PROPERTIES OF MEAN DIMENSION AND METRIC MEAN DIMENSION
COMING FROM THE TOPOLOGICAL ENTROPY

JEOVANNY DE JESÚS MUNITES ACEVEDO AND CARLOS RAFAEL PAYARES GUEVARA

Abstract. In the late 1990’s, M. Gromov introduced the notion of mean dimension for a continuous map, which is, as well as the topological entropy, an invariant under topological conjugacy. The concept of metric mean dimension for a dynamical system was introduced by Lindenstrauss and Weiss in 2000. In this paper we will verify which properties coming from the topological entropy map are valid for both mean dimension and metric mean dimension. In particular, we will prove that the metric mean dimension map is not continuous anywhere on the set consisting of continuous maps on both the Cantor set, the interval or the circle.

1. Introduction

Let $X$ be a compact metric space with metric $d$. The notion of mean dimension for a topological dynamical system $(X, \phi)$, which will be denoted by $\text{mdim}(X, \phi)$, was introduced by M. Gromov in [3]. It is another invariant under topological conjugacy. Applications of the mean dimension to the embedding of dynamical systems problem can be found in [4], [5], [10], [11], [12] (these applications are summarized in the introduction of [15]).

Lindenstrauss and Weiss in [10], introduced the notion of metric mean dimension for any continuous map $\phi$ on $X$. It notion depends on the metric $d$ on $X$ (consequently it is not invariant under topological conjugacy) and it is zero for any map with finite topological entropy. Some well-known properties of the topological entropy are valid for both the mean dimension and the metric mean dimension (see Section 3, where we will also show some counterexamples for the properties which are not valid). Then it is a very interesting work to study which not so well-known properties of the entropy are maintained by the mean dimension and the metric mean dimension.

Let $\text{dim}(X)$ be the topological dimension of $X$, $\text{dim}_H(X, d)$ is the Hausdorff dimension of $X$ with respect to $d$, $\text{dim}_B(X, d)$ is the lower box dimension of $X$ with respect to $d$ and $\overline{\text{dim}}_B(X, d)$ is the upper box dimension of $X$ with respect to $d$. We have

$$\text{dim}(X) \leq \text{dim}_H(X, d) \leq \text{dim}_B(X, d) \leq \overline{\text{dim}}_B(X, d),$$

(see [7], Section II, A). In [10], Proposition 3.1, is proved that $\text{mdim}(X^\mathbb{Z}, \sigma) \leq \text{dim}(X)$, where $\sigma$ is the shift map on $X^\mathbb{Z}$. In Section 2 we will present the definitions of the lower metric mean dimension of $(X, \phi, d)$ (denoted by $\text{mdim}_M(X, \phi, d)$) and the upper metric mean dimension of $(X, \phi, d)$ (denoted by $\overline{\text{mdim}}_M(X, \phi, d)$). In [15], Theorem 4.4 and [17], Theorem 5, is proved that for $\mathbb{K} = \mathbb{Z}$ or $\mathbb{N}$, we have $\text{mdim}_M(X^\mathbb{K}, \sigma, d) = \text{dim}_B(X, d)$ and $\overline{\text{mdim}}_M(X^\mathbb{K}, \sigma, d) = \overline{\text{dim}}_B(X, d)$. This fact implies that $\text{mdim}_M(X, \phi, d) \leq \overline{\text{dim}}_B(X, d)$ and...
mdim_M(X, φ, d) ≤ dim_B(X, d) for any continuous map φ on X (see [15], Proposition 4.5 and [17], Remark 4). Consequently, if dim_B(X, d) is finite, then mdim_M : C^0(X) → R is bounded.

It is well-known that any homeomorphisms on both the interval or the circle has zero topological entropy. Furthermore, Seidler in [16], proved that every homeomorphism on a regular curve has zero topological entropy. Therefore, the metric mean dimension of any homeomorphism on the interval or on the circle or on any regular curve is zero. An example of a continuous map on the interval with positive metric mean dimension can be found in [15], Example 4.7 (see Example 3.4). On the other hand, Bobok and Zindulka, in [2], showed if X is an uncountable compact metrizable space of topological dimension zero, then given any a ∈ [0, ∞] there is a homeomorphism on X whose topological entropy is a. In particular, there exist homeomorphisms on the Cantor set with positive topological entropy. In Example 4.2 we will prove that there exist homeomorphisms on the Cantor set with positive metric mean dimension.

One of the most studied problem on the topological entropy is its continuity (see [1], [14], [18]). In Section 4 we will study the continuity of mdim_M : C^0(X) → R when X is the interval, the circle or the Cantor set. Note that if φ is any differentiable map, then the topological entropy h_{top}(φ) < ∞ and therefore φ has zero metric mean dimension (see Remark 2.6). Then, mdim_M : C^r(X) → R, φ ↦→ mdim_M(X, φ, d), is obviously continuous for r ≥ 1. Hence, it remains to analyze only the case r = 0 and X is any metric space. Now, Yano in [18] proved that the set consisting of continuous maps with infinity topological entropy defined on any manifold is residual. In particular, the set consisting of continuous map with infinity topological entropy defined on the interval and on the circle is residual. He also showed that the topological entropy map is continuous on any continuous map, defined on a manifold, with infinite topological entropy. In Lemma 4.10 we will prove that mdim_M is not continuous on maps with maximum metric mean dimension (that is, maps with metric mean dimension equal to one).

Block, in [1], proved that h_{top} is not continuous anywhere on the set consisting of continuous map on the Cantor set. Furthermore, he showed that if X is the interval or the circle, the topological entropy map is not continuous on continuous maps on X with finite topological entropy. In Theorem 4.3 we will prove that mdim_M : C^0(X) → R is not continuous anywhere when X is the Cantor set, and if X is the interval or the circle, it is not continuous on maps with metric mean dimension less than 1 (see Proposition 4.6 and Corollary 4.8). In conclusion, mdim_M : C^0(X) → R is not continuous anywhere if X is the interval or the circle.

