Abstract

The goal of this paper is two folds: we generalize the arithmetic Chern-Simons theory over totally imaginary number fields to arbitrary number fields (with real places) and provide new examples of non-trivial arithmetic Chern-Simons invariant with coefficient $\mathbb{Z}/n\mathbb{Z}$ ($n \geq 2$) associated to a non-abelian gauge group. The main idea for the generalization is to use cohomology with compact support to deal with real places. So far, the non-trivial examples are limited to some non-abelian gauge group with coefficient $\mathbb{Z}/2\mathbb{Z}$ and the abelian cyclic gauge group with coefficient $\mathbb{Z}/n\mathbb{Z}$. Our non-trivial examples with non-abelian gauge group and general coefficient $\mathbb{Z}/n\mathbb{Z}$ will be given by a simple twisting argument. In the appendix, we explain alternative method of generalization based on the work of Zink and Conrad-Masullo.

Keywords: Arithmetic Chern-Simons action, Arithmetic duality theorem, Galois cohomology.

1 Introduction

The arithmetic Chern-Simons theory was initiated by Minhyong Kim in [7], who applied the ideas of Dijkgraaf and Witten ([5]) on 3-dimensional topological quantum field theory to an arithmetic curve, namely the spectrum of the ring of integers in an algebraic number field. Then, in [2], H. Chung, D. Kim, M. Kim, J. Park, and H. Yoo continued to study the theory to provide non-trivial examples of
the arithmetic Chern-Simons action. Also, an intimate connection between the abelian arithmetic Chern-Simons theory and arithmetic linking numbers of prime ideals is investigated in [3].

Let us briefly recall the setting of [7, 2]. Let $F$ be a totally imaginary number field and $\mathcal{O}_F$ the ring of integers of $F$. Let $X = \text{Spec}(\mathcal{O}_F)$ and $n \geq 2$ be a natural number. Assume that $F$ contains a primitive $n$-th root of unity. Then there is a canonical isomorphism
\[ H^3(X, \mathbb{Z}/n\mathbb{Z}) \overset{\text{inv}}{\cong} \frac{1}{n}\mathbb{Z}/\mathbb{Z}. \] (1)

Denote $\pi^\text{un} := \text{Gal}(F^\text{un}/F)$ where $F^\text{un}$ is the maximal unramified extension of $F$ in the algebraic closure $\overline{F}$. Let $A$ be a finite group (called the gauge group). Consider the space of fields on the space-time $X$:
\[ \mathcal{M}(A) := \text{Hom}_\text{cont}(\pi^\text{un}, A)/A, \]
where $A$ acts on the target by the conjugation. Fix a group cohomology class $c \in H^3(A, \mathbb{Z}/n\mathbb{Z})$ where $A$ acts on $\mathbb{Z}/n\mathbb{Z}$ trivially. Define the **arithmetic classical Chern-Simons action (or invariant) without boundary** by a function
\[ CS_c : \mathcal{M}(A) \to \frac{1}{n}\mathbb{Z}/\mathbb{Z}, \quad [\rho] \mapsto \text{inv}(j_3^\text{un}(\rho^*(c))). \]

where $j^\text{un}_3 : H^3(\pi^\text{un}, \mathbb{Z}/n\mathbb{Z}) \to H^3(X, \mathbb{Z}/n\mathbb{Z})$ is the edge map induced from the Hochschild-Serre spectral sequence (see (2) for an alternative precise definition of $j^3_\text{un}$). Since $\rho^*(c)$ depends only on the class $[\rho]$, $CS_c$ is well-defined.

A technical reason why $F$ is assumed to be totally imaginary in [7, 2] is that the isomorphism (1) does not hold anymore when $F$ has a real place. The natural idea for generalizing the arithmetic Chern-Simons theory to an arbitrary number field is to use cohomology with compact support, since there is a canonical isomorphism (see Proposition 2.4)
\[ \text{inv} : H^3_c(X, \mathbb{Z}/n\mathbb{Z}) \simeq \frac{1}{n}\mathbb{Z}/\mathbb{Z}. \]

Based on this isomorphism, we extend the arithmetic classical Chern-Simons action without boundary to an arbitrary number field. Since we assume that $F$ contains a primitive $n$-th root of unity, the actual new case compared to [2] is that $F$ is totally real and $n = 2$. But we will state propositions and theorems for arbitrary number field $F$ and natural number $n$ for efficiency of the presentation of proofs and examples.

