A PRIME-CHARACTERISTIC ANALOGUE OF A THEOREM OF HARTSHORNE-POLINI

NICHOLAS SWITALA AND WENLIANG ZHANG

Abstract. Let $R$ be an $F$-finite Noetherian regular ring containing an algebraically closed field $k$ of positive characteristic, and let $M$ be an $\mathcal{F}$-finite $\mathcal{F}$-module over $R$ in the sense of Lyubeznik (for example, any local cohomology module of $R$). We prove that the $\mathfrak{p}$-dimension of the space of $\mathcal{F}$-module morphisms $M \to E(R/\mathfrak{m})$ (where $\mathfrak{m}$ is any maximal ideal of $R$ and $E(R/\mathfrak{m})$ is the $R$-injective hull of $R/\mathfrak{m}$) is equal to the $k$-dimension of the Frobenius stable part of $\text{Hom}_R(M, E(R/\mathfrak{m}))$. This is a positive-characteristic analogue of a recent result of Hartshorne and Polini for holonomic $\mathcal{D}$-modules in characteristic zero. We use this result to calculate the $\mathcal{F}$-module length of certain local cohomology modules associated with projective schemes.

1. Introduction

In the study of finiteness properties of local cohomology modules there has been an emerging theme: the parallel between (holonomic) $\mathcal{D}$-modules in characteristic zero and ($\mathcal{F}$-finite) $\mathcal{F}$-modules in characteristic $p > 0$ (cf. [13,15]). This paper continues the line of research under the same theme: we prove $\mathcal{F}$-module analogues of results obtained by Hartshorne and Polini in [7] and by the authors in [16] for $\mathcal{D}$-modules over formal power series or polynomial rings. The theory of ($\mathcal{F}$-finite) $\mathcal{F}$-modules will be reviewed in the next section. We begin by recalling the results for holonomic $\mathcal{D}$-modules in characteristic zero.

Theorem 1.1. (a) [7, Corollary 5.2], [14, Theorem 5.1] Let $R = k[[x_1, \ldots, x_n]]$ where $k$ is a field of characteristic zero, let $\mathfrak{m} \subseteq R$ be the maximal ideal, and let $\mathcal{D} = \mathcal{D}(R, k)$ be the ring of $k$-linear differential operators on $R$. Denote by $E$ the $R$-module $H^0_{\mathfrak{m}}(R)$, which is an $R$-injective hull of $k$. If $M$ is a holonomic $\mathcal{D}$-module, then
\[
dim_k H^i_{\text{CR}}(M) = \dim_k H^0_{\text{CR}}(D(M)) = \dim_k \text{Hom}_\mathcal{D}(M, E) = \max\{t \in \mathbb{N} \mid \exists \mathfrak{D} \text{-module surjection } M \to E^t\},
\]
where $H^i_{\text{CR}}(-)$ denotes the de Rham cohomology of a $\mathcal{D}$-module, and $D(-) = \text{Hom}_R(-, E)$ is the Matlis dual functor.

(b) [16, Theorem 5.3] Let $R = k[x_1, \ldots, x_n]$ where $k$ is a field of characteristic zero, let $\mathfrak{m} \subseteq R$ be the maximal ideal, and let $\mathcal{D} = \mathcal{D}(R, k)$ be the ring of $k$-linear differential operators on $R$. Denote by $E$ the $R$-module $H^0_{\mathfrak{m}}(R)$, which (with the correct choice of grading) is a graded $R$-injective hull of $k$. If $M$ is a finitely generated graded $\mathcal{D}$-module with finite-dimensional de Rham cohomology spaces (for example, a graded holonomic $\mathcal{D}$-module), then
\[
\dim_k H^i_{\text{CR}}(M) = \dim_k H^0_{\text{CR}}(*D(M)) = \dim_k \text{Hom}_\mathcal{D}(M, E) = \max\{t \in \mathbb{N} \mid \exists \mathfrak{D} \text{-module surjection } M \to E^t\},
\]
where $*D(-) = *\text{Hom}_R(-, E)$ is the graded Matlis dual functor.

In Theorem 1.1(b), a graded $\mathcal{D}$-module is a graded $R$-module on which the operators $\partial_j = \frac{\partial}{\partial x_j} \in \mathcal{D}$ act as graded $k$-linear maps of degree $-1$. If $I \subseteq k[[x_1, \ldots, x_n]]$ is an ideal (resp. $I \subseteq k[x_1, \ldots, x_n]$ is
a homogeneous ideal), the local cohomology modules $H^j_I(R)$ are holonomic (resp. graded holonomic) $\mathcal{D}$-modules, and so Theorem 1.1 can be applied to them. The following formulas of Hartshorne and Polini for the $\mathcal{D}$-module length of certain local cohomology modules associated with projective schemes can be deduced from this theorem (either Theorem 1.1(a) or Theorem 1.1(b) on its own suffices, though different arguments are required in each case).

**Theorem 1.2.** [7] Theorems 4.8, 6.4] Let $X \subseteq \mathbb{P}^n_k$ be a smooth, irreducible projective scheme of codimension $c < n$, where $k$ is an algebraically closed field of characteristic zero. Let $I \subseteq R = k[x_0, \ldots, x_n]$ be the homogeneous defining ideal of $X$. Then we have

$$\ell_D(H^j_I(R)) = \begin{cases} \beta_{n-c} - \beta_{n-c-2} + 1 & i = c \\ \beta_{n-i} - \beta_{n-i-2} & c < i < n \\ 0 & 0 \leq i < c \text{ or } i \geq n \end{cases}$$

where $\ell_D(-)$ denotes the length of a $\mathcal{D}$-module and $\beta_i = \dim_k H^j_{dR}(X)$ is the $k$-dimension of the $j$th algebraic de Rham cohomology space of $X$ as defined in [6].

The main result of this paper, Theorem A, is an $\mathcal{F}$-module analogue of Theorem 1.1. The finiteness condition analogous to the holonomicity of $\mathcal{D}$-modules is the $\mathcal{F}$-finiteness of $\mathcal{F}$-modules, and local cohomology modules satisfy this condition. De Rham cohomology for $\mathcal{F}$-modules is ill-behaved in positive characteristic, so any analogue of Theorem 1.1 will require a replacement for $H^0_{dR}(D(M))$. The desired replacement turns out to be the (Frobenius) stable part of $D(M)$. (See section 2 below for the relevant definitions.) The hypotheses of Theorem A are more general than those of Theorem 1.1 and include both the cases of polynomial and formal power series rings; observe that there is no need to state and prove a graded version separately.

