On the uniqueness of solutions to quadratic BSDEs with non-convex generators and unbounded terminal conditions

Shengjun Fan\(^\ast\), Ying Hu\(^{\ast\ast}\), Shanjian Tang\(^\dagger\)

Abstract

We prove a uniqueness result of the unbounded solution for a quadratic backward stochastic differential equation whose terminal condition is unbounded and whose generator \(g\) may be non-Lipschitz continuous in the state variable \(y\), non-convex (non-concave) in the state variable \(z\), and instead satisfies a strictly quadratic condition and an additional assumption. The key observation is that if the generator is strictly quadratic, then the quadratic variation of the first component of the solution admits an exponential moment. Typically, a Lipschitz perturbation of some convex (concave) function satisfies the additional assumption mentioned above. This generalizes some results obtained in [1] and [2].

Keywords: Backward stochastic differential equation, Existence and uniqueness, Quadratic growth, Unbounded terminal condition, Strictly quadratic condition.

2010 MSC: 60H10

1. Introduction

Since the nonlinear backward stochastic differential equation (BSDE in short) was initially introduced in [7], a lot of efforts have been made to study the well posedness, and many applications have been found in various fields such as mathematical finance, stochastic control and PDEs etc. In particular, quadratic BSDEs were first investigated in [6] for bounded terminal conditions, which have attracted much attention in recent years and it is the subject of this article.

We consider the following quadratic BSDE:

\[
Y_t = \xi + \int_t^T g(s,Y_s,Z_s)ds - \int_t^T Z_s \cdot dB_s, \quad t \in [0,T],
\]

where the terminal value \(\xi\) is an unbounded random variable, and the generator \(g\) has a quadratic growth in the variable \(z\). In [1], the authors obtained the first existence result for this kind of BSDEs, when the terminal value has a certain exponential moment. The uniqueness results were established in [2], [4] and [5] when the generator \(g\) is Lipschitz continuous in \(y\), and either convex or concave in \(z\). The case of a
non-convex generator $g$ was tackled in [8] and [3], but more assumptions are imposed on the terminal value $\xi$ than the exponential integrability. In this paper, we prove a uniqueness result for the unbounded solution of quadratic BSDEs, where the generator $g$ may be non-Lipschitz and has a general growth in $y$, and non-convex (non-concave) in $z$, and no additional assumption is required on the terminal value.

We suppose instead that the generator $g$ satisfies an additional assumption which holds typically for a (locally) Lipschitz perturbation of some convex (concave) function (see (H4) and Proposition 2.3 for details), and is strictly quadratic, i.e., either

$$g(\omega, t, y, z) \geq \frac{\gamma}{2} |z|^2 - \beta |y| - \alpha_t(\omega),$$

or

$$g(\omega, t, y, z) \leq -\frac{\gamma}{2} |z|^2 + \beta |y| + \alpha_t(\omega)$$

holds for two constants $\gamma > 0, \beta \geq 0$ and a nonnegative process $\alpha_t$. Under this condition, we can prove that if $(Y, Z)$ is a solution satisfying $E[\sup_{t \in [0,T]} \exp(p|Y_t| + p \int_0^T \alpha_s ds)] < +\infty$ for some $p > 0$, then there exists a constant $\varepsilon > 0$ such that $E[\exp(\varepsilon \int_0^T |Z_t|^2 dt)] < +\infty$. See Proposition 2.2 for details.

Let us close this introduction by introducing some notations that will be used later. Fix the terminal time $T > 0$ and a positive integer $d$, and let $x \cdot y$ denote the Euclidean inner product for $x, y \in \mathbb{R}^d$. Suppose that $(B_t)_{t \in [0,T]}$ is a $d$-dimensional standard Brownian motion defined on some complete probability space $(\Omega, \mathcal{F}, \mathbb{P})$. Let $(\mathcal{F}_t)_{t \in [0,T]}$ be the natural filtration generated by $B$ and augmented by all $\mathbb{P}$-null sets of $\mathcal{F}$. All the processes are assumed to be $(\mathcal{F}_t)$-adapted.