Let $S_f$ be any finite set of finite primes of $F$, $X_\infty$ be a set of all real places of $F$, $S := S_f \cup X_\infty$, $\tilde{S}$ be any set satisfying $S_f \subset \tilde{S} \subset S$, $U_S := \text{Spec}(\mathcal{O}_F \left[ \frac{1}{S_f} \right])$ and $\pi_{\tilde{S}} := \text{Gal}(F^\text{un}_{\tilde{S}}/F)$ where $F^\text{un}_{\tilde{S}}$ is the maximal extension of $F$ in $\overline{F}$ unramified outside $\tilde{S}$. When working with the arithmetic classical Chern-Simons action with boundary (see (3)) and proving the decomposition formula (see Section 3), which provides a way of computing the arithmetic classical Chern-Simons action without boundary using a comparison between local unramified and global ramified trivializations of a Galois 3-cocycle, the vanishing of the étale cohomology group $H^3(U_S, \mathbb{Z}/n\mathbb{Z})$ plays an important role. Another key difference between totally imaginary fields ($S_\infty = \phi$) and totally real fields ($S_\infty \neq \phi$) lies in the vanishing behavior of $H^3$. If $S_f$ contains places of $F$ above $n$, then $H^3(U_{S_f}, \mathbb{Z}/n\mathbb{Z}) = 0$ for an arbitrary number field $F$ but $H^3(U_S, \mathbb{Z}/n\mathbb{Z}) \neq 0$ for a totally real field $F$. Due to this difference, our Chern-Simons action and decomposition formula differ from those in [2].

In section 5, [2], the authors used the decomposition formula to construct infinitely many totally imaginary number fields $F$ in which the action $CS_c([\rho])$ is non-zero for some $c$ and $\rho$ when $n = 2$ and the gauge group $A$ is $\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z},$ or the symmetric group $S_4$. We provide the analogues of those examples for the totally real case.
In section 6, [2], they showed non-solvability of a certain case of the embedding problem (biquadratic fields are involved) based on non-vanishing ( [2, Theorem 6.2]) of arithmetic Chern-Simons action with the gauge group $V_4$, the Klein four group. Unfortunately, such an arithmetic application is not available in our case with totally real fields.

The example of non-vanishing of $CS_c([\rho])$ for the case $n > 2$ but with the abelian cyclic gauge group $A = \mathbb{Z}/n\mathbb{Z}$ was first provided by the work of F. M. Bleher, T. Chinburg, R. Greenberg, M. Kakde, G. Pappas and M. J. Taylor, in [1]. When $A = \mathbb{Z}/n\mathbb{Z}$ for any $n \geq 2$, for a particular choice of $c$ they found an infinitely many totally imaginary number fields $F$ and representations $\rho$ such that $CS_c([\rho]) \neq 0$ (see [1, Theorem 1.2]). We prove that there is a simple twisting argument (see Lemma 4.2 and Theorem 4.3) to provide infinitely many totally imaginary number fields $F$ such that $CS_c([\rho]) \neq 0$ for some $\rho$ and $c$, when the gauge group is $A = G \rtimes \mathbb{Z}/n\mathbb{Z}$ (the semidirect product of some finite group $G$ by $\mathbb{Z}/n\mathbb{Z}$) for any $n \geq 2$. For instance, we will give examples of non-vanishing arithmetic Chern-Simons action (see Example 4.5) where the gauge group is the general linear group $\text{GL}(r, \mathbb{F}_p)$ over a finite field $\mathbb{F}_p$ ($r \geq 2$) and $n = p - 1$.

There exists the method of Zink [12] and Conrad-Masullo [4] of generalizing the étale cohomology of $X = \text{Spec}(\mathcal{O}_F)$ for totally imaginary number fields $F$, which was studied by Mazur [8], to arbitrary number fields. This provides an alternative way of defining the arithmetic classical Chern-Simons action. In the appendix, we add such a viewpoint. Note that the approach based on cohomology with compact support has a benefit of providing a natural framework to prove the decomposition formula.

