Abstract. We present a Kleene realizability semantics for the intensional level of the Minimalist Foundation, for short mTT, extended with inductively generated formal topologies, Church’s thesis and axiom of choice.

This semantics is an extension of the one used to show consistency of the intensional level of the Minimalist Foundation with the axiom of choice and formal Church’s thesis in previous work.

A main novelty here is that such a semantics is formalized in a constructive theory represented by Aczel’s constructive set theory CZF extended with the regular extension axiom.

1. Introduction

A main motivation for introducing the Minimalist Foundation, for short MF, in [MS05, Mai09] was the desire to provide a foundation where to formalize constructive point-free topology in a way compatible with most relevant constructive foundations. In particular, MF was designed with the purpose of formalizing the topological results developed by adopting the approach of Formal Topology by P. Martin-Löf and G. Sambin introduced in [Sam87]. This approach was further enriched with the introduction of Positive Topology by Sambin in [Sam03]. A remarkable novelty of this approach to constructive topology was the advent of inductive topological methods (see [CSSV03, CMS13]) to represent the point-free topologies of the real number line, of Baire space and of Cantor space.

However, while the basic notions of Formal Topology can be formalized in the Minimalist Foundation in [Mai09], the construction of inductively generated topologies cannot.

Key words and phrases: Realizability, Axiom of Choice, Church’s thesis, Point-free topology.
Projects EU-MSCA-RISE project 731143 “Computing with Infinite Data” (CID), MIUR-PRIN 2010-2011 and Correctness by Construction (EU 7th framework programme, grant no. PIRSES-GA-2013-612638) provided support for the research presented in the paper.
This is indeed done on purpose since the Minimalist Foundation, for short MF, was introduced to be a minimalist foundation compatible with (or interpretable in) the most relevant constructive and classical foundations for mathematics in the literature (see [Mai09]). Observe indeed that the intensional level of MF is quite weak in proof-theoretic strength being interpretable in the fragment of Martin-Löf’s type theory with one universe, or directly in Feferman’s theory of non-iterative fixpoints \( \text{id}_1 \) as first shown in [MM16].

Moreover, MF is presented in [Mai09] as a two level system in accordance with the notion of constructive foundation in [MS05]. Indeed MF consists of an intensional level based on an intensional type theory à la Martin-Löf, aimed at exhibiting the computational contents of mathematical proofs, and an extensional level formulated in a language as close as possible to that of present day mathematics which is interpreted in the intensional level by means of a quotient model (see [Mai09]).

Here we present an extension \( \text{MF}_{\text{ind}} \) of MF with the inductive definitions sufficient to define inductively generated formal topologies and necessary to define inductive suplattices. This is due to the fact that in [CSSV03] the problem of generating formal topologies inductively is reduced to that of generating inductive suplattices. The rules added to the intensional level \( \text{mTT} \) of MF to form the intensional level of \( \text{MF}_{\text{ind}} \), called \( \text{mTT}_{\text{ind}} \), are driven by those of well-founded sets in Martin-Löf’s type theory in [NPS90] without assuming generic well-founded sets as in the representations given in [CSSV03, Val07].

The main purpose of our paper is then to show that the intensional level \( \text{mTT}_{\text{ind}} \) of \( \text{MF}_{\text{ind}} \) is consistent with the axiom of choice (AC) and the formal Church’s thesis (CT). More in detail AC states that from any total relation we can extract a type-theoretic function as follows:

\[
(\text{AC}) \quad (\forall x \in A) (\exists y \in B) R(x, y) \rightarrow (\exists f \in (\Pi x \in A) B) (\forall x \in A) R(x, \text{Ap}(f, x))
\]

with \( A \) and \( B \) generic collections and \( R(x, y) \) any relation, while CT (see also [Tv88]) states that from any total relation on natural numbers we can extract a (code of a) recursive function by using the Kleene predicate \( T \) and the extracting function \( U \)

\[
(\text{CT}) \quad (\forall x \in \mathbb{N}) (\exists y \in \mathbb{N}) R(x, y) \rightarrow (\exists e \in \mathbb{N}) (\forall x \in \mathbb{N}) (\exists z \in \mathbb{N}) (T(e, x, z) \land R(x, U(z))).
\]

Such a consistency property is essential to fulfill the requirement of the intensional level of a constructive foundation proposed in [MS05].

In order to meet our purpose, we produce a realizability semantics for \( \text{mTT}_{\text{ind}} \) by extending the one used to show the consistency of the intensional level of MF with AC+CT in [IMMS18], which in turn extends Kleene realizability interpretation of intuitionistic arithmetic.

A main novelty of our semantics is that it is formalized in a constructive theory as the (generalized) predicative set theory CZF+REA, namely Aczel’s constructive Zermelo-Fraenkel set theory extended with the regular extension axiom REA.

To this purpose it is crucial to modify the realizability interpretation in [IMMS18] in the line of the realizability interpretations of Martin-Löf type theories in extensions of Kripke-Platek set theory introduced in [Rat93] (published as [GR94]).

Therefore, contrary to the semantics in [IMMS18], which was formalized in a classical theory as Feferman’s theory of non-iterative fixpoints \( \text{id}_1 \), here we produce a proof that \( \text{mTT}_{\text{ind}} \), and hence \( \text{mTT} \), is constructively consistent with AC+CT.
As in [IMMS18], we actually build a realizability model for a fragment of Martin-Löf’s type theory [NPS90], called $\text{ML}_{\text{ind}}$, where $\text{MTT}_{\text{ind}}$ extended with the axiom of choice can be easily interpreted.

As it turns out, $\text{CZF} + \text{REA}$ and $\text{ML}_{\text{ind}}$ possess the same proof-theoretic strength.

In the future we intend to further extend our realizability to model $\text{MTT}_{\text{ind}}$ enriched with coinductive definitions to represent Sambin’s generated Positive Topologies. Another possible line of investigation would be to employ our realizability semantics to establish the consistency strength of $\text{MTT}_{\text{ind}}$ or the extension of $\text{MTT}$ with particular inductively generated topologies, like that of the real line.

2. **The extension $\text{MF}_{\text{ind}}$ with inductively generated formal topologies**

Here we describe the extension $\text{MF}_{\text{ind}}$ of $\text{MF}$ capable of formalizing most relevant examples of formal topologies defined by inductive methods introduced in [CSSV03].

In that paper, the problem of generating the minimal formal topology which satisfies some given axioms is reduced to show how to generate a complete suplattice in terms of an infinitary relation called **basic cover relation**

$$a \prec V$$

between elements $a$ of a set $A$, thought of as basic opens, and subsets $V$ of $A$, meaning that **the basic open $a$ is covered by the union of basic opens in the subset $V$**.

Then the elements of the generated suplattice would be fixpoints of the associated **closure operator**

$$\prec(-) : \mathcal{P}(A) \rightarrow \mathcal{P}(A)$$

defined by putting

$$\prec(V) \equiv \{ x \in A \mid x \prec V \}$$

which are **complete** with respect to families of subsets indexed over a set.