**Theorem A** (Corollary 3.4). Let $R$ be a regular Noetherian ring containing an algebraically closed field $k$ of characteristic $p > 0$, and let $m \subseteq R$ be any maximal ideal. Let $E = E_R(R/m)$ be the $R$-injective hull of $R/m$, and denote by $D(-)$ the exact functor $\text{Hom}_R(-, E)$ on the category of $R$-modules. Assume that the Frobenius $F : R \rightarrow R$ is a finite morphism. If $M$ is an $\mathcal{F}$-finite $\mathcal{F}$-module over $R$, then

$$\dim_{\mathcal{F}_p} \text{Hom}_{\mathcal{F}}(M, E) = \dim_k D(M)_s$$

$$= \max\{t \in \mathbb{N} \mid \exists \text{ an } \mathcal{F}\text{-module surjection } M \rightarrow E^t\},$$

where $(-)_s$ denotes the stable part of a Frobenius module, and $\text{Hom}_{\mathcal{F}}$ denotes the $\mathbb{F}_p$-space of $\mathcal{F}$-module morphisms.

We can use Theorem A to obtain formulas for the $\mathcal{F}$-module length of certain local cohomology modules associated with projective schemes, which constitute a positive-characteristic analogue of Theorem 1.2. Étale cohomology replaces algebraic de Rham cohomology in these formulas.

**Theorem B.** Let $X \subseteq \mathbb{P}^n_k$ be a projective scheme over an algebraically closed field $k$ of characteristic $p > 0$, and let $I \subseteq R = k[x_0, \ldots, x_n]$ be the homogeneous defining ideal of $X$.

(a) (Theorem 4.1) Let $m \subseteq R$ be the irrelevant maximal ideal, and let $E = H^{n+1}_m(I)(R)$. Then we have

$$H^j_{\text{std}}(X, \mathbb{F}_p) \cong \text{Hom}_{\mathcal{F}}(H^{n-j}_I(R), E)$$

as $\mathbb{F}_p$-spaces, for all $j > 0$.

(b) (Corollary 4.3) If $X$ is Cohen-Macaulay, then

$$\ell_{\mathcal{F}}(H^{n-j}_I(R)) = \dim_{\mathbb{F}_p}(H^j_{\text{std}}(X, \mathbb{F}_p))$$

for all $0 < j < \dim(X)$, where $\ell_{\mathcal{F}}(-)$ denotes the length of a $\mathcal{F}$-module.
In section 2, we collect the necessary preliminary material on Frobenius modules and \( \mathcal{F} \)-modules. Much of this section recalls definitions and results due to Hartshorne and Speiser, Lyubeznik, and Bhatt and Lurie, but Proposition 2.13 appears to us to be new. We prove Theorem A in section 3 and finally deduce Theorem B in section 4.

Acknowledgments. The first author thanks Rankeya Datta, Linquan Ma, and Mircea Mustaţă for helpful discussions.

2. Frobenius Modules and \( \mathcal{F} \)-modules

We begin with some notation and conventions. All rings considered in this paper are commutative with identity 1. Except in section 1, all rings are of characteristic \( p > 0 \) unless otherwise noted. Throughout this section, \( A \) denotes such a ring, and we reserve the letter \( R \) for regular Noetherian rings; we will repeat these assumptions in the hypotheses of definitions and theorems. All local rings are assumed to be Noetherian.

We denote by \( F \) (or \( F_A \) if the context demands) the Frobenius endomorphism \( F : A \to A \) defined by \( F(a) = a^p \) for all \( a \in A \). If \( M \) is an \( A \)-module, we can consider the \( A \)-modules \( F^*M \) and \( F_*M \). The \( A \)-module \( F_*M \) has the same underlying Abelian group as \( M \), with \( A \)-action defined by \( a \cdot m = a^p m \). On the other hand, as an Abelian group, \( F^*M \) can be expressed as \( A \otimes_{F_A} M \), where the notation means that we form the tensor product by regarding \( A \) as a right \( A \)-module via the Frobenius. Explicitly, for \( a,b \in A \) and \( m \in M \), we have \( a(b \otimes m) = ab \otimes m \) and \( a \otimes bm = ab^p \otimes m \).

The following is just the well-known adjunction between restriction and extension of scalars; we record it here separately so as to have a specific reference for the formulas in the sequel.

**Proposition 2.1.** Let \( A \) be a ring of characteristic \( p > 0 \), and let \( M \) be an \( A \)-module. There is a bijective correspondence between \( A \)-linear maps \( M \to F_*M \) and \( A \)-linear maps \( F^*M \to M \).

**Proof.** If \( \varphi : M \to F_*M \) is an \( A \)-linear map, the corresponding \( A \)-linear map \( \psi : F^*M = A \otimes_{F_A} M \to M \) is defined by \( \psi(a \otimes m) = a \varphi(m) \). Conversely, if \( \psi : F^*M = A \otimes_{F_A} M \to M \) is an \( A \)-linear map, the corresponding \( A \)-linear map \( \varphi : M \to F_*M \) is defined by \( \varphi(m) = \psi(1 \otimes m) \). \( \square \)

The main objects of this paper are \( A \)-modules equipped with \( A \)-linear maps to or from their pushforwards and pullbacks along the Frobenius \( F_A \). Frobenius modules over \( A \) (that is, \( A \)-modules \( M \) equipped with a choice of \( A \)-linear map \( M \to F_*M \)) were studied by Hartshorne and Speiser in [8] and, more recently, by Bhatt and Lurie in [11]. On the other hand, \( \mathcal{F} \)-modules (that is, \( A \)-modules \( M \) equipped with a choice of \( A \)-linear isomorphism \( M \to F^*M \)), also known as unit Frobenius modules, were introduced by Lyubeznik in [12] and studied further by Emerton and Kisin in [5] and Bhatt and Lurie in [11], in the case where \( A \) is regular and Noetherian. (By a celebrated theorem of Kunz [11] Theorem 2.1, the functor \( F^* \) is exact under these hypotheses, and this exactness is crucial to the theory of \( \mathcal{F} \)-modules.)

We now proceed to give the basic definitions and relationships between these objects.

**Definition 2.2.** Let \( A \) be a ring of characteristic \( p > 0 \). A Frobenius module over \( A \) is a pair \((M, \varphi_M)\) where \( M \) is an \( A \)-module and \( \varphi_M : M \to F_*M \) is an \( A \)-linear map. (When there is no danger of confusion, we sometimes write \( \varphi \) for \( \varphi_M \); we also sometimes refer simply to \( M \) as a “Frobenius module”.)

An \( A \)-linear map \( M \to F_*M \) is the same thing as an additive map \( \varphi_M : M \to M \) such that \( \varphi_M(am) = a^p \varphi_M(m) \) for all \( a \in A \) and \( m \in M \). In particular, the iterates \( \varphi_M^i \) for \( i \geq 0 \) make sense. Frobenius modules over \( A \) form a category \( \text{Mod}_{\mathcal{F}}^A \), where a morphism \((M, \varphi_M) \to (N, \varphi_N)\) is an \( A \)-linear map \( f : M \to N \) such that \( \varphi_N \circ f = F_*f \circ \varphi_M \). We denote by \( \text{Hom}_{A[F]}(M, N) \) the \( \mathbb{F}_p \)-space of Frobenius module morphisms \((M, \varphi_M) \to (N, \varphi_N)\). The reason for the notation is that a Frobenius module over \( A \) is the same thing as a left module over the non-commutative ring \( A[F] \) generated over \( A \) by the symbol \( F \), subject to the relations \( Fa = a^p F \) for all \( a \in A \).
Definition 2.3. Let $A$ be a ring of characteristic $p > 0$, and let $(M, \varphi_M)$ be a Frobenius module over $A$.

