May 30, 2019

Abstract

We consider a family of stochastic 2D Euler equations in vorticity form on the torus, with transport type noises and $L^2$-initial data. Under a suitable scaling of the noises, we show that the solutions converge weakly to that of the deterministic 2D Navier–Stokes equations. Consequently, we deduce that the weak solutions of the stochastic 2D Euler equations are approximately unique and “weakly quenched exponential mixing”.

1 Introduction

Let $\mathbb{T}^2 = \mathbb{R}^2/\mathbb{Z}^2$ be the 2D torus and $\mathbb{Z}_0^2 = \mathbb{Z}^2 \setminus \{0\}$ the nonzero lattice points. Define

$$\sigma_k(x) = \frac{k^\perp}{|k|} e_k(x), \quad x \in \mathbb{T}^2, \ k \in \mathbb{Z}_0^2,$$

where $k^\perp = (k_2, -k_1)$ and $\{e_k\}_{k \in \mathbb{Z}_0^2}$ is the usual trigonometrical basis of $L^2(\mathbb{T}^2)$, see the beginning of Section 2. Then $\{\sigma_k\}_{k \in \mathbb{Z}_0^2}$ is a complete orthonormal basis of the space of square integrable, divergence free vector fields on $\mathbb{T}^2$ with zero mean.

In a previous work [15], the first and the third named authors studied the vorticity form of the stochastic 2D Euler equations with transport type noise:

$$d\xi^N + u^N \cdot \nabla \xi^N \, dt = 2\sqrt{\nu} \varepsilon_N \sum_{|k| \leq N} \frac{1}{|k|} \sigma_k \cdot \nabla \xi^N \circ dW^k,$$  \hspace{1cm} (1.1)

where $\nu > 0$ is a constant, $\{\varepsilon_N\}_{N \geq 1}$ a sequence of positive numbers and $\{W_k\}_{k \in \mathbb{Z}_0^2}$ is a family of independent standard Brownian motions on some filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, \mathbb{P})$. In the above equation, $u^N = (u_1^N, u_2^N)$ is the velocity field and $\xi^N = \nabla^\perp \cdot u^N = \partial_2 u_1^N - \partial_1 u_2^N$ is the vorticity; conversely, $u^N = K \ast \xi^N$ where $K$ is the Biot–Savart kernel. The equation (1.1) has the enstrophy measure $\mu$ on $\mathbb{T}^2$ as the invariant measure, which is supported on $H^{-1}(\mathbb{T}^2) = \bigcap_{s < -1} H^s(\mathbb{T}^2), \ H^s(\mathbb{T}^2)$ being the usual Sobolev space on $\mathbb{T}^2$. For any fixed $N \geq 1$, it is known that (1.1) admits a stationary solution $\xi^N$ with paths in $C([0, T], H^{-1}(\mathbb{T}^2))$ (taking $\rho_0 \equiv 1$ in [14, Theorem 1.3]). We choose the parameter $\varepsilon_N$ in such a way that it compensates the coefficient appearing in the Itô–Stratonovich correction term. More precisely, let

$$\varepsilon_N = \left( \sum_{|k| \leq N} \frac{1}{|k|^2} \right)^{-1/2} \sim (\log N)^{-1/2},$$

then, in the Itô formulation, (1.1) becomes
\[ \begin{align*}
\frac{d\xi^N}{\sqrt{\nu}} + u^N \cdot \nabla \xi^N \, dt &= 2\sqrt{\nu} \varepsilon^N \sum_{|k| \leq N} \frac{1}{|k|} \sigma_k \cdot \nabla \xi^N \, dW^k + \nu \Delta \xi^N \, dt.
\end{align*} \]

It was proved in [15] that the stationary solutions \( \xi^N \) of (1.1) converge to the unique-in-law stationary solution of the stochastic 2D Navier–Stokes equations driven by additive space-time white noise
\[ \begin{align*}
d\xi + u \cdot \nabla \xi \, dt &= \nu \Delta \xi \, dt + \sqrt{2\nu} \nabla \perp \cdot dW.
\end{align*} \] (1.2)

Here, \( W = \sum_{k \in \mathbb{Z}^2_0} \sigma_k W_k \) is a cylindrical Brownian motion in the Hilbert space of divergence-free vector fields on \( \mathbb{T}^2 \). The equation (1.2), in the velocity form, has been studied intensively in the past three decades, see for instance [3, 4, 10]. In particular, it was shown in [10] that (1.2) has a pathwise unique strong solution for \( \mu \) almost every initial data in Besov spaces of negative order. As a consequence of the Yamada–Watanabe type theorem (see e.g. [20]), the stationary solutions of (1.2) are unique in law.

On the other hand, the second named author considered in [16] a similar scaling limit for a sequence of stochastic transport linear equations, but in a different regime, namely for function-valued solutions of suitable regularity. To state the result we introduce the notation \( \ell^p \) \( (p \in [1, \infty]) \) which are the usual spaces of real sequences indexed by \( \mathbb{Z}^2_0 \) and denote the norm by \( \| \cdot \|_{\ell^p} \). Let \( \theta^N \in \ell^2(N \geq 1) \) be a sequence verifying, for all \( N \in \mathbb{N} \),
\[ \begin{align*}
\theta_k^N = \theta_j^N \quad \text{whenever } |k| = |j| \quad (1.3)
\quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad 
We will prove that such more regular solutions of equation \((1.6)\) converge to the unique solution of the \textit{deterministic} 2D Navier–Stokes equations
\[
\partial_t \xi + u \cdot \nabla \xi = \nu \Delta \xi, \quad \xi(0) = \xi_0. \tag{1.7}
\]
According to the classical theory of 2D Navier–Stokes equations (see [25, Theorem 3.2] for the velocity form), the above equation has a unique solution.

A direct consequence of the above scaling limit is that the transport type noises considered here regularize the 2D Euler equations asymptotically. More precisely, it is well known that the 2D Euler equations has a unique solution if the initial data \(\xi_0\) belongs to \(L^\infty(\mathbb{T}^2)\), while the uniqueness of solutions remains an open problem in the case \(\xi_0 \in L^p(\mathbb{T}^2)\) for \(p < \infty\). Although we cannot prove that the stochastic 2D Euler equation \((1.6)\) has a unique solution for \(L^2(\mathbb{T}^2)\)-initial data, the above result shows that, in the limit, we get the uniquely solvable 2D Navier–Stokes equation \((1.7)\). As a result, the distances between the laws of weak solutions of \((1.6)\) tend to zero as \(N \to \infty\). We call such a property the approximate weak uniqueness, see Section 6.1 for more details.

Our main result is the convergence to deterministic Navier–Stokes equations; however, tuning parameters in the right way we may construct sequences converging to deterministic Euler equation. More precisely, given any viscosity solution of 2D Euler, we can find a suitable sequence converging to it, see Section 6.2 for more details. We do not know the converse, namely if every limiting measure constructed in this way is a superposition of viscosity solutions, but our result makes this conjecture plausible. It is very important to identify selection criteria, for instance by viscosity, by noise or by additional physical requirements, in view of the multiplicity of solutions found recently by the method of convex integration [12]; although our result is not conclusive, it makes plausible that the zero-noise limit selects viscosity solutions. Notice that this is different from what happens for certain examples of linear transport equations [5].

Our result also has interesting implications related to the mixing behavior of incompressible flows, a phenomenon which recently attracted a lot of attention, see for instance [1, 2, 26] and the references therein. In [2], Alberti et al. considered the solutions to the continuity equation
\[
\partial_t \rho_t + \text{div}(\rho_t u) = 0 \tag{1.8}
\]
and estimated the “mixedness” of \(\rho_t\) as \(t \to \infty\) in terms of the negative Sobolev norm \(\|\rho_t\|_{\dot{H}^{-s}}\). Here \(\dot{H}^s(\mathbb{T}^2)\) \((s \in \mathbb{R})\) denote the homogeneous Sobolev spaces. They constructed a bounded and divergence free vector field \(u \in C^\infty([0, \infty) \times \mathbb{R}^d, \mathbb{R}^d)\) and a bounded solution \(\rho \in C^\infty([0, \infty) \times \mathbb{R}^d)\) to \((1.8)\) such that, for any \(0 < s < 2\), it holds
\[
\|\rho_t\|_{\dot{H}^{-s}} \leq C_s e^{-ct}, \quad t \geq 0,
\]
where \(C_s > 0\) and \(c > 0\) are constants. Such exponential mixing result is in fact optimal, taking into account the lower bounds on functional mixing scale proved in [18, 23]. Using our limit result and the exponential decay of the energy and the enstrophy of the solution to the Navier–Stokes equation \((1.7)\), we can prove that the solutions to the stochastic 2D Euler equations \((1.6)\) satisfy the “weakly quenched exponential mixing” property, see Section 6.3 for more precise statements.

However, the decay in \(\dot{H}^{-s}\)-norms does not extend to the \(L^2\)-norm and our result does not imply anomalous dissipation of enstrophy. This is a difficult open question, which is discussed in Section 6.4.

This paper is organized as follows. In Section 2, we introduce some notations and state the main results, including the existence of weak solutions to the stochastic 2D Euler equations \((1.6)\) and the scaling limit to the deterministic 2D Navier–Stokes equation \((1.7)\), as well as a finite dimensional convergence result. The proofs of these results are provided in Sections 3 to 5. In the last sections, we discuss the consequences of the scaling limit in more detail.
2 Functional settings and main results

In this section, we give some more notations for functional spaces and state the main results of the paper. Let \( C^\infty(\mathbb{T}^2) \) be the space of smooth function on \( \mathbb{T}^2 \). We write \( \langle \cdot, \cdot \rangle \) and \( \| \cdot \|_{L^2} \) for the inner product and the norm in \( L^2(\mathbb{T}^2) \). Recall also the Sobolev spaces \( H^s(\mathbb{T}^2) \), \( s \in \mathbb{R} \).

Denote by
\[
\epsilon_k(x) = \sqrt{2} \begin{cases}
\cos(2\pi k \cdot x), & k \in \mathbb{Z}_0^2,
\sin(2\pi k \cdot x), & k \in \mathbb{Z}_+^2,
\end{cases} \quad x \in \mathbb{T}^2,
\]
where \( \mathbb{Z}_0^2 = \{ k \in \mathbb{Z}_0^2 : (k_1 > 0) \text{ or } (k_1 = 0, k_2 > 0) \} \) and \( \mathbb{Z}_+^2 = -\mathbb{Z}_+^2 \). To save notations, we shall write the vector valued spaces \( L^2(\mathbb{T}^2, \mathbb{R}^2) \) and \( H^s(\mathbb{T}^2, \mathbb{R}^2) \) simply as \( L^2(\mathbb{T}^2) \) and \( H^s(\mathbb{T}^2) \).

We denote by \( df_k(x) \) where \( \xi \in \mathbb{Z}_0^2 \). From this we deduce the Itô formulation of (2.1):
\[
d\xi + u \cdot \nabla \xi \, dt = \nu \Delta \xi \, dt + \epsilon \sum_{k \in \mathbb{Z}_0^2} \theta_k \sigma_k \cdot \nabla \xi \, dW^k, \quad \xi(0) = \xi_0 \in H, \quad (2.1)
\]
with
\[
\epsilon = \frac{2\sqrt{\nu}}{\| \theta \|_{L^2}}. \quad (2.2)
\]
Using (1.3), it is not difficult to prove the simple equality (cf. [15] Lemma 2.6)
\[
\sum_{k \in \mathbb{Z}_0^2} \theta_k^2 \sigma_k(x) \otimes \sigma_k(x) = \frac{1}{2} \| \theta \|_{L^2}^2 I_2, \quad x \in \mathbb{T}^2, \quad (2.3)
\]
where \( I_2 \) is the \( 2 \times 2 \) identity matrix. From this we deduce the Itô formulation of (2.1):
\[
d\xi + u \cdot \nabla \xi \, dt = \nu \Delta \xi \, dt + \epsilon \sum_{k \in \mathbb{Z}_0^2} \theta_k \sigma_k \cdot \nabla \xi \, dW^k. \quad (2.4)
\]
This equation is understood as follows: for any \( \phi \in C^\infty(\mathbb{T}^2) \), it holds \( \mathbb{P} \)-a.s. for all \( t \in [0, T] \),
\[
\langle \xi_t, \phi \rangle = \langle \xi_0, \phi \rangle + \int_0^t \langle \xi_s, u_s \cdot \nabla \phi \rangle \, ds + \nu \int_0^t \langle \xi_s, \Delta \phi \rangle \, ds - \epsilon \sum_{k \in \mathbb{Z}_0^2} \theta_k \int_0^t \langle \xi_s, \sigma_k \cdot \nabla \phi \rangle \, dW^k_s. \quad (2.5)
\]
Recall that \( u \) is related to \( \xi \) via the Biot–Savart kernel \( K \) on \( \mathbb{T}^2 \): \( u = K \ast \xi \). Thus if \( \xi \in L^2(\Omega, L^2(0, T; H)) \), then \( u \in L^2(\Omega, L^2(0, T; V)) \). Under this condition, if \( \xi \) (and also \( u \)) is \( \mathcal{F}_t \)-progressively measurable, it is clear that all the terms in the above equation makes sense.