Furthermore, a formal topology is defined as a basic cover relation satisfying a convergence property and a positivity predicate (see [CSSV03, MV04, CMS13]). Indeed in this case the resulting complete suplattice of $\prec$-fixpoints actually forms a predicative locale which is overt (or open in the original terminology by Joyal and Tierney) for the presence of the positivity predicate.

The tool of basic covers appears to be the only one available in the literature to represent complete suplattices in most-relevant predicative constructive foundations including Aczel’s **CZF**, Martin-Löf’s type theory and also **MF**.

The reason is that **there exist no non-trivial examples of complete suplattices that form a set** in such predicative foundations (see [Cur10]). As a consequence, there exist no non-trivial examples of locales which form a set and the approach of formal topology based on a cover relation seems to be compulsory (see also [MS13a]) when developing topology in a constructive predicative foundation, especially in **MF**.

In [CSSV03] it was introduced a method for generating basic covers inductively starting from an indexed set of axioms, called **axiom set**. Such a method allows to generate a formal topology inductively when the basic cover relation $\prec$ is defined on a preordered set $(A, \leq)$ and it is generated by an axiom set satisfying a so called **localization condition** which refers to the preorder defined on $A$. An algebraic study of the relation between basic covers and formal covers including their inductive generation is given in [CMS13].
In the following we describe a suitable extension of MF capable of representing inductively generated basic covers, and hence also formal topologies.

We start by describing how to enrich the extensional level \( \text{emTT} \) of \( \text{MF} \) in [Mai09] with such inductive basic covers. The reason is that the language of \( \text{emTT} \) is more apt to represent the topological axioms given that it is very close to that of everyday mathematical practice (with proof-irrelevance of propositions and an encoding of the usual language of first order arithmetic and of subsets of a set, see [Mai09]).

We recall that in \( \text{emTT} \) we have four kinds of types, namely \textbf{collections}, \textbf{sets}, \textbf{propositions} and \textbf{small propositions} according to the following subtyping relations:

\[
\begin{array}{c}
\text{small propositions} \rightarrow \text{sets} \\
\text{propositions} \rightarrow \text{collections}
\end{array}
\]

where collections include the power-collection \( \mathcal{P}(A) \) (which is not a set!) of any set \( A \) and small propositions are defined as those propositions closed under intuitionistic connectives and quantifiers restricted to sets.

We first extend \( \text{emTT} \) with new primitive \textbf{small propositions}

\[
a \triangleleft_{I,C,V} \text{prop}
\]

expressing that \textit{the basic open } \( a \text{ is covered by the union of basic opens in } V \) for any \( a \text{ element of a set } A \text{ and subset of } A \), assuming that the basic cover is generated by a family of (open) subsets of \( A \) indexed on a family of sets \( I(x) \text{ set } |x \in A| \) and representing by

\[
C(x,j) \in \mathcal{P}(A) \ |x \in A, j \in I(x)|.
\]

The precise rules extending \( \text{emTT} \) to form a new type system \( \text{emTT}_{\text{ind}} \) are the following:

\begin{align*}
\text{Rules of inductively generated basic covers in } \text{emTT}_{\text{ind}} \\
\text{F-\triangleleft} & : \quad \begin{array}{c}
A \text{ set } I(x) \text{ set } |x \in A| \\
V \in \mathcal{P}(A) \\
a \in A
\end{array} \quad C(x,j) \in \mathcal{P}(A) \ |x \in A, j \in I(x)| \quad a \triangleleft_{I,C,V} \text{prop} \\
\text{rf-\triangleleft} & : \quad \begin{array}{c}
A \text{ set } I(x) \text{ set } |x \in A| \\
V \in \mathcal{P}(A) \\
a \in V \text{ true}
\end{array} \quad a \triangleleft_{I,C,V} \text{true} \\
\text{tr-\triangleleft} & : \quad \begin{array}{c}
A \text{ set } I(x) \text{ set } |x \in A| \\
a \in A \\
i \in I(a) \\
V \in \mathcal{P}(A)
\end{array} \quad C(x,j) \in \mathcal{P}(A) \ |x \in A, j \in I(x)| \quad \forall y \in C(a,i) \quad y \triangleleft_{I,C,V} \text{true} \\
\text{ind-\triangleleft} & : \quad \begin{array}{c}
A \text{ set } I(x) \text{ set } |x \in A| \\
P(x) \text{ prop } |x \in A| \\
V \in \mathcal{P}(A) \\
\text{cont}(V,P) \text{ true}
\end{array} \quad C(x,j) \in \mathcal{P}(A) \ |x \in A, j \in I(x)| \quad a \in A \quad a \triangleleft_{I,C,V} \text{true} \\
\text{P(\text{true})} & : \quad P(a) \text{ true}
\end{align*}
where
\[
\text{cont}(V, P) \equiv \forall x \in A \ ( x \in V \rightarrow P(x) ) \land \forall x \in A \ ( \forall j \in I(x) \ \forall y \in A \ ( y \in C(x, j) \rightarrow P(y) ) \rightarrow P(x) )
\]

where above we adopted the convention of writing \( \phi \ true \) for a proposition \( \phi \) instead of \( \text{true} \in \phi \) as in [Mai09].

A main example of formal topology that can be formalized in \texttt{emTT}_\text{ind} with the rules above is that of \textit{real line}, represented by Joyal’s inductive formal cover \( \leq_r \) of Dedekind real numbers defined on the set \( \mathbb{Q} \times \mathbb{Q} \) which acts as \( A \) in the rules above and where \( \mathbb{Q} \) is the set of \textit{rational numbers}. This formal cover is generated by a family of open subsets \( C((p, q), j) \) indexed on \( j \in I((p, q)) \) for \( (p, q) \in \mathbb{Q} \times \mathbb{Q} \) which is defined as an encoding of the following rules:

\[
\begin{align*}
q \leq p & \quad (p, q) \leq_r U \\
(p, q) < r & \quad (p, q) < r U \\
p \leq r < s \leq q & \quad (p, s) <_r U \quad (r, q) <_r U \\
(p, q) <_r U & \quad \text{wc}((p, q)) <_r U
\end{align*}
\]

where in the last axiom we have used the abbreviation

\[
\text{wc}((p, q)) \equiv \{ (p', q') \in \mathbb{Q} \times \mathbb{Q} \mid p < p' < q' < q \}
\]

(\text{wc} stands for ‘well-covered’). For relevant applications see for instance [Pal05, MS13b] and loc.cit.

It is worth noting that different presentations of basic covers may yield to the same complete suplattice. For example, any complete suplattice presented by \( B \) itself which behaves like \( \leq_{I,C} \) but in addition it considers equal opens those elements which are related by \( R \).

In order to properly show this fact, which it will be useful in the next, we define a correspondence between subsets of \( B/R \) and subsets of \( B \) as follows:

**Definition 2.1.** In \texttt{emTT}_\text{ind}, given a quotient set \( B/R \), for any subset \( W \in \mathcal{P}(B/R) \) we define

\[
\text{es}(W) \equiv \{ b \in B \mid [b] \in W \}
\]

and given any \( V \in \mathcal{P}(B) \) we define \( \text{es}^{-}(V) \equiv \{ z \in B/R \mid \exists b \in B \ ( b \in V \land z \equiv_{B/R} [b] ) \} \).