The methods of this paper using cohomology with compact support carry over mutatis mutandis to the case of global function fields provided $n$ is prime to the characteristic of the field. So there is also a version of arithmetic Chern-Simons theory for a finite extension $F$ of the field of rational functions $F_q(T)$ when $n$ is prime to a prime number $p$ and $q = p^k$ for some $k \geq 1$.

We briefly explain contents of each section. In subsection 2.1, we set up basic definitions and notations. In subsection 2.2 we review the theory of cohomology with compact support based on Milne’s book [9]. We define the arithmetic classical Chern-Simons action without boundary (in subsection 2.3) and with boundary (in subsection 2.4). Since we do not deal with the quantization of the theory and we will omit the word “classical” in the body of the paper. Section 3 is devoted to the statement and the proof of the decomposition formula.

Section 4 is about examples. In subsection 4.1, we provide non-vanishing examples with general $n$ and some non-abelian gauge group based on the result of [1]. We provide analogous examples to section 5, [2] (in subsection 4.2) in the case of totally real number fields with the coefficient $\mathbb{Z}/2\mathbb{Z}$ and the gauge group $A = \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, or $S_4$ and its analogue to biquadratic fields (in subsection 4.3). Finally, we add an alternative viewpoint of the arithmetic Chern-Simons theory with real places based on the generalized étale cohomology theory developed by Zink and Conrad-Masullo.

2 Arithmetic Chern-Simons action

In this section, we define arithmetic Chern-Simons action for an arbitrary number field. To deal with the real places of a number field $F$, we use cohomology with compact support.

2.1 Definitions and notations

Let $F$ be a number field, $X = \text{Spec}(\mathcal{O}_F)$, $G_F := \text{Gal}(\overline{F}/F)$, $b : \text{Spec}(\overline{F}) \to X$ be a geometric point and $\pi := \pi_1(X, b)$. Then $\pi \cong \text{Gal}(F_{\text{un}}^f/F)$ where $F_{\text{un}}^f$ is the maximal extension of $F$ in $\overline{F}$ unramified at all finite primes. Denote $\pi^{un} := \text{Gal}(F_{\text{un}}/F)$ where $F_{\text{un}}$ is the maximal unramified extension of $F$ in
For an abelian étale sheaf $F$, let $S_f$ be any finite set of finite primes of $F$, $X_\infty$ be a set of all real places of $F$, $S := S_f \cup X_\infty$, $\tilde{S}$ be any set satisfying $S_f \subset \tilde{S} \subset S$, $U_S := \text{Spec}(\mathcal{O}_F[\frac{1}{S_f}])$ and $b_S : \text{Spec}(\mathbb{F}) \to U_S$ be a geometric point and $\pi_{\tilde{S}} := \text{Gal}(F_{\text{un}}^\mathbb{F}/F)$ where $F_{\text{un}}^\mathbb{F}$ is the maximal extension of $F$ in $\mathbb{F}$ unramified outside $\tilde{S}$.

Let $\mathbb{F}$ be any set satisfying $S_f \subset \tilde{S} \subset S$, $U_S := \text{Spec}(\mathcal{O}_F[\frac{1}{S_f}])$ and $b_S : \text{Spec}(\mathbb{F}) \to U_S$ be a geometric point and $\pi_{\tilde{S}} := \text{Gal}(F_{\text{un}}^\mathbb{F}/F)$ where $F_{\text{un}}^\mathbb{F}$ is the maximal extension of $F$ in $\mathbb{F}$ unramified outside $\tilde{S}$. Then $\pi_1(U_S, b_S) \cong \pi_{\tilde{S}}$.

