AUTOMORPHISMS OF FANO WEIGHTED COMPLETE INTERSECTIONS

VICTOR PRZYJALKOWSKI AND CONSTANTIN SHRAMOV

Abstract. We show that smooth well formed Fano weighted complete intersections of dimension at least 3 have finite automorphism groups, with two obvious exceptions.

1. Introduction

Throughout the paper we work over an algebraically closed field \( k \) of characteristic zero.

Studying algebraic varieties, it is important to understand their automorphism groups. In some particular cases these groups have especially nice structure. For instance, recall the following classical result due to H. Matsumura and P. Monsky.

**Theorem 1.1** (see [MaMo63, Theorems 1 and 2]). Let \( X \subset \mathbb{P}^N, N \geq 3 \), be a smooth hypersurface of degree \( d \geq 3 \). Suppose that \( (N, d) \neq (3, 4) \). Then the group \( \text{Aut}(X) \) is finite.

The following beautiful generalization of Theorem 1.1 was proved by O. Benoist.

**Theorem 1.2** ([Be13, Theorem 3.1]). Let \( X \) be a smooth complete intersection of dimension at least 2 in \( \mathbb{P}^N \) that is not contained in a hyperplane. Suppose that \( X \) does not coincide with \( \mathbb{P}^N \), is not a quadric hypersurface in \( \mathbb{P}^N \), and is not a K3 surface. Then the group \( \text{Aut}(X) \) is finite.

The goal of this paper is to generalize Theorems 1.1 and 1.2 to the case of smooth Fano weighted complete intersections. We refer the reader to [Do82] and [IP00] (or to \( \S \) below) for definitions and basic properties of weighted projective spaces and complete intersections therein. Our main result is as follows.

**Theorem 1.3.** Let \( X \subset \mathbb{P} \) be a smooth well formed Fano weighted complete intersection of dimension at least 2 that is not an intersection with a linear cone. Then the group \( \text{Aut}(X) \) is finite unless \( X \equiv \mathbb{P} \cong \mathbb{P}^n \) or \( X \) is a quadric hypersurface in \( \mathbb{P} \cong \mathbb{P}^{n+1} \).

**Question 1.4** (cf. Corollary 4.5(ii)). Is it true that the assertion of Theorem 1.3 holds (with an exception of K3 surfaces) without the assumption that \( X \) is Fano?

We refer the reader to [KPS18, Theorem 1.1.2] and [CPS19, Theorem 1.2] for other results concerning finiteness of automorphism groups of Fano varieties.

**Theorem 1.3** is mostly implied by the results of [Fle81] (see Theorem 4.3 below). However, some cases are not covered by [Fle81] and have to be classified and treated separately.
(see Proposition 3.6(iv) and Lemma 4.6). To approach these cases we need the following assertion that is well known to experts but for which we did not manage to find a proper reference (and which we find interesting on its own). We will say that a weighted complete intersection $X \subset \mathbb{P} = \mathbb{P}(a_0, \ldots, a_N)$ of multidegree $(d_1, \ldots, d_k)$ is normalized if the inequalities $a_0 \leq \ldots \leq a_N$ and $d_1 \leq \ldots \leq d_k$ hold.

**Proposition 1.5** (cf. [IF00 Lemma 18.3]). Let $X \subset \mathbb{P}(a_0, \ldots, a_N)$ and $X' \subset \mathbb{P}(a'_0, \ldots, a'_N)$ be normalized quasi-smooth well formed weighted complete intersections of multidegrees $(d_1, \ldots, d_k)$ and $(d'_1, \ldots, d'_k)$, respectively, such that $X$ and $X'$ are not intersections with linear cones. Suppose that $X \cong X'$ and $\dim X \geq 3$. Then $N = N'$, $k = k'$, $a_i = a'_i$ for every $0 \leq i \leq N$, and $d_j = d'_j$ for every $1 \leq j \leq k$.

The plan of our paper is as follows. In §2 we recall some preliminary facts on weighted complete intersections. In §3 we show uniqueness of presentation of a variety as a weighted complete intersection, that is, we prove Proposition 1.5. Finally, in §4 we show that all but two types of Fano weighted complete intersections have finite automorphism groups, that is, we prove Theorem 1.3.

We are grateful to B. Fu, A. Kuznetsov, and T. Sano for useful discussions.

2. Preliminaries

In this section we recall the basic properties of weighted complete intersections. We refer the reader to [Do82] and [IF00] for more details. Some properties of smooth weighted complete intersections can be also found in the earlier paper [Mo75].