**Definition 2.2.** Given an axiom set represented by a set \( A \equiv B/R \) with \( I(x) \) set \( [x \in A] \) and \( C(x, j) \in \mathcal{P}(A) \) \( [x \in A, j \in I(x)] \), we define a new axiom set as follows:

\[
A^R \equiv B \quad I^R(x) \equiv I([x]) + (\Sigma y \in B) \ R(x, y)
\]

for \( x \in B \)

where \( C^R(b, j) \) is the formalization of

\[
\begin{align*}
C^R(b, j) & \equiv \begin{cases} 
\text{es}^{-}(C([b], j)) & \text{if } j \in I([b]) \\
\{ \pi_1(j) \} & \text{if } j \in (\Sigma y \in B) \ R(b, y)
\end{cases}
\end{align*}
\]

for \( b \in B \) and \( j \in I^R(x) \).

We then call \( \leq^R_{I,C} \) the inductive basic cover generated from this axiom set.

It is then easy to check that
Lemma 2.3. For any axiom set in $\mathbf{emTT}_{ind}$ represented by a set $A \equiv B/R$ with $I(x)$ set $[x \in A]$ and $C(x,j) \in \mathcal{P}(A) \ [x \in A, j \in I(x)]$, the suplattice defined by $<_{I,C}$ is isomorphic to that defined by $<_{R_I,C}$ by means of an isomorphism of suplattices.

Proof. It is immediate to check that for any subset $W$ of $B/R$ which is a fixpoint for $<_{I,C}$ the subset $\text{es}(W)$ is a fixpoint for $<_{R_I,C}$ and that, conversely, for any subset $V$ of $B$ which is a fixpoint for $<_{I,C}$ the subset $\text{es}^{-}(V)$ is a fixpoint for $<_{I,C}$. Moreover, this correspondence preserves also the suprema defined as in [CMS13]. Alternatively, one could check that the relation $z F b \equiv \text{Id}(B/R, z, [b])$ defines a basic cover isomorphism in the sense of [CMS13] between the basic cover $<_{R_I,C}$ and $<_{I,C}$.

3. The intensional level $\mathbf{mTT}_{ind}$

Here we describe the extension $\mathbf{mTT}_{ind}$ of the intensional level $\mathbf{mTT}$ of MF capable of interpreting the extension $\mathbf{emTT}_{ind}$.

We recall that in $\mathbf{mTT}$ as well as in $\mathbf{emTT}$ we have the same four kinds of types with the difference that in $\mathbf{mTT}$ power-collections of sets are replaced by the existence of a collection of small propositions $\text{prop}_s$ and function collections $A \rightarrow \text{prop}_s$ for any set $A$. Such collections are enough to interpret power-collections of sets in $\mathbf{emTT}$ within a quotient model of dependent extensional types built over $\mathbf{mTT}$, as explained in [Mai09].

Therefore, in order to define $\mathbf{mTT}_{ind}$ we cannot simply add the rules of inductively generated basic covers of $\mathbf{emTT}_{ind}$ but we need to add an intensional version of them. To this purpose in $\mathbf{mTT}_{ind}$ in addition to the new small proposition

$$a <_{I,C} V \text{prop}_s$$

we need to add new proof-term constructors associated to it in such a way that judgements asserting that some proposition is true in $\mathbf{emTT}_{ind}$ are turned into judgements of $\mathbf{mTT}_{ind}$ producing a proof-term of the corresponding proposition.

It is worth noting that the equality rules of the inductive basic covers are driven by those of well-founded sets in Martin-Löf’s type theory in [NPS90] without assuming generic well-founded sets as in the representations given in [CSSV03, Val07]. However, in accordance with the idea that proof-terms of propositions of $\mathbf{mTT}$ represent just a constructive rendering of the proofs of propositions in $\mathbf{emTT}$, we do restrict the elimination rules of inductive basic covers to act toward propositions non depending on their proof-terms, since these proof-terms do not appear at the extension level of $\mathbf{emTT}$.

When expressing the rules of inductive basic covers we use the abbreviation

$$a \epsilon V \quad \text{to mean} \quad Ap(V, a)$$

for any set $A$, any small propositional function $V \in A \rightarrow \text{prop}_s$ and any element $a \in A$.

The precise rules of inductive basic covers extending $\mathbf{mTT}$ to form a new type system $\mathbf{mTT}_{ind}$ are the following:
Rules of inductively generated basic covers in $\mathbf{mTT}_{\text{ind}}$

\[ \begin{array}{ll}
F_\text{ind} & A \text{ set } I(x) \set x \in A \quad C(x, j) \in A \rightarrow \text{prop}_s \ [x \in A, j \in I(x)] \\
& V \in A \rightarrow \text{prop}_s \quad a \in A \hfill a \triangleleft_{I, C} V \ \text{prop}_s \\
\hline
& A \text{ set } I(x) \set x \in A \quad C(x, j) \in A \rightarrow \text{prop}_s \ [x \in A, j \in I(x)] \\
& V \in A \rightarrow \text{prop}_s \quad a \in A \quad q \in a \epsilon V \hfill rf(a, q) \in a \triangleleft_{I, C} V \\
\hline
\text{tr}_\text{ind} & A \text{ set } I(x) \set x \in A \quad C(x, j) \in A \rightarrow \text{prop}_s \ [x \in A, j \in I(x)] \\
& P(x) \ \text{prop} \ [x \in A] \quad V \in A \rightarrow \text{prop}_s \\
& a \in A \quad m \in a \triangleleft_{I, C} V \hfill q_1(x, z) \in P(x) \ [x \in A, z \in x \epsilon V] \\
& q_2(y, j, f) \in P(y) \ [y \in A, j \in I(y), f \in \forall z \in A \ (z \epsilon C(y, j) \rightarrow P(z))] \\
\text{ind}_\text{ind} & \hfill \text{ind}(m, q_1, q_2) \in P(a) \\
\hline
& A \text{ set } I(x) \set x \in A \quad C(x, j) \in A \rightarrow \text{prop}_s \ [x \in A, j \in I(x)] \\
& P(x) \ \text{prop} \ [x \in A] \quad V \in A \rightarrow \text{prop}_s \\
& a \in A \quad q \in a \epsilon V \hfill q_1(x, z) \in P(x) \ [x \in A, z \in x \epsilon V] \\
& \text{C}_1\text{-ind} \hfill q_2(y, j, f) \in P(y) \ [y \in A, j \in I(y), f \in \forall z \in A \ (z \epsilon C(y, j) \rightarrow P(z))] \\
\hline
& \text{C}_2\text{-ind} \hfill \text{ind}(\text{tr}(a, i, q), q_1, q_2) = q_2(a, i, \lambda z. \lambda u. \text{ind}(\text{Ap}(\text{Ap}(q, z), u), q_1, q_2)) \in P(a) \\
\end{array} \]

Note that the cover relation preserves extensional equality of subsets represented as small propositional functions thanks to the induction principle:

**Lemma 3.1.** For any axiom set in $\mathbf{mTT}_{\text{ind}}$ represented by a set $A$ with $I(x) \set x \in A$ and $C(x, j) \in A \rightarrow \text{prop}_s \ [x \in A, j \in I(x)]$, for any propositional functions $V_1 \in A \rightarrow \text{prop}_s$
and $V_2 \in A \rightarrow \text{prop}$, there exists a proof-term

$$q \in V_1 =_{\text{ext}} V_2 \rightarrow a \triangleleft_{I,C} V_1 =_{\text{ext}} a \triangleleft_{I,C} V_2$$

where for any small propositional functions $W_1$ and $W_2$ on a set $A$ we abbreviate

$$W_1 =_{\text{ext}} W_2 \equiv \forall x \in A (W_1(x) \leftrightarrow W_2(x))$$

Recalling that the interpretation of $\text{emTT}$ in $\text{mTT}$ in [Mai09] interprets a set $A$ as an extensional quotient defined in $\text{mTT}$ as a set $A^J$ of $\text{mTT}$ equipped with an equivalence relation $=_{A^J}$ over $A^J$, as well as families of sets are interpreted as families of extensional sets preserving the equivalence relations in their telescopic contexts, it is crucial to use lemma 2.3 to interpret basic covers of $\text{emTT}_{\text{ind}}$ on a base $A$ as basic covers $\vdash_{I,J,C,J}^=_{A^J}$ of $\text{mTT}_{\text{ind}}$ defined on the support $A^J$:

**Proposition 3.1.** The interpretation of $\text{emTT}$ in $\text{mTT}$ in [Mai09] extends to an interpretation of $\text{emTT}_{\text{ind}}$ in $\text{mTT}_{\text{ind}}$ by interpreting $a \triangleleft_{I,C} V$ for $a \in A$ and $V \in \mathcal{P}(A)$ in the corresponding basic cover in $\text{mTT}_{\text{ind}}$ induced over the support of $A^J$ which is an extensional proposition in the sense of [Mai09].

4. The fragment $\text{MLtt}_{\text{ind}}$ of intensional Martin-Löf’s type theory with inductive basic covers

We here briefly describe the theory $\text{MLtt}_{\text{ind}}$ obtained by adding the rules of inductive basic covers to the first order fragment of intensional Martin-Löf’s type theory in [NPS90] with one universe.

This is essentially a fragment of intensional Martin-Löf’s type theory which interprets $\text{mTT}_{\text{ind}}$ as soon as propositions are identified as sets following the Curry-Howard correspondence in [NPS90] but with the warning that we strengthen the elimination rule of inductive basic covers to act towards sets depending on their proof-terms according to inductive generation of types in Martin-Löf’s type theory.

Actually the interpretation of $\text{mTT}_{\text{ind}}$ into $\text{MLtt}_{\text{ind}}$ validates also the axiom of choice $\text{AC}$ as formulated in the introduction.

Therefore in order to show the consistency of $\text{mTT}_{\text{ind}}$ with $\text{AC} + \text{CT}$ (with $\text{CT}$ formulated as in the introduction) is enough to show the consistency of $\text{MLtt}_{\text{ind}}$ extended with (the translation of) $\text{CT}$.

Here we adopt the notation of types and terms within the first order fragment $\text{MLtt}_1$ of intensional Martin-Löf’s type theory with one universe $U_0$ à la Tarski in [IMMS18] and we just describe the rule of inductive basic covers added to it.

To this purpose we add to $\text{MLtt}_1$ the code

$$a \hat{\triangleleft}_{s,i,c} v \in U_0 \quad \text{for } a \in T(s) \text{ and } v \in T(s) \rightarrow U_0$$

meaning that the element $a$ of a small set $T(s)$ represented by the code $s \in U_0$ is covered by the subset $v$ represented by a small propositional function from $T(s)$ to the (large) set of small propositions identified with $U_0$ by the propositions-as-sets correspondence.

Moreover, we use the abbreviations

$$a \triangleleft_{s,i,c} v \equiv T(a \hat{\triangleleft}_{s,i,c} v) \quad x \in y \equiv T( Ap(y,x))$$

and the notation

$$\text{axcov}(s,i,c)$$
to abbreviate the following judgements

\[ s \in U_0 \quad i(x) \in U_0 \quad [x \in T(s)] \quad c(x,y) \in U_0 \quad [x \in T(s), y \in T(i(x))] \]

Then, the precise rules of inductive basic covers extending $\text{MLtt}_1$ to form a new type system $\text{MLtt}_{ind}$ are the following:

**Rules of inductively generated basic covers in $\text{MLtt}_{ind}$**

\[
\begin{array}{ll}
F_{\text{-}q} & \quad s \in U_0 \quad i(x) \in U_0 \quad [x \in T(s)] \quad c(x,y) \in T(s) \quad [x \in T(s), y \in T(i(x))] \\
& \quad a \in T(s) \quad v \in T(s) \quad \rightarrow U_0 \quad \rightarrow U_0 \\
& \quad \quad a \lhd_{s,i,c} v \in U_0 \\
\hline
rf_{\text{-}q} & \quad s \in U_0 \quad i(x) \in U_0 \quad [x \in T(s)] \quad c(x,y) \in T(s) \quad [x \in T(s), y \in T(i(x))] \\
& \quad a \in T(s) \quad v \in T(s) \quad \rightarrow U_0 \quad r \in a e v \\
& \quad \quad rf(a,r) \in a \lhd_{s,i,c} v \\
\hline
tr_{\text{-}q} & \quad s \in U_0 \quad i(x) \in U_0 \quad [x \in T(s)] \quad c(x,y) \in T(s) \quad [x \in T(s), y \in T(i(x))] \\
& \quad a \in T(s) \quad j \in T(i(a)) \quad v \in T(s) \quad \rightarrow U_0 \\
& \quad r \in (\Pi x \in T(s))(x c(a,j) \rightarrow x \lhd_{s,i,c} v) \\
& \quad \quad \quad \quad tr(a,j,r) \in a \lhd_{s,i,c} v \\
\hline
\end{array}
\]

\[\text{axcov}(s,i,c)\]
\[v \in T(s) \rightarrow U_0 \quad P(x,u) \quad \text{type} \quad [x \in T(s), u \in x \lhd_{s,i,c} v]\]
\[a \in T(s) \quad m \in a \lhd_{s,i,c} v\]
\[q_1(x,z) \in P(x,rf(x,z)) \quad [x \in T(s), z \in x e v]\]
\[q_2(x,j,f,k) \in P(x, tr(x,j,k))\]
\[\quad [x \in T(s), j \in T(i(x)), f \in (\Pi z \in T(s))(z c(x,j) \rightarrow P(z)), k \in (\Pi x \in T(s))(x c(a,j) \rightarrow x \lhd_{s,i,c} v)]\]
\[\text{ind}_{\text{-}q}\]
\[\text{ind}(m,q_1,q_2) \in P(a,m)\]