Let $\kappa_S : \pi_{\tilde{S}} \to \pi_{\tilde{S}}$ and $\kappa_S : \pi_{\tilde{S}} \to \pi_{\text{un}}$ be natural quotient maps. For each (possibly infinite) prime $v$ of $F$, let $\pi_v := \text{Gal}(\mathbb{F}_v/F_v)$, $I_v \subset \pi_v$ be the inertia group and $\kappa_v : \pi_v \to G_F \to \pi_{\text{un}}$ be given by choices of embeddings $\mathbb{F} \to \mathbb{F}_v$. For each $v \in \tilde{S}$, let $i_v := i_{v, \tilde{S}} : \pi_v \to G_F \to \pi_{\tilde{S}}$ be given by the embeddings $\mathbb{F} \to \mathbb{F}_v$ same as above and $i_v = i_{v, \tilde{S}} : \text{Spec}(F_v) \to \text{Spec}(F) \to U_S$ be the natural map.

For a $\pi_{\tilde{S}}$-module $M$, let $M_v := M$ equipped with a $\pi_v$-module structure given by $i_v$. Similarly, for an abelian étale sheaf $F$ on $U_S$, denote an abelian étale sheaf on $\text{Spec}(F_v)$ induced by $i_v$ be $F_v$. For a finite abelian group $G$, its Pontryagin dual $G^D := \text{Hom}(G, \mathbb{Q}/\mathbb{Z})$ is isomorphic to $G$. For a Galois group $G = \text{Gal}(L/K)$ and a $G$-module $M$, denote the dual group of $M$ by $M^* := \text{Hom}_G(M, L^*)$. For a locally constant abelian étale sheaf $F$ on $U_S$, its Cartier dual $F^\vee := \text{Hom}_{U_S}(F, \mathbb{G}_m)$ is also locally constant and $F^\vee \cong F$.

### 2.2 Cohomology with compact support

We write $r_v$ for the restriction map of cochains or cohomology classes from $\pi_{\tilde{S}}$ to $\pi_v$ (induced by $i_v$) or $U_S$ to $\text{Spec}(F_v)$ (induced by $i_v$). Since the category of abelian étale sheaves on $\text{Spec}(F_v)$ is equivalent to the category of $\pi_v$-modules ([6, Proposition 5.7.8]), the second map can be also viewed as the map of cochains or cohomology classes from $U_S$ to $\pi_v$.

Let $C(G, M)$ be the standard inhomogeneous group cochain complex of a group $G$ with values in $M$. For any finite $\pi_{\tilde{S}}$-module $M$, we define the complex defined as a mapping fiber:

$$C_c(\pi_{\tilde{S}}, M) := \text{Fiber}[C(\pi_{\tilde{S}}, M) \to \prod_{v \in \tilde{S}} C(\pi_v, M_v)]$$

and

$$H^r_c(\pi_{\tilde{S}}, M) := H^r \left( C_c(\pi_{\tilde{S}}, M) \right).$$

Explicitly,

$$C^n_c(\pi_{\tilde{S}}, M) = C^n(\pi_{\tilde{S}}, M) \times \prod_{v \in \tilde{S}} C^{n-1}(\pi_v, M_v)$$

and $d(a, (b_v)_{v \in \tilde{S}}) = (da, (r_v(a) - db_v)_{v \in \tilde{S}})$ for $(a, (b_v)_{v \in \tilde{S}}) \in C^n_c(\pi_{\tilde{S}}, M)$. By the definition of $H^r_c(\pi_{\tilde{S}}, M)$, there is a long exact sequence

$$\cdots \to H^r_c(\pi_{\tilde{S}}, M) \to H^r(\pi_{\tilde{S}}, M) \to \prod_{v \in \tilde{S}} H^r(\pi_v, M_v) \to H^{r+1}(\pi_{\tilde{S}}, M) \to \cdots.$$ 

For an abelian étale sheaf $F$ on $U_S$, the complex

$$C_c(U_S, F) := \text{Fiber}[C(U_S, F) \to \prod_{v \in S} C(\pi_v, F_v)]$$

and

$$H^r_c(U_S, F) := H^r \left( C_c(U_S, F) \right)$$

are defined by the same way and fit into the same exact sequence.

**Proposition 2.1.** ([9, Proposition 2.2.6]) $H^2_c(U_S, \mathbb{G}_m) = 0$, $H^3_c(U_S, \mathbb{G}_m) = \mathbb{Q}/\mathbb{Z}$ and $H^r_c(U_S, \mathbb{G}_m) = 0$ for all $r > 3$. 