Let $a_0, \ldots, a_N$ be positive integers. Consider the graded algebra $\mathbb{k}[x_0, \ldots, x_N]$, where the grading is defined by assigning the weights $a_i$ to the variables $x_i$. Put

$$\mathbb{P} = \mathbb{P}(a_0, \ldots, a_N) = \text{Proj} \mathbb{k}[x_0, \ldots, x_N].$$

The weighted projective space $\mathbb{P}$ is said to be **well formed** if the greatest common divisor of any $N$ of the weights $a_i$ is 1. Every weighted projective space is isomorphic to a well formed one, see [Do82 1.3.1]. A subvariety $X \subset \mathbb{P}$ is said to be **well formed** if $\mathbb{P}$ is well formed and

$$\text{codim}_X (X \cap \text{Sing}\, \mathbb{P}) \geq 2,$$

where the dimension of the empty set is defined to be $-1$.

We say that a subvariety $X \subset \mathbb{P}$ of codimension $k \geq 1$ is a **weighted complete intersection of multidegree** $(d_1, \ldots, d_k)$ if its weighted homogeneous ideal in $\mathbb{k}[x_0, \ldots, x_N]$ is generated by a regular sequence of $k$ homogeneous elements of degrees $d_1, \ldots, d_k$. This is equivalent to the requirement that the codimension of (every irreducible component of) the variety $X$ equals $k$, cf. [Ha77 Theorem 8.21A(c)]. Note that $\mathbb{P}$ can be thought of as a complete intersection of codimension 0 in itself which gives us a smooth Fano variety if and only if $\mathbb{P} \cong \mathbb{P}^N$. The weighted complete intersection $X$ is said to be an **intersection with a linear cone** if one has $d_j = a_i$ for some $i$ and $j$. In this case one can exclude the $i$-th weighted homogeneous coordinate and think about $X$ as a weighted complete intersection in a weighted projective space of lower dimension, provided that $X$ is general enough, cf. [PSh16 Remark 5.2].

**Definition 2.1** (see [IF00 Definition 6.3]). Let $p : \mathbb{A}^{N+1} \setminus \{0\} \to \mathbb{P}$ be a natural projection to a weighted projective space. A subvariety $X \subset \mathbb{P}$ is called **quasi-smooth** if $p^{-1}(X)$ is smooth.
Note that a smooth well formed weighted complete intersection is always quasi-smooth, see \cite[Corollary 2.14]{PSh16}.

Given a weighted complete intersection $X \subset \mathbb{P}$, we denote by $\mathcal{O}_X(1)$ the restriction of the sheaf $\mathcal{O}_\mathbb{P}(1)$ to $X$, see \cite[1.4.1]{Do82}. Note that the sheaf $\mathcal{O}_\mathbb{P}(1)$ may be not invertible. However, if $X$ is well formed, then $\mathcal{O}_X(1)$ is a well-defined divisorial sheaf on $X$. Furthermore, if $X$ is well formed and smooth, then $\mathcal{O}_X(1)$ is a line bundle on $X$.

**Lemma 2.2** (\cite[Remark 4.2]{Ok16}, \cite[Proposition 2.3]{PST17}, cf. \cite[Theorem 3.7]{Mo75}). Let $X$ be a quasi-smooth well formed weighted complete intersection of dimension at least 3 in $\mathbb{P}$. Then the class of the line bundle $\mathcal{O}_\mathbb{P}(1)|_X$ generates the group $\text{Cl}(X)$ of classes of Weil divisors on $X$. In particular, if $X$ is smooth, then the class of $\mathcal{O}_\mathbb{P}(1)|_X$ generates the group $\text{Pic}(X)$.

One can describe the canonical class of a weighted complete intersection. For a weighted complete intersection $X$ of multidegree $(d_1, \ldots, d_k)$ in $\mathbb{P}$, define

$$i_X = \sum a_j - \sum d_i.$$ 

Let $\omega_X$ be the dualizing sheaf on $X$.

**Theorem 2.3** (see \cite[Theorem 3.3.4]{Do82}, \cite[6.14]{IF00}). Let $X$ be a quasi-smooth well formed weighted complete intersection of multidegree $(d_1, \ldots, d_k)$ in $\mathbb{P}$. Then

$$\omega_X = \mathcal{O}_X(-i_X).$$

Recall that the *Fano index* of a Fano variety $X$ is defined as the maximal integer $m$ such that the canonical class $K_X$ is divisible by $m$ in the Picard group of $X$. Lemma 2.2 and Theorem 2.3 immediately imply the following.

**Corollary 2.4.** Let $X$ be a smooth Fano well formed weighted complete intersection of dimension at least three. Then the Fano index of $X$ equals $i_X$.

Using the bounds on numerical invariants of smooth weighted complete intersections found in \cite[Theorem 1.3]{CCC11}, \cite[Theorem 1.1]{PSh16}, and \cite[Corollary 5.3(i)]{PST17}, one can easily obtain the classically known lists of all smooth Fano weighted complete intersections of small dimensions. Namely, we have the following.