On the other hand, if the topological dimension of X is finite then mdim(X, φ) = 0 (see [10]). Consequently, if dim(X) < ∞, mdim : C^0(X) → R, φ ↦→ mdim(X, φ), is the constant map zero. Therefore, it remains to study the continuity of mdim : C^0(X) → R when dim(X) = ∞.

Next, we present the structure of the paper. In the next section we will present the definition of the mean dimension and the metric mean dimension for continuous maps and non-autonomous dynamical systems. In Section 3 we will recall some well-known properties of the topological entropy map and we will discuss what of these properties are also valid for the the dimension map and the metric mean dimension map. We will consider the cases of single maps and non-autonomous dynamical systems. The proof of most of the results that we are going to present in Section 3 can be found in [8], [10], [13] and
Examples 5.1 (which proves that the metric mean dimension depends on the metric on $X$) and 3.8 (which proves that the metric mean dimension of the direct product of two maps can be strictly smaller that the sum of the metric mean dimension of each map) are provided by the authors. As we said above, the continuity of $\text{mdim}_\mu$ will be discussed on Section 4.

2. Mean dimension and metric mean dimension

Let $X$ be a compact metric space endowed with a metric $d$. In this section we will define the mean dimension and the metric mean dimension for non-autonomous dynamical systems (see [15]) and for single continuous maps (see [10]), since some properties will proved in the next section hold for both non-autonomous and autonomous systems. Suppose that $f = (f_n)_{n \in \mathbb{N}}$ is a non-autonomous dynamical system, where $f_n : X \to X$ is a continuous map for all $n \geq 1$. We write $(X, f, d)$ to denote a non-autonomous dynamical system $f$ on $X$. For $n, k \in \mathbb{N}$ define

$$f_n^{(0)} := I_X := \text{the identity on } X \quad \text{and} \quad f_n^{(k)}(x) := f_{n+k-1} \circ \cdots \circ f_n(x) \text{ for } k \geq 1.$$

Set

$$C(X) = \{(f_n)_{n \in \mathbb{N}} : f_n \text{ is continuous on } X\} \quad \text{and} \quad C^0(X) = \{\phi : \phi \text{ is continuous on } X\}.$$

Single continuous map are classified by topological conjugacy. Non-autonomous dynamical systems are classified by uniform equiconjugacy:

**Definition 2.1.** We say that the systems $f = (f_n)_{n \in \mathbb{N}} \in C(X)$ and $g = (g_n)_{n \in \mathbb{N}} \in C(Y)$, where $Y$ is a compact metric space, are *uniformly equiconjugate* if there exists an equicontinuous sequence of homeomorphisms $h_n : X \to Y$ (which will be called a *uniform equiconjugacy*) so that $h_{n+1} \circ f_n = g_n \circ h_n$, for all $n \in \mathbb{N}$. In the case where $h_n = h$, for all $n \in \mathbb{N}$, we say that $f$ and $g$ are *uniformly conjugate*.

Given $\alpha$ an open cover of $X$ define

$$\alpha_0^{n-1} = \alpha \lor f_1^{-1}(\alpha) \lor (f_1^{(2)})^{-1}(\alpha) \lor \cdots \lor (f_1^{(n-1)})^{-1}(\alpha)$$

and set

$$\text{ord}(\alpha) = \sup_{x \in X} \sum_{U \in \alpha} 1_U(x) - 1 \quad \text{and} \quad \mathcal{D}(\alpha) = \min_{\beta < \alpha} \text{ord}(\beta),$$

where $1_U$ is the indicator function and $\beta < \alpha$ means that $\beta$ is a partition of $X$ finer than $\alpha$.

**Definition 2.2.** The *mean dimension* of $f \in C(X)$ is defined to be

$$\text{mdim}(X, f) = \sup_{\alpha} \lim_{n \to \infty} \frac{\mathcal{D}(\alpha_0^{n-1})}{n}. \quad (2.1)$$

The mean dimension of a continuous map $\phi : X \to X$ will be denoted by $\text{mdim}(X, \phi)$.

**Remark 2.3.** In [15], Remark 2.2, we provide a list of properties of the mean dimension.

For any non-negative integer $n$ we define $d_n : X \times X \to [0, \infty)$ by

$$d_n(x, y) = \max\{d(x, y), d(f_1(x), f_1(y)), \ldots, d(f_1^{(n-1)}(x), f_1^{(n-1)}(y))\}.$$

Fix $\varepsilon > 0$. We say that $A \subset X$ is an $(n, f, \varepsilon)$-separated set if $d_n(x, y) > \varepsilon$, for any two distinct points $x, y \in A$. We denote by $\text{sep}(n, f, \varepsilon)$ the maximal cardinality of a $(n, f, \varepsilon)$-separated subset of $X$. Furthermore, let $\text{cov}(n, f, \varepsilon)$ denotes the minimum cardinality of $\varepsilon$-balls in the $d_n$ metric to cover $X$. We say that $E \subset X$ is a $(n, f, \varepsilon)$-spanning set if for any $x \in X$ there exists $y \in E$ so that $d_n(x, y) < \varepsilon$. Let $\text{span}(n, f, \varepsilon)$ be the minimum cardinality of $(n, f, \varepsilon)$-spanning
subset of $X$. Given an open cover $\alpha$, we say that $\alpha$ is a $(n,f,\varepsilon)$-cover if the $d_n$-diameter of any element of $\alpha$ is less than $\varepsilon$. Let $\text{cov}(n,f,\varepsilon)$ be the minimum cardinality of a $(n,f,\varepsilon)$-cover. By the compacity of $X$, $\text{sep}(n,f,\varepsilon)$, $\text{span}(n,f,\varepsilon)$ and $\text{cov}(n,f,\varepsilon)$ are finite real numbers.