Denote by $1_A(\cdot)$ the indicator of set $A$, and $\sgn(x) := 1_{x>1} - 1_{x<1}$. Let $a \land b$ be the minimum of $a$ and $b$, $a^{-} := -(a \land 0)$ and $a^{+} := (-a)^{+}$. For any real $p \geq 1$, let $\mathcal{S}^p$ be the set of all progressively measurable and continuous real-valued processes $(Y_t)_{t \in [0,T]}$ such that

$$\|Y\|_{\mathcal{S}^p} := \left( E[\sup_{t \in [0,T]} |Y_t|^p] \right)^{1/p} < +\infty,$$

and $\mathcal{M}^p$ the set of all progressively measurable $\mathbb{R}^d$-valued processes $(Z_t)_{t \in [0,T]}$ such that

$$\|Z\|_{\mathcal{M}^p} := \left( E\left[ \left( \int_0^T |Z_t|^2 dt \right)^{p/2} \right] \right)^{1/p} < +\infty.$$

As mentioned before, we will study BSDEs of type (1.1). The terminal condition $\xi$ is real-valued and $\mathcal{F}_T$-measurable, and the process $g(\cdot, \cdot, y, z) : \Omega \times [0,T] \to \mathbb{R}$ is progressively measurable for each pair $(y, z)$ and continuous in $(y, z)$. By a solution to (1.1), we mean a pair of progressively measurable processes $(Y_t, Z_t)_{t \in [0,T]}$, taking values in $\mathbb{R} \times \mathbb{R}^d$ such that $\mathbb{P}$-a.s., the function $t \mapsto Y_t$ is continuous, $t \mapsto Z_t$ is square-integrable, $t \mapsto g(t, Y_t, Z_t)$ is integrable, and verifies (1.1). And, we usually denote by BSDE $(\xi, g)$ the BSDE whose terminal condition is $\xi$ and whose generator is $g$.

Finally, we recall that a process $(X_t)_{t \in [0,T]}$ belongs to class (D) if the family of random variables $\{X_\tau : \tau$ is any stopping time taking values in $[0, T]\}$ is uniformly integrable.
2. Main result

We define the following function, for any non-negative integrable function \( f(\cdot) : [0, T] \to [0, +\infty) \) and any constants \( \kappa \geq 0 \) and \( \lambda > 0 \):

\[
\psi(s, x; f, \kappa, \lambda) = \exp \left( \lambda e^{\kappa s} x + \lambda \int_0^s f_r e^{\kappa r} \, dr \right), \quad (s, x) \in [0, T] \times [0, +\infty).
\] (2.1)

It is easy to verify that \( \psi(\cdot, \cdot, f, \kappa, \lambda) \) belongs to \( C^{1,2}([0, T] \times [0, +\infty)) \),

\[
- \psi_x(s, x; f, \kappa, \lambda)(f_s + \kappa x) + \psi_x(s, x; f, \kappa, \lambda) = 0, \quad (s, x) \in [0, T] \times [0, +\infty)
\] (2.2)

and

\[
- \lambda \psi_x(s, x; f, \kappa, \lambda) + \psi_{xx}(s, x; f, \kappa, \lambda) \geq 0, \quad (s, x) \in [0, T] \times [0, +\infty),
\] (2.3)

where and hereafter, \( \psi_x(\cdot, \cdot, f, \kappa, \lambda) \) denotes the first-order partial derivative with respect to time, and \( \psi_x(\cdot, \cdot, f, \kappa, \lambda) \) and \( \psi_{xx}(\cdot, \cdot, f, \kappa, \lambda) \) are the first-order and second-order partial derivatives with respect to space of the time-space function \( \psi(\cdot, \cdot, f, \kappa, \lambda) \).

In the whole paper, we always fix a progressively measurable non-negative process \( (\alpha_t)_{t \in [0, T]} \) and several real constants \( \beta \geq 0, \, 0 < \gamma \leq \gamma, \, k \geq 0, \, k \geq 0 \) and \( \delta \in [0, 1) \). Let us first introduce the following two assumptions on the generator \( g \).