**Lemma 2.5.** Let $X$ be a smooth well formed Fano weighted complete intersection of dimension at most 2 in $\mathbb{P}$ that is not an intersection with a linear cone. Then $X$ is one of the varieties listed in Table 1.

Corollary 2.6. Let \( X \) be a smooth Fano well formed weighted complete intersection of dimension at least two. Then the Fano index of \( X \) equals \( i_X \).

Proof. If \( \dim X = 2 \), then the assertion follows from the classification provided in Lemma 2.5. If \( \dim X \geq 3 \), then we apply Corollary 2.4. \( \square \)

Note that the assertion of Corollary 2.6 fails in dimension 1: if \( X \) is a conic in \( \mathbb{P}^2 \), then \( i_X = 1 \), while the Fano index of \( X \) equals 2.

3. Uniqueness of embeddings

In this section we prove Proposition 1.5. Let us start with a couple of facts that are well known and can be proved similarly to their analogs for complete intersections in the usual projective space. However, we provide their proofs for the reader’s convenience.

The proof of the following was suggested to us by A. Kuznetsov.

Lemma 3.1. Let \( X \subset \mathbb{P} = \mathbb{P}(a_0, \ldots, a_N) \) be a subvariety. Let \( C^*_X \) be a complement of the affine cone over \( X \) to its vertex, and let \( p: C^*_X \to X \) be the projection. Then one has

\[
p_*(\mathcal{O}_{C^*_X}) = \bigoplus_{m \in \mathbb{Z}} \mathcal{O}_X(m).
\]

Proof. Denote the polynomial ring \( \mathbb{k}[x_0, \ldots, x_N] \) by \( R \) and let

\[U = (\text{Spec } R) \setminus \{0\} \cong \mathbb{A}^{N+1} \setminus \{0\}.
\]

Let

\[Y = \text{Spec}_\mathbb{P} \left( \bigoplus_{m \geq 0} \mathcal{O}_\mathbb{P}(m) \right)
\]

be the relative spectrum. Since \( R \cong \Gamma \left( \bigoplus_{m \geq 0} \mathcal{O}_\mathbb{P}(m) \right) \), one obtains the map

\[Y \to \text{Spec } R \cong \mathbb{A}^{N+1}
\]

which is a weighted blow up of the origin (with weights \( a_0, \ldots, a_N \)). Cutting out the origin one gets the isomorphism

\[U \cong \text{Spec}_\mathbb{P} \left( \bigoplus_{m \in \mathbb{Z}} \mathcal{O}_\mathbb{P}(m) \right).
\]

Consider the fibered product

\[C^*_X \cong X \times_\mathbb{P} U.
\]

Taking into account that $O_P(m)|_X = O_X(m)$ by definition, we obtain an isomorphism

$$C_X^* \cong \text{Spec}_X \left( \bigoplus_{m \in \mathbb{Z}} O_X(m) \right),$$

and the assertion of the lemma follows. \hfill \Box

For a subvariety $X \subset \mathbb{P}(a_0, \ldots, a_N)$, we define the Poincaré series

$$P_X(t) = \sum_{m \geq 0} h^0(X, O_X(m)) t^m.$$  

The proof of the following fact was kindly shared with us by T. Sano.

**Proposition 3.2** (see [Do82, Theorem 3.4.4], [PST17, Lemma 2.4], [Do82, Theorem 3.2.4(iii)]). Let $X \subset \mathbb{P}(a_0, \ldots, a_N)$ be a weighted complete intersection of multidegree $(d_1, \ldots, d_k)$. The following assertions hold.

(i) One has

$$P_X(t) = \prod_{j=1}^{k} (1 - t^{d_j}) / \prod_{i=0}^{N} (1 - t^{a_i}).$$

(ii) One has $H^i(X, O_X(m)) = 0$ for all $m \in \mathbb{Z}$ and all $0 < i < \dim X$.

**Proof.** Denote the graded polynomial ring $k[x_0, \ldots, x_N]$ by $R$, denote the weighted homogeneous ideal $(f_1, \ldots, f_k)$ that defines $X$ by $I$, and put $S = R/I$, so that $X \cong \text{Proj } S$. From regularity of the sequence $f_1, \ldots, f_k$ it easily follows that

$$\sum_{m \geq 0} \dim(S_m) t^m = \prod_{j=1}^{k} (1 - t^{d_j}) / \prod_{i=0}^{N} (1 - t^{a_i}),$$

where $S_m$ is the $m$-th graded component of $S$.