(a) The (Frobenius) fixed part $M^{\varphi=1}$ of $M$ is the $F_p$-subspace $\{m \in M \mid \varphi_M(m) = m\} \subseteq M$.

(b) Suppose that $A$ contains a perfect field $k$ of characteristic $p > 0$. The (Frobenius) stable part $M_s$ of $M$ is the $k$-subspace $\cap_{i \geq 0} \varphi^{i}_M(M) \subseteq M$.

If $k$ is any field of characteristic $p > 0$, the only solutions $\lambda \in k$ to the equation $\lambda^p = \lambda$ are the elements of the prime subfield $F_p \subseteq k$. Therefore the fixed part $M^{\varphi=1}$ can only be an $F_p$-subspace. If $k$ is perfect, the iterated images $\varphi^{i}_M(M)$ are $k$-subspaces of $M$, and so the same is true for $M_s$.

It is clear that $M^{\varphi=1} \subseteq M_s$. Under stronger hypotheses on $k$, we can say something more about the relationship between the fixed and stable parts:

Proposition 2.4. [3, Exp. XXII, Corollaire 1.1.10] Let $A$ be a ring containing an algebraically closed field $k$ of characteristic $p > 0$. Let $(M, \varphi_M)$ be a Frobenius module over $A$. If $M_s$ is a finite-dimensional $k$-space, then there is an isomorphism

$$k \otimes_{F_p} M^{\varphi=1} \cong M_s$$

of $k$-spaces. In particular, there exists a $k$-basis $\{m_1, \ldots, m_l\}$ of $M_s$ such that $\varphi_M(m_i) = m_i$ for $i = 1, \ldots, l$.

Proposition 2.4 implies that if $M_s$ is a finite-dimensional $k$-space, then $M^{\varphi=1}$ is a finite-dimensional $F_p$-space (of the same dimension). The converse, however, is not true, as the following example shows:

Example 2.5. Let $R = k[x]$ where $k$ is a perfect field of characteristic $p > 0$, let $F_R$ be the Frobenius endomorphism on $R$, and consider the perfection $R^{1/p\infty} = k[x^{1/p\infty}]$, that is, the colimit

$$\lim_{\leftarrow} (R \xrightarrow{F_R} R \xrightarrow{F_R} R \xrightarrow{F_R} \cdots).$$

The Frobenius endomorphism $F_{R^{1/p\infty}}$ is bijective. Therefore, if we regard $(R^{1/p\infty}, F_{R^{1/p\infty}})$ as a Frobenius module over $R$, we have $(R^{1/p\infty})_s = R^{(1/p\infty)}$, which is not a finite-dimensional $k$-space. However, $(R^{1/p\infty})^{\varphi=1}$ is simply $F_p$, a one-dimensional $F_p$-space. This is true whether or not $k$ is algebraically closed.

The following result of Hartshorne and Speiser provides one useful case in which the finiteness of the stable part is known (and so Proposition 2.4 applies).

Theorem 2.6. [8, Theorem 1.12] Let $A$ be a local ring containing a perfect field $k$ of characteristic $p > 0$, and let $(M, \varphi_M)$ be a Frobenius module over $A$. If $M$ is an Artinian $A$-module, then $M_s$ is a finite-dimensional $k$-space, and the induced map $\varphi : M_s \to M$ is bijective.

If $(M, \varphi_M)$ is a Frobenius module over $A$, we have by Proposition 2.1 an $A$-linear map $\psi_M : F^* M \to M$. When $\psi_M$ is an isomorphism, $M$ is called a unit Frobenius module by some authors [5, 1]. In Lyubeznik’s [12], which deals only with the case of a regular Noetherian ring $R$, unit Frobenius modules over $R$ are called $\mathcal{F}$-modules (or $\mathcal{F}_R$-modules). We will follow Lyubeznik’s notation and terminology.

Definition 2.7. Let $R$ be a regular Noetherian ring of characteristic $p > 0$. An $\mathcal{F}$-module over $R$ (or $\mathcal{F}_R$-module) is a pair $(M, \theta_M)$ where $M$ is an $R$-module and $\theta_M : M \xrightarrow{\sim} F^* M$ is an $R$-module isomorphism, called the structure morphism. (When there is no danger of confusion, we sometimes refer simply to $M$ as an “$\mathcal{F}$-module”.)

Of course, if $(M, \theta_M)$ is an $\mathcal{F}_R$-module, then $(M, \varphi_M)$ is a Frobenius module over $R$, where $\varphi_M : M \to F_s M$ is the $R$-linear map that corresponds via adjunction to $\psi_M = \theta_M^{-1}$.

There is a category $\mathcal{F}_R$-$\text{Mod}$ of $\mathcal{F}$-modules over $R$, where a morphism $(M, \theta_M) \to (N, \theta_N)$ is an $R$-linear map $f : M \to N$ such that $\theta_N \circ f = F^* f \circ \theta_M$. We denote by $\text{Hom}_\mathcal{F}(M, N)$ the $F_p$-space of $\mathcal{F}$-module morphisms $(M, \theta_M) \to (N, \theta_N)$. In particular, we can speak of $\mathcal{F}$-submodules: an $\mathcal{F}$-submodule
of an \( \mathcal{F} \)-module \((M, \theta_M)\) is an \( R \)-submodule \( N \subseteq M \) such that the restriction \( \theta_M|_N \) is an isomorphism \( N \cong F^* N \) (since \( R \) is regular, \( F^* \) is exact and so \( F^* N \) can always be identified with an \( R \)-submodule of \( F^* M \)).

In the fruitful analogy between \( \mathcal{D} \)-modules in characteristic zero and \( \mathcal{F} \)-modules in positive characteristic, the finiteness condition of holonomicity for \( \mathcal{D} \)-modules corresponds to the condition of “\( \mathcal{F} \)-finiteness” defined below (in particular, local cohomology modules provide examples of each). Loosely speaking, an \( \mathcal{F} \)-finite \( \mathcal{F} \)-module is one built from a finitely generated \( R \)-module by repeatedly applying the functor \( F^* \) and passing to a colimit.

