Abstract

A Gallai coloring of a complete graph is an edge-coloring such that no triangle has all its edges colored differently. A Gallai $k$-coloring is a Gallai coloring that uses $k$ colors. Given a graph $H$ and an integer $k \geq 1$, the Gallai-Ramsey number $GR_k(H)$ of $H$ is the least positive integer $N$ such that every Gallai $k$-coloring of the complete graph $K_N$ contains a monochromatic copy of $H$. Let $W_{2n}$ denote an even wheel on $2n + 1 \geq 5$ vertices. In this note, we study Gallai-Ramsey number of $W_{2n}$ and completely determine the exact value of $GR_k(W_4)$ for all $k \geq 2$.

Key words: Gallai coloring, Gallai-Ramsey number, rainbow triangle

1 Introduction

All graphs in this paper are finite, simple and undirected. Given a graph $G$ and a set $S \subseteq V(G)$, we use $|G|$ to denote the number of vertices of $G$, and $G[S]$ to denote the subgraph of $G$ obtained from $G$ by deleting all vertices in $V(G) \setminus S$. For two disjoint sets $A, B \subseteq V(G)$, $A$ is complete to $B$ in $G$ if every vertex in $A$ is adjacent to all vertices in $B$. We use $K_n, C_n, P_n$ to denote the complete graph, cycle, and path on $n$ vertices, respectively; and $W_n$ to denote a wheel on $n + 1$ vertices. For any positive integer $k$, we write $[k]$ for the set $\{1, \ldots, k\}$. We use the convention “$S :=$” to mean that $S$ is defined to be the right-hand side of the relation.

Given an integer $k \geq 1$ and graphs $H_1, \ldots, H_k$, the classical Ramsey number $R(H_1, \ldots, H_k)$ is the least integer $N$ such that every $k$-coloring of the edges of $K_N$ contains a monochromatic copy of $H_i$ in color $i$ for some $i \in [k]$. Ramsey numbers are notoriously difficult to compute in general. Very little is known for Ramsey numbers of

\textsuperscript{\ast}Corresponding author. E-mail address: fangfangzh@smail.nju.edu.cn
wheels and the exact value of $R(W_n, W_n)$ is only known for $n \in \{3, 4, 5\}$ (see [11, 14, 7]). In this paper, we study Ramsey number of wheels in Gallai colorings, where a Gallai coloring is a coloring of the edges of a complete graph without rainbow triangles (that is, a triangle with all its edges colored differently). Gallai colorings naturally arise in several areas including: information theory [15]; the study of partially ordered sets, as in Gallai’s original paper [10] (his result was restated in [13] in the terminology of graphs); and the study of perfect graphs [4]. More information on this topic can be found in [8, 9].

A Gallai $k$-coloring is a Gallai coloring that uses $k$ colors. Given an integer $k \geq 1$ and graphs $H_1, \ldots, H_k$, the Gallai-Ramsey number $GR(H_1, \ldots, H_k)$ is the least integer $N$ such that every $(K_N, \tau)$ contains a monochromatic copy of $H_i$ in color $i$ for some $i \in [k]$. When $H = H_1 = \cdots = H_k$, we simply write $GR_k(H)$ and $R_k(H)$. Clearly, $GR_k(H) \leq R_k(H)$ for all $k \geq 1$ and $GR(H_1, H_2) = R(H_1, H_2)$. In 2010, Gyárfás, Sárközy, Sebő and Selkow [12] proved the general behavior of $GR_k(H)$.

**Theorem 1.1** ([12]). Let $H$ be a fixed graph with no isolated vertices and let $k \geq 1$ be an integer. Then $GR_k(H)$ is exponential in $k$ if $H$ is not bipartite, linear in $k$ if $H$ is bipartite but not a star, and constant (does not depend on $k$) when $H$ is a star.

It turns out that for some graphs $H$ (e.g., when $H = C_3$), $GR_k(H)$ behaves nicely, while the order of magnitude of $R_k(H)$ seems hopelessly difficult to determine. It is worth noting that finding exact values of $GR_k(H)$ is far from trivial, even when $|H|$ is small. The following structural result of Gallai [10] is crucial in determining the exact value of Gallai-Ramsey number of a graph $H$.

**Theorem 1.2** ([10]). For any Gallai coloring $\tau$ of a complete graph $G$ with $|G| \geq 2$, $V(G)$ can be partitioned into nonempty sets $V_1, V_2, \ldots, V_p$ with $p > 1$ so that at most two colors are used on the edges in $E(G) \setminus (E(V_1) \cup \cdots \cup E(V_p))$ and only one color is used on the edges between any fixed pair $(V_i, V_j)$ under $\tau$, where $E(V_i)$ denotes the set of edges in $G[V_i]$ for all $i \in [p]$.