(H1) \( d\mathbb{P} \times dt - a.e., \) for each \( (y, z) \in \mathbb{R} \times \mathbb{R}^d \), it holds that

\[
\text{sgn}(y) g(\omega, t, y, z) \leq \alpha_t(\omega) + \beta |y| + \frac{\gamma}{2} |z|^2;
\]

(H2) There exists a deterministic nondecreasing continuous function \( \phi(\cdot) : [0, +\infty) \to [0, +\infty) \) with \( \phi(0) = 0 \) such that \( d\mathbb{P} \times dt - a.e., \) for each \( (y, z) \in \mathbb{R} \times \mathbb{R}^d \),

\[
|g(\omega, t, y, z)| \leq \alpha_t(\omega) + \phi(|y|) + \frac{\gamma}{2} |z|^2.
\]

The following proposition gives a slight generalization of the existence result of [2] for quadratic BSDEs with unbounded terminal conditions.

**Proposition 2.1.** Suppose that the function \( \psi \) is defined in (2.1) and that \( \xi \) is a terminal condition and \( g \) is a generator which is continuous in \( (y, z) \) and satisfies assumptions (H1) and (H2).

(i) Let \( (Y, Z) \) be a solution to BSDE \( (\xi, g) \) such that \( (\psi^p(t, [Y_t]; \alpha, \beta, \gamma))_{t \in [0, T]} \) belongs to class (D) for some \( p \geq 1 \). Then, \( \mathbb{P} - a.s., \) for each \( t \in [0, T] \),

\[
p|Y_t| \leq \psi^p(t, [Y_t]; \alpha, \beta, \gamma) + \frac{1}{p}(p - 1)\gamma^2 \int_t^T |Z_s|^2 \, ds \leq \mathbb{E}[\psi^p(T, [\xi]; \alpha, \beta, \gamma)|\mathcal{F}_t].
\] (2.4)

(ii) If \( \mathbb{E}[\psi^p(T, [\xi]; \alpha, \beta, \gamma)] < +\infty \) for some \( p \geq 1 \), then BSDE \( (\xi, g) \) admits a solution such that \( (\psi^p(t, [Y_t]; \alpha, \beta, \gamma))_{t \in [0, T]} \) belongs to class (D). Moreover, if \( p > 1 \), then there exists a constant \( C > 0 \) depending only on \( p \) such that

\[
\mathbb{E} \left[ \sup_{t \in [0, T]} \psi^p(t, [Y_t]; \alpha, \beta, \gamma) \right] \leq C \mathbb{E}[\psi^p(T, [\xi]; \alpha, \beta, \gamma)]
\] (2.5)

and \( Z \in \mathcal{M}^2 \). And, if \( p > 2 \), then \( Z \in \mathcal{M}^p \).
Proof. (i) Let $L_t$ denote the local time of $Y$ at 0. Itô-Tanaka’s formula applied to $\psi(s, |Y_s|; \alpha, \beta, p\gamma)$ gives, in view of assumption (H1),

\[
d\psi(s, |Y_s|; \alpha, \beta, p\gamma) = -\psi(s, |Y_s|; \alpha, \beta, p\gamma)\text{sgn}(Y_s)g(s, Y_s, Z_s)ds + \psi_x(s, |Y_s|; \alpha, \beta, p\gamma)\text{sgn}(Y_s)Z_s \cdot dB_s \\
+ \psi_z(s, |Y_s|; \alpha, \beta, p\gamma)dL_s + \frac{1}{2}\psi_{xx}(s, |Y_s|; \alpha, \beta, p\gamma)|Z_s|^2 ds + \psi(s, |Y_s|; \alpha, \beta, p\gamma)ds
\]

Then, by virtue of (2.2) and (2.3) together with the fact that $\psi_x(\cdot, \cdot, \kappa, \lambda) \geq \lambda$, we have

\[
d\psi(s, |Y_s|; \alpha, \beta, p\gamma) \geq \frac{1}{2}p(p - 1)\gamma^2|Z_s|^2 ds + \psi(s, |Y_s|; \alpha, \beta, p\gamma)\text{sgn}(Y_s)Z_s \cdot dB_s, \quad s \in [0, T]. \tag{2.6}
\]