**Definition 2.8.** Let \( R \) be a regular Noetherian ring of characteristic \( p > 0 \), and let \((M, \theta_M)\) be an \( \mathcal{F} \)-module. We say that \( M \) is \( \mathcal{F} \)-finite if there exists a finitely generated \( R \)-module \( M' \) and an \( R \)-linear map \( \beta : M' \rightarrow F^* M' \) such that

\[
\lim_{\rightarrow}(M' \xrightarrow{\beta} F^* M' \xrightarrow{F^* \beta} (F^*)^2 M' \rightarrow \cdots) \cong M,
\]

and the structure morphism \( \theta_M \) is induced by taking the colimit over \( l \) of \((F^*)^l \beta : (F^*)^l M' \rightarrow (F^*)^{l+1} M' \).

In this case we call \( M' \) a generator of \( M \) and \( \beta \) a generating morphism.

**Example 2.9.** Let \( R \) be a regular Noetherian ring of characteristic \( p > 0 \). The following are the most relevant examples of \( \mathcal{F} \)-finite \( \mathcal{F} \)-modules for the purposes of this paper.

(a) \( R \) itself is an \( \mathcal{F} \)-finite \( \mathcal{F} \)-module. The corresponding Frobenius module structure is given by \( \varphi_R = F_R \), and \( \text{id}_R \) is an \( \mathcal{F} \)-module generating morphism for \( R \). Moreover, \( R \) is a simple \( \mathcal{F} \)-module, since \( \mathcal{F} \)-submodules of \( R \) are ideals \( I \subseteq R \) such that the natural surjection \( R/I^{[p]} \rightarrow R/I \) is an isomorphism (here \( I^{[p]} \) is the ideal generated by all \( p \)-th powers of elements of \( I \)), and as \( R \) is Noetherian, this can only happen if \( I = (0) \) or \( I = R \).

(b) If \( I \subseteq R \) is an ideal and \( i \geq 0 \), the local cohomology module \( H^i_I(R) \) is an \( \mathcal{F} \)-finite \( \mathcal{F} \)-module [12 Example 2.2(b)].

(c) If \( \mathfrak{m} \subseteq R \) is a maximal ideal, then the \( R \)-injective hull \( E = E_R(R/\mathfrak{m}) \) of the \( R \)-module \( R/\mathfrak{m} \) is an \( \mathcal{F} \)-finite \( \mathcal{F} \)-module [15 Proposition 5.4(d)]. Moreover, \( E \) is a simple \( \mathcal{F} \)-module, since \( R/\mathfrak{m} \) is a simple \( R \)-module as well as an \( \mathcal{F} \)-module generator of \( E \).

**Definition 2.10.** Let \( A \) be a ring of characteristic \( p > 0 \). We say that \( A \) is \( F \)-finite\(^1\) if \( F_n A \) is a finitely generated \( A \)-module.

For example, if \( k \) is a perfect field of characteristic \( p > 0 \), the rings \( k[x_1, \ldots, x_n] \) and \( k[[x_1, \ldots, x_n]] \) are \( F \)-finite. We recall the well-known facts that if \( R \) is an \( F \)-finite regular Noetherian ring of characteristic \( p > 0 \), then \( R \) is \( F \)-split (meaning that the \( R \)-module homomorphism \( R \rightarrow F_n R \) defined by the Frobenius admits a section) and \( F_n R \) is locally free as an \( R \)-module (because it is finitely generated as well as flat).

In what follows, for each commutative ring \( A \) of characteristic \( p > 0 \) and each \( A \)-module \( M \), we will use \((A \otimes F_\Lambda M)|_{F_\Lambda} \) to denote \( A \otimes F_\Lambda M \) viewed as an \( A \)-module by restriction of scalars along \( F_\Lambda : A \rightarrow A \), so that \( a \ast (b \otimes z) = a^p b \otimes z = b \otimes a^p z \) for all \( a, b \in A \) and \( z \in M \).

**Proposition 2.11.** Let \( R \) be a regular Noetherian ring of characteristic \( p > 0 \), and let \( J \) be an injective \( R \)-module. Denote by \( D_J(\cdot) \) the exact functor \( \text{Hom}_R(\cdot, J) \) on the category of \( R \)-modules. There are \( R \)-module homomorphisms

\[
\delta_M : F^* D_J(M) \rightarrow D_J(F^* M)
\]

for all \( R \)-modules \( M \), functorial in \( M \). Furthermore, if \( R \) is \( F \)-finite and \( M \) is a finitely generated \( R \)-module, then the \( \delta_M \) is an isomorphism.

\(^1\)Note the distinction between \( F \)-finiteness, a property of a ring, and \( \mathcal{F} \)-finiteness, a property of an \( \mathcal{F} \)-module.
Proof. By [9, Proposition 1.5], since $R$ is Gorenstein, $J \cong F^* J$ as $R$-modules. Fix a choice of $R$-module isomorphism $\theta_J : J \to F^* J$. For $M$ an $R$-module, we define $\delta_M$ to be the composite

(i) $F^* D_J(M) = R \otimes_{F_R} \text{Hom}_R(M, J) \to \text{Hom}_R(M, (R \otimes_{F_R} J)|_{F_R})$

(ii) $\to \text{Hom}_R(R \otimes_{F_R} M, R \otimes_{F_R} J)$

(iii) $\to \text{Hom}_R(R \otimes_{F_R} M, J) = D_J(F^* M),$

where

- the map in (i) carries $r \otimes \varphi \in R \otimes_{F_R} \text{Hom}_R(M, J)$ to the element of $\text{Hom}_R(M, (R \otimes_{F_R} J)|_{F_R})$ whose value on $m \in M$ is $r \otimes \varphi(m)$ (given our construction of $(R \otimes_{F_R} J)|_{F_R}$, the map $m \mapsto r \otimes \varphi(m)$ is indeed $R$-linear);
- the map in (ii) is the isomorphism arising from the adjunction between extension and restriction of scalars; and
- the map in (iii) is given by post-composition with $\theta_J^{-1}$.

It is easy to see that all three maps are functorial in $M$ and that the middle and bottom arrows are isomorphisms for all $R$-modules $M$, so it remains to show that if $R$ is $F$-finite, the top arrow is an isomorphism whenever $M$ is finitely generated. This statement can be checked locally. Let $p \in \text{Spec}(R)$ be given, and let $M$ be a finitely generated $R$-module. The localization

$$(R \otimes_{F_R} \text{Hom}_R(M, J))_p \to \text{Hom}_R(M, (R \otimes_{F_R} J)|_{F_R})_p$$

of the top displayed arrow at $p$ factors naturally as

$$(R \otimes_{F_R} \text{Hom}_R(M, J))_p \to R_p \otimes_{F_{R_p}} \text{Hom}_R(M, J)_p$$

$$\to R_p \otimes_{F_{R_p}} \text{Hom}_{R_p}(M_p, J_p)$$

$$\to \text{Hom}_{R_p}(M_p, (R_p \otimes_{F_{R_p}} J_p)|_{F_{R_p}})$$

$$\to \text{Hom}_R(M, (R \otimes_{F_R} J)|_{F_R})_p,$$

where the top arrow is an isomorphism for all $R$-modules $M$ and the second and fourth arrows are isomorphisms because $R$ is Noetherian and so $M$ is finitely presented. Finally, the third arrow is an isomorphism because $R$ is regular and $F$-finite, so $(F_{R_p})_p$ is a finite free $R_p$-module, and therefore $(R_p \otimes_{F_{R_p}} J_p)|_{F_{R_p}}$ is isomorphic as an $R_p$-module to a finite direct sum of copies of $J_p$. This completes the proof.