**Definition 2.4.** The topological entropy of $(X,f,d)$ is defined by

$$h_{\text{top}}(f) = \lim_{\varepsilon \to 0} \frac{1}{\varepsilon} \text{sep}(f,\varepsilon) = \lim_{\varepsilon \to 0} \frac{1}{\varepsilon} \text{span}(f,\varepsilon) = \lim_{\varepsilon \to 0} \frac{1}{\varepsilon} \text{cov}(f,\varepsilon),$$

(2.2)

respectively, where $\text{sep}(f,\varepsilon) = \lim_{n \to \infty} \frac{1}{n} \log \text{sep}(n,f,\varepsilon)$, $\text{span}(f,\varepsilon) = \lim_{n \to \infty} \frac{1}{n} \log \text{span}(n,f,\varepsilon)$ and $\text{cov}(f,\varepsilon) = \lim_{n \to \infty} \frac{1}{n} \log \text{cov}(n,f,\varepsilon)$.

For any continuous map $\phi : X \to X$, we denote the topological entropy of $\phi$ by $h_{\text{top}}(\phi)$.

**Definition 2.5.** We define the lower metric mean dimension of $(X,f,d)$ and the upper metric mean dimension of $(X,f,d)$ by

$$\underline{\text{mdim}}_M(X,f,d) = \liminf_{\varepsilon \to 0} \frac{\text{sep}(f,\varepsilon)}{|\log \varepsilon|} \quad \text{and} \quad \overline{\text{mdim}}_M(X,f,d) = \limsup_{\varepsilon \to 0} \frac{\text{sep}(f,\varepsilon)}{|\log \varepsilon|},$$

(2.3)

respectively.

It is not difficult to see that

$$\underline{\text{mdim}}_M(X,f,d) = \liminf_{\varepsilon \to 0} \frac{\text{span}(f,\varepsilon)}{|\log \varepsilon|} = \liminf_{\varepsilon \to 0} \frac{\text{cov}(f,\varepsilon)}{|\log \varepsilon|}.$$  

The same holds for the upper metric mean dimension.

For any continuous map $\phi : X \to X$, we denote the lower metric mean dimension and the upper metric mean dimension of $\phi$ by $\underline{\text{mdim}}_M(X,\phi,d)$ and $\overline{\text{mdim}}_M(X,\phi,d)$, respectively.

The inequalities

$$\text{mdim}(X,f) \leq \underline{\text{mdim}}_M(X,f,d) \leq \overline{\text{mdim}}_M(X,f,d) < h_{\text{top}}(f)$$

always hold. The proof for the first inequality for single map can be seen in [10], Theorem 4.2, and for non-autonomous dynamical systems in [15], Theorem 3.7.

**Remark 2.6.** Following the definition of topological entropy for non-autonomous dynamical systems introduced in [18] one can see that if the topological entropy of the system $(X,f,d)$ is finite then its metric dimension is zero.

**Remark 2.7.** Throughout the paper, we will omit the underline and the overline on the notations of the mean dimension and on the metric mean dimension when the result be valid for both cases.

3. Properties coming from the topological entropy map

In this section we will verify what properties coming from the topological entropy map (which are well-known) are also valid for the map $\Phi$ as being the topological entropy map, the mean dimension map and the metric mean dimension map, for both, autonomous and non-autonomous dynamical systems. These properties are:

i) Invariance under conjugacy.

ii) $\Phi(\phi^n) = n \Phi(\phi)$, where $\phi$ is a continuous map or a sequence of continuous map on $X$.

iii) Boundedness.

iv) Monotonicity for the case of non-autonomous dynamical systems.

v) $\Phi(\phi \times \psi) = \Phi(\phi) + \Phi(\psi)$ for any continuous maps $\phi$ and $\psi$ on $X$. 
Throughout this section, \( f = (f_n)_{n \in \mathbb{N}} \) will be denotes a non-autonomous dynamical system in \( C(X) \) and \( \phi : X \to X \) a continuous map.

Firstly, we will discuss about i). One of the most important properties of the topological entropy is that it is invariant by topological conjugacy. It is also an invariant under uniform equiconjugacy between non-autonomous dynamical systems (see \[8\] and \[13\]). Mean dimension (for both, autonomous and non-autonomous dynamical systems) is invariant under topological conjugacy (see \[15\], Theorem 5.1). In the next example we prove that the metric mean dimension for single continuous maps depends on the metric \( d \) on \( X \). Consequently, it is not an invariant under topological conjugacy between continuous maps and therefore it is not an invariant under uniform equiconjugacy between non-autonomous dynamical systems.

From now on, we will consider the metric \( \tilde{d} \) on \( X^\mathbb{N} \) defined by

\[
\tilde{d}(\bar{x}, \bar{y}) = \frac{1}{2^n} d(x_i, y_i) \quad \text{for} \quad \bar{x} = (x_i)_{i \in \mathbb{N}}, \bar{y} = (y_i)_{i \in \mathbb{N}} \in X^\mathbb{N}. \quad (3.1)
\]

**Example 3.1.** Let \( \dim_B(X, d) \) and \( \dim_B(X, d) \) be respectively the upper and lower box dimension of \( X \) with respect to \( d \). In \[15\], Theorem 4.4 and \[17\], Theorem 5, is proved that for \( \mathbb{K} = \mathbb{Z} \) or \( \mathbb{N} \), we have

\[
\overline{\text{mdim}}_M(X^\mathbb{K}, \sigma, \tilde{d}) = \dim_B(X, d) \quad \text{and} \quad \underline{\text{mdim}}_M(X^\mathbb{K}, \sigma, \tilde{d}) = \dim_B(X, d). \quad (3.2)
\]

Consequently, if \( X_1 = \mathbb{S}^1 \) endowed with the metric \( d_1 \) inherited from \( \mathbb{R}^2 \), we have

\[
\text{mdim}_M(X_1^\mathbb{Z}, \sigma, \tilde{d}_1) = \text{mdim}_M(X_1^\mathbb{N}, \sigma, \tilde{d}_1) = 1.
\]

Let \( X_2 \) be the Koch curve endowed with the metric \( d_2 \) inherited from the plane \( \mathbb{R}^2 \). Therefore,

\[
\dim_B(X_2, d_2) = \frac{\log 4}{\log 3} \quad \text{and hence}
\]

\[
\overline{\text{mdim}}_M(X_2^\mathbb{K}, \sigma, \tilde{d}_2) = \underline{\text{mdim}}_M(X_2^\mathbb{K}, \sigma, \tilde{d}_2) = \dim_B(X_2, d_2) = \frac{\log 4}{\log 3}.
\]

Since \( X_1 \) and \( X_2 \) are homeomorphic, \((X_1^\mathbb{K}, \sigma)\) and \((X_2^\mathbb{K}, \sigma)\) are topologically conjugate, however their metric mean dimensions are different.