The partition given in Theorem [12] is a Gallai partition of the complete graph $G$ under $\tau$. Given a Gallai partition $V_1, \ldots, V_p$ of the complete graph $G$ under $\tau$, let $v_i \in V_i$ for all $i \in [p]$ and let $\mathcal{R} := G[\{v_1, \ldots, v_p\}]$. Then $\mathcal{R}$ is the reduced graph of $G$ corresponding to the given Gallai partition under $\tau$. By Theorem [12] all edges in $\mathcal{R}$ are colored by at most two colors under $\tau$. One can see that any monochromatic copy of $H$ in $\mathcal{R}$ will result in a monochromatic copy of $H$ in $G$ under $\tau$. It is not surprising that Gallai-Ramsey number $GR_k(H)$ is closely related to the classical Ramsey number $R_2(H)$. The following is a conjecture of Fox, Grinshpun and Pach [8] on $GR_k(H)$ when $H$ is a complete graph.
Conjecture 1.3. For all $k \geq 1$ and $t \geq 3$,

$$GR_k(K_t) = \begin{cases} (R_2(K_t) - 1)^{k/2} + 1 & \text{if } k \text{ is even} \\ (t - 1)(R_2(K_t) - 1)^{(k-1)/2} + 1 & \text{if } k \text{ is odd.} \end{cases}$$

The first case $k = 3$ of Conjecture 1.3 follows directly from a result of Chung and Graham [6] from 1983, and a simpler proof can be found in [12]. Recently, the case $k = 4$ of Conjecture 1.3 was proved in [18].

In this note, we study Gallai-Ramsey number of even wheels. We use $(G, \tau)$ to denote a Gallai $k$-colored complete graph if $G$ is a complete graph and $\tau : E(G) \to [k]$ is a Gallai $k$-coloring. For any $A, B \subseteq V(G)$, if all the edges between $A$ and $B$ are colored the same color, say blue, under $\tau$, we say that $A$ is blue-complete to $B$ in $(G, \tau)$. We simply say $a$ is blue-complete to $B$ in $(G, \tau)$ when $A = \{a\}$. We first prove the following general lower bound for $GR_k(W_{2n})$ for all $k \geq 2$ and $n \geq 2$.

**Proposition 1.4.** For all $n \geq 2$ and $k \geq 2$,

$$GR_k(W_{2n}) \geq \begin{cases} (R_2(W_{2n}) - 1) \cdot 5^{(k-2)/2} + 1 & \text{if } k \text{ is even} \\ 2(R_2(W_{2n}) - 1) \cdot 5^{(k-3)/2} + 1 & \text{if } k \text{ is odd.} \end{cases}$$

**Proof.** Let $m := R_2(W_{2n}) - 1$ and $G_2 := K_m$. Let $(G_2, \tau_2)$ be Gallai 2-colored with colors 1, 2 such that $G_2$ has no monochromatic copy of $W_{2n}$ under $\tau_2$. We then construct $(G_k, \tau_k)$ recursively for all $k \geq 3$. When $k \geq 3$ is even, let $(H, c) := (K_5, c)$ be such that edges of $H$ are colored by colors $k$ and $k - 1$ with no monochromatic copy of $K_3$. Let $(G_k, \tau_k)$ be obtained from $(H, c)$ by replacing each vertex of $H$ with $(G_{k-2}, \tau_{k-2})$. When $k \geq 3$ is odd, let $(G_k, \tau_k)$ be the join of two disjoint copies of $(G_{k-1}, \tau_{k-1})$, with all the new edges colored by color $k$. Clearly, $(G_k, \tau_k)$ has no rainbow triangle and no monochromatic copy of $W_{2n}$. Hence, $GR_k(W_{2n}) \geq |G_k| + 1$, as desired.

The main result in this note is Theorem 1.5 below, which establishes the exact value of $GR_k(W_4)$ for all $k \geq 2$.

**Theorem 1.5.** For all $k \geq 2$,

$$GR_k(W_4) = \begin{cases} 14 \cdot 5^{\frac{k-2}{2}} + 1, & \text{if } k \text{ is even,} \\ 28 \cdot 5^{\frac{k-2}{2}} + 1, & \text{if } k \text{ is odd.} \end{cases}$$

With the support of Theorem 1.5, it seems that the lower bound given in Proposition 1.4 is also the desired upper bound for $GR_k(W_{2n})$. We propose the following conjecture.
**Conjecture 1.6.** For all $k \geq 2$ and $n \geq 2$,

$$GR_k(W_{2n}) = \begin{cases} (R_2(W_{2n}) - 1) \cdot 5^{\frac{k+2}{3}} + 1, & \text{if } k \text{ is even}, \\ 2(R_2(W_{2n}) - 1) \cdot 5^{\frac{k-3}{2}} + 1, & \text{if } k \text{ is odd}. \end{cases}$$

It is worth noting that very recently, Gallai-Ramsey number of some other graphs with at most five vertices were studied by Li and Wang [17]. More recent work on Gallai-Ramsey numbers of cycles can be found in [3, 1, 2, 5, 20, 19, 16].