Let us denote, for each $t \in [0, T]$ and each integer $m \geq 1$, the following stopping time

\[
\tau_m := \inf \left\{ s \in [t, T] : \int_t^s (\psi_x(r, |Y_r|; \alpha, \beta, p\gamma))^2 |Z_r|^2 dr \geq m \right\} \wedge T
\]

with the convention inf $\Phi = +\infty$. It follows from (2.6) and the definition of $\tau_m$ that for each $m \geq 1$,

\[
\psi(t, |Y_t|; \alpha, \beta, p\gamma) + \frac{1}{2}p(p - 1)\gamma^2E \left[ \int_t^{\tau_m} |Z_r|^2 dr \right| \mathcal{F}_t] \leq E \left[ \psi(\tau_m, |Y_{\tau_m}|; \alpha, \beta, p\gamma) \right| \mathcal{F}_t], \quad t \in [0, T].
\]

Thus, since $(\psi(s, |Y_s|; \alpha, \beta, p\gamma))_{s \in [0, T]}$ belongs to class (D), the desired inequality (2.4) follows by letting $m \to \infty$ and using Fatou’s lemma in the last inequality.

(ii) Thanks to (i), proceeding as in the proof of Proposition 3 in [2] with a localization argument, we conclude that if $E[\psi^p(T, |\xi|; \alpha, \beta, \gamma)] < +\infty$ for some $p \geq 1$, then BSDE $(\xi, g)$ has a solution such that $(\psi^p(t, |Y_t|; \alpha, \beta, \gamma))_{t \in [0, T]}$ belongs to class (D) and (2.4) holds. Moreover, for $p > 1$, it is clear from (2.4) that $Z \in \mathcal{M}^2$. Since (2.4) holds for $p = 1$, we apply Doob’s maximal inequality to get (2.5). Finally, the conclusion that $Z \in \mathcal{M}^p$ for $p > 2$ has been given in Corollary 4 of [2].

To obtain a stronger integrability with respect to the process $Z$, we need the following assumption, called strictly quadratic condition:

(H3) $d\mathbb{P} \times dt - a.e.$, for each $(y, z) \in \mathbb{R} \times \mathbb{R}^d$, it holds that

\[
g(\omega, t, y, z) \geq \frac{\gamma}{2} \sqrt{|z|^2 - \beta|y|} - \alpha(\omega), \tag{2.7}
\]

or

\[
g(\omega, t, y, z) \leq -\frac{\gamma}{2} \sqrt{|z|^2 + \beta|y|} + \alpha(\omega). \tag{2.8}
\]

Proposition 2.2. Let $\psi$ be defined in (2.1), $\xi$ be a terminal condition, $g$ be a generator satisfying (H3), and $(Y_t, Z_t)$ be a solution to BSDE $(\xi, g)$. If $E[\sup_{t \in [0, T]} \psi(t, |Y_t|; \alpha, 0, p_0)] < +\infty$ for some $p_0 > 0$, then for each $\varepsilon \in (0, \varepsilon_0]$ with $\varepsilon_0 := \frac{\gamma^2}{\alpha^2} \wedge \frac{p_0 \gamma}{12 + 6\sqrt{p_0}}$, we have

\[
E \left[ \exp \left( \varepsilon \int_0^T |Z_s|^2 ds \right) \right] < +\infty. \tag{2.9}
\]

In particular, for each $p > 0$ and $\delta \in (0, 1)$, $E[\exp(p \int_0^T |Z_s|^{1+\delta} ds)] < +\infty$. 