Given two $\mathcal{F}$-modules over $R$ (say $M$ and $N$) we can regard them as Frobenius modules, and consider the $\mathbb{F}_p$-space of $\mathcal{F}$-module (resp. Frobenius module) morphisms between them. We show in Proposition 2.13 below that not only are these two sets of morphisms the same, but that this set arises as the fixed part of a certain Frobenius module structure on $\text{Hom}_R(M, N)$ itself, explained next.

Remark 2.12. Let $R$ be a regular Noetherian ring of characteristic $p > 0$. Let $(M, \theta_M)$ and $(N, \theta_N)$ be $\mathcal{F}$-modules over $R$. Then $\text{Hom}_R(M, N)$ admits a natural Frobenius module structure as follows. Define $\varphi : \text{Hom}_R(M, N) \to F_* \text{Hom}_R(M, N)$ by

$$\varphi(f) = \theta_N^{-1} \circ (\text{id}_R \otimes f) \circ \theta_M$$

for each $f \in \text{Hom}_R(M, N)$. It is clear that $\varphi$ is additive; it remains to show it is $R$-linear. Given any $r \in R$, we have

$$\varphi(r f) = \theta_N^{-1} \circ (\text{id}_R \otimes r f) \circ \theta_M = \theta_N^{-1} \circ (\mu_r \otimes f) \circ \theta_M = \mu_r \circ \theta_N^{-1} \circ (\text{id}_R \otimes f) \circ \theta_M = r \varphi(f)$$

for all $f \in \text{Hom}_R(M, N)$, where $\mu_s$ (for any $s \in R$) denotes multiplication by $s$. It follows that $\varphi$ is $R$-linear, and hence it provides a Frobenius module structure on $\text{Hom}_R(M, N)$.
Proposition 2.13. Let $R$ be a regular Noetherian ring of characteristic $p > 0$. Let $(M, \theta_M)$ and $(N, \theta_N)$ be $\mathcal{F}$-modules over $R$. Regard $M$ (resp. $N$) as a Frobenius module via the $R$-linear map $\varphi_M : M \to F_* M$ (resp. $\varphi_N : N \to F_* N$) corresponding via adjunction to $\theta_M^{-1}$ (resp. $\theta_N^{-1}$).

\[ \text{Hom}_{R[F]}(M, N) = \text{Hom}_{\mathcal{F}}(M, N) = \text{Hom}_R(M, N)_{\varphi=1} \]

as $\mathbb{F}_p$-subspaces of $\text{Hom}_R(M, N)$, where the Frobenius module structure $\varphi$ on $\text{Hom}_R(M, N)$ is defined as in Remark 2.12.

Proof. The first equality has nothing to do with the choice of $\varphi$. Let $f \in \text{Hom}_R(M, N)$ be given. On the one hand, the map $f$ belongs to $\text{Hom}_{R[F]}(M, N)$ if and only if $\varphi_M \circ f = F_* f \circ \varphi_M$. On the other hand, $f$ belongs to $\text{Hom}_{\mathcal{F}}(M, N)$ if and only if $\theta_M \circ f = F_* f \circ \theta_M$; equivalently, $f \circ \theta_M^{-1} = \theta_N^{-1} \circ F_* f$. We have

\[ f(\theta_M^{-1}(r \otimes m)) = f(r \varphi_M(m)) = r f(\varphi_M(m)) \]

and

\[ \theta_N^{-1}(F_* f(r \otimes m)) = \theta_N^{-1}(r \otimes f(m)) = r \varphi_N(f(m)) \]

for all $r \in R$ and $m \in M$, and so the equality $f \circ \theta_M^{-1} = \theta_N^{-1} \circ F_* f$ is equivalent to $\varphi_M \circ f = F_* f \circ \varphi_M$.

Thus $\text{Hom}_{R[F]}(M, N) = \text{Hom}_{\mathcal{F}}(M, N)$.

For the second equality, observe that a map $f \in \text{Hom}_R(M, N)$ belongs to the fixed part $\text{Hom}_R(M, N)_{\varphi=1}$ if and only if $f = \theta_N^{-1} \circ (\text{id}_R \otimes f) \circ \theta_M$, or equivalently, $\theta_N \circ f = F_* f \circ \theta_M$. This is exactly the criterion for $f$ to be an $\mathcal{F}$-module morphism, completing the proof. \qed

Remark 2.14. Let $R$ be a regular Noetherian ring of characteristic $p > 0$, and let $(M, \theta_M)$ be an $\mathcal{F}$-module over $R$. By Example 2.9(a), the $R$-module $R$ itself is an $\mathcal{F}$-module with corresponding Frobenius module structure given by $\varphi_R = F_R$. Under the canonical identification of $M$ with $\text{Hom}_R(R, M)$, the Frobenius module structure on $\text{Hom}_R(R, M)$ provided by Remark 2.12 coincides with the Frobenius module structure $\varphi_M$ corresponding by adjunction to the given $\mathcal{F}$-module structure on $M$ itself. Indeed, if $f : R \to M$ is defined by $f(1) = m$, then the composite $R \xrightarrow{\theta_R} F_* R \xrightarrow{\text{id}_R \otimes f} F_* M \xrightarrow{\theta_M^{-1}} M$ maps $1 \mapsto 1 \otimes 1 \mapsto 1 \otimes m \mapsto \varphi_M(m)$.

3. PROOF OF THE MAIN THEOREM

Lemma 3.1. Let $R$ be a regular Noetherian ring of characteristic $p > 0$, and let $J$ be an injective $R$-module. Denote by $D_J(\cdot)$ the exact functor $\text{Hom}_R(\cdot, J)$ on the category of $R$-modules. If $M$ is an $R$-module, then any $R$-module homomorphism $M \to F_* M$ induces a Frobenius module structure on $D_J(M)$.

Proof. Apply the functor $D_J$ to the given map, obtaining an $R$-linear map $D_J(F_* M) \to D_J(M)$. Pre-composition with the map $\delta_M$ defined in Proposition 2.11 gives an $R$-linear map $F_* D_J(M) \to D_J(M)$, which corresponds by adjunction (Proposition 2.11) to an $R$-linear map $D_J(M) \to F_* D_J(M)$, the desired Frobenius module structure. \qed

In particular, if $M$ is an $\mathcal{F}$-module (resp. a generator of an $\mathcal{F}$-finite $\mathcal{F}$-module), then for any injective $R$-module $J$, $D_J(M)$ has a Frobenius module structure obtained by applying Lemma 3.1 to the structure morphism $\theta_M$ (resp. the generating morphism $\beta$).