Set \( B = \{ \rho : \rho \text{ is a metric on } X \text{ equivalent to } d \} \) and take

\[
\text{mdim}_M(X, f) = \inf_{\rho \in B} \text{mdim}_M(X, f, \rho) \quad \text{and} \quad \underline{\text{mdim}}_M(X, f) = \inf_{\rho \in B} \underline{\text{mdim}}_M(X, f, \rho).
\]

Both \( \text{mdim}_M(X, \phi) \) and \( \underline{\text{mdim}}_M(X, \phi) \) are invariant under topological conjugacy for single continuous maps. For non-autonomous dynamical systems we have:

**Theorem 3.2.** *If \( f \) and \( g \) are uniformly equiconjugate by a sequence of homeomorphisms \((h_n)_{n \in \mathbb{N}}\) such that \( \inf_n \{d(h_n^{-1}(y_1), h_n^{-1}(y_2)), d(h_n(x_1), h_n(x_2))\} > 0 \) for any \( x_1, x_2, y_1, y_2 \in X \), then

\[
\overline{\text{mdim}}_M(X, f) = \overline{\text{mdim}}_M(X, g) \quad \text{and} \quad \underline{\text{mdim}}_M(X, f) = \underline{\text{mdim}}_M(X, g).
\]

About ii). It is well-known that \( h_{\text{top}}(\phi^p) = p h_{\text{top}}(\phi) \) for any \( p \geq 1 \). For the case of non-autonomous dynamical systems, we have the inequality \( h_{\text{top}}(f^{(p)}) \leq p h_{\text{top}}(f) \), where \( f^{(p)} = \{f_1^{(p)}, f_2^{(p)}, f_3^{(p)}, \ldots\} \) (see \[8\], Lemma 4.2). In general, the equality \( h_{\text{top}}(f^{(p)}) = p h_{\text{top}}(f) \) is not valid, as we can see in the next example, which was given by Kolyada and Snoha in \[8\].
Example 3.3. Take \( \psi : [0,1] \to [0,1] \) defined by \( \psi(x) = 1 - |2x - 1| \) for any \( x \in [0,1] \). Consider \( f = (f_n)_{n \in \mathbb{N}} \), where
\[
    f_n(x) = \begin{cases} 
        \psi(n+1/2)(x), & \text{if } n \text{ is odd}, \\
        x/2^n/2, & \text{if } n \text{ is even},
    \end{cases}
\]
for any \( n \in \mathbb{N} \). Then \( h_{top}(f^{2^n}) = 0 \) and \( h_{top}(f) \geq \frac{\log 2}{2} \).

The equality \( h_{top}(f^{(p)}) = p h_{top}(f) \) holds if the sequence \( f = (f_n)_{n \in \mathbb{N}} \) is equicontinuous (see [8], Lemma 4.4).

Next, for any \( p \geq 1 \) we have \( \text{mdim}(X, \phi^p) = p \text{mdim}(X, \phi) \) (see [10], Proposition 2.7). In [15], Proposition 2.3, we proved that \( \text{mdim}(X, f^{(p)}) = p \text{mdim}(X, f) \). For the metric mean dimension case, the inequality \( \text{mdim}_M(X, f^{(p)}) \leq p \text{mdim}_M(X, f) \) always hold. However, this inequality can be strict for single continuous map (and hence for non-autonomous dynamical systems), as we can see in the next example (see [15], Example 4.7).

Example 3.4. Take \( g : [0,1] \to [0,1] \), defined by \( x \mapsto |1 - |3x - 1|| \), and \( 0 = a_0 < a_1 < \cdots < a_n < \cdots \), where \( a_n = \sum_{k=1}^{n} 6/\pi^2 k^2 \) for \( n \geq 1 \). For each \( n \geq 1 \), let \( T_n : J_n := [a_{n-1}, a_n] \to [0,1] \) be the unique increasing affine map from \( J_n \) (which has length \( 6/\pi^2 n^2 \)) onto \([0,1]\) and take any strictly increasing sequence of natural numbers \( m_n \). Consider the continuous map \( \psi : [0,1] \to [0,1] \) such that, for each \( n \geq 1 \), \( \psi|_{J_n} = T_n^{-1} \circ g^{m_n} \circ T_n \). In [15], Example 4.7, we proved that \( \text{mdim}_M([0,1], \psi) = 1 \). On the other hand, \( \text{mdim}_M([0,1], \phi) \leq 1 \) for any continuous map \( \phi : [0,1] \to [0,1] \). Therefore \( \text{mdim}_M([0,1], \psi^2) \leq 1 < 2 \text{mdim}_M([0,1], \psi) = 2 \).

Given that 0 and 1 are fixed points of \( \psi \), it induces a map on the circle with metric mean dimension equal to 1.

iii) Boundedness. Note that if there exists a continuous map \( \psi : X \to X \) with \( h_{top}(\psi) > 0 \), then \( h_{top}(\psi) \) is unbounded as \( \psi \) ranges over the continuous maps on \( X \) (since \( h_{top}(\psi^p) = ph_{top}(\psi) \) for any \( p \geq 1 \)). Therefore:

**Lemma 3.5.** \( h_{top}(\phi) = 0 \) for any \( \phi \) or \( h_{top}(\phi) \) is unbounded as \( \psi \) ranges over the continuous maps on \( X \).

If the topological dimension of \( X \) is finite, then \( \text{mdim}(X, \phi) = 0 \) (see [10]). On the other hand, if \( X \) has infinite topological dimension and there exists a continuous map on \( X \) with positive mean dimension then the mean dimension is unbounded (since \( \text{mdim}(X, \phi^p) = p \text{mdim}(X, \phi) \) for any \( p \geq 1 \)), that is:

**Lemma 3.6.** \( \text{mdim}(X, \phi) = 0 \) for any \( \phi \) or \( \text{mdim}(X, \phi) \) is unbounded as \( \phi \) ranges over the continuous maps on \( X \).