Denote the affine cone

$$\text{Spec } S \subset \text{Spec } R \cong \mathbb{A}^{N+1}$$

over $X$ by $C_X$. By construction, one has an isomorphism of graded algebras

$$S \cong H^0(C_X, O_{C_X}).$$

Following Lemma 3.1 denote the complement of $C_X$ to its vertex $P$ by $C_X^*$. Consider the local cohomology groups $H^i_p(C_X, O_{C_X})$, see, for instance, [Ha67] p. 2, Definition. We have the exact sequence

$$\ldots \to H^i_p(C_X, O_{C_X}) \to H^i(C_X, O_{C_X}) \to H^i(C_X^*, O_{C_X^*}) \to H^{i+1}_p(C_X, O_{C_X}) \to \ldots,$$

see [Ha67, Corollary 1.9]. Since $C_X$ is a complete intersection in the affine space, it is Cohen–Macaulay. Therefore, by [Ha67, Proposition 3.7] and [Ha67, Theorem 3.8] one has

$$H^i_p(C_X, O_{C_X}) = 0$$

for all $i < \dim C_X = \dim X + 1$. Hence, we obtain an isomorphism

$$H^i(C_X, O_{C_X}) \cong H^i(C_X^*, O_{C_X^*})$$

for all $i < \dim X$.

Finally, denote the natural projection $C_X^* \to X$ by $p$. Then

$$H^i(C_X^*, O_{C_X^*}) \cong H^i(X, p_* O_{C_X^*})$$
for all $i$. On the other hand, by Lemma 3.1 we have
\begin{equation}
\label{3.5}
p_*(\mathcal{O}_{C_X}) = \bigoplus_{m \in \mathbb{Z}} \mathcal{O}_X(m).
\end{equation}

For $i = 0$, we combine the isomorphisms (3.2), (3.3), (3.4), and (3.5) to obtain an isomorphism of graded algebras
\[ S \cong \bigoplus_{m \geq 0} \mathcal{H}^0(X, \mathcal{O}_X(m)). \]

This together with (3.1) gives assertion (i).

For $0 < i < \dim X$, we combine the isomorphisms (3.3), (3.4), and (3.5) to obtain an isomorphism
\[ \mathcal{H}^i(C_X, \mathcal{O}_{C_X}) \cong \bigoplus_{m \in \mathbb{Z}} \mathcal{H}^i(X, \mathcal{O}_X(m)). \]

Since $C_X$ is an affine variety, we have $\mathcal{H}^i(C_X, \mathcal{O}_{C_X}) = 0$ for all $i > 0$, see for instance [Ha77, Theorem 3.5]. This proves assertion (ii). \qed

Proposition 3.2(i) implies the following property that can be considered as an analog of linear normality for usual complete intersections.

Corollary 3.3. Let $X \subset \mathbb{P}$ be a quasi-smooth well formed weighted complete intersection. Then the restriction map
\[ \mathcal{H}^0(\mathbb{P}, \mathcal{O}_\mathbb{P}(m)) \to \mathcal{H}^0(X, \mathcal{O}_X(m)) \]
is surjective for every $m \in \mathbb{Z}$.

Proof. The dimension of the image of the restriction map is computed by the coefficient in the Poincaré series (3.1). On the other hand, by Proposition 3.2(i) this coefficient also equals the dimension of $\mathcal{H}^0(X, \mathcal{O}_X(m))$. \qed

To proceed, we will need an elementary observation.

Lemma 3.4 (see [IF00, Lemma 18.3]). Let $N$ and $N'$ be positive integers, and $k$ and $k'$ be non-negative integers. Let $a_0 \leq \ldots \leq a_N$, $a'_0 \leq \ldots \leq a'_N$, $d_1 \leq \ldots \leq d_k$, and $d'_1 \leq \ldots \leq d'_k$ be positive integers. Suppose that
\begin{equation}
\label{3.6}
\frac{\prod_{j=1}^{k}(1-t^{d_j})}{\prod_{i=0}^{N}(1-t^{a_i})} = \frac{\prod_{j'=1}^{k'}(1-t^{d'_{j'}})}{\prod_{i'=0}^{N'}(1-t^{a'_{i'}})}
\end{equation}
as rational functions in the variable $t$. Suppose that $a_i \neq d_j$ for all $i$ and $j$, and $a'_{i'} \neq d'_{j'}$ for all $i'$ and $j'$. Then $N = N'$, $k = k'$, $a_i = a'_{i'}$ for every $0 \leq i \leq N$, and $d_j = d'_{j'}$ for every $1 \leq j \leq k$.

Proof. Note that the numerator and the denominator of the rational functions in the left and the right hand sides of (3.6) may have common divisors (for instance, if some $d_j$ is divisible by some $a_i$, or another way around). To prove the assertion, we will keep track of the numbers that are roots of either the numerator or the denominator, but not both of them.