For instance, the stochastic integral is a square integrable martingale since
\[
\mathbb{E} \left( \sum_{k \in \mathbb{Z}_0^2} \theta_k^2 \int_0^T \langle \xi_s, \sigma_k \cdot \nabla \phi \rangle^2 \, ds \right) \leq \| \theta \|_{L^\infty} \mathbb{E} \left( \int_0^T \sum_{k \in \mathbb{Z}_0^2} \langle \xi_s \nabla \phi, \sigma_k \rangle^2 \, ds \right)
\leq \| \theta \|_{L^\infty} \mathbb{E} \left( \int_0^T \| \xi_s \nabla \phi \|_{L^2}^2 \, ds \right)
\leq \| \theta \|_{L^\infty} \| \nabla \phi \|_{L^2}^2 \mathbb{E} \int_0^T \| \xi_s \|_{L^2}^2 \, ds < +\infty,
\]
where we used the fact that \( \{ \sigma_k \}_{k \in \mathbb{Z}_0^2} \) form an (incomplete) orthonormal system in \( L^2(\mathbb{T}^2, \mathbb{R}^2) \). From this result we can give the definition of solutions to (2.5).
Definition 2.1. We say that (2.5) has a weak solution if there exist a filtered probability space \((\Omega, \mathcal{F}, \mathcal{F}_t, \mathbb{P})\), a sequence of independent \(\mathcal{F}_t\)-Brownian motions \(\{W^k\}_{k \in \mathbb{Z}_0^2}\) and an \(\mathcal{F}_t\)-progressively measurable process \(\xi \in L^2(\Omega, L^2(0, T; H))\) with \(\mathbb{P}\)-a.s. weakly continuous trajectories such that for any \(\phi \in C^\infty(\mathbb{T}^2)\), the equality (2.5) holds \(\mathbb{P}\)-a.s. for all \(t \in [0, T]\).

Note that the solution is weak in both the probabilistic and the analytic sense. Our first result is the existence of solutions to (2.5).

Theorem 2.2. For any \(\xi_0 \in H\), there exists at least one weak solution to (2.5), satisfying
\[
\sup_{t \in [0, T]} \|\xi_t\|_{L^2} \leq \|\xi_0\|_{L^2} \quad \mathbb{P}\text{-a.s.} \tag{2.6}
\]

Next, we take a sequence \(\theta^N \in \ell^2\), satisfying (1.3) and (1.4), and consider the stochastic 2D Euler equations (1.6). Similarly to the above discussions, (1.6) is understood as follows: for any \(\phi \in C^\infty(\mathbb{T}^2)\) and \(t \in [0, T]\),
\[
\langle \xi^N_t, \phi \rangle = \langle \xi_0, \phi \rangle + \int_0^t \langle \xi^N_s, u^N_s \cdot \nabla \phi \rangle \, ds + \nu \int_0^t \langle \xi^N_s, \Delta \phi \rangle \, ds - \varepsilon_N \sum_{k \in \mathbb{Z}_0^2} \xi^N_k \int_0^t \langle \xi^N_s, \sigma_k \cdot \nabla \phi \rangle \, dW^k_s. \tag{2.7}
\]
We remark that Theorem 2.2 only provides us with weak solutions, thus the processes \(\xi^N\) might be defined on different probability spaces. The relevant notion of convergence of these processes is the weak convergence of their laws. Here is the main result of this paper.

Theorem 2.3. Let \(Q^N\) be the law of \(\xi^N\), \(N \geq 1\). Then the family \(\{Q^N\}_{N \geq 1}\) is tight in \(C([0, T]; H^-)\) and it converges weakly to \(\delta_\xi\), where \(\xi\) is the unique solution of the 2D Navier–Stokes equations (1.7).

Theorem 2.3 also implies convergence of the associated advected passive scalars, see Corollary 4.6 for the precise statement.

Remark 2.4. If \(\xi_0 \in L^\infty(\mathbb{T}^2)\), then under slightly stronger conditions on \(\theta\) (e.g. assume \(\theta_k \sim |k|^{-2-\delta}\) for some \(\delta > 0\)), the equation (2.1) has a unique solution in \(L^\infty([0, T] \times \mathbb{T}^2)\), see for instance [8, Theorem 2.10]. Note that in the approximating equations (2.7), we can take \(\theta^N \in \ell^2\) such that there are only finitely many \(k\) for which \(\theta^N_k \neq 0\), and at the same time satisfying (1.4), for instance, \(\theta^N_k = 1_{\{|k| \leq N\}}\). Therefore, if we approximate \(\xi_0 \in L^2(\mathbb{T}^2)\) by a sequence of bounded functions \(\xi^N_0 \in L^\infty(\mathbb{T}^2)\), then the approximating sequence \(\xi^N\) \((N \geq 1)\) are unique solutions of the equations (2.7). Moreover in this case we can consider the sequence \(\xi^N\) to be defined on the same probability space \((\Omega, \mathcal{F}, \mathbb{P})\), again by the results in [8]; thus convergence in law to a deterministic limit implies also convergence in probability. The energy bound (2.6) then also implies convergence in \(L^p(\Omega, \mathbb{P})\), for any \(p > \infty\).

In Sections 3 and 4 we prove Theorems 2.2 and 2.3 respectively. Then in Section 5 we show that the same result can be achieved, under the same scaling, already working with finite dimensional approximations of Galerkin type. More precisely, denoting by \(\Pi_N\) the orthogonal projection of \(L^2(\mathbb{T}^2)\) into \(H_N = \text{span}\{\epsilon_k : k \in \mathbb{Z}_0^2, |k| \leq N\}\), we consider for each \(N\) the solution \(\xi^N\) of the SDE:
\[
d\xi^N = -\Pi_N((K \ast \tilde{\xi}^N) \cdot \nabla \tilde{\xi}^N) \, dt + \varepsilon_N \sum_{k \in \mathbb{Z}_0^2} \theta^N_k \Pi_N(\sigma_k \cdot \nabla \tilde{\xi}^N) \, dW^k, \quad \xi^N_0 = \Pi_N \xi_0. \tag{2.8}
\]

The variables \(\{\xi^N\}_{N \in \mathbb{N}}\) are defined on the same probability space with respect to the same Brownian motions \(\{W^k\}_{k \in \mathbb{Z}_0^2}\). In this case we can prove the following
Theorem 2.5. Suppose the sequence \( \{\theta^N\}_N \subset \ell^2 \) satisfies (1.4) and the additional condition
\[
\lim_{N \to \infty} \left\| \theta^N \right\|_{\ell^2}^2 \sum_{k : |k| \geq j \geq N} (\theta^N_k)^2 = 0 \quad \forall j \in \mathbb{Z}_0^2. \tag{2.9}
\]
Then the sequence \( \{\xi^N\}_{N \geq 1} \) converges in probability to \( \xi \), where \( \xi \) is the unique solution of Navier–Stokes equation (1.7) with initial data \( \xi_0 \).

Remark 2.6. It can be checked for instance that condition (2.9) is satisfied for \( \{\theta^N\}_N \) given by \( \theta^N_k = |k|^{-\alpha} \mathbf{1}_{\{ |k| \leq N \}} \), for any \( \alpha \in [0, 1] \).

3 Existence of solutions to \((2.5)\)

In this section we give a proof of Theorem 2.2 by using the Galerkin approximation and the compactness method.

To use the method of Galerkin approximation, we introduce some notations. For \( N \geq 1 \), let \( H_N = \text{span}\{ \epsilon_k : k \in \mathbb{Z}_0^2, |k| \leq N \} \) which is a finite dimensional subspace of \( H \). Denote by \( \Pi_N : H \to H_N \) the orthogonal projection: \( \Pi_N \xi = \sum_{|k| \leq N} \langle \xi, \epsilon_k \rangle \epsilon_k \). \( \Pi_N \) can also act on vector valued functions. Let
\[
b_N(\xi) = \Pi_N((K * \Pi_N \xi) \cdot \nabla (\Pi_N \xi)), \quad G^k_N(\xi) = \Pi_N(\sigma_k \cdot \nabla (\Pi_N \xi)), \quad k \in \mathbb{Z}_0^2.
\]
Note that, for fixed \( N \), there are only finitely many \( k \in \mathbb{Z}_0^2 \) such that \( G^k_N \) is not zero. We shall view \( b_N \) and \( G^k_N \) as vector fields on \( H_N \) whose generic element is denoted by \( \xi_N \). These vector fields have the following useful properties:
\[
\langle b_N(\xi_N), \xi_N \rangle = \langle G^k_N(\xi_N), \xi_N \rangle = 0 \quad \text{for all} \ \xi_N \in H_N, \tag{3.1}
\]
which can be proved easily from the definitions of \( b_N \) and \( G^k_N \), and the integration by parts formula. Consider the finite dimensional version of (2.4) on \( H_N \):
\[
d\xi_N(t) = -b_N(\xi_N(t)) \, dt + \nu \Delta \xi_N(t) \, dt + \varepsilon \sum_{k \in \mathbb{Z}_0^2} \theta_k G^k_N(\xi_N(t)) \, dW^k_t, \quad \xi_N(0) = \Pi_N \xi_0, \tag{3.2}
\]
where \( \xi_0 \in H \) is the initial condition in Theorem 2.2. We remark that the sum over \( k \) is a finite sum. Its generator is
\[
\mathcal{L}_N \varphi(\xi_N) = \langle -b_N(\xi_N) + \nu \Delta \xi_N, \nabla \varphi(\xi_N) \rangle + \frac{\varepsilon}{2} \sum_{k \in \mathbb{Z}_0^2} \theta_k^2 \text{Tr}[(G^k_N \otimes G^k_N) \nabla^2 \varphi](\xi_N)
\]
for any \( \varphi \in C^2_b(H_N) \).

Lemma 3.1. The equation \((3.2)\) has a unique strong solution \( \xi_N(t) \) satisfying
\[
\sup_{t \in [0, T]} ||\xi_N(t)||_{L^2} \leq ||\xi_N(0)||_{L^2} \quad \text{P-a.s.}
\]
Proof. The vector fields \( b_N \) and \( G^k_N \) are respectively quadratic and linear on the finite dimensional space \( H_N \), therefore they are smooth. By the standard SDE theory, local existence and uniqueness of strong solutions to \((3.2)\) holds for any initial data. By the Itô formula, we have
\[
d||\xi_N(t)||_{L^2}^2 = -2 \langle \xi_N(t), b_N(\xi_N(t)) \rangle \, dt + 2\nu \langle \xi_N(t), \Delta \xi_N(t) \rangle \, dt + \varepsilon \sum_{k \in \mathbb{Z}_0^2} \theta_k^2 \| G^k_N(\xi_N(t)) \|^2_{L^2} \, dt.
\]

(3.3)
The first and the third terms on the right hand side vanish due to (3.1). Moreover, noting that $\Pi_N : H \to H_N$ is an orthogonal projection,
\[ \|G^k_N(\xi_N(t))\|_{L^2} = \|\Pi_N(\sigma_k \cdot \nabla \xi_N(t))\|_{L^2} \leq \|\sigma_k \cdot \nabla \xi_N(t)\|_{L^2}. \]
Therefore,
\[ \varepsilon^2 \sum_{k \in \mathbb{Z}_0^2} \theta_k^2 \|G^k_N(\xi_N(t))\|_{L^2} \leq \varepsilon^2 \sum_{k \in \mathbb{Z}_0^2} \theta_k^2 \int_{T^2} (\sigma_k \cdot \nabla \xi_N(t))^2 \, dx = 2\nu \|\nabla \xi_N(t)\|_{L^2}^2, \]
where the last equality is due to (2.3) and (2.2). Combining these results with (3.3) we obtain $d\|\xi_N(t)\|_{L^2}^2 \leq 0$, which implies the desired inequality and also the global existence of solution to (3.2). \[ \square \]

Lemma 3.1 shows that $\{\xi_N(\cdot)\}_{N \geq 1}$ is bounded in $L^p(\Omega, L^p(0, T; H))$ for any $p > 2$:
\[ \mathbb{E} \int_0^T \|\xi_N(t)\|^p_{L^2} \, dt \leq T \|\xi_N(0)\|^p_{L^2} \leq T \|\xi_0\|^p_{L^2}. \] (3.4)
Thus we can find a weakly convergent subsequence. Denote by $u_N = K \ast \xi_N$, $N \geq 1$; then $\{u_N(\cdot)\}_{N \geq 1}$ is bounded in $L^2(\Omega, L^2(0, T; V))$. In order to pass to the limit in the nonlinear term, we need $u_N$ to be strongly convergent in $L^2(\Omega, L^2(0, T; H))$. In fact, we will show that the laws $\eta_N$ of $u_N(\cdot)$ are tight in $C([0, T], H^1(\mathbb{T}^2))$. To this end we first recall the compactness result by J. Simon [24, Corollary 9, p.90].

Take any $\delta \in (0, 1)$ small enough and $\beta > 4$ (this choice is due to computations below). We have the compact inclusions
\[ V = H^1 \subset H^{1-\delta} \subset H^{-\beta}, \]
and there exists $C > 0$ such that
\[ \|f\|_H \leq C \|f\|_{V}^{-\kappa} \|f\|_{H^{-\beta}}, \quad f \in V, \]
where $\kappa = \delta/(1 + \beta)$. Recall that, for $\alpha \in (0, 1)$, $p > 1$ and a normed linear space $(Y, \| \cdot \|_Y)$, the fractional Sobolev space $W^{\alpha, p}(0, T; Y)$ is defined as those functions $f \in L^p(0, T; Y)$ such that
\[ \int_0^T \int_0^T \frac{\|f(t) - f(s)\|_Y^p}{|t-s|^{1+\alpha p}} \, dt \, ds < +\infty. \]
The next result follows from [24, Corollary 9, p.90].