The equalities in Equation 3.2 allow us to prove the following proposition (see [15], Proposition 4.5 and [17], Remark 4).

**Proposition 3.7.** For any \( \phi : X \to X \) we have
\[
    \text{mdim}_M(X, \phi, d) \leq \text{dim}_g(X, d) \quad \text{and} \quad \text{mdim}_M(X, \phi, d) \leq \text{dim}_h(X, d).
\]

For instance, if \( X = [0,1] \), endowed with the metric \( d(x,y) = |x-y| \) for \( x, y \in X \), then \( \text{mdim}_M(X, \phi, d) \leq \text{mdim}_M(X, \phi, d) \leq 1 \). Example [2.4] shows that there exists a continuous map \( \psi : X \to X \) such that \( \text{mdim}_M(X, \psi, d) = \text{mdim}_M(X, \psi, d) = 1 \).

On the other hand, \( \text{mdim}_M(X, f, d) \) as is unbounded as \( f \) ranges over the elements in \( C(X) \), regardless of the box dimension of \( X \) (see [15], Example 4.8).
iv) Monotonicity for the case of non-autonomous dynamical systems: In [8], Lemma 4.5, Kolyada and Snoha proved that $h_{top}(\sigma^j(f)) \leq h_{top}(\sigma^i(f))$ for any $i \leq j$, where $\sigma$ is the right shift $\sigma((f_n)_{n \in \mathbb{N}}) = (f_{n+1})_{n \in \mathbb{N}}$. Furthermore, in [13], Corollary 5.6, the author showed that if each $f_i$ is a homeomorphism then the equality holds, that is, the topological entropy for non-autonomous dynamical systems is independent on the first maps on a sequence of homeomorphisms $f = (f_n)_{n \in \mathbb{N}}$. These properties are also valid for the mean dimension of non-autonomous dynamical systems (see [15], Proposition 2.4). Furthermore, we have if $f = (f_n)_{n \in \mathbb{N}}$ converges uniformly to a continuous map $f : X \to X$, then

$$\lim_{n \to \infty} h_{top}(\sigma^n(f)) \leq h_{top}(f)$$  \hspace{1cm} (see [8], Theorem E)

$$\limsup_{n \to \infty} \text{mdim}(X, \sigma^n(f)) \leq \text{mdim}(X, f)$$ \hspace{1cm} (see [15], Theorem 2.6)

$$\liminf_{n \to \infty} \text{mdim}_M(X, \sigma^n(f)) \leq \text{mdim}_M(X, f)$$ \hspace{1cm} (see [15], Theorem 3.8).

All the inequalities can be strict (see [8], Section d, and [15], Example 2.7).

Finally, we discuss v). Take $\phi : X \to X$ and $\psi : Y \to Y$ where $Y$ is a compact metric space with metric $d'$. On $X \times Y$ we consider the metric

$$(d \times d')(x_1, y_1), (x_2, y_2) = d(x_1, x_2) + d'(y_1, y_2), \quad \text{for } x_1, x_2 \in X \text{ and } y_1, y_2 \in Y. \quad (3.3)$$

The map $\phi \times \psi : X \times Y \to X \times Y$ is defined to be $(\phi \times \psi)(x, y) = (\phi(x), \psi(y))$ for any $(x, y) \in X \times Y$. The equality $h_{top}(\phi \times \psi) = h_{top}(\phi) + h_{top}(\psi)$ always hold. Lindenstrauss in [10], Proposition 2.8, proved that $\text{mdim}(X \times Y, \phi \times \psi) \leq \text{mdim}(X, \phi) + \text{mdim}(Y, \psi)$ and this inequality can be strict. It is not difficult to prove that the inequality

$$\text{mdim}_M(X \times Y, \phi \times \psi) \leq \text{mdim}_M(X, \phi) + \text{mdim}_M(Y, \psi)$$

is valid. In the next example we will prove that this inequality can be strict.

**Example 3.8.** Let $(X, d)$ and $(Y, d')$ be any compact metric spaces such that $\text{dim}_B(X \times Y, d \times d') < \text{dim}_B(X, d) + \text{dim}_B(Y, d')$. The metric $d \times d'$ on $X^2 \times Y^2$ is defined by

$$\bar{d}((\bar{x}, \bar{y}), (\bar{z}, \bar{w})) = \sum_{i \in \mathbb{N}} \frac{1}{2^i} d(x_i, z_i) + \sum_{i \in \mathbb{N}} \frac{1}{2^i} d'(y_i, w_i),$$

for $\bar{x} = (x_i)_{i \in \mathbb{N}}, \bar{z} = (z_i)_{i \in \mathbb{N}} \in X^2, \bar{y} = (y_i)_{i \in \mathbb{N}}, \bar{w} = (w_i)_{i \in \mathbb{N}} \in Y^2$ (see (3.1) and (3.3)). Furthermore, the metric $(d \times d')^* = (\bar{d} \times \bar{d})$ on $(X \times Y)^2$ is given by

$$(d \times d')^*((\bar{x}, \bar{y}), (\bar{z}, \bar{w})) = \sum_{i \in \mathbb{N}} \frac{1}{2^i} d((x_i, y_i), (z_i, w_i)) = \sum_{i \in \mathbb{N}} \frac{1}{2^i} d(x_i, z_i) + \sum_{i \in \mathbb{N}} \frac{1}{2^i} d'(y_i, w_i),$$

for $(\bar{x}, \bar{y}) = (x_i, y_i)_{i \in \mathbb{N}}$ and $(\bar{z}, \bar{w}) = (z_i, w_i)_{i \in \mathbb{N}}$ in $(X \times Y)^2$. Consequently, the bijection

$$\Theta : (X \times Y)^2 \to (X \times Y)^2, \quad \text{given by } (x_i, y_i)_{i \in \mathbb{N}} \mapsto ((x_i)_{i \in \mathbb{N}}, (y_i)_{i \in \mathbb{N}}),$$