Theorem 3.2. Let $R$ be an $\mathcal{F}$-finite regular Noetherian ring containing an algebraically closed field $k$ of characteristic $p > 0$, and let $J$ be an injective $R$-module. Denote by $D_J(\cdot)$ the exact functor $\text{Hom}_R(\cdot, J)$ on the category of $R$-modules. Assume that the following conditions are satisfied:

(i) $J$, which is an $\mathcal{F}$-module by [9] Proposition 1.5, is simple as an $\mathcal{F}$-module;
Then, for each $M/N$ all $i$ we wish to construct an is a finitely generated $\mathbb{F}_p$-module for $D$ notation of \[8\], we have

$$M_i \leq \mathbb{F}_p \cdot J$$

Since $R$ is $F$-finite, as desired.

Finally, we prove the equality of (3) and (4). By definition, $M = \lim_{\rightarrow} (M' \xrightarrow{\beta} F^* M' \xrightarrow{F^* \beta} (F^*)^2 M' \rightarrow \cdots)$ and the $\mathcal{F}$-module structure on $M$ is induced by $\beta$ and its $F^*$-iterates. Applying $D_f(-)$, we find

$$D_f(M) \cong \lim_{\rightarrow} (\cdots \rightarrow D_f((F^*)^{l+1} M') \xrightarrow{D_f(F^* \beta)} D_f(F^* M') \xrightarrow{D_f(D^\beta)} D_f(M')).$$

Since $R$ is $F$-finite, not only $M'$ but also $(F^*)^l M'$ for all $l \geq 0$ are finitely generated $R$-modules. Therefore, using Proposition 2.11 to identify $D((F^*)^l M')$ with $(F^*)^l D_f(M')$ for all $l \geq 0$, we can rewrite the limit as

$$D_f(M) \cong \lim_{\rightarrow} (\cdots \rightarrow (F^*)^{l+1} D_f(M') \rightarrow F^* D_f(M') \rightarrow D_f(M')).$$

Since $(F^*)^l$ and $(F^l)^*$ are isomorphic functors, this is exactly the leveling functor of [8] p. 47. (In the notation of [8], we have $D_f(M) = G(D_f(M'))$.) It follows from the proof of [8 Proposition 1.2(b)] (see proof).
Remark 3.3 below) that

\[ D_J(M)_s \cong \lim \cdots \to k \otimes_{F_k} D_J(M')_s \to k \otimes F_k D_J(M')_s \to D_J(M')_s, \]

where \( F_k : k \to k \) is the Frobenius endomorphism of \( k \), and the maps

\[ k \otimes_{F_k} D_J(M')_s \to k \otimes_{F_k} D_J(M')_s \]

are given by the identity on the first tensor factor and the restriction of the map \( D_J(M') \to D_J(M') \) defining the Frobenius module structure on \( D_J(M') \) in the second. But by our condition (ii), this last map restricts to a bijection from \( D_J(M')_s \) to itself. That is, the displayed limit can be identified with \( D_J(M')_s \), so that \( D_J(M)_s \cong D_J(M')_s \) as \( k \)-spaces, completing the proof of the equality of (3) and (4) and therefore the proof of the theorem.

Remark 3.3. In the proof of Theorem 3.2 above, we appealed to [8, Proposition 1.2(b)]. This proposition is stated in [8] only for a ring \( R \) of characteristic \( p > 0 \) such that \( F_p R \) is a free \( R \)-module, a hypothesis that is stronger than ours. However, examining the proof of [8, Proposition 1.2(b)], it is clear that this hypothesis is only used in the form of the following consequence: if \( M \) is an \( R \)-module and \( m, m' \in M \) are such that \( 1 \otimes m = 1 \otimes m' \) in \( F^p M = R \otimes_{F_R} M \), then \( m = m' \). But since we assumed in Theorem 3.2 that \( R \) is regular and \( F \)-finite, it is also \( F \)-split, from which the previous statement is immediate.

The following corollary of Theorem 3.2, which identifies a class of injective modules for which the hypotheses of the theorem are satisfied, is the main result of this paper.

Corollary 3.4. Let \( R \) be a regular, \( F \)-finite Noetherian ring containing an algebraically closed field \( k \) of characteristic \( p > 0 \), and let \( m \subseteq R \) be any maximal ideal. Let \( E = E_R(R/m) \) be the \( R \)-injective hull of \( R/m \), and denote by \( D(-) \) the exact functor \( \text{Hom}_R(-, E) \) on the category of \( R \)-modules. Then, for each \( \mathcal{F} \)-finite \( \mathcal{F} \)-module \( M \), the following numbers are all equal (and, in particular, are all finite):

1. the \( F \)-dimension of \( \text{Hom}_R[F](M, E) = \text{Hom}_\mathcal{F}(M, E) \),
2. the \( F \)-dimension of \( D(M) \) is \( = 1 \),
3. the \( k \)-dimension of \( D(M)_s \),
4. the \( k \)-dimension of \( D(M')_s \), where \( M' \) is any \( \mathcal{F} \)-module generator of \( M \),
5. the maximal integer \( t \) such that there exists a surjective \( \mathcal{F} \)-module morphism (equivalently, surjective Frobenius module morphism) \( M \to E^t \).

Proof. By Example 2.9(c), \( E \) is a simple \( \mathcal{F} \)-module, so condition (i) of Theorem 3.2 is satisfied. Now let \( M' \) be a finitely generated \( R \)-module equipped with a choice of \( R \)-module homomorphism \( M' \to F^* M' \). There exists an \( R \)-linear surjection \( R^l \) \( \to M' \) for some \( l \geq 0 \); applying the exact functor \( D \), we obtain an \( R \)-linear injection \( D(M') \to D(R^l) = E^l \). Since \( E \) (and hence \( E^l \)) is an Artinian \( R \)-module supported only at \( m \), the same is true of \( D(M') \), so \( D(M') \) has a natural structure as a module over the \( m \)-adic completion \( \hat{R}^m \) of \( R \). In fact, \( D(M') \) is a Frobenius module over \( \hat{R}^m \), with the Frobenius structure given by the same underlying additive map \( D(M') \to D(M') \) defined by Lemma 3.1. The ring \( \hat{R}^m \) is local (since \( m \) is maximal) and contains an algebraically closed (hence perfect) field \( k \); moreover, \( D(M') \) is Artinian as an \( \hat{R}^m \)-module. Therefore, Theorem 2.6 applies. We conclude that \( D(M')_s \) is a finite-dimensional \( k \)-space and the Frobenius structure on \( D(M') \) restricts to a bijection on \( D(M')_s \), so condition (ii) of Theorem 3.2 is satisfied. The corollary now follows from Theorem 3.2 applied to \( J = E \).