**Theorem 3.2.** Let $\beta > 4$ be given. If $p > 12(1 + \beta - \delta)/\delta$, then
\[ L^p(0, T; V) \cap W^{1/3, 4}(0, T; H^{-\beta}) \subset C([0, T]; H^{1-\delta}) \]
with compact inclusion.

If we can prove that $\{\eta_N\}_{N \in \mathbb{N}}$ are tight on $C([0, T]; H^{1-\delta})$ for any $\delta \in (0, 1)$, then the tightness of $\{\eta_N\}_{N \in \mathbb{N}}$ on $C([0, T], H^1(\mathbb{T}^2))$ follows immediately.

To show the tightness of $\{\eta_N\}_{N \geq 1}$ on $C([0, T]; H^{1-\delta})$, by Theorem 3.2 it is sufficient to prove, for each $N \geq 1$,
\[ \mathbb{E} \int_0^T \|u_N(t)\|_V^p \, dt + \mathbb{E} \int_0^T \int_0^T \frac{\|u_N(t) - u_N(s)\|_{H^{-\beta}}^4}{|t-s|^{7/3}} \, dt \, ds \leq C. \] (3.5)
By (3.4), we immediately get the uniform boundedness of $\{u_N(\cdot)\}_{N \geq 1}$ in $L^p(\Omega, L^p(0, T; V))$. It remains to estimate the second expected value.
Lemma 3.3. There is a constant $C > 0$ such that for any $N \geq 1$ and $0 \leq s < t \leq T$,
\[
\mathbb{E}(\langle \xi_N(t) - \xi_N(s), e_k \rangle^4) \leq C|k|^8|t - s|^2 \quad \text{for all } k \in \mathbb{Z}_0^2.
\]

Proof. It is enough to consider $|k| \leq N$. By (3.2), we have
\[
\langle \xi_N(t) - \xi_N(s), e_k \rangle = \int_s^t \langle \xi_N(r), u_N(r) \cdot \nabla e_k \rangle \, dr + \nu \int_s^t \langle \xi_N(r), \Delta e_k \rangle \, dr
\]
\[
- \varepsilon \sum_{l \in \mathbb{Z}_0^2} \theta_l \int_s^t \langle \xi_N(r), \sigma_l \cdot \nabla e_k \rangle \, dW^l_r.
\]

Using the Hölder inequality and Lemma 3.1, we obtain
\[
\mathbb{E}\left( \left| \int_s^t \langle \xi_N(r), u_N(r) \cdot \nabla e_k \rangle \, dr \right|^4 \right) \leq |t - s|^3 \mathbb{E} \int_s^t \langle \xi_N(r), u_N(r) \cdot \nabla e_k \rangle^4 \, dr
\]
\[
\leq |t - s|^3 \mathbb{E} \int_s^t \|\xi_N(r)\|_{L^4}^4 \|u_N(r)\|_{L^2}^4 \|\nabla e_k\|_{L^8}^4 \, dr
\]
\[
\leq C \|\xi_0\|_{L^2}^4 |k|^4 |t - s|^4,
\]
where the last step is due to the fact $\nabla e_k = 2\pi k e_{-k}$. In the same way, since $\Delta e_k = -4\pi^2 |k|^2 e_k$,
\[
\mathbb{E}\left( \left| \int_s^t \langle \xi_N(r), \Delta e_k \rangle \, dr \right|^4 \right) \leq C \|\xi_0\|_{L^2}^4 |k|^8 |t - s|^4.
\]

Next, by Burkholder’s inequality,
\[
\mathbb{E}\left( \left| \varepsilon \sum_{l \in \mathbb{Z}_0^2} \theta_l \int_s^t \langle \xi_N(r), \sigma_l \cdot \nabla e_k \rangle \, dW^l_r \right|^4 \right) \leq C\varepsilon^4 \mathbb{E} \left( \left| \sum_{l \in \mathbb{Z}_0^2} \theta_l^2 \int_s^t \langle \xi_N(r), \sigma_l \cdot \nabla e_k \rangle^2 \, dr \right|^2 \right).
\]

We have
\[
\sum_{l \in \mathbb{Z}_0^2} \theta_l^2 \langle \xi_N(r), \sigma_l \cdot \nabla e_k \rangle^2 \leq \|\theta\|_{L^\infty}^2 \sum_{l \in \mathbb{Z}_0^2} \langle \xi_N(r) \nabla e_k, \sigma_l \rangle^2
\]
\[
\leq \|\theta\|_{L^\infty}^2 \|\xi_N(r) \nabla e_k\|_{L^2}^2 \leq C \|\theta\|_{L^\infty}^2 |k|^2 \|\xi_0\|_{L^2}^2,
\]
where we have used the fact that $\{\sigma_l\}_{l \in \mathbb{Z}_0^2}$ is an orthonormal family. Therefore,
\[
\mathbb{E}\left( \left| \varepsilon \sum_{l \in \mathbb{Z}_0^2} \theta_l \int_s^t \langle \xi_N(r), \sigma_l \cdot \nabla e_k \rangle \, dW^l_r \right|^4 \right) \leq C\varepsilon^4 \|\theta\|_{L^\infty}^4 |k|^4 \|\xi_0\|_{L^2}^4 |t - s|^2 \leq C' |k|^4 |t - s|^2.
\]

Combining the above estimates with (3.6) we finally get the desired inequality. \hfill \Box

Using the above estimate and Cauchy’s inequality,
\[
\mathbb{E}\left[ \|\xi_N(t) - \xi_N(s)\|_{H^{-\beta-1}}^4 \right] = \mathbb{E} \left[ \sum_{k \in \mathbb{Z}_0^2} \frac{\langle \xi_N(t) - \xi_N(s), e_k \rangle^2}{|k|^{2(\beta+1)}} \right]^2
\]
\[
\leq \left[ \sum_{k \in \mathbb{Z}_0^2} \frac{1}{|k|^{2(\beta+1)}} \right] \left[ \sum_{k \in \mathbb{Z}_0^2} \frac{\mathbb{E}(\langle \xi_N(t) - \xi_N(s), e_k \rangle^4)}{|k|^{2(\beta+1)}} \right]
\]
\[
\leq C|t - s|^2 \sum_{k \in \mathbb{Z}_0^2} \frac{1}{|k|^{2(\beta+1)-8}} \leq C'|t - s|^2,
\]
since $\beta > 4$. Consequently,

$$\mathbb{E}[\|u_N(t) - u_N(s)\|^{4}_{H^{-\beta}}] \leq C'|t-s|^2,$$

which implies

$$\mathbb{E} \int_0^T \int_0^T \frac{\|u_N(t) - u_N(s)\|^{4}_{H^{-\beta}}}{|t-s|^{7/3}} \, dt \, ds \leq C.$$

Thus we have proved \text{(3.5)} and we obtain the tightness of $\{\eta_N\}_{N \geq 1}$ on $C([0, T]; H^1)$. Equivalently, we have proved the tightness of the laws $\tilde{\eta}_N$ of $\xi_N (N \geq 1)$ on $\mathcal{X} := C([0, T]; H^1)$.

Since we are dealing with the SDEs \text{(3.2)}, we need to consider $\tilde{\eta}_N$ together with the laws of Brownian motions $\{(W_t^k)_{0 \leq t \leq T} : k \in \mathbb{Z}_0^2\}$. To this end, we endow $\mathbb{R}^{\mathbb{Z}_0^2}$ with the metric

$$d_\infty(a, b) = \sum_{k \in \mathbb{Z}_0^2} \frac{|a_k - b_k| \wedge 1}{2^{|k|}}, \quad a, b \in \mathbb{R}^{\mathbb{Z}_0^2}.$$

Then $(\mathbb{R}^{\mathbb{Z}_0^2}, d_\infty(\cdot, \cdot))$ is separable and complete (see \cite{6} Example 1.2, p.9]). The distance in $\mathcal{Y} := C([0, T], \mathbb{R}^{\mathbb{Z}_0^2})$ is given by

$$d_\mathcal{Y}(w, \hat{w}) = \sup_{t \in [0, T]} d_\infty(w(t), \hat{w}(t)), \quad w, \hat{w} \in \mathcal{Y},$$

which makes $\mathcal{Y}$ a Polish space. Denote by $\mathcal{W}$ the law on $\mathcal{Y}$ of the sequence of independent Brownian motions $\{(W_t^k)_{0 \leq t \leq T} : k \in \mathbb{Z}_0^2\}$.

To simplify the notations, we write $W_t = (W_t)_{0 \leq t \leq T}$ for the whole sequence of processes $\{(W_t^k)_{0 \leq t \leq T} : k \in \mathbb{Z}_0^2\}$ in $\mathcal{Y}$. For any $N \geq 1$, denote by $P_N$ the joint law of $(\xi_N(\cdot), W_t)$ on

$$\mathcal{X} \times \mathcal{Y} = C([0, T]; H^1) \times C([0, T], \mathbb{R}^{\mathbb{Z}_0^2}).$$

Since the marginal laws $\{\tilde{\eta}_N\}_{N \in \mathbb{N}}$ and $\{W\}$ are respectively tight on $\mathcal{X}$ and $\mathcal{Y}$, we conclude that $\{P_N\}_{N \in \mathbb{N}}$ is tight on $\mathcal{X} \times \mathcal{Y}$. The Prohorov theorem (see \cite{6} Theorem 5.1, p.59]) implies that there exists a subsequence $\{N_i\}_{i \in \mathbb{N}}$ such that $P_{N_i}$ converge weakly as $i \to \infty$ to some probability measure $P$ on $\mathcal{X} \times \mathcal{Y}$. By Skorokhod’s representation theorem (\cite{6} Theorem 6.7, p.70]), there exist a probability space $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}})$, and stochastic processes $(\tilde{\xi}_N(\cdot), \tilde{W}_t)_{i \in \mathbb{N}}$ and $(\tilde{\xi}(\cdot), \tilde{W}_t)$ on this space with the corresponding laws $P_{N_i}$ and $P$ respectively, such that $(\tilde{\xi}_N(\cdot), \tilde{W}_t)$ converge $\tilde{\mathbb{P}}$-a.s. in $\mathcal{X} \times \mathcal{Y}$ to the limit $(\tilde{\xi}(\cdot), \tilde{W}_t)$. We are going to prove that $(\tilde{\xi}(\cdot), \tilde{W}_t)$ is a weak solution to the equation \text{(2.5)}.

Denote by $\tilde{u}_{N_i} = K \ast \tilde{\xi}_N$ and $\tilde{u} = K \ast \tilde{\xi}$ which are the velocity fields defined on the new probability space $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}})$. By the above discussions, we know that

$$\tilde{\mathbb{P}}\text{-a.s., } \tilde{\xi}_N(\cdot) \text{ converge strongly to } \tilde{\xi}(\cdot) \text{ in } C([0, T]; H^1),$$

which implies that

$$\tilde{\mathbb{P}}\text{-a.s., } \tilde{u}_{N_i}(\cdot) \text{ converge strongly to } \tilde{u}(\cdot) \text{ in } C([0, T]; H^1).$$

The new processes $\tilde{\xi}_N(\cdot)$ (resp. $\tilde{u}_{N_i}(\cdot)$) have the same law with $\xi_N(\cdot)$ (resp. $u_{N_i}(\cdot)$), and thus by Lemma \text{3.1} we have

$$\sup_{t \in [0, T]} \|\nabla \cdot \tilde{u}_{N_i}(t)\|_{L^2} = \sup_{t \in [0, T]} \|\tilde{\xi}_N(t)\|_{L^2} \leq \|\xi_0\|_{L^2} \quad \tilde{\mathbb{P}}\text{-a.s.} \quad(3.8)$$
Lemma 3.4. The process $\tilde{\xi}$ has $\tilde{\mathbb{P}}$-a.s. weakly continuous trajectories in $L^2$ and satisfies

$$\sup_{t \in [0,T]} \|\tilde{\xi}(t)\|_{L^2} \leq \|\xi_0\|_{L^2}$$  \hspace{1cm} (3.9)$$

Proof. Thanks to (3.8), there exists a set $\Gamma \subset \tilde{\Omega}$ of full measure such that, for every $\omega \in \Gamma$, (3.7) holds and

$$\sup_{i \geq 1} \sup_{t \in [0,T]} \|\tilde{\xi}_N(\omega, t)\|_{L^2} \leq \|\xi_0\|_{L^2}.$$  \hspace{1cm} (3.10)$$

Let us fix $\omega \in \Gamma$. Then by (3.10) the sequence $\{\tilde{\xi}_N(\omega, \cdot)\}_{i \geq 1}$ is bounded in $L^\infty(0, T; L^2)$ and so we can extract a subsequence (not relabelled for simplicity) which is weak-$*$ convergent. But weak-$*$ convergence in $L^\infty(0, T; L^2)$ implies weak-$*$ convergence in $L^\infty(0, T; H^-)$, which implies by (3.7) that the limit is necessarily $\tilde{\xi}$; therefore by properties of weak-$*$ convergence

$$\|\tilde{\xi}(\omega, \cdot)\|_{L^\infty(0, T; L^2)} \leq \liminf_N \|\tilde{\xi}_N(\omega, \cdot)\|_{L^\infty(0, T; L^2)} \leq \|\xi_0\|_{L^2}.$$$$