Proof. We only consider the case that (2.7) holds. The other case is similar. Since \((Y, Z)\) is a solution to \(\text{BSDE } (\xi, g)\) and (2.7) holds, we have for each \(n \geq 1\),
\[
\frac{\gamma}{2} \int_{0}^{\sigma_n} |Z_s|^2 ds \leq Y_0 - Y_{\sigma_n} + \int_{0}^{\sigma_n} (\alpha_s + \beta |Y_s|) ds + \int_{0}^{\sigma_n} Z_s \cdot dB_s \leq X + \int_{0}^{\sigma_n} Z_s \cdot dB_s,
\]
where \(X := (2 + \beta T)\sup_{t \in [0, T]} |Y_t| + \int_{0}^{T} \alpha ds\), and
\[
\sigma_n := \inf \left\{ s \in [0, T] : \int_{0}^{s} |Z_r|^2 dr \geq n \right\} \wedge T.
\]
Then, for each \(\varepsilon > 0\) such that \(3\varepsilon (2 + \beta T) \leq p_0\), we have
\[
\exp \left( \frac{\gamma}{2} \int_{0}^{\sigma_n} |Z_s|^2 ds \right) \leq \exp(\varepsilon X) \exp \left( \varepsilon \int_{0}^{\sigma_n} Z_s \cdot dB_s - \frac{3}{2} \varepsilon^2 \int_{0}^{\sigma_n} |Z_s|^2 ds \right) \exp \left( \frac{3}{2} \varepsilon^2 \int_{0}^{\sigma_n} |Z_s|^2 ds \right).
\]
Observe that the process
\[
H(t) := \exp \left( 3\varepsilon \int_{0}^{t \wedge \sigma_n} Z_s \cdot dB_s - \frac{9}{2} \varepsilon^2 \int_{0}^{t \wedge \sigma_n} |Z_s|^2 ds \right)
\]
is a positive martingale with \(H(0) = 1\). By taking mathematical expectation in the last inequality and applying Hölder’s inequality, we obtain
\[
\mathbb{E} \left[ \exp \left( \frac{\gamma}{2} \int_{0}^{\sigma_n} |Z_s|^2 ds \right) \right] \leq (\mathbb{E} [\exp(3\varepsilon X)])^{\frac{1}{3}} \left( \mathbb{E} \left[ \exp \left( \frac{9}{2} \varepsilon^2 \int_{0}^{\sigma_n} |Z_s|^2 ds \right) \right] \right)^{\frac{1}{3}}.
\]
Consequently, for \(\varepsilon \leq \gamma/9\), we have
\[
\left( \mathbb{E} \left[ \exp \left( \frac{\gamma}{2} \int_{0}^{\sigma_n} |Z_s|^2 ds \right) \right] \right)^{\frac{1}{3}} \leq (\mathbb{E} [\exp(3\varepsilon X)])^{\frac{1}{3}} < +\infty,
\]
which yields the inequality (2.9) immediately from Fatou’s lemma. Finally, for each \(p > 0\), \(\delta \in [0, 1)\), \(x \geq 0\) and \(\varepsilon \in (0, \varepsilon_0]\), it follows from Young’s inequality that
\[
p^{1+\delta} = \left( \frac{2}{1 + \delta} x^2 \right)^{\frac{1-\delta}{2}} (p^{\frac{2}{1 + \delta}} \left( \frac{2}{1 + \delta} \varepsilon \right)^{\frac{1-\delta}{2}} \leq \varepsilon x^2 + \frac{1 - \delta}{2} p^{\frac{2}{1 + \delta}} \left( \frac{1 + \delta}{2 \varepsilon} \right)^{\frac{1-\delta}{2}}.
\]
Thus, the desired conclusion follows from (2.9). The proof is complete. \(\square\)

In what follows, the following assumption on the generator \(g\) will be used.

(H4) \(d\mathbb{P} \times dt - a.e.,\) for each \((y_i, z_i) \in \mathbb{R} \times \mathbb{R}^d, i = 1, 2\) and each \(\theta \in (0, 1),\) it holds that
\[
1_{\{y_1 - \theta y_2 > 0\}} \left( g(\omega, t, y_1, z_1) - \theta g(\omega, t, y_2, z_2) \right) \leq (1 - \theta) \left( \beta |\delta_y y| + \gamma |\delta_y z|^2 + h(\omega, t, y_1, y_2, z_1, z_2, \delta) \right)
\]
(2.10)
or
\[
1_{\{\theta y_1 - y_2 > 0\}} \left( \theta g(\omega, t, y_1, z_1) - g(\omega, t, y_2, z_2) \right) \leq (1 - \theta) \left( \beta |\delta_y y| + \gamma |\delta_y z|^2 + h(\omega, t, y_1, y_2, z_1, z_2, \delta) \right),
\]
(2.11)
where
\[
\delta_y y := \frac{y_1 - \theta y_2}{1 - \theta}, \quad \delta_y z := \frac{z_1 - \theta z_2}{1 - \theta}, \quad \delta_y y := \frac{\theta y_1 - y_2}{1 - \theta}, \quad \delta_y z := \frac{\theta z_1 - z_2}{1 - \theta},
\]
and
\[
h(\omega, t, y_1, y_2, z_1, z_2, \delta) := \alpha_t(\omega) + k(|y_1| + |y_2|) + \bar{k} \left( |z_1|^{1+\delta} + |z_2|^{1+\delta} \right).
\]
One typical example of (H4) is

\[ g(\omega, t, y, z) := g_1(z) + g_2(y), \]

where \( g_1 : \mathbb{R}^d \rightarrow \mathbb{R} \) is convex or concave with quadratic growth, and \( g_2 : \mathbb{R}^d \rightarrow \mathbb{R} \) is Lipschitz continuous, i.e., \( g \) is a Lipschitz perturbation of some convex (concave) function. More generally, we have