## 2 Proof of Theorem 1.5

Let $f(1) := 4$ and for all $k \geq 2$, let

$$f(k) := \begin{cases} 14 \cdot 5^{\frac{k+2}{3}}, & \text{if } k \text{ is even}, \\ 28 \cdot 5^{\frac{k-3}{2}}, & \text{if } k \text{ is odd}. \end{cases}$$

Then for all $k \geq 3$, $f(k) \geq 2f(k-1)$, and

$$f(k) \geq \begin{cases} 2f(k-1), & \text{if } k \text{ is even}, \\ 5f(k-2), & \text{if } k \text{ is odd}. \end{cases} \quad (*)$$

By Proposition 1.4, it suffices to show that for all $k \geq 2$, $GR_k(W_4) \leq f(k) + 1$. By a result in [14], $R_2(W_4) = 15$ and so $GR_2(W_4) = R_2(W_4) = f(2) + 1$. We may assume that $k \geq 3$. Let $G := K_{f(k)+1}$ and let $\tau : E(G) \to [k]$ be any Gallai $k$-coloring of $G$. Suppose that $(G, \tau)$ does not contain any monochromatic copy of $W_4$. Then $\tau$ is bad. Among all complete graphs on $f(k)+1$ vertices with a bad Gallai $k$-coloring, we choose $(G, \tau)$ with $k$ minimum. We next prove several claims.

**Claim 1.** Let $A \subseteq V(G)$ and let $i \in [k]$ be a color, say blue. If $(G[A], \tau)$ has no blue $P_3$, then $|A| \leq f(k-1)$.

**Proof.** Suppose $|A| \geq f(k-1) + 1$. By the minimality of $k$, $GR_{k-1}(W_4) \leq f(k-1) + 1$. Then $|A| \geq GR_{k-1}(W_4)$. Since $k \geq 3$, let red be another color in $[k] \setminus \{i\}$, and let $\tau^*$ be obtained from $\tau$ by replacing colors red and blue with a new color, say $\beta \notin [k]$. Then $\tau^*$ is a Gallai $(k-1)$-coloring of $G$ and so $(G[A], \tau^*)$ contains a monochromatic copy of $W := W_4$ because $|A| \geq GR_{k-1}(W_4)$. Since $(G[A], \tau)$ contains no monochromatic $W_4$, it follows that $W$ must be a monochromatic $W_4$ in color $\beta$. For the remaining proof of this claim, we use $W_4 = (u_1, u_2, u_3, u_4; u_0)$ to denote a wheel on 5 vertices, where $W_4 \setminus u_0$ is a cycle with vertices $u_1, u_2, u_3, u_4$ in order, and $u_0$ is complete to $\{u_1, u_2, u_3, u_4\}$. Let $W = (u_1, u_2, u_3, u_4; u_0)$. Then $W$ has at most two independent blue edges under $\tau$, because $(G[A], \tau)$ has no blue $P_3$. Thus $W[\{u_1, u_2, u_3, u_4\}]$ must be a red $C_4$ under $\tau$, otherwise, say $u_1u_2$ is blue. Then $\{u_1, u_2\}$ is red-complete to $\{u_3, u_4, u_0\}$ in $G$ under $\tau$. We may further assume that $u_0u_3$ is red under $\tau$. But then we obtain a red $W_4 = (u_1, u_4, u_2, u_3; u_0)$ under $\tau$ when $u_0u_4$ is red; and a red
Let $W_4 = (u_0, u_2, u_4, u_1; u_3)$ under $\tau$ when $u_0u_4$ is blue, a contradiction. This proves that $W[[u_1, u_2, u_3, u_4]]$ is a red $C_4$ under $\tau$. Since $(G[A], \tau)$ has no blue $P_3$, we see that exactly one of the edges $u_0u_1, u_0u_2, u_0u_3, u_0u_4$, say $u_0u_1$ is blue under $\tau$. But then we obtain a red $W_4 = (u_1, u_2, u_0, u_4; u_3)$ under $\tau$, a contradiction.  