\[\text{C}_1\text{-ind}_{\text{-}q}\]
\[v \in T(s) \rightarrow U_0 \quad P(x,u) \quad \text{type} \quad [x \in T(s), u \in x \lhd_{s,i,c} v]\]
\[a \in T(s) \quad r \in a e v\]
\[q_1(x,z) \in P(x,rf(x,z)) \quad [x \in T(s), z \in x e v]\]
\[q_2(x,j,f,k) \in P(x, tr(x,j,k))\]
\[\quad [x \in T(s), j \in T(i(x)), f \in (\Pi z \in T(s))(z c(x,j) \rightarrow P(z)), k \in (\Pi x \in T(s))(x c(a,j) \rightarrow x \lhd_{s,i,c} v)]\]
\[\text{ind}(rf(a,r),q_1,q_2) = q_1(a,r) \in P(a,rf(a,r))\]
A crucial difference from the ordinary versions of Martin-Löf’s type theory is that for 
\( \text{ML}_{\text{ind}} \) we postulate just the replacement rule repl)
\[
c(x_1, \ldots, x_n) \in C(x_1, \ldots, x_n) \ [x_1 \in A_1, \ldots, x_n \in A_n(x_1, \ldots, x_{n-1})] \\
repl) 
\[
a_1 = b_1 \in A_1 \ldots a_n = b_n \in A_n(a_1, \ldots, a_{n-1}) \\
\frac{c(a_1, \ldots, a_n) = c(b_1, \ldots, b_n) \in C(a_1, \ldots, a_n)}{c = c' \in C \ [x \in B]} \\
\xi \lambda x^B.c = \lambda x^B.c' \in (\Pi x \in B)C
\]
which is instead valid in \( \text{NPS}90 \).

It is indeed an open problem whether the original intensional version of Martin-Löf’s

The motivaition for this restriction in \( \text{mTT}_{\text{ind}} \) and in \( \text{MLTT}_{\text{ind}} \) is due to the fact that the

Since its term equality rules suffice to interpret an extensional level including extensionality
functions, as that represented by \( \text{emTT} \), by means of the quotient model as introduced
in \( \text{Mai}09 \) and studied abstractly in \( \text{MR12} \) \( \text{MR13} \) \( \text{MR15} \).

Furthermore our realizability semantics interprets terms as applicative terms in the first
Kleene algebra and their equality as numerical equality turning into an extensional equality
in the context-dependent case. Hence we need a suitable encoding of lambda-terms which
validates the replacement rule under the interpretation. As observed in \( \text{IMMS18} \) not each
translation of pure lambda calculus in the first Kleene algebras satisfies this requirement
(see pp.881-882 in \( \text{IMMS18} \)).

**Theorem 4.1.** The interpretation of \( \text{mTT} \) into \( \text{MLtt}_1 \) given in \( \text{Mai}09 \) extends to that
of \( \text{mTT}_{\text{ind}} \) in \( \text{MLTT}_{\text{ind}} \) by interpreting each basic cover \( \llbracket I,C \rrbracket \) of \( \text{mTT}_{\text{ind}} \) associated to an
axiom set \( I(\cdot) \) and \( C(\cdot, \cdot) \) in the corresponding basic cover of \( \text{MLTT}_{\text{ind}} \) associated to the
interpreted axiom set.

**Proof.** Note that small propositions are encoded in the universe \( U_0 \) as well as axiom sets
generating a basic cover inductively in \( \text{mTT}_{\text{ind}} \).

---

1Notice that a trivial instance of the \( \xi \)-rule is derivable from repl) when \( c \) and \( c' \) don’t depend on \( x^B \).
Remark 4.2. It is worth recalling that for any axiom set represented by a set $A$ with $I(x)$ set $\{x \in A\}$ and $C(x, j) \in A \rightarrow U_0$ $\{x \in A, j \in I(x)\}$ and any propositional function $V \in A \rightarrow U_0$ representing a subset of $A$, the propositional function representing the subset

$$\prec_{I, C}(V) \equiv \{x \in A \mid x \prec_{I, C} V\}$$

is definable in the extension with well-founded sets as shown in [Val07]. A direct representation of $\prec_{I, C}(V) \in A \rightarrow U_0$ is obtained as the well founded set $(\forall x \in D) B(x)$ where

$$D \equiv (\Sigma x \in A) (a \in V + I(x))$$

and $B(x) [x \in D]$ is the inductive type defined by recursion on $D$ toward the first universe $U_0$ satisfying the following conditions:

$$B(x) \equiv \begin{cases} N_0 & \text{if } x = \langle a, \text{inl}(z) \rangle \text{ for } z \in a \in V \\ C( a, j ) & \text{if } x = \langle a, \text{inr}(j) \rangle \text{ for } j \in I(a) \end{cases}$$

where we recall that inl and inr are the injections in the sum and $\pi_1$ and $\pi_2$ are the projections of the indexed sum. Then the terms of the introduction and elimination rules for basic covers can be represented by means of those of well founded sets. For example we can put

$$\text{rf}(a, r) \equiv \sup( \langle a, \text{inl}(q) \rangle, \lambda x. r_0(x) )$$

$$\text{tr}(a, i, q) \equiv \sup( \langle a, \text{inr}(j) \rangle, \lambda y. q(a, j, y) )$$

where $r_0(x)$ is the eliminator of the empty set $N_0$.

5. A Realizability Interpretation of $MLtt_{ind}$ with Formal Church’s Thesis

Here we are going to describe a realizability model of $MLtt_{ind}$ with CT extending that of $MLtt_1$ in [IMMS18].

A main novelty here is that we formalize such a model in the (generalized) predicative and constructive theory $CZF + \text{REA}$ where $CZF$ stands for Constructive Zermelo-Fraenkel Set Theory and $\text{REA}$ stands for the regular extension axiom (for details see [AR01] [AR10]).

Since the interpretation in [IMMS18] is performed in $\hat{\it{ID}}_1$ which is a classical theory of fixed points, we cannot follow the proof technique in [IMMS18] to fulfill our purpose. Moreover $\hat{\it{ID}}_1$ is a too weak theory to accommodate inductively defined topologies as it can be gleaned from [CR12]. The solution is to adopt the proof-technique in [Rat93] [GR94] to fulfill our goal.

As usual in set theory we identify the natural numbers with the finite ordinals, i.e. $\mathbb{N} := \omega$. To simplify the treatment we will assume that $CZF$ has names for all (meta) natural numbers. Let $\bar{n}$ be the constant designating the $n^{th}$ natural number. We also assume that $CZF$ has function symbols for addition and multiplication on $\mathbb{N}$ as well as for a primitive recursive bijective pairing function $p : \mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N}$ and its primitive recursive inverses $p_0$ and $p_1$, that satisfy $p_0(p(n, m)) = n$ and $p_1(p(n, m)) = m$. We also assume that $CZF$ is endowed with symbols for a primitive recursive length function $\ell : \mathbb{N} \rightarrow \mathbb{N}$ and a primitive recursive component function $(\cdot)_- : \mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N}$ determining a bijective encoding of finite lists of natural numbers by means of natural numbers. $CZF$ should also have a symbol $T$ for Kleene’s $T$-predicate and the result extracting function $U$. Let $P(\{e\}(n))$ be a shorthand for $\exists m(T(e, n, m) \land P(U(m)))$. Further, let $p(n, m, k) := p(p(n, m), k)$, $p(n, m, k, h) := p(p(n, m, k), h)$, etc. . . . We use $a, b, c, d, e, d, f, n, m, l, k, s, t, j, i$ as metavariables for natural numbers.
We first need to introduce some abbreviations:

(1) $n_0$ is $p(0,0)$, $n_1$ is $p(0,1)$ and $n$ is $p(0,2)$.
(2) $\sigma(a,b)$ is $p(1,p(a,b))$, $\pi(a,b)$ is $p(2,p(a,b))$ and $+(a,b)$ is $p(3,p(a,b))$
(3) list$(a)$ is $p(4,a)$ and $\text{id}(a,b,c)$ is $p(5,p(a,b,c))$
(4) $\tilde{\alpha}_{c,d,e}b$ is $p(6,p(a,b,c,d,e))$
(5) $\rho(a,r)$ is $p(7,p(a,r))$
(6) $\tau(a,j,r)$ is $p(8,p(a,j,r))$

Recall that, in intuitionistic set theories, ordinals are defined as transitive sets all of whose members are transitive sets, too. Unlike in the classical case, one cannot prove that they are linearly ordered but they are perfectly good as a scale along which one can iterate various processes. The trichotomy of 0, successor, and limit ordinal, of course, has to be jettisoned.