Observe that equality (3.6) is equivalent to the equality obtained from (3.6) by interchanging the collections $\{a_i\}$, $\{a'_{i'}\}$ with $\{d_k\}$, $\{d'_{k'}\}$, respectively. Thus we may assume that $d_k$ is the maximal number among $a_N$, $a'_N$, $d_k$, and $d'_k$. By assumption we know
that $a_N < d_k$. Let $ζ$ be a primitive $d_k$-th root of unity. Then $ζ$ is a root of the numerator of the left hand side of (3.6) but not the root of its denominator. Hence $ζ$ is a root of the numerator $ν(t)$ of the right hand side of (3.6) as well. Since $d_j' \leq d_k$ for all $j'$, we see that $ν(t)$ is divisible by $1 - t^{d_k}$. Cancelling the factor $1 - t^{d_k}$ from (3.6), we complete the proof of the lemma by induction.

Now we prove the main result of this section.

**Proof of Proposition 1.5.** By Lemma 2.2, the group $\text{Cl}(X)$ is generated by the class of the line bundle $\mathcal{O}_X(1)$, while the group $\text{Cl}(X')$ is generated by the class of the line bundle $\mathcal{O}_X'(1)$. Therefore, we see from Proposition 3.2(i) that

$$\prod_{j=1}^{k} (1 - t^{d_j}) = P_X(t) = P_{X'}(t) = \prod_{j'=1}^{k'} (1 - t^{d'_j}) \prod_{i'=0}^{N'} (1 - t^{a'_i}).$$

Since neither $X$ nor $X'$ is an intersection with a linear cone, the required assertion follows from Lemma 3.4.

**Remark 3.5.** The assertion of Proposition 1.5 also holds for smooth Fano weighted complete intersections of dimension 2. This follows from their explicit classification, see Lemma 2.5. Note however that the assertion fails in dimension 1. Indeed, a conic in $\mathbb{P}^2$ is isomorphic to $\mathbb{P}^1$ (which can be considered as a complete intersection of codimension 0 in itself).

We point out that the assumption that $X$ is Fano is essential for the validity of Proposition 1.5 in dimension 2. Indeed, let $X$ be a smooth double cover of $\mathbb{P}^2$ branched over a sextic curve, so that $X$ can be embedded in $\mathbb{P} = \mathbb{P}(1,1,1,3)$ as a surface of degree 6. Let $H = \mathcal{O}_\mathbb{P}|_X$. Then one immediately obtains from the Riemann–Roch formula and Kodaira vanishing that

$$h^0(X, \mathcal{O}_X(2H)) = \frac{(2H)^2}{2} + 2 = 6,$$

so that the linear system $|2H|$ defines an embedding of $X$ into the projective space $\mathbb{P}' = \mathbb{P}^5$. Applying the Riemann–Roch formula to the divisor $4H$, we find that the image $X' \subset \mathbb{P}'$ of $X$ is contained in a complete intersection of three quadrics, and since $(2H)^2 = 8$, we conclude that $X'$ is actually a complete intersection of these three quadrics. Therefore, the embedding of the $K3$ surface $X$ as a weighted complete intersection is not unique.

We do not know if the assertion of Proposition 1.5 holds in dimension 2 in the case when $X$ and $X'$ are quasi-smooth del Pezzo surfaces. We point out that the assumption that $X$ alone is quasi-smooth is not enough for this. Indeed, the weighted projective plane $\mathbb{P}(1,1,2)$ (which can be considered as a quasi-smooth well formed weighted complete intersection of codimension 0 in itself) can be embedded as a quadratic cone into $\mathbb{P}^3$ (which is not quasi-smooth).

Proposition 1.5 allows us to prove further classification results concerning Fano weighted complete intersections.

**Proposition 3.6** (cf. [PSh18, Theorem 2.7]). Let $X$ be a smooth well formed Fano weighted complete intersection of dimension $n \geq 2$ in $\mathbb{P}$ that is not an intersection with a linear cone. Then

(i) one has $i_X \leq n + 1$;

(ii) one has $i_{X'} \leq n + 1$ for every $X'$ in the linear system $|H|$.

□

Now we prove the main result of this section.

**Proof of Proposition 1.5.** By Lemma 2.2, the group $\text{Cl}(X)$ is generated by the class of the line bundle $\mathcal{O}_X(1)$, while the group $\text{Cl}(X')$ is generated by the class of the line bundle $\mathcal{O}_X'(1)$. Therefore, we see from Proposition 3.2(i) that

$$\prod_{j=1}^{k} (1 - t^{d_j}) = P_X(t) = P_{X'}(t) = \prod_{j'=1}^{k'} (1 - t^{d'_j}) \prod_{i'=0}^{N'} (1 - t^{a'_i}).$$

Since neither $X$ nor $X'$ is an intersection with a linear cone, the required assertion follows from Lemma 3.4.

□

**Remark 3.5.** The assertion of Proposition 1.5 also holds for smooth Fano weighted complete intersections of dimension 2. This follows from their explicit classification, see Lemma 2.5. Note however that the assertion fails in dimension 1. Indeed, a conic in $\mathbb{P}^2$ is isomorphic to $\mathbb{P}^1$ (which can be considered as a complete intersection of codimension 0 in itself).