In particular, there exists a subset $S_{\omega} \subset [0, T]$ of full Lebesgue measure (thus dense) such that $\|\tilde{\xi}(\omega, s)\|_{L^2} \leq \|\xi_0\|_{L^2}$ for every $s \in S_{\omega}$. Now let $t \in [0, T] \setminus S_{\omega}$ and consider a sequence $t_n \to t$, $t_n \in S_{\omega}$. Then the sequence $\{\tilde{\xi}(\omega, t_n)\}_n$ is uniformly bounded in $L^2$ and we can therefore extract a weak-$*$ convergent subsequence; but $\tilde{\xi}(\omega, \cdot) \in C([0, T]; H^-)$, therefore $\tilde{\xi}(\omega, t_n) \to \tilde{\xi}(\omega, t)$ in $H^-$ and so the weak limit must be $\tilde{\xi}(\omega, t)$. By properties of weak convergence we have

$$\|\tilde{\xi}(\omega, t)\|_{L^2} \leq \liminf_n \|\tilde{\xi}(\omega, t_n)\|_{L^2} \leq \|\xi_0\|_{L^2}.$$$$

As the reasoning holds for any $t \in [0, T] \setminus S_{\omega}$, for any $\omega \in \Gamma$, we have obtained

$$\sup_{t \in [0,T]} \|\tilde{\xi}(\omega, t)\|_{L^2} \leq \|\xi_0\|_{L^2} \quad \forall \omega \in \Gamma,$$$$

namely (3.9). It remains to show that, for every $\omega \in \Gamma$, $t \mapsto \tilde{\xi}(\omega, t)$ is weakly continuous in $L^2$. Let $t_n \to t$, then by (3.9) the sequence $\{\tilde{\xi}(\omega, t_n)\}_n$ is bounded in $L^2$ and so it admits a weakly convergent subsequence. But $\tilde{\xi}(\omega, \cdot) \in C([0, T]; H^-)$, therefore the weak limit is necessarily $\tilde{\xi}(\omega, t)$; as the reasoning holds for any subsequence of $\{\tilde{\xi}(\omega, t_n)\}_n$, we deduce that the whole sequence is weakly converging to $\tilde{\xi}(\omega, t)$.

Finally we can give the

Proof of Theorem 2.2. The processes $(\tilde{\xi}_N(\cdot), \tilde{W}^N)$ on the new probability space $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}})$ have the same laws with that of $(\xi_N(\cdot), W)$, which satisfy the equation (3.2) with $N$ replaced by $N_i$. Some classical arguments show that the stochastic integrals involved below make sense, see e.g. [19 Section 2.6, p.89]. Therefore, for any $\phi \in C^\infty(\mathbb{T}^2)$, one has, $\tilde{\mathbb{P}}$-a.s for all $t \in [0, T]$,

$$\langle \tilde{\xi}_N(t), \phi \rangle = \langle \xi_N(0), \phi \rangle + \int_0^t \langle \tilde{\xi}_N(s), \bar{u}_N(s) \cdot \nabla \phi \rangle \, ds + \nu \int_0^t \langle \tilde{\xi}_N(s), \Delta \phi \rangle \, ds$$

$$- \varepsilon \sum_{k \in \mathbb{Z}^2} \theta_k \int_0^t \langle \tilde{\xi}_N(s), \sigma_k \cdot \nabla \phi \rangle \, d\tilde{W}^N_{s,k}. \hspace{1cm} (3.11)$$

We regard all the quantities as real valued stochastic processes. From the above discussions, we can prove that, as $i \to \infty$, all the terms of the first line converge in $L^1(\tilde{\Omega}, C([0, T], \mathbb{R}))$ to the corresponding ones. Indeed, considering $\langle \cdot, \cdot \rangle$ as the duality between distributions and
smooth functions, then (3.7) implies that, \( \tilde{P}\)-a.s., \( \langle \tilde{\xi}_N(\cdot), \phi \rangle \) converge in \( C([0, T], \mathbb{R}) \) to \( \langle \tilde{\xi}(\cdot), \phi \rangle \). Moreover, by (3.8),

\[
|\langle \tilde{\xi}_N(t), \phi \rangle| \leq \|\xi_0\|_{L^2} \|\phi\|_{L^2} \quad \tilde{P}\text{-a.s. for all } t \in [0, T].
\]

Thus the dominated convergence theorem implies the desired result. For the nonlinear term, we have

\[
E_{\tilde{P}} \left[ \sup_{t \in [0, T]} \left| \int_0^t \langle \tilde{\xi}_N(s), \tilde{u}_N(s) \cdot \nabla \phi \rangle \, ds - \int_0^t \langle \tilde{\xi}(s), \tilde{u}(s) \cdot \nabla \phi \rangle \, ds \right| \right] \\
\leq E_{\tilde{P}} \left[ \sup_{t \in [0, T]} \left| \int_0^t \langle \tilde{\xi}_N(s), \tilde{u}_N(s) \cdot \nabla \phi \rangle \, ds - \int_0^t \langle \tilde{\xi}_N(s), \tilde{u}(s) \cdot \nabla \phi \rangle \, ds \right| + E_{\tilde{P}} \left[ \sup_{t \in [0, T]} \left| \int_0^t \langle \tilde{\xi}(s), \tilde{u}(s) \cdot \nabla \phi \rangle \, ds - \int_0^t \langle \tilde{\xi}_N(s), \tilde{u}(s) \cdot \nabla \phi \rangle \, ds \right| \right].
\]

Thanks to (3.8) and (3.9), and the strong convergence of \( \tilde{u}_N \) to \( \tilde{u} \) in \( L^2(\tilde{\Omega}, L^2(0, T; H)) \), the first term on the right hand side vanishes as \( i \to \infty \). For the second term, by (3.7), the quantity in the square bracket tends to 0 \( \tilde{P}\)-a.s., which together with the bounds (3.8) and (3.9), the dominated convergence theorem leads to the desired result.

It remains to show the convergence of the stochastic integrals. Fix any \( M \in \mathbb{N} \); we have

\[
E_{\tilde{P}} \left[ \sup_{t \in [0, T]} \left| \sum_{|k| \leq M} \theta_k \int_0^t \langle \tilde{\xi}_N(s), \sigma_k \cdot \nabla \phi \rangle \, d\tilde{W}^{N,k}_s - \sum_{|k| \leq M} \theta_k \int_0^t \langle \tilde{\xi}(s), \sigma_k \cdot \nabla \phi \rangle \, d\tilde{W}_s^{N,k} \right| \right] \\
\leq E_{\tilde{P}} \left[ \sup_{t \in [0, T]} \left| \sum_{|k| \leq M} \theta_k \left( \int_0^t \langle \tilde{\xi}_N(s), \sigma_k \cdot \nabla \phi \rangle \, d\tilde{W}^{N,k}_s - \int_0^t \langle \tilde{\xi}(s), \sigma_k \cdot \nabla \phi \rangle \, d\tilde{W}_s^{N,k} \right) \right| \right] \\
+ E_{\tilde{P}} \left[ \sup_{t \in [0, T]} \left| \sum_{|k| > M} \theta_k \int_0^t \langle \tilde{\xi}_N(s), \sigma_k \cdot \nabla \phi \rangle \, d\tilde{W}_s^{N,k} \right| \right] \\
+ E_{\tilde{P}} \left[ \sup_{t \in [0, T]} \left| \sum_{|k| > M} \theta_k \int_0^t \langle \tilde{\xi}(s), \sigma_k \cdot \nabla \phi \rangle \, d\tilde{W}_s^{N,k} \right| \right].
\]

We denote the three expectations on the right hand side by \( J_{N_i}^{(n)}, n = 1, 2, 3 \). First,

\[
|J_{N_i}^{(2)}| \leq C E_{\tilde{P}} \left[ \left( \sum_{|k| > M} \theta_k^2 \int_0^T \langle \tilde{\xi}_N(s), \sigma_k \cdot \nabla \phi \rangle^2 \, ds \right)^{1/2} \right] \\
\leq C \|\theta\|_{L^\infty_{>M}} \mathbb{E}_{\tilde{P}} \left[ \left( \sum_{|k| > M} \int_0^T \langle \tilde{\xi}_N(s)\nabla \phi, \sigma_k \rangle^2 \, ds \right)^{1/2} \right] \\
\leq C \|\theta\|_{L^\infty_{>M}} T^{1/2} \|\xi_0\|_{L^2} \|\nabla \phi\|_{\infty},
\]

where \( \|\theta\|_{L^\infty_{>M}} = \sup_{|k| > M} |\theta_k| \) tends to 0 as \( M \to \infty \). Similar estimate holds for \( J_{N_i}^{(3)} \) by Lemma 3.7.4

Finally, we deal with \( J_{N_i}^{(1)} \) for which we need Skorohod’s result for convergence of stochastic integrals, see for instance [17] Lemma 5.2 and [22] Lemma 3.2 for a slightly more general version. By the discussions above Lemma 3.7.4 we known that as \( i \to \infty \), \( \tilde{P}\)-a.s. for all
\begin{align*}
s \in [0,T], \langle \tilde{\xi}_N(s), \sigma_k \cdot \nabla \phi \rangle & \to \langle \tilde{\xi}(s), \sigma_k \cdot \nabla \phi \rangle \quad \text{and} \quad \tilde{W}^{N_i,k} \to \tilde{W}^k. \quad \text{Since there are only finitely many stochastic integrals, by } [22 \text{ Lemma 3.2}], \text{ it is sufficient to show that, for any } |k| \leq M, \\
\left( E_{\tilde{P}} \int_0^T \langle \tilde{\xi}(s), \sigma_k \cdot \nabla \phi \rangle^4 \, ds \right) \vee \left( \sup_{i \geq 1} E_{\tilde{P}} \int_0^T \langle \tilde{\xi}_N(s), \sigma_k \cdot \nabla \phi \rangle^4 \, ds \right) & < +\infty.
\end{align*}

Indeed, by Lemma 3.3
\begin{align*}
E_{\tilde{P}} \int_0^T \langle \tilde{\xi}(s), \sigma_k \cdot \nabla \phi \rangle^4 \, ds & \leq E_{\tilde{P}} \int_0^T \| \tilde{\xi}(s) \|_{L^2}^4 \| \sigma_k \cdot \nabla \phi \|_{L^2}^4 \, ds \\
& \leq T \| \xi_0 \|_{L^2}^4 \| \nabla \phi \|_{L^\infty}^4.
\end{align*}

Analogous uniform estimate holds for the second part. Therefore we obtain \( \lim_{i \to \infty} J^{(1)}_{N_i} = 0. \)

First letting \( i \to \infty \) and then \( M \to \infty \) in (3.12), we have proved the convergence of stochastic integrals.

Therefore, letting \( i \to \infty \) in (3.11), we obtain, \( \tilde{P}\)-a.s. for all \( t \in [0,T] \),
\begin{align*}
\langle \tilde{\xi}(t), \phi \rangle & = \langle \xi(0), \phi \rangle + \int_0^t \langle \tilde{\xi}(s), \tilde{u}(s) \cdot \nabla \phi \rangle \, ds + \nu \int_0^t \langle \tilde{\xi}(s), \Delta \phi \rangle \, ds \\
& \quad - \epsilon \sum_{k \in \mathbb{Z}_0^2} \int_0^t \langle \tilde{\xi}(s), \sigma_k \cdot \nabla \phi \rangle \, d\tilde{W}^k.
\end{align*}

This completes the proof. \( \square \)

4 Convergence to 2D Navier–Stokes equations

In this section we show that the solutions to (2.7) converge weakly to the unique solution of the deterministic 2D Navier–Stokes equations.

Let us briefly recall the setting: we fix \( \xi_0 \in L^2 \) and \( \nu > 0 \), we consider a sequence \( \{ \theta^N \}_{N \geq 1} \) satisfying (1.3) and (1.4), and define \( \epsilon_N \) by (1.5). For each \( N \), we consider a weak solution \( \xi^N \) of (2.7) with initial data \( \xi_0 \) satisfying (2.6), whose existence is granted by Theorem 2.2. Since we are dealing with weak solutions, the processes \( \xi^N \) might be defined on different probability space; however, for the sake of simplicity, in the following we do not distinguish the notation \( E, \mathbb{P}, \Omega, \) etc.

Let us immediately remark that conditions (1.4) and (1.5) together imply
\[
\lim_{N \to \infty} \epsilon_N \| \theta^N \|_{L^\infty} = 0,
\]
therefore the sequence \( \{ \epsilon_N \| \theta^N \|_{L^\infty} \}_{N \geq 1} \) is bounded by a suitable constant.

Let \( Q^N \) denote the law of \( \xi^N \); we are going to show that the sequence \( \{ Q^N \}_{N \geq 1} \) is tight in \( L^2(0,T; H^{-1}) \). To this end, let us recall the following Aubin–Lions theorem (see [21 Theorem 5.2, p.61]).