is an isometry and furthermore the diagram

\[
\begin{array}{ccc}
(X \times Y)^2 & \xrightarrow{\sigma} & (X \times Y)^2 \\
\downarrow \Theta & & \downarrow \Theta \\
X^2 \times Y^2 & \xrightarrow{\sigma_1 \times \sigma_3} & X^2 \times Y^2
\end{array}
\]
is commutative, where \( \sigma \) is the shift on \((X \times Y)^Z\), \( \sigma_1 \) is the shift on \(X^Z\) and \( \sigma_2 \) is the shift on \(Y^Z\). It is clear that the metric mean dimension is invariant under isometric topological conjugacy. Therefore,

\[
\text{mdim}_M(X^Z \times Y^Z, \sigma_1 \times \sigma_2, \hat{d}_1 \times \hat{d}_2) = \text{mdim}_M((X \times Y)^Z, \sigma, (d \times d'))
\]

\[
= \dim_B(X \times Y, d \times d') < \dim_B(X, d) + \dim_B(Y, d')
\]

\[
= \text{mdim}_M(X^Z, \sigma_1, \hat{d}_1) + \text{mdim}_M(Y^Z, \sigma_2, \hat{d}').
\]

4. On the continuity of the metric mean dimension

As we said in Introduction, Block, in [1], studied the continuity of the topological entropy map on the set consisting of continuous maps on the Cantor set, the interval and the circle. In this section we will study the continuity of \( \text{mdim}_M : C^0(X) \to \mathbb{R} \) when \( X \) is both, the Cantor set, the interval and the circle. Note that in the both cases the metric mean dimension of any map on \( C^0(X) \) is finite (it is less or equal to \( \log \frac{2}{\log Z} \)) in the case of the Cantor set and it is less or equal to 1 in the case of the interval by Proposition 3.7.

On \( C^0(X) \) we will consider the metric

\[
d(\phi, \varphi) = \max_{x \in X} d(\phi(x), \varphi(x)) \quad \text{for any } \phi, \varphi \in C^0(X). \tag{4.1}
\]

Note that if \( d' \) is other metric on \( X \) which induces the same topology that \( d \) on \( X \), then \( d'(\phi, \varphi) = \max_{x \in X} d'(\phi(x), \varphi(x)) \), for any \( \phi, \varphi \in C^0(X) \), induces the same topology that the metric \( d \) defined on \( 4.1 \) on \( C^0(X) \). Therefore:

**Lemma 4.1.** The continuity of the map \( \text{mdim}_M : C^0(X) \to \mathbb{R} \cup \{\infty\} \) does not depend on equivalent metrics on \( X \).

Any \( x \in [0, 1] \) is written in base 3 as

\[
x = \sum_{n=1}^{\infty} x_n 3^{-n} \quad \text{where } x_n \in \{0, 1, 2\}.
\]

A number \( x \) belongs to the middle third Cantor set if and only if no \( x_n \) is equal to one. Therefore, we can consider

\[
C = \{(x_1, x_2, \ldots) : x_n = 0, 2 \text{ for } n \in \mathbb{N}\} = \{0, 2\}^N
\]

as being the Cantor set endowed with the metric

\[
d((x_1, x_2, \ldots), (y_1, y_2, \ldots)) = \sum_{n=1}^{\infty} 3^{-n}|x_n - y_n| = \sum_{n=1}^{\infty} x_n 3^{-n} \cdot \sum_{n=1}^{\infty} y_n 3^{-n}. \tag{4.2}
\]

Bobok and Zindulka shown that if \( X \) is an uncountable compact metrizable space of topological dimension zero, then given any \( a \in [0, \infty] \) there is a homeomorphism on \( X \) whose topological entropy is \( a \). In particular, there exist homeomorphisms on the Cantor set with infinite topological entropy. In the next example we prove that there exists a homeomorphism on the Cantor set with positive metric mean dimension.

**Example 4.2.** For any \( k \geq 1 \) and \( z_1, \ldots, z_k \in \{0, 2\} \), set

\[
C_{z_1,\ldots,z_k} = \{(z_1, \ldots, z_k, z_1, x_2 \ldots) : x_j \in [0, 2] \text{ for } j \geq 1\}.
\]

Note that if \((z_1, \ldots, z_k) \neq (w_1, \ldots, w_k)\), then \( C_{z_1,\ldots,z_k} \cap C_{w_1,\ldots,w_k} = \emptyset \) for \( j, l = 1, 2 \). Furthermore, each \( C_{z_1,\ldots,z_k} \) is homeomorphic to \( C \) via the homeomorphism

\[
T_{z_1,\ldots,z_k} : C_{z_1,\ldots,z_k} \to C, \quad (z_1, \ldots, z_k, x_1, x_2, \ldots) \mapsto (x_1, x_2, \ldots),
\]
which is Lipschitz. Take \( \psi : \mathcal{C} \to \mathcal{C} \) defined by
\[
\psi|_{C_{z_1 \ldots z_k}} = T_{z_1 \ldots z_k}^{-1} \sigma^k T_{z_1 \ldots z_k}.
\]
For any \( k \geq 1 \), take \( \epsilon_k > 0 \) such that \( 2^{-(k+1)} \leq \epsilon_k < 2^{-k} \). Any \((nk, \epsilon_k)\)-separated set for the shift map on \( C_{z_1 \ldots z_k} \) of maximum cardinality is a \((n, \epsilon_k)\)-separated set for \( \psi \) on \( C_{z_1 \ldots z_k} \). For \( n > k + 1 \) we have \( \text{sep}(n + k, \psi, \epsilon_k) \geq 2^{nk} \) and then
\[
\log \text{sep}(n + k, \psi, \epsilon_k) \geq \frac{(nk) \log 2}{nk} = \log 2.
\]
Therefore
\[
\text{mdim}_M(X, \psi, d) \geq \text{mdim}_M(X, \psi, d) \geq \log 2.
\]