**Definition 5.1.** Let transfinite recursion on ordinals (cf. [AR10], Proposition 9.3.3) we define simultaneously two relations $\text{Set}_\alpha(n)$ and $n \varepsilon_\alpha m$ on $\mathbb{N}$ in CZF + REA.

In the following definition we use the shorthand $\text{Fam}_\alpha(e,k)$ to convey that $\text{Set}_\alpha(k)$ and $\forall j \varepsilon_\alpha k \rightarrow \text{Set}_\alpha(\{e\}(j))$ and we shall write $\text{Set}_\varepsilon_\alpha(n)$ for $\exists \beta \in \alpha(\text{Set}_\beta(n))$, $n \varepsilon_\alpha m$ for $\exists \beta \in \alpha(n \varepsilon_\beta m)$ and $\text{Fam}_\varepsilon_\alpha(e,k)$ for $\exists \beta \in \alpha(\text{Fam}_\beta(e,k))$.

(1) $\text{Set}_\alpha(n_j)$ iff $j = 0$ or $j = 1$, and $m \varepsilon_\alpha n_j$ iff $m < j$;
(2) $\text{Set}_\alpha(n)$ holds, and $m \varepsilon_\alpha n$ iff $m \in \mathbb{N}$.

(3) If $\text{Fam}_\varepsilon_\alpha(e,k)$, then $\text{Set}_\alpha(\pi(k,e))$ and $\text{Set}_\alpha(\sigma(k,e))$;
   if $\text{Fam}_\varepsilon_\alpha(e,k)$, then
   (a) $n \varepsilon_\alpha \pi(k,e)$ iff there exists $\beta \in \alpha$ such that $\text{Fam}_\beta(e,k)$ and $\forall i (i \varepsilon_\beta k \rightarrow \{n\}(i) \varepsilon_\beta \{e\}(i))$
   (b) $n \varepsilon_\alpha \sigma(k,e)$ iff there exists $\beta \in \alpha$ such that $\text{Fam}_\beta(e,k)$, $p_0(n) \varepsilon_\beta k \wedge p_1(n) \varepsilon_\beta \{e\}(p_0(n))$

(4) If there exists $\beta \in \alpha$ such that $\text{Set}_\beta(n)$ and $\text{Set}_\beta(m)$, then $\text{Set}_\alpha(+(n,m))$, and
   $i \varepsilon_\alpha + (n,m)$ iff there exists $\beta \in \alpha$ such that $\text{Set}_\beta(n)$, $\text{Set}_\beta(m)$ and
   $(p_0(i) = 0 \wedge p_1(i) \varepsilon_\beta n) \vee (p_0(i) = 1 \wedge p_1(i) \varepsilon_\beta m)$

(5) If there exists $\beta \in \alpha$ such that $\text{Set}_\beta(n)$, then $\text{Set}_\alpha(\text{id}(n,m))$, and
   $i \varepsilon_\alpha \text{id}(n,m,k)$ iff there exists $\beta \in \alpha$ such that $\text{Set}_\beta(n)$ and $\forall j (j < \ell(i) \rightarrow (i)_j \varepsilon_\beta n)$.

(6) If $\text{Set}_\varepsilon_\alpha(n)$, then $\text{Set}_\alpha(\text{id}(n,m,k))$, and
   $s \varepsilon_\alpha \text{id}(n,m,k)$ iff there exists $\beta \in \alpha$ such that $\text{Set}_\beta(n)$, $m \varepsilon_\beta n$ and $s = m = k$.

(7) Let $\beta \in \alpha$. Suppose that the following conditions (collectively called $*_\beta$) are satisfied:
   (a) $\text{Set}_\beta(s)$,
   (b) $\alpha \varepsilon_\beta s$,
   (c) $\text{Fam}_\beta(v,s)$,
   (d) $\text{Fam}_\beta(i,s)$ and
   (e) $\forall x \forall y (x \varepsilon_\beta s \land y \varepsilon_\beta \{i\}(x) \rightarrow \text{Fam}_\beta(\{c\}(x),(y),s)$),
   then $\text{Set}_\alpha(\tilde{\alpha}_{s,i,c}v)$;
assuming \(*_\beta\), let \(C_\beta(a\tilde{s}_{i,c}v)\) be the smallest subsets of \(\mathbb{N}\) such that whenever \(r \in \beta\{v\}(a)\) then \(\rho(a,r) \in C_\beta(a\tilde{s}_{i,c}v)\) and whenever \(j \in \beta\{i\}(a)\) and

\[
\forall z \forall s(z \in \beta a \land s \in \beta\{(c\{a\})\}(j)) \rightarrow \{r\}(z, s) \in C_\beta(z\tilde{s}_{i,c}v))
\]

then \(r(a,j) \in C_\beta(a\tilde{s}_{i,c}v)\).

The existence of the set \(C_\beta(a\tilde{s}_{i,c}v)\) is guaranteed by the axiom REA.

Finally we define \(q \in \alpha \tilde{s}_{i,c}v\) iff \(\exists \beta \in \alpha(*_\beta \land q \in C_\beta(a\tilde{s}_{i,c}v))\).

**Remark 5.2.** It is worth noting that in the above definition the interpretation of the Propositional Identity \(Id(s,a,b) \in U_0\) for \(s \in U_0\) and \(a \in T(s)\) and \(b \in T(s)\) agrees with that in [IMMS18] which validates the rules of the extensional Propositional Identity in [NPS90].

Then also our realizability semantics actually validates the extensional version of MLtt\(_{ind}\). Hence the elimination rule of inductive basic covers can be equivalently weakened to act towards types non dipendent on proof-terms of basic covers, as soon as we add a suitable \(\eta\)-rule in a similarly way to what happens to the rules of first-order types (like disjoint sums or natural numbers or list types) in the extensional type theories in [Mai05].

Here we have a crucial lemma.

**Lemma 5.1.** In CZF + REA, for all \(m \in \mathbb{N}\), if \(\text{Set}_\alpha(m)\), then for all \(\rho\) such that \(\text{Set}_\rho(m)\),

\[
\forall i \in \mathbb{N}(i \in \alpha m \leftrightarrow i \in \rho m).
\]

**Proof.** We proceed by induction on \(\alpha\). Suppose \(\text{Set}_\alpha(m)\) and \(\text{Set}_\rho(m)\). We look at the forms \(m\) can have.