**Theorem 4.1** (Aubin–Lions). Let \( \alpha \in (0,1/2) \) and \( \beta > 0 \). Then
\[
L^2(0,T; L^2) \cap W^{\alpha,2}(0,T; H^{-1-\beta}) \subset L^2(0,T; H^{-1})
\]
with compact inclusion.
To show the tightness of \( \{ Q^N \}_{N \geq 1} \) in \( L^2(0, T; H^{-1}) \), by the Aubin–Lions theorem and the estimate (2.6), it is enough to show that
\[
\sup_{N \geq 1} \mathbb{E} \int_0^T \int_0^T \left\| \xi_t^N - \xi_s^N \right\|^2_{H^{-1-\beta}} |t - s|^{1+2\alpha} \, dt \, ds < \infty.
\]
To this aim, it suffices to obtain estimates similar to those of Lemma 3.3, taking care that all the constants involved do not depend on \( \theta^N \) nor \( \varepsilon_N \).

**Lemma 4.2.** There is a constant \( C > 0 \) such that for any \( N \geq 1 \), \( 0 \leq s < t \leq T \),
\[
\mathbb{E}(\langle \xi_t^N - \xi_s^N, e_k \rangle^2) \leq C|k|^4|t - s| \quad \text{for all } k \in \mathbb{Z}_0^2.
\]

**Proof.** For any fixed \( k \), since \( \xi^N \) is a solution of (2.7), it holds
\[
\langle \xi_t^N - \xi_s^N, e_k \rangle = \int_s^t \langle \xi_r^N, u_r^N \cdot \nabla e_k \rangle \, dr + \nu \int_s^t \langle \xi_r^N, \Delta e_k \rangle \, dr - \varepsilon_N \sum_{l \in \mathbb{Z}_0^2} \theta_l^N \int_s^t \langle \xi_r^N, \sigma_l \cdot \nabla e_k \rangle \, dW_r^l
\]
and therefore
\[
\mathbb{E}(\langle \xi_t^N - \xi_s^N, e_k \rangle^2) \leq 3 \left( \mathbb{E}\left| \int_s^t \langle \xi_r^N, u_r^N \cdot \nabla e_k \rangle \, dr \right|^2 + \nu^2 \mathbb{E}\left| \int_s^t \langle \xi_r^N, \Delta e_k \rangle \, dr \right|^2 + \varepsilon_N^2 \mathbb{E}\left| \sum_{l \in \mathbb{Z}_0^2} \theta_l^N \int_s^t \langle \xi_r^N, \sigma_l \cdot \nabla e_k \rangle \, dW_r^l \right|^2 \right).
\]
Since \( \|\nabla e_k\|_{L^\infty} = 2\sqrt{2}\pi|k| \), the first term on the right hand side can be estimated by
\[
\mathbb{E}\left| \int_s^t \langle \xi_r^N, u_r^N \cdot \nabla e_k \rangle \, dr \right|^2 \leq |t - s| \mathbb{E}(\langle \xi_t^N, u_t^N \cdot \nabla e_k \rangle^2) \leq 8\pi^2|k|^2|t - s| \mathbb{E}(\|\xi_t^N\|^2_{L^2} \|u_t^N\|^2_{L^2}) \leq 8\pi^2|k|^2\|\xi_0\|^4_{L^2}|t - s|^2.
\]
Using the fact that \( \Delta e_k = -4\pi^2|k|^2 e_k \), the second term can be similarly estimated by
\[
\mathbb{E}\left| \int_s^t \langle \xi_r^N, \Delta e_k \rangle \, dr \right|^2 \leq 32\pi^4|k|^4\|\xi_0\|^2_{L^2}|t - s|^2.
\]
Finally, for the last term, by the Itô isometry,
\[
\varepsilon_N^2 \mathbb{E}\left| \sum_{k \in \mathbb{Z}_0^2} \theta_k^N \int_s^t \langle \xi_r^N, \sigma_k \cdot \nabla e_k \rangle \, dW_r^k \right|^2 = \varepsilon_N^4 \mathbb{E}\left\| \sum_{k \in \mathbb{Z}_0^2} \theta_k^N \int_s^t \langle \xi_r^N, \sigma_k \cdot \nabla e_k \rangle \, dW_r^k \right\|^2 \leq \varepsilon_N^2 \left\| \theta^N \right\|^2_{\ell^\infty}\int_s^t \mathbb{E}\left| \sum_{k \in \mathbb{Z}_0^2} \langle \xi_r^N, \sigma_k \cdot \nabla e_k \rangle \right|^2 \, dr \leq C \int_s^t \mathbb{E}(\|\xi_r^N \nabla e_k\|^2_{L^2}) \, dr \leq 8\pi^2|k|^2C \|\xi_0\|^2_{L^2}|t - s|.
\]
Combining all the estimates we obtain the conclusion. \( \square \)
From Lemma 4.2 we deduce the following:

**Lemma 4.3.** The family \( \{Q^N\}_{N \geq 1} \) is tight in \( L^2(0, T; H^{-1}) \).

**Proof.** It holds

\[
E\left( \left\| \xi_t^N - \xi_s^N \right\|^2_{H^{-\beta-1}} \right) = \sum_{k \in \mathbb{Z}_0^2} \frac{1}{|k|^{2\beta+2}} E\left( \left( \xi_t^N - \xi_s^N, \epsilon_k \right)^2 \right) \leq C|t-s| \sum_{k \in \mathbb{Z}_0^2} \frac{1}{|k|^{2\beta-2}} \leq C'|t-s|
\]

for \( \beta > 2 \); for such choice of \( \beta \),

\[
E \int_0^T \int_0^T \frac{\left\| \xi_t^N - \xi_s^N \right\|^2_{H^{-\beta-1}}}{|t-s|^{1+2\alpha}} \, dt \, ds \leq C' \int_0^T \int_0^T \frac{ds}{|t-s|^{2\alpha}} < \infty
\]

for any \( \alpha < 1/2 \). Therefore Aubin–Lions theorem can be applied and the conclusion follows. \( \Box \)

**Remark 4.4.** Sharper estimates allow us to show that, similarly to Section 3, the sequence \( \{Q^N\}_{N \geq 1} \) is tight in \( C([0, T]; H^{-}) \). This fact will be used in Section 6. We omit the proof here since it is the same as those in Section 3.

By estimate (2.6) we know that, for all \( N \), almost every realization of \( \xi^N \) satisfies

\[
\int_0^T \left\| \xi_t^N \right\|^2_{L^2} \, dt \leq T\left\| \xi_0^N \right\|^2_{L^2}.
\]

In particular, if we fix a radius \( R \geq \sqrt{T}\left\| \xi_0 \right\|_{L^2} \) and consider the space

\[
L^2_{R,w} = \{ f \in L^2(0, T; H) : \|f\|_{L^2(0, T; H)} \leq R \}
\]

endowed with the weak topology, then it is a metrizable, compact space (see for instance [7]); we can regard \( \{\xi^N\}_{N \geq 1} \) as random variables taking values in \( L^2_{R,w} \) and so by compactness their laws form a tight sequence in such space. Together with Lemma 4.3 this implies tightness of \( \{Q^N\}_{N \geq 1} \) in \( L^2(0, T; H^{-1}) \cap L^2_{R,w} \).

Before giving the proof of the second part of Theorem 2.3 we need the following lemma.

**Lemma 4.5.** For any \( \phi \in C^\infty(\mathbb{T}^2) \), consider the map

\[
F_\phi(f) = \langle f, \phi \rangle - \langle \xi_0, \phi \rangle - \int_0^T \langle (K * f_s) \cdot \nabla \phi, f_s \rangle \, ds - \nu \int_0^T \langle f_s, \Delta \phi \rangle \, ds.
\]

Then \( F_\phi \) is a continuous bounded map from \( L^2(0, T; H^{-1}) \cap L^2_{R,w} \) into \( L^2(0, T; \mathbb{R}) \).

**Proof.** Let us show boundedness first. We have

\[
|F_\phi(f)| \leq \|f_t\|_{L^2} \|\phi\|_{L^2} + \|\xi_0\|_{L^2} \|\phi\|_{L^2} + \int_0^T \| (K * f_s) \cdot \nabla \phi, f_s \| \, ds + \nu \int_0^T \| f_s, \Delta \phi \| \, ds
\]

\[
\leq \|f_t\|_{L^2} \|\phi\|_{L^2} + \|\xi_0\|_{L^2} \|\phi\|_{L^2} + \|\nabla \phi\|_{L^\infty} \int_0^T \|f_s\|_{L^2}^2 \, ds + \nu \|\Delta \phi\|_{L^\infty} \int_0^T \|f_s\|_{L^2}^2 \, ds
\]

\[
\leq \|\phi\|_{C^2} \left( \|f_t\|_{L^2} + \|\xi_0\|_{L^2} + C_{R,T} \right),
\]

where we used the fact that \( f \in L^2_{w,R} \) and \( C_{R,T} \) is a constant depending on \( R \) and \( T \). Therefore

\[
\|F_\phi(f)\|_{L^2(0, T; \mathbb{R})} \leq \|\phi\|_{C^2} \left( \|f\|_{L^2(0, T; L^2)} + \|\xi_0\|_{L^2} + C_{R,T} \right) \leq \|\phi\|_{C^2} \left( \|\xi_0\|_{L^2} + C'_{R,T} \right).
\]
Regarding continuity: let \( f^n \) be a sequence converging to \( f \) in \( L^2(0, T; H^{-1}) \cap L^2_{R_w} \), namely \( f^n \to f \) strongly in \( L^2(0, T; H^{-1}) \) and weakly in \( L^2(0, T; L^2) \). Strong convergence in \( L^2(0, T; H^{-1}) \) implies convergence of \( \langle f^n, \phi \rangle \) to \( \langle f, \phi \rangle \) in \( L^2(0, T) \), similarly for \( \int_0^T \langle f^n, \Delta \phi \rangle \, ds \) to \( \int_0^T \langle f, \Delta \phi \rangle \, ds \); so we only need to check convergence of the nonlinear term. By properties of the Biot–Savart kernel, \( K \ast f^n \to K \ast f \) strongly in \( L^2(0, T; L^2) \); combining the strong convergence of \( K \ast f^n \) and the weak convergence of \( f^n \) we obtain, that for any \( t \in (0, T) \),

\[
\int_0^t \langle (K \ast f^n) \cdot \nabla \phi, f^n \rangle \, ds \to \int_0^t \langle (K \ast f) \cdot \nabla \phi, f \rangle \, ds.
\]

Therefore pointwise convergence holds; the previous estimates also show uniform boundedness of the integral processes, therefore by dominated convergence we obtain the conclusion. \( \square \)

Finally we can complete the

**Proof of Theorem 2.3.** The fact that \( \xi^N \) are solutions of (2.7) may be formulated as follows: for every \( \phi \in C^\infty(\mathbb{T}^2) \), the equality \( F_\phi(\xi^N) = M_\phi^N \), holds, where \( F_\phi \) is defined as in Lemma 4.5 and \( M_\phi^N \) is the process given by

\[
M_\phi^N = -\varepsilon_N \sum_{k \in \mathbb{Z}_0^2} \theta_k^N \int_0^t \langle \xi^N_s, \sigma_k \cdot \nabla \phi \rangle \, dW_s^k.
\]

The sequence \( \{Q^N\}_{N \geq 1} \) is tight in \( L^2(0, T; H^{-1}) \cap L^2_{R_w} \), therefore by Prohorov theorem we can extract a subsequence (not relabelled for simplicity) which is weakly converging to the law \( Q \) of some \( L^2(0, T; H^{-1}) \cap L^2_{R_w} \)-valued random variable \( \xi \). By Lemma 4.5 \( F_\phi \) is a continuous and bounded map, therefore by properties of convergence in law \( F_\phi(\xi^N) \) are also converging in distribution to \( F_\phi(\xi) \); in particular this implies that \( M_\phi^N \) are also converging to some limit. On the other side, by Itô’s isometry we have

\[
\mathbb{E} \int_0^T |M_\phi^N(t)|^2 \, dt = \varepsilon_N^2 \int_0^T \mathbb{E} \int_0^t \sum_{k \in \mathbb{Z}_0^2} (\theta_k^N)^2 \langle \xi^N_s, \sigma_k \cdot \nabla \phi \rangle^2 \, ds \, dt
\]

\[\leq T \varepsilon_N^2 \|\theta^N\|_{L^\infty}^2 \int_0^T \sum_{k \in \mathbb{Z}_0^2} \langle \xi^N_s \nabla \phi, \sigma_k \rangle^2 \, ds\]

\[\leq T \varepsilon_N^2 \|\theta^N\|_{L^\infty}^2 \int_0^T \mathbb{E} \left( \|\xi^N_s \nabla \phi\|_{L^2}^2 \right) \, ds\]

\[\leq T^2 \|\xi_0\|_{L^2}^2 \|\nabla \phi\|_{L^2}^2 \varepsilon_N^2 \|\theta^N\|_{L^\infty}^2 \to 0 \quad \text{as } N \to \infty\]

which implies that \( M_\phi^N \) is converging in law to 0; therefore \( F_\phi(\xi) = 0 \), up to a \( Q \)-negligible set. Given a countable dense set \( \{\phi_n\}_n \), we can deduce that the support of \( Q \) satisfies \( F_{\phi_n}(\xi) = 0 \) for all \( n \). This, together with its \( L^2 \)-boundedness, implies that \( F_\phi(\xi) = 0 \) for all \( \phi \). Namely, the support of \( Q \) is made of solutions of the deterministic 2D Navier–Stokes equation (1.7) starting at \( \xi_0 \); therefore by uniqueness \( Q \) is given by \( \delta_\xi \), where \( \xi \) is such unique solution. As the reasoning applies to any subsequence of \( \{Q^N\}_{N \geq 1} \), we deduce convergence in law of the whole sequence to \( \delta_\xi \). \( \square \)