Claim 2. Let $A \subseteq V(G)$ and let $i, j \in [k]$ be two distinct colors, say red and blue. If $(G[A], \tau)$ has neither red nor blue $P_3$, then $|A| \leq f(k-2)$.

Proof. Let $\tau^*$ be obtained from $\tau$ by replacing colors red and blue with a new color, say $\beta \notin [k]$. Then $\tau^*$ is a Gallai $(k-1)$-coloring of $G$. We claim that $(G[A], \tau^*)$ has no monochromatic copy of $P_3$ in color $\beta$. Suppose not. Let $x_1, x_2, x_3 \in A$ be such that $x_1x_2, x_2x_3$ are colored by color $\beta$ under $\tau^*$. Since $(G[A], \tau)$ has neither red nor blue $P_3$, we may assume that $x_1x_2$ is colored blue and $x_2x_3$ is colored red under $\tau$. Then $x_1x_3$ is colored neither red nor blue under $\tau$. But then $(G[[x_1, x_2, x_3]], \tau)$ is a rainbow triangle, a contradiction. Thus $(G[A], \tau^*)$ has no monochromatic copy of $P_3$ in color $\beta$, as claimed. Then $(G, \tau^*)$ has no monochromatic copy of $W_4$. By Claim 1 applied to $A$, $\tau^*$ and color $\beta$, we have $|A| \leq f(k-2)$.  

Claim 3. Let $A \subseteq V(G)$ and $x, y \in V(G) \setminus A$. If all the edges between $\{x, y\}$ and $A$ are colored the same color, say blue, under $\tau$, then $G[A]$ contains no blue $P_3$.

Proof. Suppose $(G[A], \tau)$ contains a blue copy of $P_3$ with vertices, say $v_1, v_2, v_3$ in order. Then $G[[v_1, x, v_3, y, v_2]]$ has a blue copy of $W_4$, a contradiction.

Let $x_1, x_2, \ldots, x_m \in V(G)$ be a maximum sequence of vertices chosen as follows: for each $j \in [m]$, all edges between $x_j$ and $V(G) \setminus \{x_1, x_2, \ldots, x_j\}$ are colored by the same color under $\tau$. Let $X := \{x_1, x_2, \ldots, x_m\}$. Note that $X$ is possibly empty. For each $x_j \in X$, let $\tau(x_j)$ be the unique color on the edges between $x_j$ and $V(G) \setminus \{x_1, x_2, \ldots, x_j\}$.

Claim 4. $\tau(x_i) \neq \tau(x_j)$ for all $i, j \in [m]$ with $i \neq j$.

Proof. Suppose there exist $i, j \in [m]$ with $i \neq j$ such that $\tau(x_i) = \tau(x_j)$. We may assume that the color $\tau(x_i)$ is blue, $i < j$, and $x_j$ is the first vertex in the sequence $x_1, \ldots, x_m$ such that $\tau(x_j) = \tau(x_i)$ for some $i \in [m]$ with $i < j$. By the pigeonhole principle, $j \leq k+1$. Let $A := \{x_1, x_2, \ldots, x_j\}$. By Claim 3, $G \setminus A$ has no blue $P_3$. By Claim 1, $|G \setminus A| \leq f(k-1)$. But then $|G| \leq f(k-1)+k+1 < f(k)+1$, a contradiction.

By Claim 3, $|X| \leq k$. Note that $G \setminus X$ has no monochromatic copy of $W_4$ under $\tau$. Consider a Gallai-partition of $G \setminus X$, as given in Theorem 1.2 with parts $V_1, V_2, \ldots, V_p$, where $p \geq 2$. We may assume that $|V_1| \geq |V_2| \geq \ldots \geq |V_p|$. Let $R$ be the reduced graph of $G \setminus X$ with vertices $a_1, \ldots, a_p$. By Theorem 1.2 we may assume that every edge of $R$ is colored red or blue. Note that any monochromatic copy of $W_4$ in $R$ would yield a monochromatic copy of $W_4$ in $G \setminus X$. Thus $R$ has neither red nor blue $W_4$. 

Since \( R_2(W_4) = 15 \), we see that \( p \leq 14 \). Then \(|V_1| \geq 2\) because \(|G \setminus X| \geq 26\) for all \( k \geq 3 \). Let

\[
B := \{v \in \bigcup_{i=2}^{p} V_i \mid v \text{ is blue-complete to } V_1 \text{ under } \tau\}
\]

\[
R := \{v \in \bigcup_{i=2}^{p} V_i \mid v \text{ is red-complete to } V_1 \text{ under } \tau\}
\]

Then \(|B| + |R| + |V_1| = |G| - |X|\). We may assume that \(|B| \leq |R|\). By the choice of \( x_1, \ldots, x_m \), \(|R| \geq 2\). By Claim 3, neither \((G[V_1], \tau)\) nor \((G[R], \tau)\) contains a red copy of \( P_3 \). Note that \((G[V_1 \cup R], \tau)\) has a red copy of \( C_4 \). Thus no vertex in \( X \) is red-complete to \( V(G) \setminus X \) under \( \tau \).