The proof of the equality of (1) and (5) in Corollary 3.4 works in characteristic zero as well, replacing “\( \mathcal{F} \)-finite \( \mathcal{F} \)-module” with “holonomic \( \mathcal{D} \)-module”. Therefore we obtain an alternate proof of the fact that if \( \hat{R} = k[[x_1, \ldots, x_n]] \) or \( k[[x_1, \ldots, x_n]] \) where \( k \) is a field of characteristic zero, and \( M \) is a holonomic \( \mathcal{D}(R, k) \)-module, then \( \dim_k \text{Hom}_\mathcal{D}(M, E) \) is equal to the maximal integer \( t \) for which there exists a \( \mathcal{D} \)-linear surjection \( M \to E^t \). This statement is part of [7, Corollary 5.2]. An easier “dual” statement is the following [16, Lemma 2.3]: \( \dim_k \text{Hom}_\mathcal{D}(R, M) \) is equal to the maximal integer \( t \) for which there exists
a $\mathcal{D}$-linear injection $R^t \to M$. We can prove a version of this in the Frobenius module setting, as part of a “dual” version of Corollary 3.4. Note, however, that Theorem 3.5 has a finite-dimensionality hypothesis whose analogue is not needed (because it is automatically satisfied) in Corollary 3.4.

**Theorem 3.5.** Let $R$ be a regular Noetherian ring containing an algebraically closed field $k$ of characteristic $p > 0$, and let $M$ be an $\mathcal{F}$-finite $\mathcal{F}$-module over $R$. Assume that $M_s$ is a finite-dimensional $k$-space. Then the following numbers are all equal (and, in particular, are all finite):

1. the $\mathbb{F}_p$-dimension of $\text{Hom}_{R,F}(R, M) = \text{Hom}_R(R, M)$,
2. the $\mathbb{F}_p$-dimension of $M^\varphi = 1$,
3. the $k$-dimension of $M_s$,
4. the maximal integer $t$ such that there exists an injective $\mathcal{F}$-module morphism (equivalently, injective Frobenius module morphism) $R^t \to M$.

**Proof.** By Remark 2.14 we can identify $M$ with $\text{Hom}_R(R, M)$ as Frobenius modules over $R$, and therefore we can identify $M^\varphi = 1$ with $\text{Hom}_R(R, M)^\varphi = 1$ as $\mathbb{F}_p$-spaces. Therefore the equality of (1) and (2) follows from Proposition 2.13. We have assumed that $M_s$ is a finite-dimensional $k$-space, so the equality of (2) and (3) follows from Proposition 2.4. Finally, the proof of the equality of (1) and (4) is essentially dual to the proof of the equality of (1) and (5) in Theorem 3.2 using the fact that $R$ is a simple $\mathcal{F}$-module (Example 2.9(a)). The arguments are similar enough that we omit the details, providing a sketch. An $\mathcal{F}$-module injection $R^t \to M$ gives rise to $t \mathbb{F}_p$-linearly independent $\mathcal{F}$-module morphisms $R \to M$ by pre-composition with the coordinate inclusions; conversely, given $t$ distinct isomorphic copies of $R$ (say $M_1, \ldots, M_t$) as $\mathcal{F}$-submodules of $M$, it can be shown (since all $M_i$ are simple $\mathcal{F}$-submodules) that the sum $\sum_{i=1}^t M_i \subseteq M$ is a direct sum for $j = 1, \ldots, t$ by induction on $j$, and the case $j = t$ is the desired assertion.

**Question 3.6.** If $R$ is a regular Noetherian ring containing an algebraically closed field $k$ of characteristic $p > 0$, and $M$ is an $\mathcal{F}$-finite $\mathcal{F}$-module over $R$, is $M_s$ a finite-dimensional $k$-space?

A positive answer to Question 3.6 would, of course, permit us to remove the finite-dimensionality hypothesis in Theorem 3.5 since Proposition 2.4 would apply.

4. AN APPLICATION TO LOCAL COHOMOLOGY

Our Corollary 3.4 allows us to relate certain étale and local cohomology groups associated with projective schemes.

**Theorem 4.1.** Let $X \subseteq \mathbb{P}_k^n$ be a projective scheme over an algebraically closed field $k$ of characteristic $p > 0$. Let $I \subseteq R = k[x_0, \ldots, x_n]$ be the homogeneous defining ideal of $X$, let $m \subseteq R$ be the irrelevant maximal ideal, and let $E = H_{m}^{n+1}(R)$. Then we have

$$H^j_{\text{et}}(X, \mathbb{F}_p) \cong \text{Hom}_{\mathcal{F}}(H^{n-j}_I(R), E)$$

as $\mathbb{F}_p$-spaces, for all $j > 0$.

In the proof of Theorem 4.1 we will need the notion of a *graded* Frobenius module.

**Definition 4.2.** Let $R = k[x_0, \ldots, x_n]$ where $k$ is a field of characteristic $p > 0$. View $R$ as a graded ring $\oplus_{i \geq 0} R_i$ with respect to the standard grading (so $R_0 = k$ and $\text{deg}(x_j) = 1$ for $0 \leq j \leq n$). A *graded Frobenius module* over $R$ is a pair $(M, \varphi_M)$ where $M = \oplus_{i \in \mathbb{Z}} M_i$ is a graded $R$-module and $\varphi_M : M \to F_M M$ is a graded $R$-linear homomorphism (equivalently, $\varphi_M$ is an additive map $M \to M$ such that $\varphi_M(r m) = r^p \varphi_M(m)$ for all $r \in R$ and $m \in M$ and $\varphi_M(M_I) \subseteq M_{pl}$ for all $l \in \mathbb{Z}$).
Proof of Theorem 4.1. By [8] Proposition 5.1, we can identify $k \otimes_{F_p} H^j_{\text{et}}(X, F_p)$ with the Frobenius stable part $H^j(X, O_X)_s$ of the Zariski cohomology (which carries a natural structure of Frobenius module over $R$). By [4] Theorem A4.1, this is the well-known long exact sequence relating local cohomology and Zariski cohomology, we have

$$\bigoplus_{l \in \mathbb{Z}} H^j(X, O_X(l)) \cong H^{j+1}_m(R)$$

as graded $R$-modules (in fact, as graded Frobenius modules) for $j > 0$. Since $\bigoplus_{l \in \mathbb{Z}} H^j(X, O_X(l))$ is a graded Frobenius module, its stable part is contained in its degree-zero component, so $H^j(X, O_X)_s \cong H^{j+1}_m(R)_s$.