As a consequence of Theorem 2.3 we deduce convergence of the passive scalars advected by \( u^N \) to those advected by \( u \), where as usual \( u^N \) and \( u \) denote the velocity fields associated to \( \xi^N \) and \( \xi \). To state the result, we assume for simplicity the sequence \( u^N \) to be defined on the
same filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, \mathbb{P})$ and such that $u^N(\omega) \to u$ in $L^2(0, T; L^2)$ for every $\omega \in \Gamma$, a set of full probability; this comes without loss of generality by applying Skorokhod’s theorem. For a given $\rho_0 \in L^p(\mathbb{T}^2)$, $p \in (1, \infty)$, we denote by $\rho^N$ the passive scalar advected by $u^N$ with initial configuration $\rho_0$, i.e. the solution of

\[
\begin{align*}
\partial_t \rho^N + u^N \cdot \nabla \rho^N &= 0, \\
\rho^N(0) &= \rho_0;
\end{align*}
\]  

(4.2)
similarly for $\rho$ and $u$. By [13], we can take $\Gamma$ such that $\sup_{N \geq 1} \|u^N(\omega)\|_{L^\infty(0, T; H^1)} \leq \|\xi_0\|_{L^2}$ for every $\omega \in \Gamma$ and thus, by the DiPerna–Lions theory, equation (4.2) admits a unique weak solution, which belongs to $C([0, T]; L^p)$; similarly for $\rho$. We have the following

**Corollary 4.6.** For any $\omega \in \Gamma$, any $p \in (1, +\infty)$ and any $\rho_0 \in L^p$, $\rho^N(\omega) \to \rho$ in $C([0, T]; L^p)$.

**Proof.** It follows immediately from [13] Theorem II.5, p. 527].

## 5 Convergence of finite dimensional approximations

The setting of this section is the same as Section 4 in terms of $\xi_0$, $\nu$, $\{\theta^N\}_N$ and $\varepsilon_N$. However, for any $N$ we now consider $\xi^N$ to be an $H_N$-valued solution of the following SDE:

\[
d\xi^N = -b_N(\xi^N) \, dt + \varepsilon_N \sum_{k \in \mathbb{Z}_N^d} \theta^N_k G^N_k(\xi^N) \circ dW^k, \quad \xi^N_0 = \Pi_N \xi_0,
\]

(5.1)

where the vector fields $b_N$ and $G^N_k$ are defined at the beginning of Section 3. Recall that $G^N_k(\xi^N) = 0$ whenever $|k| > 2N$, thus the series appearing on the right hand side is finite. We are interested in determining conditions on $\{\theta^N\}_N$ under which $\xi^N$ converge in law to the unique solution of (1.7). Different finite dimensional schemes, like (3.2), can also be considered; here we use (5.1) in order to show that the method is fairly robust and does not depend directly on the nature of the system, (3.2) being dissipative while (5.1) being conservative. The additional difficulty with respect to the previous sections is that the Itô–Stratonovich corrector is not exactly $\nu \Delta \xi$, but is dependent of the finite-dimensional approximation, therefore we need to take care of its convergence in the limit.

**Lemma 5.1.** Equation (5.1) admits a unique strong solution $\xi^N$, satisfying

\[
\mathbb{P}(\|\xi^N_t\|_{L^2} = \|\xi^N_0\|_{L^2} \text{ for all } t \in [0, T]) = 1.
\]

(5.2)

**Proof.** All vector fields in (5.1) are smooth and $H_N$ is finite dimensional, so local existence and uniqueness follows. By Stratonovich chain rule,

\[
d\left(\frac{1}{2}\|\xi^N\|_{L^2}^2\right) = \langle \xi^N, d\xi^N \rangle = -\langle b_N(\xi^N), \xi^N \rangle \, dt + \varepsilon_N \sum_{k \in \mathbb{Z}_N^d} \theta^N_k \langle G^N_k(\xi^N), \xi^N \rangle \circ dW^k = 0
\]

where the last equality follows from (3.11). This shows that $\|\cdot\|_{L^2}$ is invariant and implies global existence as well as the last statement. 

Before deriving the corresponding weak Itô formulation of equation (5.1), we need to introduce some notation. Recall that $\Pi_N$ is the orthogonal projection on $H_N$; with a slight abuse
we identify it with the associated convolution kernel: \(\Pi_N \xi = \Pi_N * \xi\). We denote the scalar product between matrices by \(A : B = \text{Tr}(A^T B)\). For fixed \(N\), let us define

\[
A_N(x, y) := \sum_{k \in \mathbb{Z}^2} (\theta_k^N)^2 \sigma_k(x) \otimes \sigma_k(y),
\]

which is the covariance operator associated to the noise

\[
W_N(t, x) = \sum_{k \in \mathbb{Z}^2} \theta_k^N \sigma_k(x) W^k(t).
\]

It is easy to check that \(A_N\) is homogeneous and it holds

\[
A_N(x, y) = A_N(x - y) = \sqrt{2} \sum_{k \in \mathbb{Z}^2} (\theta_k^N)^2 \frac{k^+ \otimes k^+}{|k|^2} e_k(x - y);
\]

in particular, identity (2.3) can be rewritten as

\[
A_N(x, x) = A_N(0) = \frac{1}{2} \|\theta^N\|^2 \mathbf{I}_2.
\]

Moreover, \(A_N\) has Fourier transform given by

\[
\hat{A}_N(k) = \sqrt{2} (\theta_k^N)^2 \frac{k^+ \otimes k^+}{|k|^2} 1_{\{k \in \mathbb{Z}^2\}},
\]

which implies

\[
\|\hat{A}_N\|_{\ell^1} = \sqrt{2} \sum_{k \in \mathbb{Z}^2} (\theta_k^N)^2 = \frac{\sqrt{2}}{2} \|\theta^N\|_{\ell^2}.
\]

We can now prove the following

**Lemma 5.2.** \(\xi^N\) is a solution of (5.1) if and only if \(\xi^N(0) = \Pi_N \xi_0\) and for any \(\phi \in H_N\),

\[
d\langle \xi^N, \phi \rangle = \langle (K * \xi^N) \cdot \nabla \phi, \xi^N \rangle dt - \varepsilon_N \sum_{k \in \mathbb{Z}^2} \theta_k^N \langle \sigma_k \cdot \nabla \phi, \xi^N \rangle dW^k + \frac{\varepsilon_N^2}{2} \langle C_N \phi, \xi^N \rangle dt,
\]

where the operator \(C_N\) is given by

\[
C_N \phi(x) = (\Pi_N A_N) \ast \nabla^2 \phi(x) = \int_{\mathbb{T}^2} \Pi_N(x - y) A_N(x - y) : \nabla^2 \phi(y) dy
\]

and satisfies

\[
\|C_N \phi\|_{L^2} \leq \|\theta^N\|_{\ell^2} \|\nabla^2 \phi\|_{L^2}.
\]

**Proof.** It is clear that \(\xi^N\) is a solution of (5.1) if and only if, for any \(\phi \in H_N\), it holds

\[
d\langle \xi^N, \phi \rangle = -\langle b_N(\xi^N), \phi \rangle dt + \varepsilon_N \sum_{k \in \mathbb{Z}^2} \theta_k^N \langle G_k^N(\xi^N), \phi \rangle \circ dW^k.
\]

Integration by parts and properties of the Stratonovich integral then yield

\[
d\langle \xi^N, \phi \rangle = \langle (K * \xi^N) \cdot \nabla \phi, \xi^N \rangle dt - \varepsilon_N \sum_{k \in \mathbb{Z}^2} \theta_k^N \langle \Pi_N(\sigma_k \cdot \nabla \phi), \xi^N \rangle \circ dW^k
\]

\[
= \langle (K * \xi^N) \cdot \nabla \phi, \xi^N \rangle dt - \varepsilon_N \sum_{k \in \mathbb{Z}^2} \theta_k^N \langle \sigma_k \cdot \nabla \phi, \xi^N \rangle dW^k + \frac{\varepsilon_N^2}{2} \langle C_N \phi, \xi^N \rangle dt,
\]

\[17\]
where $C_N$ is given by
\[ C_N \phi = \sum_{k \in \mathbb{Z}_0^2} (\theta_k^N)^2 \sigma_k \cdot \nabla(\Pi_N(\sigma_k \cdot \nabla \phi)). \]

Recall that for fixed $N$, the sum over $k$ has a finite amount of non zero terms, so all the above calculations (and the following) are rigorous. It remains to compute $C_N$ explicitly; using the fact that $\Pi_N$ and $\nabla$ commute, we have
\[ C_N \phi(x) = \sum_{k \in \mathbb{Z}_0^2} (\theta_k^N)^2 \sigma_k(x) \cdot \Pi_N(\nabla(\sigma_k \cdot \nabla \phi))(x) \]
\[ = \sum_{k \in \mathbb{Z}_0^2} (\theta_k^N)^2 \int_{T^2} \Pi_N(x - y) \sigma_k(x) \cdot \nabla(\sigma_k \cdot \nabla \phi)(y) \, dy. \]

Note that $\sigma_k(x) \cdot \nabla \sigma_k(y) = 0$ for all $k$, $x$ and $y$, thus by (5.3),
\[ C_N \phi(x) = \sum_{k \in \mathbb{Z}_0^2} (\theta_k^N)^2 \int_{T^2} \Pi_N(x - y) \sigma_k(x) \otimes \sigma_k(y) : \nabla^2 \phi(y) \, dy \]
\[ = \int_{T^2} \Pi_N(x - y) A_N(x - y) : \nabla^2 \phi(y) \, dy. \]

Finally, by Parseval identity and Young inequality we have
\[ \|C_N \phi\|_{L^2} = \|\Pi_N A_N \ast \nabla^2 \phi\|_{L^2} \leq \|\Pi_N \ast \hat{A}_N\|_{\ell^2} \|\nabla^2 \phi\|_{\ell^2} \]
\[ \leq \|\Pi_N\|_{\ell^\infty} \|\hat{A}_N\|_{\ell^1} \|\nabla^2 \phi\|_{L^2} \leq \|\theta^N\|_{\ell^2} \|\nabla^2 \phi\|_{L^2}. \]

We have only shown that the Stratonovich formulation implies the corresponding Itô one, but all calculations done backwards provide the converse implication. \qed

It follows from Lemma 5.2 and our choice (1.5) of $\varepsilon_N$ that for any $\phi \in H_N$ it holds
\[ \frac{\varepsilon_N^2}{2}\|C_N \phi\|_{L^2} \leq 2\nu\|\nabla^2 \phi\|_{L^2}. \tag{5.5} \]

This allows to control the correctors $C_N$ when taking the limit as $N \to \infty$. Let $Q^N$ denote the law of $\xi^N$, then we can prove the following:

**Lemma 5.3.** The family $\{Q^N\}_N$ is tight in $C([0, T]; H^-(T^2))$.

**Proof.** We only sketch the proof briefly since most of the calculations are identical to those of Section 3. Indeed by the energy equality (5.2) and Theorem 5.2 we only need to show that there exists a constant $C$ such that, for any $N \geq 1$,
\[ \mathbb{E}(\langle \xi^N_t - \xi^N_s, e_k \rangle^4) \leq C|k|^8 |t - s|^2 \quad \text{for all} \; k \in \mathbb{Z}_0^2, \]
again, we only need to show the estimate for $|k| \leq N$ and by Lemma 5.2 it holds
\[ \langle \xi^N_t - \xi^N_s, e_k \rangle = \int_s^t \langle (K \ast \xi^N_r) \cdot \nabla e_k, \xi^N_r \rangle \, dr + \frac{\varepsilon_N^2}{2} \int_s^t \langle C_N e_k, \xi^N_r \rangle \, dr \]
\[ - \varepsilon_N \sum_{k \in \mathbb{Z}_0^2} \theta_k^N \int_s^t \langle \sigma_k \cdot \nabla e_k, \xi^N_r \rangle \, dW^k_r. \]
This shows that, under condition (2.9), claim (5.6) holds and the conclusion follows.