**Proposition 2.3.** Assumption (H4) holds for the generator \( g \) as soon as it is continuous in \((y, z)\) and satisfies (H1) together with anyone of the following conditions:

(i) \( d\mathbb{P} \times dt - a.e., g(\omega, t, \cdot, \cdot) \) is convex or concave;

(ii) \( g \) is Lipschitz in the variable \( y \) and \( \delta \)-locally Lipschitz in the variable \( z \), i.e., \( d\mathbb{P} \times dt - a.e., \) for each \((y_i, z_i) \in \mathbb{R} \times \mathbb{R}^d, i = 1, 2, \) we have

\[ |g(\omega, t, y_1, z_1) - g(\omega, t, y_2, z_2)| \leq \beta |y_1 - y_2| + \gamma (1 + |z_1|^\delta + |z_2|^\delta)|z_1 - z_2|; \]  \( (2.12) \)

(iii) \( d\mathbb{P} \times dt - a.e., \) for each \((y, z) \in \mathbb{R} \times \mathbb{R}^d, g(\omega, t, \cdot, z) \) is Lipschitz, and \( g(\omega, t, y, \cdot) \) is convex or concave;

(iv) \( d\mathbb{P} \times dt - a.e., \) for each \((y, z) \in \mathbb{R} \times \mathbb{R}^d, g(\omega, t, \cdot, \cdot) \) is \( \delta \)-locally Lipschitz, i.e., \((2.12)\) holds with \( y_1 = y_2 = y \).

Before giving the proof of this proposition, we first make the following important remark.

**Remark 2.4.** It is easy to verify that assumption (H4) also holds for the linear combination of two or several generators that is continuous in \((y, z)\) and satisfies assumption (H1) together with anyone of conditions in Proposition 2.3 (with the same convexity or concavity when available), but with different parameters. Hence, the generator \( g \) satisfying assumption (H4) is not necessarily convex (concave) or Lipschitz with the variables \( y \) and \( z \), and it may have a general growth with respect to the variable \( y \).

**Proof of Proposition 2.3.** Given \((y_i, z_i) \in \mathbb{R} \times \mathbb{R}^d, i = 1, 2 \) and \( \theta \in (0, 1) \).

(i) Assume that \( d\mathbb{P} \times dt - a.e., g(\omega, t, \cdot, \cdot) \) is convex. In view of (H1), if \( \delta_{\theta y} > 0 \), then

\[
g(\omega, t, y_1, z_1) = g(\omega, t, \theta y_2 + (1 - \theta)\delta_{\theta y}, \theta z_2 + (1 - \theta)\delta_{\theta y}) \\
\leq \theta g(\omega, t, y_2, z_2) + (1 - \theta)g(\omega, t, \delta_{\theta y}) \\
\leq \theta g(\omega, t, y_2, z_2) + (1 - \theta)\left(\alpha_\theta(\omega) + \beta|\delta_{\theta y}| + \frac{\gamma}{2} |\delta_{\theta y}|^2 \right).
\]

Thus, the inequality \((2.10)\) holds with \( \gamma/2 \) instead of \( \gamma, k = 0 \) and \( \bar{k} = 0 \). The concave case is similar.