Graded local duality [2] Theorem 14.4.1 implies that

$$H^{j+1}_m(R) \cong \text{D}(\text{Ext}_R^{(n+1)-(j+1)}(R/I, R)) = \text{D}(\text{Ext}_R^{n-j}(R/I, R))$$

as graded $R$-modules (in fact, as graded Frobenius modules), where $\text{D}$ denotes the graded Matlis dual functor $^*\text{Hom}_R(\cdot, E)$. Since $\text{Ext}_R^{n-j}(R/I, R)$ is a finitely generated $R$-module, we have

$$^*\text{Hom}_R(\text{Ext}_R^{n-j}(R/I, R), E) = \text{Hom}_R(\text{Ext}_R^{n-j}(R/I, R), E)$$

as $R$-modules. At this point we begin systematically to ignore the gradings. The $R$-linear map

$$\text{Ext}_R^{n-j}(R/I, R) \rightarrow \text{Ext}_R^{n-j}(R/I^{[p]}, R) \cong F^*(\text{Ext}_R^{n-j}(R/I, R))$$

induced by the surjection $R/I^{[p]} \rightarrow R/I$ is a generating morphism [12] Proposition 1.11] for the $\mathcal{F}$-finite $\mathcal{F}$-module $H^{n-j}_m(R)$ (here $I^{[p]}$ is the ideal generated by all $p$th powers of elements of $I$, and the displayed isomorphism holds because $R/I$ is a finitely generated $R$-module and $R$ is regular so that $F^*$ is exact). The ring $R$ satisfies the hypotheses of Corollary 3.4 and $E = H^{n+1}_m(R)$ is the $R$-injective hull of $R/m$, so we have equalities

$$\text{dim}_F H^j_{\text{et}}(X, F_p) = \text{dim}_k H^j(X, O_X)_s = \text{dim}_k H^{j+1}_m(R)_s = \text{dim}_k \text{Hom}_R(\text{Ext}_R^{n-j}(R/I, R), E)_s = \text{dim}_k \text{Hom}_R(H^{n-j}_m(R), E)_s = \text{dim}_{F_p} \text{Hom}_\mathcal{F}(H^{n-j}_m(R), E),$$

where the last two equalities are part of Corollary 3.4 (and all these numbers are finite). This completes the proof. \qed

If $X \subseteq \mathbb{P}^n_k$ is a projective scheme over a field $k$, defined by a homogeneous ideal $I \subseteq R = k[x_0, \ldots, x_n]$, the length of the local cohomology modules $H^j_I(R)$ as $\mathcal{D}$-modules (if $\text{char}(k) = 0$) or as $\mathcal{F}$-modules (if $\text{char}(k) = p > 0$) is of particular interest. Theorem 1.2 calculates these $\mathcal{D}$-module lengths when $\text{char}(k) = 0$ and $X$ is smooth. In positive characteristic, Katzman, Ma, Smirnov, and the second author’s [10] Theorem 4.3] gives an explicit formula for the $\mathcal{F}$-module length of $H^j_I(R)$ (where $c$ is the codimension of $X$ in $\mathbb{P}^n_k$) under the assumption that $R/I$ has an isolated non-$\mathcal{F}$-rational point at the origin. Our Theorem 4.1 gives some new information about the $\mathcal{F}$-module length of $H^j_I(R)$ in the case $i \neq c$.

**Corollary 4.3.** Keep the notation and hypotheses of Theorem 4.1.

(a) Let $j > 0$ be given, and suppose that the local cohomology module $H^{n-j}_I(R)$ is supported only at $m$. Then

$$H^{n-j}_I(R) \cong E^{\lambda_j},$$

where $\lambda_j = \text{dim}_{F_p}(H^j_{\text{et}}(X, F_p))$

and hence the $\mathcal{F}$-module length of $H^{n-j}_I(R)$ is precisely $\text{dim}_{F_p}(H^j_{\text{et}}(X, F_p))$. 
(b) In particular, if $X$ is Cohen-Macaulay (i.e., each local ring $\mathcal{O}_{X,x}$ of $X$ is a Cohen-Macaulay local ring), then
$$H^n_{I_j}(R) \cong E^{\lambda_j},$$
where $\lambda_j = \dim_{F_p}(H^j_{\text{ét}}(X, \mathbb{F}_p))$, for all $0 < j < \dim(X)$.

Proof. Under the assumption on $H^n_{I_j}(R)$, we have $H^n_{I_j}(R) \cong E^{a_j}$ (as $F$-modules) for some non-negative integer $a_j$ by [12, Theorem 1.4]. It is straightforward to check that $\text{Hom}_F(E^{a_j}, E) \cong \mathbb{F}_p^{a_j}$. Therefore, $a_j = \lambda_j = \dim_{F_p}(H^j_{\text{ét}}(X, \mathbb{F}_p))$ by Theorem 4.1 proving part (a).

When $X$ is Cohen-Macaulay, it follows from the Peskine-Szpiro vanishing theorem [13, Proposition III.4.1] that $\text{Supp}_R(H^n_{I_j}(R)) \subseteq \{m\}$ for all $j$ such that $n - j \neq \text{codim}(X, \mathbb{F}_p^n) = n - \dim(X)$. Part (b), and hence the corollary, follows.

Remark 4.4. Let $X$ be a projective scheme over any field $k$ of characteristic $p > 0$. Let $I$ be the homogeneous defining ideal in $R = k[x_0, \ldots, x_n]$ of $X$ for a choice of embedding $X \hookrightarrow \mathbb{P}^n_k$. The numbers
$$\lambda_{i,j} = \dim_k(\text{Ext}^1_R(k, H^{n+1-j}_{I_i}(R)))$$
are called the Lyubeznik numbers of $X$ and were shown in [17, Theorem 1.1] to be independent of the choice of the embedding of $X$. As a consequence of Corollary 4.1 one can calculate explicitly each $\lambda_{i,j}$ under the assumption that $X$ is Cohen-Macaulay; we will leave the details to the interested reader. (The $\lambda_{i,j}$ do not change under a field extension, so the hypothesis in Corollary 4.1 that $k$ is algebraically closed causes no difficulty.)

Remark 4.5. Let $X, R, I$ be the same as in Remark 4.4 and, additionally, assume that $X$ is irreducible and each local ring $\mathcal{O}_{X,x}$ is $F$-rational for each point $x \in X$. Our Theorem 4.1 implies that $H^{n-\dim(X)}_{I_i}(R)$ admits a $F$-module quotient that is isomorphic to $E^{\lambda_i}$ where $\lambda_i = \dim_{F_p}(H^i_{\text{ét}}(X, \mathbb{F}_p))$. This does not fully recover the prime-characteristic analogue of Theorem 12 in the case when $i = c = n - \dim(X)$; the length differs by one from the desired analogous result. The reason is that the simple $F$-submodule of $H^c_{I_i}(R)$ does not admit any non-zero $F$-module morphism to $E$. However, it follows directly from [10, Theorem 4.3] that $H^c_{I_i}(R)$ admits a simple $F$-submodule $H_0$ such that $H^c_{I_i}(R)/H_0 \cong E^{\lambda_i}$. This completes our analogue of the theorem of Hartshorne-Polini.