If \(m\) is \(n_0, n_1\) or \(n\), then the claim is immediate in view of clauses (1) and (2) in the previous definition.

If \(m\) is of the form \(\pi(k,e)\), then there exists \(\beta \in \alpha\) such that \(\text{Fam}_\beta(e,k)\). The induction hypothesis applied to \(\beta\) yields that whenever \(\text{Fam}_\xi(e,k)\), then

\[
\forall j \in \mathbb{N}(i \in \beta m \leftrightarrow i \in \xi m)
\]

\[
\forall i \in \mathbb{N} \forall j \in \mathbb{N}(i \in \beta m \rightarrow (j \in \beta \{e\}(i) \leftrightarrow j \in \xi \{e\}(i)))
\]

The thesis follows from these. If \(m\) is either \(\sigma(k,e), +(a,b)\), list\((a)\) or id\((a,b,c)\) the argument proceeds as in the previous case.

If \(m\) is of the form \(a\tilde{s}_{i,c}v\), the proof is similar, although more involved. \(\square\)

**Definition 5.3.** We define in CZF + REA the formula \(\text{Set}(n)\) as \(\exists \alpha(\text{Set}_\alpha(n))\) and \(x \in y\) as \(\exists \alpha(x \in y)\).

**Theorem 5.4.** The theory MLtt\(_{ind}\) is consistent with the formal Church thesis CT.

**Proof.** We outline a realizability semantics in CZF + REA. Every preterm is interpreted as a \(K_1\)-applicative term (that is, a term built with numerals and Kleene application) as it is done in [IMMS18]. We only need to interpret the new preterms of MLtt\(_{ind}\) that is:

1. \((a\tilde{s}_{i,c}v)^I\) is defined as \(\{p\}(6, \{p_5\}(a^I,v^I,s^I,\Lambda x.i^I,\Lambda x.Ay.c^I))\), where \(p\) and \(p_5\) are numeral representing the encoding of pairs of natural numbers and of 5-tuples of natural numbers, respectively.
2. \((r(a,r))^I := \{p\}(7, \{p\}(a^I,r^I));\)
3. \((t(a,j,r))^I := \{p\}(8, \{p_3\}(a^I,j^I,r^I)),\) where \(p_3\) is a numeral representing the encoding of triples of natural numbers;

\[\text{when we write } \{b\}(a_1,...,a_n), \text{ we mean } \{...,\{b\}(a_1)\}(a_2)...\}(a_n)\]
(4) \( \text{ind}(m, q_1, q_2) \) is \( \text{ind}_{q_1, q_2}(m) \) where \( \text{ind}_{q_1, q_2} \) is the code of a recursive function such that

(a) \( \text{ind}_{q_1, q_2}(\rho(a, r)) \simeq \{ \{ \text{Ax.Az}q_1 \}(a') \}(r') \)
(b) \( \text{ind}_{q_1, q_2}(\tau(a, j, r)) \simeq \{ \text{Ax.Ak.Af.Ak}q_2 \}(a, j, \Lambda y.As.\text{ind}_{q_1, q_2}(\{ \{ y \}(y)(s) \}, r) \)

If \( \tau \) is an \( \mathcal{K}_1 \)-applicative term, we will define \( \tau \in A \) as an abbreviation for \( \phi[\tau/x] \).

We will interpret pretypes as definable subclasses of \( N \) in \( \text{CZF + REA} \) as follows:

1. \( N_0^I := \{ x \in N \mid \perp \} \)
2. \( N_1^I := \{ x \in N \mid x = 0 \} \)
3. \( (\Sigma y \in A)B \) := \( \{ x \in N \mid p_0(x) = A \wedge p_1(x) = B \} \)
4. \( (\Pi y \in A)B \) := \( \{ x \in N \mid \forall y \in N \{ y \in A \to \{ x \}(y) \in B \} \}
5. \( A + B \) := \( \{ x \in N \mid (p_0(x) = 0 \wedge p_1(x) = A) \vee (p_0(x) = 1 \wedge p_1(x) = B) \} \)
6. \( \text{List}(A) \) := \( \{ x \in N \mid \forall i \in N \{ i < f(x) \to (x)_i \in A \} \}
7. \( \text{Id}(A, a, b) \) := \( \{ x \in N \mid x = a \wedge x = b \} \wedge \Lambda i. a = b \in A \}
8. \( U_0^I := \{ x \mid \text{Set}(x) \}
9. \( T(a)^I := \{ x \mid x \in a \}

Precontexts are interpreted as conjunctions of formulas of \( \text{CZF + REA} \) as follows.

1. \( [I]^I \) is the formula \( T \);
2. \( [\Gamma, x \in A]^I \) is the formula \( \Gamma^I \wedge x^I \in A^I \).

Validity of judgements \( J \) in the model is defined as follows:

1. \( A \text{ type } [\Gamma] \) holds if \( \Gamma^I \vdash \text{CZF + REA} \forall x (x \in A^I \to x \in N) \)
2. \( A = B \text{ type } [\Gamma] \) holds if \( \Gamma^I \vdash \text{CZF + REA} \forall x (x \in A \leftrightarrow x \in B) \)
3. \( a \in A [\Gamma] \) holds if \( \Gamma^I \vdash \text{CZF + REA} a^I \in A^I \)
4. \( a = b \in A [\Gamma] \) holds if \( \Gamma^I \vdash \text{CZF + REA} a^I \in A^I \wedge a^I = b^I \)

where \( x \) is a fresh variable.

The encoding of lambda-abstraction in terms of \( \mathcal{K}_1 \)-applicative terms can be chosen (see [IMMS18]) in such a way that if \( a \) and \( b \) are terms and \( x \) is a variable which is not bounded in \( a \), then the terms \( (a[b/x]^I) \) and \( a^I[b^I/x] \) coincide.

The proof that for every judgement if \( \text{MLtt}_{\text{ind}} \vdash J \), then \( J \) holds in the realizability model is a long, but straightforward verification.

We just prove for the sake of example that the rules for the inductively generated covers (rf-\( \psi \)) and (tr-\( \psi \)) preserve the validity of judgments in the empty-context case.

(rf-\( \psi \)) Suppose the premisses of the following rule are valid in the model.

\[
\begin{array}{cccc}
s & i(s) & c(s, y) & r \\
U_0 & U_0 & U_0 & U_0 \end{array}
\]

Then, in particular \( a^I \in s^I \) and \( r^I \in \{ v^I \}(a^I) \) hold in \( \text{CZF + REA} \). As a consequence of definition [53], we hence have that \( rf(a, r)^I = \rho(a^I, r^I) \in a^I \in \text{REA} \) holds in \( \text{CZF + REA} \), but this is equivalent to the validity of the judgement \( rf(a, r) \in a \in \text{REA} \) in the model.