**Theorem 4.3.** The map \( \text{mdim}_M : C^0(\mathcal{C}) \to \mathbb{R} \) is not continuous anywhere.

**Proof.** Fix a continuous map \( \phi : \mathcal{C} \to \mathcal{C} \). Set \( \bar{x} = (x_1, x_2, \ldots) \in \mathcal{C} \) and assume that \( \phi(x_1, x_2, \ldots) = (y_1(x), y_2(x), \ldots) \). First, suppose that \( \text{mdim}_M(\mathcal{C}, \phi) > 0 \). Consider the sequence of continuous maps on \( \mathcal{C} \), \((\phi_n)_{n \in \mathbb{N}}\), defined by
\[
\phi_n(x) = (y_1(x), y_2(x), \ldots, y_n(x), 1, 1, \ldots) \quad \text{for any } n \in \mathbb{N}.
\]
It is clear that \( \text{mdim}_M(\mathcal{C}, \phi_n) = 0 \) for any \( n \in \mathbb{N} \) and \( \phi_n \) converges uniformly to \( \phi \) as \( n \to \infty \).

Now, assume that \( \text{mdim}_M(\mathcal{C}, \phi) = 0 \). Consider the sequence of continuous maps on \( \mathcal{C} \), \((\phi_n)_{n \in \mathbb{N}}\), where for any \( n \geq 1 \), \( \phi_n \) is defined by
\[
\phi_n(x) = (y_1(x), y_2(x), \ldots, y_n(x), z_1(x), z_2(x), \ldots) \quad \text{for any } x \in \mathcal{C},
\]
where \((z_1(x), z_2(x), \ldots) = \psi(x) \) and \( \psi \) is the map of the Example 4.2. Then \( \phi_n \) converges uniformly to \( \phi \) as \( n \to \infty \). Furthermore, we can to prove that \( \text{mdim}_M(\mathcal{C}, \phi_n, d) \geq \text{mdim}_M(\mathcal{C}, \psi, d) \) for any \( n \geq 1 \).

It is well-known that any perfect, compact, metrizable, zero-dimensional space is homeomorphic to the middle third Cantor set (see [2], 6.2.A(c)). Hence, suppose that \( X \) is a perfect, compact, metrizable, zero-dimensional space and let \( \psi : X \to \mathcal{C} \) be an homeomorphism. Consider the metric on \( X \) given by
\[
d_\phi(x, y) = d(\psi(x), \psi(y)) \quad \text{for } x, y \in X,
\]
where \( d \) is the metric given in [4.2]. It follows from Theorem 4.3 and Lemma 4.1 that:

**Corollary 4.4.** The map \( \text{mdim}_M : C^0(X, d_\phi) \to \mathbb{R} \) is not continuous anywhere. Therefore, for any perfect, compact, metric, zero-dimensional space \((X, d)\), the map \( \text{mdim}_M : C^0(X, d) \to \mathbb{R} \) is not continuous anywhere.

Proposition 3.7 says for any \( \phi : X \to X \) we have \( \text{mdim}_M(X, \phi, d) \leq \dim_B(X, d) \) and \( \text{mdim}_M(X, \phi, d) \leq \dim_B(X, d) \). However, there exist compact metric spaces \( X \) with positive box dimension such that any continuous map on \( X \) has zero metric mean dimension, as we will see in the next example.

**Example 4.5.** Let \( A = \{0\} \cup \{1/n : n \geq 1\} \) endowed with the metric \( d(x, y) = |x - y| \) for \( x, y \in A \). In [4], Lemma 3.1, is proved that \( \dim_B(A) = 1/2 \). However, for any countable, compact metric space \( X \) and any continuous map \( \phi : X \to X \) we have \( h_{top}(\phi) = 0 \) (see [2], Proposition 5.1). Consequently, \( \text{mdim}_M(X, \phi) = 0 \) for any continuous map \( \phi \) on \( X \).
Note that the set $A$ in the above example is compact, countable zero topological dimensional. An example such that the space $X$ is compact, uncountable and zero topological dimensional and such that any continuous map on $X$ has zero metric mean dimension can be seen in (2), Proposition 5.4.

Finally, we will consider the cases $X = [0, 1]$ and $X = S^1$ (the unitary circle) endowed with the metric inherited from the line.

**Proposition 4.6.** The map $mdim_M : C^0([0, 1]) \to \mathbb{R}$ is not continuous at any map with metric mean dimension less than 1.

*Proof.* Let $\varphi \in C^0([0, 1])$ with $M = mdim_M([0, 1], \varphi, |·|) < 1$. Let $x_0$ be a fixed point of $\varphi$. First, suppose that $x_0 < 1$. Fix $\varepsilon > 0$. There exists $\delta \in (0, \min(\varepsilon/2, 1 - x_0))$ such that if $|x - x_0| < \delta$ then $|\varphi(x) - x_0| < \varepsilon/2$. Let $T : [x_0, x_0 + \delta/2] \to [0, 1]$ be the unique increasing affine map from $[x_0, x_0 + \delta/2]$ onto $[0, 1]$. Define $\varphi$ on $[x_0, x_0 + \delta/2]$ by $\varphi = T^{-1}\psi T$, where $\psi$ is the continuous map of the Example 3.4. Note that $\psi(x_0) = x_0$ and $\psi(x_0 + \delta/2) = x_0 + \delta/2$. Define $\varphi$ linearly on $[x_0 + \delta/2, x_0 + \delta]$ onto $[x_0 + \delta/2, \varphi(x_0 + \delta)]$ (or onto $[\varphi(x_0 + \delta), x_0 + \delta/2]$ if $\varphi$ is decreasing on $[x_0 + \delta/2, x_0 + \delta]$) and take $\varphi(x) = \varphi(x)$ for any $x \in [0, 1] \setminus [x_0, x_0 + \delta]$. If $x \in [x_0, x_0 + \delta]$, then

$$|\varphi(x) - \varphi(x)| < |\varphi(x) - x_0| + |x_0 - \varphi(x)| < \varepsilon.$$

Consequently, $d(\varphi, \varphi(x)) < \varepsilon$. Furthermore,

$$mdim_M([0, 1], \varphi, |·|) = mdim_M([0, 1], \varphi, |·|) = 1 > mdim_M([0, 1], \varphi, |·|),$$

which proves the theorem for $x_0 \neq 1$. If $x_0 = 1$, we can make the construction above on the interval $[x_0 - \delta/2, x_0]$. □

A corollary of the proof of the above proposition is:

**Corollary 4.7.** The set $\{\varphi \in C^0([0, 1]) : mdim_M([0, 1], \varphi, |·|) = 1\}$ is dense in $C^0([0, 1])$.

Other consequence of Proposition 4.6 is the following corollary.