We point out that the assumption that $X$ is Fano is essential for the validity of Proposition 1.5 in dimension 2. Indeed, let $X$ be a smooth double cover of $\mathbb{P}^2$ branched over a sextic curve, so that $X$ can be embedded in $\mathbb{P} = \mathbb{P}(1,1,1,3)$ as a surface of degree 6. Let $H = \mathcal{O}_\mathbb{P}|_X$. Then one immediately obtains from the Riemann–Roch formula and Kodaira vanishing that

$$h^0(X, \mathcal{O}_X(2H)) = \frac{(2H)^2}{2} + 2 = 6,$$

so that the linear system $|2H|$ defines an embedding of $X$ into the projective space $\mathbb{P}' = \mathbb{P}^5$. Applying the Riemann–Roch formula to the divisor $4H$, we find that the image $X' \subset \mathbb{P}'$ of $X$ is contained in a complete intersection of three quadrics, and since $(2H)^2 = 8$, we conclude that $X'$ is actually a complete intersection of these three quadrics. Therefore, the embedding of the $K3$ surface $X$ as a weighted complete intersection is not unique.

We do not know if the assertion of Proposition 1.5 holds in dimension 2 in the case when $X$ and $X'$ are quasi-smooth del Pezzo surfaces. We point out that the assumption that $X$ alone is quasi-smooth is not enough for this. Indeed, the weighted projective plane $\mathbb{P}(1,1,2)$ (which can be considered as a quasi-smooth well formed weighted complete intersection of codimension 0 in itself) can be embedded as a quadratic cone into $\mathbb{P}^3$ (which is not quasi-smooth).

Proposition 1.5 allows us to prove further classification results concerning Fano weighted complete intersections.

**Proposition 3.6** (cf. [PSh18, Theorem 2.7]). Let $X$ be a smooth well formed Fano weighted complete intersection of dimension $n \geq 2$ in $\mathbb{P}$ that is not an intersection with a linear cone. Then

(i) one has $i_X \leq n + 1$;

(ii) one has $i_{X'} \leq n + 1$ for every $X'$ in the linear system $|H|$.

□
(ii) if \( i_X = n + 1 \), then \( X = \mathbb{P} = \mathbb{P}^n \);
(iii) if \( i_X = n \), then \( X \) is a quadric in \( \mathbb{P} = \mathbb{P}^{n+1} \);
(iv) if \( i_X = n - 1 \), then \( X \) is either a hypersurface of weighted degree 6 in \( \mathbb{P} = \mathbb{P}(1^n, 2, 3) \), or a hypersurface of weighted degree 4 in \( \mathbb{P} = \mathbb{P}(1^{n+1}, 2) \), or a cubic hypersurface in \( \mathbb{P} = \mathbb{P}^{n+1} \), or an intersection of two quadrics in \( \mathbb{P} = \mathbb{P}^{n+2} \).

Proof. If \( n = 2 \), everything follows from the explicit classification, see Lemma 2.5. Therefore, we will assume that \( n \geq 3 \). In particular, this means that \( i_X \) equals the Fano index of \( X \) by Corollary 2.6 (or Corollary 2.4).

By [IP99, Corollary 3.1.15], we know that \( i_X \leq n + 1 \); if \( i_X = n + 1 \), then \( X = \mathbb{P} \); and if \( i_X = n \), then \( X \) is isomorphic to a quadric in \( \mathbb{P}^{n+1} \). In particular, this gives a proof of assertion (i). Furthermore, applying Proposition 1.5, we obtain assertions (ii) and (iii).

Now suppose that \( i_X = n - 1 \). Note that \( \text{Pic}(X) \cong \mathbb{Z} \) by Lemma 2.2. Thus it follows from the classification of smooth Fano varieties of Fano index \( n - 1 \) (see [Fu80-84] or [IP99, Theorem 3.2.5]) that \( X \) is either isomorphic to one of the weighted complete intersections listed in assertion (iv), or \( X \) is isomorphic to a linear section of the Grassmannian \( \text{Gr}(2, 5) \) in its Plücker embedding. In the former case assertion (iv) follows from Proposition 1.5.

It remains to show that a weighted complete intersection \( X \) cannot be isomorphic to a linear section of dimension at most 6 of the Grassmannian \( \text{Gr}(2, 5) \). Suppose that \( X \) is isomorphic to such a variety. Then \( n \leq 6 \). We know from Lemma 2.5 that \( n \geq 3 \). If \( n = 3 \), then the Fano index of \( X \) equals 2 and its anticanonical degree is equal to 40. This is impossible by a classification of three-dimensional smooth Fano weighted complete intersections, see [PSh18, Table 2] (cf. [IP99, §12]). If \( n = 4 \), then the Fano index of \( X \) equals 3 and its anticanonical degree is equal to 405. This is impossible by a classification of four-dimensional smooth Fano weighted complete intersections, see [PSh16, Table 1].

