d_0(x_1, \ldots, x_n) = (x_1^{-1} * x_2, \ldots, x_{1}^{-1} * x_n).$$

Similar arguments give, for $i > 0$,

$$d_i(x_1, \ldots, x_n) = (x_1, \ldots, \hat{x}_i, \ldots, x_n).$$

As for the degeneracies, starting from

$$\sigma^i(a_{0r}) = \begin{cases} a_{0r} & \text{if } r \leq i \\ a_{0,r+1} & \text{if } r > i \end{cases} \quad \text{for } i > 0,$$

$$\sigma^0(a_{0r}) = a_{0,r+1} \quad \text{if } r > 1, \quad \text{and } \sigma^0(a_{01}) = 0,$$

we get

$$s_0(a_1, \ldots, a_n) = (0, a_1, \ldots, a_n)$$

and for $i > 0$,

$$s_i(a_1, \ldots, a_n) = (a_1, \ldots, a_i, \ldots, a_n).$$

Now a straightforward and easy computation shows that the morphism

$$\Psi : \text{Hom}_{\mathbf{cdgl}}(L_\bullet, L) \to B_\bullet(L)$$

defined by

$$\Psi(a_1, \ldots, a_n) = (a_1, a_1^{-1} a_2, a_2^{-1} a_3, \ldots, a_{n-1}^{-1} a_n)$$

is an isomorphism of simplicial sets.