**Claim 5.** \((G[B], \tau)\) contains a red copy of \( P_3 \). Furthermore, \(|V_1 \cup X| \leq f(k-2)\).

**Proof.** Suppose \((G[B], \tau)\) has no red \( P_3 \). Then \((G[B \cup V_1 \cup X], \tau)\) has no red \( P_3 \), because no vertex in \( X \) is red-complete to \( V(G) \setminus X \) under \( \tau \) and \((G[V_1], \tau)\) has no red \( P_3 \). Note that \((G[R], \tau)\) has no red \( P_3 \). By Claim 1, \(|R| \leq f(k-1)\) and \(|B \cup V_1 \cup X| \leq f(k-1)\). By (*) \( 2f(k-1) \leq f(k) \) for all \( k \geq 3 \). But then \(|G| = |R| + |B \cup V_1 \cup X| \leq 2f(k-1) \leq f(k)\), a contradiction. Thus \((G[B], \tau)\) contains a red copy of \( P_3 \) and so \(|B| \geq 3\). Then no vertex in \( X \) is blue-complete to \( V(G) \setminus X \) under \( \tau \). By Claim 3, \((G[V_1], \tau)\) has no blue \( P_3 \). Thus \((G[V_1 \cup X], \tau)\) contains neither red nor blue \( P_3 \). By Claim 2 \(|V_1 \cup X| \leq f(k-2)\), as desired. \( \blacksquare \)

**Claim 6.** \(|V_3| \leq 1\).

**Proof.** Suppose \(|V_1| \geq |V_2| \geq |V_3| \geq 2\). Since \((G, \tau)\) contains no monochromatic \( W_4 \), we see that \( \mathcal{R}([a_1, a_2, a_3]) \) is not a monochromatic triangle. Let \( A_1, A_2, A_3 \) be a permutation of \( V_1, V_2, V_3 \) such that \( A_2 \) is, say, blue-complete, to \( A_1 \cup A_3 \) in \( G \). Then \( A_1 \) must be red-complete to \( A_3 \). Let \( A := V(G) \setminus (A_1 \cup A_2 \cup A_3 \cup X) \). Then no vertex in \( A \) is red-complete to \( A_1 \cup A_3 \), and no vertex in \( A \) is blue-complete to \( A_1 \cup A_2 \) or \( A_2 \cup A_3 \). This implies that \( A \) must be red-complete to \( A_2 \). Note that every vertex in \( A \) is blue-complete to either \( A_1 \) or \( A_3 \). Let \( A^* := \{v \in A \mid v \text{ is blue-complete to } A_1 \text{ under } \tau\} \). Then \( A \setminus A^* \) is blue-complete to \( A_3 \) under \( \tau \). Note that \( A_1 \) is blue-complete to \( A^* \) and \( A_2 \) is red-complete to \( A^* \). By Claim 3, \((G[A^*], \tau)\) has neither red nor blue \( P_3 \). By Claim 2 \(|A^*| \leq f(k-2)\). Similarly, \(|A \setminus A^*| \leq f(k-2)\). By Claim 5 \(|A_i| \leq f(k-2) - |X|\) for all \( i \in \{1, 2, 3\} \). By (*) \( 5f(k-2) \leq f(k) \) for all \( k \geq 3 \). But then

\[
|G| = |A^*| + |A \setminus A^*| + |A_1| + |A_2| + |A_3| + |X| \leq 5f(k-2) - 2|X| \leq f(k),
\]

a contradiction. \( \blacksquare \)

By Claim 6 \(|V_3| \leq 1\). By Claim 5 \(|V_1 \cup X| \leq f(k-2)\) and so \(|V_2| \leq f(k-2)\). By
(*) again, $5f(k - 2) \leq f(k)$ for all $k \geq 3$. But then

$$|G| = |V_1 \cup X| + |V_2| + |V_3| + \cdots + |V_p|$$
$$\leq 2f(k - 2) + (p - 2)$$
$$\leq 2f(k - 2) + 12$$
$$\leq 5f(k - 2)$$
$$\leq f(k),$$

because $p \leq 14$ and $f(k - 2) \geq 4$, a contradiction.

This completes the proof of Theorem 1.5. ■