Let \( \Pi^\perp \) be the orthogonal projection on \( \mathcal{H}_N \) identified with the associated convolution kernel. In this way, \( \Pi^\perp \) is a sequence of linear operators on \( L^2 \) and the stochastic integral can be treated in the same way as in Section 2. The only term which requires a different analysis is the convergence in a suitable sense of the corrector \( \varepsilon_N^2 C_N / 2 \) to \( \nu \Delta \). In particular, given a countable dense set \( \{ \phi_n \} \), it suffices to show that, for all \( n \),

\[
\frac{\varepsilon_N^2}{2} C_N \phi_n \rightarrow \nu \Delta \phi_n \quad \text{in } L^2,
\]

as this implies that, for all \( n \),

\[
\frac{\varepsilon_N^2}{2} \int_0^t \langle C_N \phi_n, \xi^N_s \rangle \, ds \rightarrow \nu \int_0^t \langle \Delta \phi_n, \xi^N_s \rangle \, ds \quad \text{in law}.
\]

Let \( \Pi_N^+ \) denote the orthogonal projection on \( H_N^+ \), which, with a slight abuse of notation, is identified with the associated convolution kernel. In this way, \( \Pi_N + \Pi_N^+ = I \) in the sense of linear operators on \( L^2 \) and \( \Pi_N + \Pi_N^+ = \delta \) in the sense of convolution with a distribution. Then for any fixed \( N \) and any \( \phi \) smooth, by (5.4), it holds

\[
\nu \Delta \phi(x) = \frac{\varepsilon_N^2}{2} \int_{T^2} A_N(x - y) : \nabla^2 \phi(y) \, \delta(dy)
\]

\[
= \frac{\varepsilon_N^2}{2} \left[ \int_{T^2} \Pi_N(x - y) A_N(x - y) : \nabla^2 \phi(y) \, dy + \int_{T^2} \Pi_N^+(x - y) A_N(x - y) : \nabla^2 \phi(y) \, dy \right]
\]

\[
= : \frac{\varepsilon_N^2}{2} C_N \phi + \frac{\varepsilon_N^2}{2} C_N^+ \phi.
\]

Assertion (5.7) then is equivalent to showing that, for all \( n \), \( \varepsilon_N^2 C_N^+ \phi_n \rightarrow 0 \) as \( N \rightarrow \infty \). We can take the collection \( \{ \phi_n \} \) to be finite linear combinations of \( e^{-i2\pi j \cdot x} \), \( j \in \mathbb{Z}_0^2 \). In this case, it is enough to prove that, for any \( j \in \mathbb{Z}_0^2 \), \( \varepsilon_N^2 C_N e^{-i2\pi j \cdot x} \rightarrow 0 \) as \( N \rightarrow \infty \). We have

\[
\varepsilon_N^2 \| C_N e^{-i2\pi j \cdot x} \|_{L^2} = 4\pi^2 \varepsilon_N^2 \left| \int \overline{A_N \Pi_N^+(j) : (j \otimes j)} \right| \leq K |j|^2 \| \theta_N^N \|_2^{-2} \sum_{k:|k-j|>N} (\theta_k^N)^2.
\]

This shows that, under condition (2.9), claim (5.6) holds and the conclusion follows.
Remark 5.4. In this case the tightness of \( \{Q^N\}_N \) in \( C([0,T];H^-) \) is optimal, in the sense that it is not possible to prove tightness in \( C([0,T];L^2) \). Indeed, if this were true, since the sequence \( \xi^N \) satisfies (5.2), the same should hold for the limit \( \xi \), namely \( \|\xi_t\|_{L^2} \) being constant; but we know that \( \xi \) is a solution of Navier–Stokes equation, which is dissipative.

6 Consequences of the scaling limit

In this section we discuss some implications of our scaling limit on the stochastic 2D Euler equations (2.7), including the approximate weak uniqueness, the existence of recovery sequences for Euler equations and a “weak quenched mixing property” of the weak solutions. We also give a discussion on possible dissipation of enstrophy in Section 6.4.

6.1 Approximate uniqueness

Uniqueness of solutions for 2D Euler equations when vorticity is in \( L^2 \) is a famous open problem. In view of certain regularization by noise results, where uniqueness is restored by a suitable noise, it is natural to ask whether a suitable noise may provide uniqueness, at least in law, for the solution of the corresponding stochastic 2D Euler equations with vorticity in \( L^2 \). We cannot prove such a strong result but we identify a new kind of property which we may call “approximate uniqueness” in law. The precise statement is given in Corollary 6.3 below; roughly speaking it claims that all different solutions of a suitable stochastic 2D Euler equations, with a given initial vorticity in \( L^2 \), are very close to each other in law; for any degree of closedness we find a noise with such property.

On the family of all Borel probability measures on \( C([0,T];H^-) \), let \( d(\cdot,\cdot) \) be a distance that metrizes weak convergence.

For every \( N \), let \( C_N \) be the class of all weak solutions of equation (2.7) satisfying (2.6) and let \( C = \bigcup_{N \in \mathbb{N}} C_N \). We denote by \( Q_N \) the elements of \( C_N \) and generically by \( Q \) those of \( C \), interpreting weak solutions as measures on the path space \( C([0,T];H^-) \).

Definition 6.1. The family of weak solutions \( \{Q;Q \in C\} \) is said to converge to a probability measure \( \mu \) on \( C([0,T];H^-) \) if, for every \( \epsilon > 0 \), there is \( N_0 \in \mathbb{N} \) such that for all \( N \geq N_0 \), it holds \( d(Q_N,\mu) < \epsilon \) for all \( Q_N \in C_N \).

Theorem 6.2. Given \( \xi_0 \in L^2 \), the family of weak solutions \( \{Q;Q \in C\} \) converges to \( \delta_\xi \) on \( C([0,T];H^-) \), where \( \xi \) is the unique solution of the deterministic Navier–Stokes equations (1.7).

Proof. We argue by contradiction. Assume there is \( \epsilon > 0 \) such that for every \( k \in \mathbb{N} \) there exist \( N_k \geq k \) and \( Q_{N_k} \in C_{N_k} \) with the property \( d(Q_{N_k},\delta_\xi) \geq \epsilon \). The family \( \{Q_{N_k}\}_{k \in \mathbb{N}} \) is tight on \( C([0,T],H^-) \) (for reasons similar to those proved above for a generic sequence of the form \( \{Q_n\}_{n \in \mathbb{N}} \)). Hence it has a subsequence \( \{Q_{N_{k_i}}\}_{i \in \mathbb{N}} \), where we may assume \( \{N_{k_i}\} \) increasing, which converges weakly, thus to \( \delta_\xi \) by the argument developed above. This is in contradiction with \( d(Q_{N_{k_i}},\delta_\xi) \geq \epsilon \) for every \( k \in \mathbb{N} \).

Corollary 6.3. For every \( \epsilon > 0 \), there is \( N_0 \in \mathbb{N} \) such that for all \( N \geq N_0 \), we have \( d(Q_N,Q'_N) < \epsilon \) for all \( Q_N,Q'_N \in C_N \).

Proof. It follows from the previous theorem by triangle inequality.

Remark 6.4. If we denote by \( d_p \) the \( p \)-th Wasserstein distance for Borel probability measures on \( C([0,T];H^-) \), then Theorem 2.3 implies convergence of \( Q_N \) to \( \delta_\xi \) in the \( p \)-th Wasserstein
distance, for any \( p < \infty \). To see this, we can consider by Skorokhod Theorem a sequence \( \xi^N \) distributed as \( Q_N \), converging \( \mathbb{P} \)-a.s. to \( \xi \) and satisfying the energy bound \( \| \xi^N - \xi \|_{C([0,T];H^\perp)}^p \rightarrow 0 \). By dominated convergence this implies

\[
\lim_{N \to \infty} \mathbb{E} \left[ \| \xi^N - \xi \|_{C([0,T];H^\perp)}^p \right] \rightarrow 0
\]

for any \( \delta > 0 \) and \( p < \infty \). In particular it is easy to see that Definition 6.1, Theorem 6.2 and Corollary 6.3 still hold if we replaced \( d \) by \( d_p \).

### 6.2 Recovery sequences for Euler equations

We are now going to show that, given any viscosity solution \( \xi \) of Euler equations, we can find a suitable sequence \( \xi^N \) of solutions of (2.7) such that their laws \( Q_N \) converge to \( \delta \xi \). This may be seen as a result of existence of recovery sequences, in a nice parallelism with the theory of \( \Gamma \)-convergence; we stress however that no variational problems are involved in our setting and this is merely an analogy. This result may help understanding the structure of viscosity solutions of Euler equations, deducing their properties from those of the sequence \( \{\xi^N\}_{N \in \mathbb{N}} \).

We consider a fixed sequence \( \theta^N \in \ell^2 \) satisfying the usual conditions and a fixed initial data \( \xi_0 \in L^2 \). However we now allow the parameter \( \nu \) to vary on \((0, +\infty)\); for fixed \( \nu \), \( \varepsilon_N \) depends on \( \nu \) and \( \theta^N \) in the usual way. We denote by \( \xi'' \) the unique solution of Navier–Stokes with initial data \( \xi_0 \) and coefficient \( \nu \); as in the previous section, we identify any solution of (2.7) satisfying (2.6) with a Borel probability measure on \( C([0,T];H^\perp) \) and we denote by \( d(\cdot, \cdot) \) the distance which metrizes weak convergence. We denote by \( \mathcal{C}_{N,\nu} \) the set of laws of weak solutions of (2.7) satisfying (2.6), with initial data \( \xi_0 \) and with respect to the parameters \( \theta^N, \nu \); a generic element of \( \mathcal{C}_{N,\nu} \) is denoted by \( Q_{N,\nu} \).

We define \( \mathcal{H} \) to be the set of viscosity solutions of Euler equations with initial data \( \xi_0 \), namely \( \xi \in \mathcal{H} \) if there exists a sequence \( \nu_n \rightarrow 0 \) such that \( \xi''^n \rightarrow \xi \) in \( C([0,T];H^\perp) \); if uniqueness of viscosity solutions of Euler were true, than \( \mathcal{H} \) would consist of a singleton.

**Corollary 6.5.** For any \( \xi \in \mathcal{H} \) there exist sequences \( \nu_i \downarrow 0 \), \( N_i \uparrow \infty \) such that

\[
\lim_{i \to \infty} d(Q_{N_i,\nu_i}, \delta \xi) = 0.
\]

**Proof.** Since \( \xi \in \mathcal{H} \), there exists a sequence \( \nu_i \downarrow 0 \) such that \( \xi''^i \rightarrow \xi \). By Theorem 6.2, for fixed \( \nu_i \), we can find \( N_i \) and an element \( Q_{N_i,\nu_i} \) such that \( d(Q_{N_i,\nu_i}, \delta \xi''^i) \leq 1/i \); moreover, since we can construct the sequence inductively, we can always take \( N_{i+1} \geq N_i \). Then by the triangle inequality,

\[
d(Q_{N_i,\nu_i}, \delta \xi) \leq d(Q_{N_i,\nu_i}, \delta \xi''^i) + d(\delta \xi''^i, \delta \xi) \leq \frac{1}{i} + \| \xi''^i - \xi \|_{C([0,T];H^\perp)}
\]

and the conclusion follows.

**Remark 6.6.** Similarly to Remark 6.4, the result still holds if we work with the \( p \)-th Wasserstein distance \( d_p \) instead of \( d \), for any \( p < \infty \).

Next, we consider two sequences \( \nu_i \rightarrow 0 \) and \( N_i \rightarrow \infty \), and for any \( i \) an element \( Q_{N_i,\nu_i} \in \mathcal{C}_{N_i,\nu_i} \). Using the same arguments in the previous sections, tightness of \( \{Q_{N_i,\nu_i}\}_i \) in \( C([0,T];H^\perp) \) can be shown; by Prohorov theorem we can therefore extract a subsequence which is weakly convergent to some probability law \( Q \). Then, repeating the arguments in Section 4 and observing that this time also the corrector \( \nu_i \Delta \) is infinitesimal, we find that almost every realization of \( Q \) is a weak solution of deterministic Euler equations with initial data \( \xi_0 \). Since uniqueness in this case is not known, we cannot conclude that \( Q \) is of the form \( \delta \xi \); rather it is a probability
distribution on the weak solutions of Euler equation starting at $\xi_0$ – a superposition solution. Observe that in the above argument in principle we did not need to vary $N$: convergence of a subsequence to a superposition solution of deterministic Euler equations also holds if we considered a sequence $Q_{N,\nu_i} \in C_{N,\nu_i}$ with $N$ fixed. However, the scaling limits we have obtained suggest that varying $N$ should allow to deduce non trivial properties in the limit which are not necessarily present for $N$ fixed; in particular, Corollary 6.5 leads us to the following conjecture.

**Conjecture 6.7.** For any weakly convergent sequence $\{Q_{N,\nu_i}\}_i$, the limit $Q$ is a probability measure supported on $H$, the set of viscosity solutions of Euler equations starting at $\xi_0$.

### 6.3 Weakly quenched exponential mixing properties

The multiplicative transport noise in Stratonovich form used above to perturb 2D Euler equations is formally vorticity-conservative but not formally energy-conservative. In general, the energy budget is not clear, namely we cannot say whether such noise increases or decreases the energy. Due to our convergence result to the Navier–Stokes equations, however, we can state an energy-dissipation result, in the precise form of Corollary 6.11 below.

**Remark 6.8.** To avoid misunderstandings, we are not claiming that this noise produces an anomalous dissipation. Such property means a true dissipation when the equation is formally energy-conservative. Our noise is not formally energy-conservative. Thus the only relevant information of Corollary 6.11 below is to clarify in which direction energy goes.