(tr-\( \psi \)) Suppose the premisses of the following rule are valid in the model.

\[
\begin{array}{cccc}
s & i(s) & c(s, y) & r \\
U_0 & U_0 & U_0 & U_0 \end{array}
\]

Then, in particular \( a^I \in s^I \) and \( r^I \in \{ v^I \}(a^I) \) hold in \( \text{CZF + REA} \). As a consequence of definition [53], we hence have that \( rf(a, r)^I = \rho(a^I, r^I) \in a^I \in \text{REA} \) holds in \( \text{CZF + REA} \), but this is equivalent to the validity of the judgement \( rf(a, r) \in a \in \text{REA} \) in the model.
Then, in $\text{CZF} + \text{REA}$, $a^I \in s^I$, $j^I \in \{i^I\}(a^I)$, $\forall x \in \mathbb{N} \ (x \in s^I \rightarrow \text{Set}(\{v^I\}(x)))$ and $\forall x \in \mathbb{N} \ \forall y \in \mathbb{N} \ (x \in s^I \land y \in \{c^I(a^I,j^I)\}(x) \rightarrow \{r^I\}(x,y) \in \triangleleft(s^I,i^I,c^I;x,v^I))$

Thus in particular, by definition $5.1$, $(\text{tr}(a,j,r))^I = \tau(a^I,j^I,r^I) \in a^I \triangleleft a,i,c^I v^I$, which means that $\text{tr}(a,j,r) \in a \triangleleft a,i,c^I v$ is valid in the model.

\[\square\]

**Corollary 5.2.** The theory $\text{mTT}_{\text{ind}}$ is consistent with the axiom of choice, $\text{AC}$, and Formal Church thesis, $\text{CT}$.

**Proof.** This follows from Theorems 4.1 and 5.4. \[\square\]

**Corollary 5.3.** The theory $\text{mTT}_{\text{ind}} + \text{AC} + \text{CT}$ has an interpretation in the intensional version of the type theory $\text{ML}_{1W}^\text{V}$ in Definition 5.1 of $[\text{Rat93}]$ (or $[\text{GR94}]$).

**Proof.** This is a consequence of the proof of the above Theorem 5.4 and Proposition 5.3 in $[\text{Rat93}]$, namely the interpretability of $\text{CZF} + \text{REA}$ in $\text{ML}_{1W}^\text{V}$. \[\square\]

**Remark 5.5.** In a certain sense there is nothing special about inductively generated basic covers in that the interpretation of $\text{ML}_{\text{tt}}_{\text{ind}}$ in $\text{CZF} + \text{REA}$ would also work if one added further inductive types such as generic well founded sets to $\text{ML}_{\text{tt}}_{\text{ind}}$. In the same vein one could add more universes or even superuniverses (see $[\text{Pal98}, \text{Rat01}]$) after beefing up the interpreting set theory by adding large set axioms. As a consequence one can conclude that intensional Martin-Löf type theory with some or all these type constructors added, but crucially missing the $\xi$-rule, is compatible with Church’s thesis.

**Theorem 5.6.** $\text{ML}_{\text{tt}}_{\text{ind}}$ and $\text{CZF} + \text{REA}$ have the same proof-theoretic strength.

**Proof.** It follows from $[\text{Rat93}]$, Theorem 5.13, Theorem 6.9, Theorem 6.13 (or the same theorems in $[\text{GR94}]$) together with the observation that the theory $\text{IARI}$ of $[\text{Rat93}]$ in Definition 6.2 can already be interpreted in $\text{ML}_{\text{tt}}_{\text{ind}}$ using the interpretation of $[\text{Rat93}]$ in Definition 6.5.

We just recall that $\text{IARI}$ is a subsystem of second order intuitionistic number theory. It has a replacement schema and an axiom of inductive generation asserting that for every binary set relation $R$ on the naturals the well-founded part of this relation is a set. The interpretation for the second order variables are the propositions on the naturals with truth conditions in $U_0$.

The crucial step is to interpret the axiom of inductive generation of $\text{IARI}$ in $\text{ML}_{\text{tt}}_{\text{ind}}$. To this purpose one has to show that if $s \in U_0$ and $R \in T(s) \times T(s) \rightarrow U_0$ then the well-founded part of $R$, $\text{WP}(R)$, can be given as a predicate $\text{WP}(R) \in T(s) \rightarrow U_0$. To this end define $i \in T(s) \rightarrow U_0$ by $i(x) := s$, $v \in T(s) \rightarrow U_0$ by $v(p) := n_0$, $c(x,y) \in T(s) \rightarrow U_0$ by $c(x,y)(z) := R(z,x)$ (so $y$ is dummy) for $x \in T(s)$ and $y \in T(s)$. Now let $\text{WP}(R)(a) := a \triangleleft a,i,c^I v$ for $a \in T(s)$. Then it follows that $a$ is in the well-founded part exactly when $\text{WP}(R)(a)$ is inhabited. To see this, suppose we have a truth maker $r$ for $(\Pi x \in T(s))(R(x,a) \rightarrow \text{WP}(R)(x))$. Then $r \in (\Pi x \in T(s))(x \epsilon c(a,a) \rightarrow x \triangleleft a,i,c^I v)$, hence $\text{tr}(a,a,r) \in a \triangleleft a,i,c^I v$ by (tr-$\triangleleft$), whence $\text{tr}(a,a,r) \in \text{WP}(R)(a)$. Thus $\text{WP}(R)$ satisfies the appropriate closure properties characterizing the well-founded part of $R$. The pertaining induction principle is then a consequence of (ind-$\triangleleft$). \[\square\]
Remark 5.7. As an evidence of the validity of the previous theorem, one can notice that well-founded sets of small sets in $\text{MLtt}_{\text{ind}}$ can be represented by suitable inductive basic covers. Hence the claim essentially follows thanks to theorem 6.13 in [Rat93].

Indeed, given a small set $s \in U_0$ and a family of small sets $b(x) \in U_0 \ [x \in T(a)]$ then the well-founded set $(\forall x \in T(s))T(b(x))$ on this family can be interpreted as the open cover on the empty subset $\emptyset \equiv \lambda x.\hat{N}0 \in T(s) \rightarrow U_0$

$$(\forall x \in T(s))T(b(x)) \equiv \langle s, x, c \rangle \emptyset$$

of the inductive basic cover generated by

$$i(x) = \hat{N}_1 \quad c(x, j) \equiv b(x)$$

for $x \in T(s)$ and $j \in N_1$.

Then the term $\sup(a, f)$, for $a \in T(s)$ and $f(x) \in (\forall x \in T(s))T(b) \ [x \in T(s)]$ - with the notation of p.98 in [NPS90] - can be defined to be $\text{tr}(a, \ast, \lambda x.\lambda y.f(a))$. Moreover, as one could expect, there is no term of the form $r f(a, j)$ since $N_0$ is the empty set.

The elimination constructor of well-founded sets $\text{wrec}(e, f)$ is defined as the term $\text{ind}(e, r_0, f)$ where $r_0$ is the elimination constructor of the empty set.

Conclusions. In the future we aim to further extend the realizability semantics presented here to model $\text{MF}_{\text{ind}}$ enriched with coinductive definitions capable of representing generated Positive Topologies in [Sam03].

A further goal would be to study the consistency strength of $\text{mTT}_{\text{ind}}$ or of $\text{mTT}$ extended with specific inductive formal topologies such as that of the real line.