**Corollary 4.8.** The map $mdim_M : C^0(S^1) \to \mathbb{R}$ is not continuous at any map with metric mean dimension less than 1.

*Proof.* Fix $\varphi \in C^0(S^1)$ with metric mean dimension less than 1 and take $\varepsilon > 0$. Since the set consisting of map with some periodic point is dense on $C^0(S^1)$, we can choose any continuous map $\varphi_1$ on $S^1$ with a periodic point and such that $d(\varphi, \varphi_1) < \varepsilon/2$. We can modify the argument of the proof of Theorem, with a periodic point of $\varphi_1$ replacing the role of the fixed point of $\varphi$. Hence, we can construct a continuous map $\varphi$ on $S^1$ with metric mean dimension equal to 1 and such that $d(\varphi, \varphi) < \varepsilon$, which proves the corollary. □

In [13], Corollary 1.1, Yano proved that $h_{top} : C^0(X) \to \mathbb{R} \cup \{\infty\}$ is continuous on any map with infinite topological entropy. We finish the work showing an example of a continuous map on the interval, with metric mean dimension equal to 1, on which the metric mean dimension map is not continuous.

**Example 4.9.** Consider the continuous map $\psi$ constructed on Example 3.4 which has metric mean dimension equal to 1. For each $n \geq 1$, take $m_n = n$ and

$$\psi_n(x) = \begin{cases} 
\psi(x), & \text{if } x \in [0, a_n] \\
 x, & \text{if } x \in [a_n, 1]. 
\end{cases}$$

Thus $\psi_n$ converges uniformly to $\psi$ as $n \to \infty$. Note that $mdim_M([0, 1], \psi_n, |·|) = 0$ for any $n \geq 1$. Therefore, $mdim_M$ is not continuous on $\psi$. 

**Theorem 4.11.** Let $X = [0, 1]$ or $S^1$. $\text{mdim}_M : C^0(X) \to \mathbb{R}$ is not continuous on maps with metric mean dimension equal to 1.

**Proof.** We will only prove the case $X = [0, 1]$. Take $\phi \in C^0(X)$ with $\text{mdim}_M(X, \phi, d) = 1$. Therefore $h_{top}(\phi) = \infty$ and hence the set consisting of periodic points of $\phi$ is infinite. Take a periodic point $x_1$ of $\phi$, being an accumulation point of the set consisting of periodic points of $\phi$. Let $\varepsilon > 0$. Choose $\delta_1 > 0$ such that $d(\phi(x), x_1) < \varepsilon/4$ for any $x \in I_1 = [x_1 - \delta_1, x_1 + \delta_1]$. Let $\tilde{x}_1 \neq x_1$ another periodic point of $\phi$ in $[x_1 - \delta_1/2, x_1 + \delta_1/2]$. Let $\phi_1$ be the continuous map defined for $x$ in the interval $[\tilde{x}_1, x_1]$ (or on $[x_1, \tilde{x}_1]$ if $x_1 < \tilde{x}_1$) as $\phi_1(x) = T^{-1}\psi(T(x))$, where $T : [\tilde{x}_1, x_1] \to [0, 1]$ is the unique affine map from $[\tilde{x}_1, x_1]$ onto $[0, 1]$ (or $T : [x_1, \tilde{x}_1] \to [0, 1]$ is the unique affine map from $[x_1, \tilde{x}_1]$ onto $[0, 1]$ if $x_1 < \tilde{x}_1$), $\phi_1(x) = \phi(x)$ if $x \in [0, 1] \setminus I_1$, and to extend it continuously and linearly on $I_1 \setminus [\tilde{x}_1, x_1]$ (or on $I_1 \setminus [x_1, \tilde{x}_1]$ if $x_1 < \tilde{x}_1$). Note that $d(\phi_1, \phi_2) < \varepsilon/2$. If $\text{mdim}_M([0, 1], \phi|_{[0,1]}|_{I_1}, d) = 1$, as above we can to construct a perturbation $\phi_2$ of $\phi_1$ on a neighborhood $I_2$ of other periodic point which is an accumulation point of the set consisting of periodic points of $\phi$, such that $d(\phi_1, \phi_2) < \varepsilon/4$. Following this process, we can to construct a sequence of perturbations $\phi_n$ of $\phi_{n-1}$ on an interval $I_n$, such that $d(\phi_n, \phi_{n-1}) < \varepsilon/2^n$ until that $\text{mdim}_M([0, 1], \phi|_{[0,1]}|_{\bigcup_{i=1}^{n} I_i}, d) = 0$. Then $d(\phi_n, \phi) < \varepsilon$. In the same way as Example 4.9 we can to construct a sequence of continuous maps $\psi_k$, converging to $\phi_n$ as $k \to \infty$, with zero metric mean dimension on $\bigcup_{i=1}^{n} I_i$ and such that coincide with $\phi$ on $[0, 1] \setminus \bigcup_{i=1}^{n} I_i$ for any $k \geq 1$. Therefore $\text{mdim}_M([0, 1], \psi_k, d) = 0$ for any $k \geq 1$ and $d(\psi_k, \phi) < \varepsilon$ for a large enough $k$, which proves the lemma. □

It follows from Proposition 4.6 Corollary 4.8 and Lemma 4.10 that:

**Theorem 4.11.** If $X = [0, 1]$ or $S^1$, then $\text{mdim}_M : C^0(X) \to \mathbb{R}$ is not continuous anywhere.