Therefore, we see that \( 5 \leq n \leq 6 \). Recall that
\[
H^4(\text{Gr}(2, 5), \mathbb{Z}) \cong \mathbb{Z}^2.
\]
Thus, Lefschetz hyperplane section theorem implies that
\[
H^4(X, \mathbb{Z}) \cong \mathbb{Z}^2.
\]
On the other hand, since \( X \) is a (quasi-smooth well formed) weighted complete intersection of dimension greater than 4, one has \( H^4(X, \mathbb{Z}) \cong \mathbb{Z} \) by the Lefschetz-type theorem for complete intersections in toric varieties, see [Ma99, Proposition 1.4]. The obtained contradiction completes the proof of assertion (iv). \( \square \)

Remark 3.7. An alternative way to prove Proposition 3.6 is by induction on dimension using classification of smooth well formed Fano weighted complete intersections of low dimension (say, one provided by Lemma 2.5) together with [PST17, Theorem 1.2].

4. Automorphisms

In this section we prove Theorem 1.3

Let \( \mathbb{P} = \mathbb{P}(a_0, \ldots, a_N) \) be a weighted projective space. For any subvariety \( X \subset \mathbb{P} \), we denote by \( \text{Aut}(\mathbb{P}; X) \) the stabilizer of \( X \) in \( \text{Aut}(\mathbb{P}) \). We denote by \( \text{Aut}_\mathbb{P}(X) \) the image of \( \text{Aut}(\mathbb{P}; X) \) under the restriction map to \( \text{Aut}(X) \). In other words, the group \( \text{Aut}_\mathbb{P}(X) \) consists of automorphisms of \( X \) induced by automorphisms of \( \mathbb{P} \). The following is well known.
Lemma 4.1. Let $X$ be a subvariety of $\mathbb{P}$. Then the group $\text{Aut}_\mathbb{P}(X)$ is a linear algebraic group.

Proof. The group $\text{Aut}(\mathbb{P})$ is obviously a linear algebraic group. The stabilizer $\text{Aut}(\mathbb{P}; X)$ of $X$ in $\text{Aut}(\mathbb{P})$ and the kernel $\text{Aut}(\mathbb{P}; X)_{\text{id}}$ of its action on $X$ are cut out in $\text{Aut}(\mathbb{P})$ by algebraic equations, so that they are linear algebraic groups. The group $\text{Aut}(\mathbb{P}; X)_{\text{id}}$ is a normal subgroup of $\text{Aut}(\mathbb{P}; X)$. Therefore, the group

$$\text{Aut}_\mathbb{P}(X) \cong \text{Aut}(\mathbb{P}; X)/\text{Aut}(\mathbb{P}; X)_{\text{id}}$$

is a linear algebraic group as well, see [Bo69, Theorem 6.8]. □

Corollary 4.2. Let $X$ be a smooth irreducible subvariety of $\mathbb{P}$. Suppose that $K_X$ is numerically effective. Then the group $\text{Aut}_\mathbb{P}(X)$ is finite.

Proof. By Lemma 4.1, the group $\text{Aut}_\mathbb{P}(X)$ is a linear algebraic group. Therefore, if $\text{Aut}_\mathbb{P}(X)$ is infinite, then it contains a subgroup isomorphic either to $k^\times$ or to $k^+$, which implies that $X$ is covered by rational curves. On the other hand, since $K_X$ is numerically effective, $X$ can’t be covered by rational curves, see [MiMo86, Theorem 1]. □

The main tool we use in the proof of Theorem 1.3 is the following result from [Fle81].

Theorem 4.3 (see [Fle81, Satz 8.11(c)]). Let $X$ be a smooth weighted complete intersection of dimension $n \geq 2$. Then

$$H^n(X, \Omega^1_X \otimes \mathcal{O}_X(-i)) = 0$$

for every integer $i \leq n-2$.

Remark 4.4. Actually, the assertion of [Fle81, Satz 8.11(c)] gives more vanishing results and holds under the weaker assumption that $X$ is quasi-smooth. However, we do not want to go into details with the definition of the sheaf $\Omega^1_X$ here, and in any case we will need smoothness of $X$ on the next step.

Theorem 4.3 allows us to prove finiteness of various automorphism groups.

Corollary 4.5. Let $X$ be a smooth well formed weighted complete intersection of dimension $n \geq 2$. Suppose that $i_X \leq n-2$. The following assertions hold.

(i) One has $H^0(X, T_X) = 0$.

(ii) The group $\text{Aut}_\mathbb{P}(X)$ is finite.