(ii) Let the inequality \((2.12)\) holds. Note by (H1) that \(|g(\omega, t, 0, 0)| \leq \alpha_\theta(\omega)\). Then, in view of the fact that \( 2\delta < 1 + \delta \) and by virtue of Young’s inequality we can deduce that for each \( \varepsilon > 0 \),

\[
g(\omega, t, y_1, z_1) - \theta g(\omega, t, y_2, z_2) \\
\leq |g(\omega, t, y_1, z_1) - g(\omega, t, y_2, z_2)| + (1 - \theta)|g(\omega, t, y_2, z_2)| \\
\leq \beta |y_1 - y_2| + \gamma (1 + |z_1|^\delta + |z_2|^\delta)|z_1 - z_2| + (1 - \theta)\left(\alpha_\theta(\omega) + \beta|y_2| + \gamma (1 + |z_2|^\delta)|z_2|\right) \\
\leq \beta(|y_1 - \theta y_2| + (1 - \theta)|y_2|) + \gamma (1 + |z_1|^\delta + |z_2|^\delta)(|z_1 - \theta z_2| + (1 - \theta)|z_2|) \\
+(1 - \theta)\left(\alpha_\theta(\omega) + \beta|y_2| + \gamma (1 + |z_2|^\delta)|z_2|\right) \\
\leq (1 - \theta)\left[\beta|\delta_{\theta y}| + 2\beta|y_2| + \alpha_\theta(\omega) + \varepsilon|\delta_{\theta y}|^2 + c (1 + |z_1|^{1+\delta} + |z_2|^{1+\delta})\right],
\]
where $c$ is a constant depending only on $(\gamma, \delta, \varepsilon)$. Thus, the inequality (2.10) holds with $\varepsilon, \alpha + c, 2\beta$ and $c$ instead of $\gamma, \alpha, k$ and $k$ respectively.

(iii) Assume that $d\mathbb{P} \times dt - a.e.$, for each $(y, z) \in \mathbb{R} \times \mathbb{R}^d$, $g(\omega, t, \cdot, z)$ is Lipschitz, and $g(\omega, t, y, \cdot)$ is convex. Then, noticing by (H1) that $|g(\omega, t, 0, z)| \leq \alpha + |z|^2/2$, we have

$$g(\omega, t, y_1, z_1) - \theta_2 g(\omega, t, y_2, z_2) \leq \beta|y_1 - y_2| + \theta_1 |g(\omega, t, y_2, z_1) - \theta g(\omega, t, y_2, z_2)|$$

where $\beta$ satisfies the monotonicity condition in the state variable $y_1$. Suppose that the function $\psi$ is defined in (2.1) and that $\xi$ is a terminal condition, $g$ is a generator which is continuous in the state variables $(y, z)$ and satisfies assumptions (H1) and (H2), and $\mathbb{E}[\psi(T, [\xi]; \alpha, \beta, \gamma)] < +\infty$ for each $p \geq 1$. Then, we have
(i) If \( g \) also satisfies assumption (H4) with \( k = 0 \), then BSDE \((\xi, g)\) admits a unique solution \((Y, Z)\) such that for each \( p \geq 1 \),
\[
E\left[ \sup_{t \in [0,T]} \psi^p(t, |Y_t|; \alpha, \beta, \gamma) \right] < +\infty.
\]
Moreover, \( Z \in \mathcal{M}^p \) for each \( p \geq 1 \).

(ii) If \( g \) also satisfies assumptions (H3) and (H4), then BSDE \((\xi, g)\) admits a unique solution \((Y, Z)\) such that for each \( p \geq 1 \),
\[
E\left[ \sup_{t \in [0,T]} \psi^p(t, |Y_t|; \alpha, \beta, \gamma) \right] < +\infty.
\]
Moreover, \( E[\exp(\varepsilon \int_0^T |Z_s|^2 ds)] < +\infty \) for some \( \varepsilon > 0 \).

Proof. The existence is a direct consequence of Propositions 2.1 and 2.2. We now show the uniqueness part. Let us assume that (2.10) in (H4) holds.