On the torus $\mathbb{T}^2$, for the unique solution $\xi_t \in C([0,T]; L^2)$ of the deterministic Navier–Stokes equations (1.7) with initial condition $\xi_0 \in L^2$, we have

$$
\frac{d}{dt} \|\xi_t\|_{L^2}^2 + \alpha \|\xi_t\|_{L^2}^2 \leq 0,
$$
$$
\frac{d}{dt} \|u_t\|_{L^2}^2 + \alpha \|u_t\|_{L^2}^2 \leq 0
$$

where $\alpha = 8\nu^2\pi^2$, as a consequence of the inequality $\langle -\Delta f, f \rangle \geq 4\pi^2 \|f\|_{L^2}^2$ for smooth $f$. It follows that

$$
\|\xi_t\|_{L^2}^2 \leq e^{-\alpha t} \|\xi_0\|_{L^2}^2,
$$
$$
\|u_t\|_{L^2}^2 \leq e^{-\alpha t} \|u_0\|_{L^2}^2.
$$

**Definition 6.9.** For every $\xi \in C([0,T]; H^-)$, we call energy profile the real valued continuous function

$$
e(t) := \frac{1}{2} \|K \ast \xi_t\|_{L^2}^2, \quad t \in [0,T].
$$

The map $\xi \mapsto e(\cdot)$ from $C([0,T]; H^-)$ to $C([0,T]; \mathbb{R})$ is continuous. Given $\xi_0 \in L^2$, the energy profile of the unique solution $\xi$ of the deterministic Navier–Stokes equations (1.7) satisfies $e(t) \leq e^{-\alpha t} e(0)$. Concerning solutions of the stochastic 2D Euler equations, always with initial condition $\xi_0 \in L^2$, since their trajectories are of class $C([0,T]; H^-)$, the energy profile is well defined also for them, being in this case a real-valued continuous stochastic process.

**Corollary 6.10.** Let $\xi^N$ be solutions of the stochastic Euler equations, converging in law to $\xi$; call $e_N$ and $e$ the corresponding energy profiles. Then $e_N$ converges in law to $e$ on $C([0,T]; \mathbb{R})$.

**Proof.** It follows from the convergence in law of $\xi^N$ to $\xi$ on $C([0,T]; H^-)$, and the stability of convergence in law by composition with continuous functions. \qed
Corollary 6.11. For every \( \epsilon > 0 \),
\[
\lim_{N \to \infty} \mathbb{P} \left( e_N(t) \leq e^{-\alpha t}(e(0) + \epsilon) \text{ for all } t \in [0, T] \right) = 1.
\]

Proof. Given \( \epsilon > 0 \), by Corollary 6.10
\[
\lim_{N \to \infty} \mathbb{P} \left( \|e_N(\cdot) - e(\cdot)\|_{C([0,T]; \mathbb{R})} \leq \epsilon \right) = 1.
\]
Since \( e(t) \leq e^{-\alpha t}e(0) \) for all \( t \in [0, T] \), we have
\[
\lim_{N \to \infty} \mathbb{P}(e_N(t) \leq e^{-\alpha t}e(0) + \epsilon \text{ for all } t \in [0, T]) = 1. \tag{6.1}
\]
Note that \( e^{-\alpha t}e(0) + e^{-\alpha T}\epsilon \leq e^{-\alpha t}(e(0) + \epsilon) \) for all \( t \in [0, T] \), replacing \( \epsilon \) by \( e^{-\alpha T}\epsilon \) in (6.1) gives us the result. \( \square \)

We cannot state a similar result for the enstrophy profile
\[
i(t) := \|\xi_i\|^2_{L_2},
\]
even if it is well defined for both \( \xi^N \) and \( \xi \). Indeed, \( \xi \in C \left( [0, T]; L^2 \right) \), hence \( i(\cdot) \in C \left( [0, T]; \mathbb{R} \right) \), but we only know that \( \xi^N \in L^\infty \left( [0, T]; L^2 \right) \) and that \( \xi^N \) converges in law to \( \xi \) in the strong topology of \( C \left( [0, T]; H^- \right) \). Thus we cannot say that enstrophy is dissipated (in a probabilistic sense). If true, this would be a result of anomalous enstrophy dissipation, because formally the enstrophy is conserved by the stochastic dynamics.

However, for the solution to the deterministic 2D Navier–Stokes equation, we have
\[
\|\xi_i\|^2_{H^{-\delta}} \leq \|\xi_i\|^2_{L_2} \leq e^{-\alpha t} \|\xi_0\|^2_{L_2}
\]
and the convergence in law of \( \xi^N \) to \( \xi \) in \( C \left( [0, T]; H^- \right) \). Repeating the argument above gives us the asymptotically exponential decay of vorticity in negative Sobolev norms.

Proposition 6.12. For every \( \epsilon, \delta > 0 \),
\[
\lim_{N \to \infty} \mathbb{P} \left( \|\xi^N\|^2_{H^{-\delta}} \leq e^{-\alpha t}(\|\xi_0\|^2_{L_2} + \epsilon) \text{ for all } t \in [0, T] \right) = 1.
\]

In the rest of this subsection, to avoid technical problems (cf. Remark 2.41), we take \( \theta_k^N = 1_{\{k \leq N\}} \), \( k \in \mathbb{Z}^2 \). Denote by \( L_0^\infty = L_0^\infty(\mathbb{T}^2) \) the space of functions in \( L^\infty(\mathbb{T}^2) \) with zero mean. Then for any \( \xi_0 \in L_0^\infty \), by [11, Theorem 2.10], the following stochastic Euler equation on \( \mathbb{T}^2 \)
\[
d\xi^N + u^N \cdot \nabla \xi^N \, dt = \epsilon_N \sum_{|k| \leq N} \theta_k^N \sigma_k \cdot \nabla \xi^N \circ dW^k, \quad \xi^N|_{t=0} = \xi_0
\]
admits a unique solution \( \xi^{N,\xi_0} \) in \( L_0^\infty \); moreover, [7, Theorem 2.14] implies that the equation of characteristics
\[
dX_t = u^N_t(X_t) \, dt + \epsilon_N \sum_{|k| \leq N} \theta_k^N \sigma_k(X_t) \circ dW^k_t
\]
generates a stochastic flow \( \varphi^N_{t,\xi_0} \) of homeomorphisms on \( \mathbb{T}^2 \), such that, \( \mathbb{P} \)-a.s. for all \( t \geq 0 \) and \( x \in \mathbb{T}^2 \), it holds
\[
\xi^N_{t,\xi_0}(\omega, x) = \xi_0 \left( \varphi^N_{-t,\xi_0}(\omega, x) \right), \tag{6.2}
\]
where \( \varphi^N_{-t,\xi_0}(\omega, \cdot) \) is the inverse map of \( \varphi^N_{t,\xi_0}(\omega, \cdot) \). Moreover, \( \mathbb{P} \)-a.s., the Lebesgue measure on \( \mathbb{T}^2 \) is invariant under the stochastic flow \( \varphi^N_{t,\xi_0} \) for all \( t \geq 0 \). The above formula implies that,
Further discussions on anomalous dissipation of enstrophy

pointed out in Remark 5.4. Equations can be indeed found. One example is given by the processes from Section 5, as

\[ \xi \]

the solution property of the stochastic flows \( \phi \)

Corollary 6.13.

\[ vorticity \text{ in positive Sobolev norms.} \]

\[ \int \left( \varphi_{t}^{N,\xi_{0}}(\omega, x) \right) \xi_{0}(x) \, dx \leq \left\| \xi_{t}^{N,\xi_{0}}(\omega) \right\|_{H^{-s}} \left\| f \right\|_{H^{s}}. \]

Proof. For any \( N \in \mathbb{N} \), there exists a null set \( \mathcal{N}_{N} \subset \Omega \) such that for all \( \omega \in \mathcal{N}_{N} \), for all \( t \geq 0 \), the formula \( 6.12 \) holds and the Lebesgue measure is invariant under the map \( \varphi_{t}^{N,\xi_{0}}(\omega, \cdot) \). For every \( f \in H^{s} \), we have

\[ \int_{T^{2}} f \left( \varphi_{t}^{N,\xi_{0}}(\omega, x) \right) \xi_{0}(x) \, dx \leq \left\| \xi_{t}^{N,\xi_{0}}(\omega) \right\|_{H^{-s}} \left\| f \right\|_{H^{s}}. \]

Now it is clear that the assertion holds.

The above result plus Proposition 6.12 gives us the weakly quenched exponential mixing property of the stochastic flows \( \varphi_{t}^{N,\xi_{0}} \).

Corollary 6.15. Under the previous notations, for every \( \xi_{0} \in L_{0}^{\infty}, f \in H^{s} \), for every \( \epsilon > 0 \),

\[ \lim_{N \to \infty} \mathbb{P} \left( \left\| \int_{T^{2}} f \left( \varphi_{t}^{N,\xi_{0}}(x) \right) \xi_{0}(x) \, dx \right\| \leq e^{-\alpha t/2} \left( \left\| \xi_{0} \right\|_{L^{2}} + \epsilon \right) \left\| f \right\|_{H^{s}} \text{ for all } t \in [0, T] \right) = 1. \]

6.4 Further discussions on anomalous dissipation of enstrophy

As already pointed out earlier, the fact that the vorticity processes \( \xi^{N} \) converge to a limit \( \xi \) which is explicitly dissipating suggests that a partial dissipation should already take place at the level of \( \xi^{N} \); the problem is that we only have convergence in \( C([0, T]; H^{-}) \) and not in \( C([0, T]; L^{2}) \), which does not allow to conclude.

The problem is not only technical: examples of processes \( \xi^{N} \) which preserve vorticity almost surely but are converging in \( C([0, T]; H^{-}) \) to the solution \( \xi \) of deterministic Navier–Stokes equations can be indeed found. One example is given by the processes from Section 5 as pointed out in Remark 5.4.

Another example is the following: let \( \xi_{0} \in C^{\infty}(T^{2}) \) and the sequence \( \theta_{N} \) be taken as in the last subsection, that is, for each fixed \( N \), only a finite number of \( \theta_{N} \) are non zero. Then the solution \( \xi^{N} \) will preserve spatial regularity over time, for instance because \( \left\| \xi^{N} \right\|_{L^{\infty}} \) can be controlled uniformly and Beale–Kato–Majda criterion can be applied, see [9]. This implies that
the formal computation on vorticity invariance is actually rigorous and so \( \| \xi_t^N \|_{L^2} = \| \xi_0 \|_{L^2} \) for all \( t > 0 \).

The above examples show that our scaling limit does not a priori give any information on whether anomalous dissipation will take place. It definitely does not take place for all solutions, but it might at least for some of them. Before proceeding further, let us give a rigorous definition.

**Definition 6.16.** Let \( \xi \) be a weak solution of \((2.5)\) satisfying \((2.6)\). We say that anomalous dissipation of enstrophy takes place with positive probability if, for some \( t \in [0, T] \), it holds

\[
P(\| \xi_t \|_{L^2} < \| \xi_0 \|_{L^2}) > 0.
\]

**(6.3)**

**Remark 6.17.** Since \( \| \xi_t \| \leq \| \xi_0 \|_{L^2} \) with probability one, condition \((6.3)\) is equivalent to requiring that, for some \( t \in [0, T] \), \( \mathbb{E}(\| \xi_t \|_{L^2}) < \mathbb{E}(\| \xi_0 \|_{L^2}) \). Such a quantity might be easier to handle because it is possible that \( \xi \) does not have trajectories in \( C([0, T]; L^2) \), yet the map \( t \mapsto \mathbb{E}(\| \xi_t \|_{L^2}) \) is continuous as an effect of the averaging. However, condition \((6.3)\) is not equivalent to

\[
P(\| \xi_t \|_{L^2} < \| \xi_0 \|_{L^2} \text{ for some } t \in [0, T]) > 0;
\]

while the latter seems a more natural definition of anomalous dissipation, the fact that it involves evaluation on an uncountable set \([0, T]\) for a process \( \xi \) with possibly not continuous trajectories in \( L^2 \) (not even right/left continuous) makes it very difficult to be handled.

The occurrence of anomalous dissipation might rely on the kind of noise we use. Here we restrict to the case of a noise constructed from \( \theta \in \ell^2 \) and \( \{\sigma_k\}_{k \in \mathbb{Z}^2_0} \) as before, but observe that this is a very specific choice: it is an isotropic, divergence-free noise whose covariance operator is a Fourier multiplier; this leaves open the question whether other choices of noise might be better suited for obtaining an anomalous dissipation effect. In any case it would be interesting to give an answer to the following:

**Problem 6.18.** Do there exist an initial data \( \xi_0 \in L^2 \), a family of coefficients \( \theta \in \ell^2 \) and an associated solution \( \xi \) which displays anomalous dissipation of enstrophy?

A different question, in the case of a positive answer for Problem 6.18, is related to anomalous dissipation occurring for all initial data.

**Problem 6.19.** Does there exist a family of coefficients \( \theta \) such that any solution of \((2.5)\) satisfying \((2.6)\), for any initial data \( \xi_0 \in L^2 \), displays anomalous dissipation of enstrophy with positive probability?

Clearly, if a positive answer to Problem 6.19 could be given, then the previous examples would show that \( \theta \) cannot consist of all but a finite number of \( \theta_k \) being 0; more refined arguments show that in general \( \theta_k \) cannot decay too fast as \( k \to \infty \). On the other hand, condition \( \theta \in \ell^2 \), which is required for the equation to be meaningful, implies that such decay cannot be too slow either. It would be interesting to explore the case of \( \theta_k \) decaying “almost as slowly as possible”, for instance taking

\[
\theta_k \sim \frac{1}{\log |k|}.
\]

Observe however that dealing with such a choice of \( \theta \) is highly non trivial: uniqueness of solutions of \((2.5)\) for such \( \theta \), even in the case of smooth initial data, is not known.