(iii) If $X$ is Fano, then the group $\text{Aut}(X)$ is finite.

Proof. By Theorem 4.3 we have

$$H^n(X, \Omega^1_X \otimes \mathcal{O}_X(-i_X)) = 0.$$ 

Recall that $\omega_X = \mathcal{O}_X(-i_X)$ by Theorem 2.3. Thus assertion (i) follows from Serre duality. Assertion (ii) follows from assertion (i), because $\text{Aut}_\mathbb{P}(X)$ is a linear algebraic group by Lemma 4.1. Similarly, assertion (iii) follows from assertion (i), because the automorphism group of any Fano variety is a linear algebraic group. □

Recall that the smooth Fano threefold $V_5$ of Fano index $\dim V_5 - 1 = 2$ that is defined as an intersection of the Grassmannian $\text{Gr}(2, 5) \subset \mathbb{P}^9$ in its Plücker embedding with a linear section of codimension 3 has infinite automorphism group $\text{Aut}(V_5) \cong \text{PGL}_2(k)$, see [Mu88, Proposition 4.4] or [CS15, Proposition 7.1.10]. The next lemma shows that such a situation is impossible for smooth weighted complete intersections.
Lemma 4.6. Let $X$ be a smooth well formed Fano weighted complete intersection of
dimension $n \geq 2$ in $\mathbb{P}$. Suppose that $i_X = n - 1$. Then the group $\text{Aut}(X)$ is finite.

Proof. One can assume that $X$ is not an intersection with a linear cone. We use the classification provided by Proposition [KPS18] iv). If $X$ is an intersection of two quadrics in $\mathbb{P} = \mathbb{P}^{n+2}$ or a cubic hypersurface in $\mathbb{P} = \mathbb{P}^{n+1}$, then the assertion follows from Theorem [L2] (in the latter case one can also use Theorem [L1]).

Now suppose that $X$ is either a hypersurface of weighted degree 4 in $\mathbb{P} = \mathbb{P}(1^{n+1}, 2)$ or
a hypersurface of weighted degree 6 in $\mathbb{P} = \mathbb{P}(1^n, 2, 3)$. The argument in these cases is similar to that in the proof of [KPS18] Lemma 4.4.1. Denote by $H$ the ample divisor such that $-K_X \sim (n-1)H$. Then there exists an $\text{Aut}(X)$-equivariant double cover $\phi: X \to Y$, where in the former case $Y \cong \mathbb{P}^n$ and $\phi$ is given by the linear system $|H|$, while in the latter case $Y \cong \mathbb{P}(1^n, 2)$ and $\phi$ is given by the linear system $|2H|$. Let $H'$ be the ample Weil divisor generating the group $\text{Cl}(Y) \cong \mathbb{Z}$, and let $B \subset Y$ be the branch divisor of $\phi$.

In the former case one has $B \sim 4H'$, and in the latter case one has $B \sim 6H'$. Note that in the latter case $H'$ is not Cartier, but $2H'$ is; note also that in this case $\phi$ is branched over the singular point of $Y$ as well. In both cases $B$ is smooth. Furthermore, it follows from

adjunction formula that either $K_B$ is ample, or $K_B \sim 0$, or $B$ is a (smooth well formed)
Fano weighted hypersurface of dimension $n - 1 \geq 3$ and Fano index $i_B \leq n - 3$.

Since the double cover $\phi$ is $\text{Aut}(X)$-equivariant, we see that the quotient of the group $\text{Aut}(X)$ by its normal subgroup of order 2 generated by the Galois involution of $\phi$ is isomorphic to a subgroup of the stabilizer $\text{Aut}(Y; B)$ of $B$ in $\text{Aut}(Y)$. Since $B$ is not contained in any divisor linearly equivalent to the very ample divisor $2H'$, we conclude that $\text{Aut}(Y; B)$ acts faithfully on $B$, see for instance [CPS19] Lemma 2.1. Hence

$$\text{Aut}(Y; B) \cong \text{Aut}_Y(B).$$

On the other hand, the group $\text{Aut}_Y(B)$ is finite by Corollary [L3] ii); alternatively, one can apply Corollaries [L2] and [L5](iii). This means that the group $\text{Aut}(X)$ is finite as well. \(\square\)

Now we prove Theorem [L3].

Proof of Theorem [L3]. Let $n = \dim X$. If $i_X \leq n - 2$, then the group $\text{Aut}(X)$ is finite by Corollary [L5](iii). If $n \geq 2$ and $i_X = n - 1$, then the group $\text{Aut}(X)$ is finite by Lemma [L6]. If $i_X \geq n$, then we know from Proposition [3.6] that either $X = \mathbb{P} \cong \mathbb{P}^n$, or $X$ is a quadric hypersurface in $\mathbb{P} \cong \mathbb{P}^{n+1}$. \(\square\)