Let both \((Y, Z)\) and \((Y', Z')\) be solutions to BSDE \((\xi, g)\) such that for each \( p \geq 1 \),
\[
E\left[ \sup_{t \in [0,T]} \psi^p(t, |Y_t|; \alpha, \beta, \gamma) \right] < +\infty \quad \text{and} \quad E\left[ \sup_{t \in [0,T]} \psi^p(t, |Y'_t|; \alpha, \beta, \gamma) \right] < +\infty. \quad (2.13)
\]
We use the \( \theta \)-difference technique developed in [2]. For each fixed \( \theta \in (0, 1) \), define
\[
\delta_\theta U_t := \frac{Y_t - \theta Y'_t}{1 - \theta} \quad \text{and} \quad \delta_\theta V_t := \frac{Z_t - \theta Z'_t}{1 - \theta}.
\]
Then, the pair \((\delta_\theta U_t, \delta_\theta V_t)\) solves the following BSDE:
\[
\delta_\theta U_t = \xi + \int_t^T \delta_\theta g(s) \, ds - \int_t^T \delta_\theta V_s \cdot dB_s, \quad t \in [0, T], \quad (2.14)
\]
where
\[
\delta_\theta g(s) := \frac{1}{1 - \theta} [g(s, Y_s, Z_s) - \theta g(s, Y'_s, Z'_s)].
\]
It follows from (2.10) that
\[
1_{\{\delta_\theta U_t > 0\}} \delta_\theta g(s) \leq \alpha_s + \beta |\delta_\theta U_s| + \gamma |\delta_\theta V_s|^2 \quad (2.15)
\]
with
\[
\alpha_s := \alpha_s + k(|Y_s| + |Y'_s|) + k \left(|Z_s|^{1+\delta} + |Z'_s|^{1+\delta}\right).
\]
(i) Let \( k = 0 \). In view of (2.13), from Hölder’s inequality it is not hard to verify that
\[
E\left[ \sup_{t \in [0,T]} \psi(t, |\delta_\theta U_t|; \alpha, \beta, \gamma) \right] < +\infty. \quad (2.16)
\]
Thus, in view of (2.14), (2.15) and (2.16), we apply Itô-Tanaka’s formula to \( \psi(s, \delta_\theta U_s^+; \bar{\alpha}, \beta, \gamma) \) and argue as in the proof of Proposition 2.1 to deduce that for each \( t \in [0, T] \),
\[
\gamma \delta_\theta U_t^+ \leq \psi(t, \delta_\theta U_t^+; \bar{\alpha}, \beta, \gamma) \leq E[\psi(T, \xi^+; \bar{\alpha}, \beta, \gamma)|\mathcal{F}_t] \leq E[\psi(T, |\xi|; \bar{\alpha}, \beta, \gamma)|\mathcal{F}_t],
\]
and then
\[
\gamma (Y_t - \theta Y'_t)^+ \leq (1 - \theta) E[\psi(T, |\xi|; \bar{\alpha}, \beta, \gamma)|\mathcal{F}_t].
\]

Letting \( \theta \to 1 \) in the last inequality yields that \( \mathbb{P} \) - a.s., for each \( t \in [0, T] \), \( Y_t \leq Y'_t \). Thus, the desired conclusion follows by interchanging the position of \( Y \) and \( Y' \).

(ii) Let assumption (H3) holds. Thanks to Proposition 2.2, we have \( E[\exp(p \int_0^T |Z_s|^{1+\delta} ds)] < +\infty \) and \( E[\exp(p \int_0^T |Z'_s|^{1+\delta} ds)] < +\infty \) for each \( p \geq 1 \). Then, in view of (2.13), from Hölder’s inequality we can conclude that (2.16) still holds. Thus, the same computation as above yields the uniqueness result.

Finally, another case that (2.11) holds can be proved in the same way. The proof is then complete. \( \square \)
Remark 2.7. In view of Proposition 2.3 and Remark 2.4, it is clear that Theorem 2.6 generalizes the uniqueness result for quadratic BSDEs with unbounded terminal conditions obtained in [2].

Example 2.8. For each $(\omega, t, y, z) \in \Omega \times [0, T] \times \mathbb{R} \times \mathbb{R}^d$, define
\[
g_1(\omega, t, y, z) = |z|^2 - |z|^3 + \sin |z| + y^2 \mathbf{1}_{y \leq 0} - |y| + |B_t(\omega)|
\]
and
\[
g_2(\omega, t, y, z) = -|z|^2 + \sin |z|^3 + |z| - y^3 \mathbf{1}_{y \geq 0} + \sin |y| + |B_t(\omega)|.
\]

By virtue of Proposition 2.3, it is not hard to verify that both $g_1$ and $g_2$ are continuous in $(y, z)$ and satisfy assumptions (H1)–(H4). However, they are non-convex (non-concave) with respect to the variable $z$, and non-Lipschitz with respect to the variable $y$.