Remark 2.2. ([9, Remark 2.2.8(a)]) Let \( O^\times_F \) be the group of totally positive units of \( F \) and \( Cl^+(F) \) be the narrow class group of \( F \). Then \( H^0_c(X, G_m) = O^\times_F \) and \( H^1_c(X, G_m) = Cl^+(F) \).

Theorem 2.3. ([9, Theorem 2.3.1]; Artin-Verdier duality) Let \( F \) be a constructible sheaf on an open subscheme \( U \) of \( X \). The Yoneda pairing

\[
H^r_c(U, F) \times \text{Ext}_{U}^{3-r}(F, G_m) \to H^3(U, G_m) \cong \mathbb{Q}/\mathbb{Z}
\]

is a nondegenerate pairing of finite abelian groups for all \( r \in \mathbb{Z} \).

For an abelian group \( A \), let \( A_{U_S} \) be the constant sheaf on the étale site \( \text{Et}(U_S) \) (defined in subsection 2.3) defined by \( A \).

Proposition 2.4. \( H^3_c(U_S, \mathbb{Z}/n\mathbb{Z}) \cong \mu_n(F)^D \).

Proof. By Artin-Verdier duality,

\[
H^3_c(U_S, \mathbb{Z}/n\mathbb{Z}) \cong \text{Hom}_{U_S}(\mathbb{Z}/n\mathbb{Z}, G_m)^D.
\]

The isomorphism \( \mathbb{Z}/n\mathbb{Z} \cong \ker(\mathbb{Z}^X \rightarrow \mathbb{Z}^Y) \) implies

\[
\text{Hom}_{U_S}(\mathbb{Z}/n\mathbb{Z}, G_m) = \mathbb{Z}/n\mathbb{Z} \cong \mu_n(U_S) = \mu_n(F).
\]

Denote the isomorphism \( H^3_c(U_S, \mathbb{Z}/n\mathbb{Z}) \to \mu_n(F)^D \) by \( \text{inv}_S \) and \( H^3_c(X, \mathbb{Z}/n\mathbb{Z}) \to \mu_n(F)^D \) by \( \text{inv} \).

2.3 Arithmetic Chern-Simons action without boundary

Let \( \text{FSet}_{\pi_S} \) be the category of finite continuous \( \pi_S \)-sets, \( \text{FSet}(U_S) \) be the category of finite étale \( U_S \)-schemes and \( \text{Et}(U_S) \) be the category of étale \( U_S \)-schemes. Each category can be understood as a site with a natural Grothendieck topology. Note that \( \text{Et}(U_S) \) is a small étale site of \( U_S \). Since the functor \( \text{FSet}(U_S) \to \text{FSet}_{\pi_S}(Y \to Y(b_S) := \text{Hom}_{U_S}(\text{Spec}(F), Y)) \) is an equivalence of categories ([6, Theorem 3.2.12]) and there is a natural morphism of sites \( \text{f} : \text{Et}(U_S) \to \text{FSet}(U_S) \) given by a functor \( \text{FSet}(U_S) \to \text{Et}(U_S) \), the map

\[
j^1 : H^1(\pi_S, \mathbb{Z}/n\mathbb{Z}) \cong H^1(\text{FSet}(U_S), \mathbb{Z}/n\mathbb{Z}) \to H^1(\text{Et}(U_S), \mathbb{Z}/n\mathbb{Z}) = H^1(U_S, \mathbb{Z}/n\mathbb{Z})
\]

is defined (the morphism of topoi \( f_* : \text{Sh}(\text{Et}(U_S)) \to \text{Sh}(\text{FSet}(U_S)) \) maps a constant sheaf \( \mathbb{Z}/n\mathbb{Z} \) on \( \text{Et}(U_S) \) to \( \mathbb{Z}/n\mathbb{Z} \) on \( \text{FSet}(U_S) \)) and it induces a homomorphism

\[
j^1_c : H^1_c(\pi_S, \mathbb{Z}/n\mathbb{Z}) \to H^1_c(U_S, \mathbb{Z}/n\mathbb{Z}).
\]

It is easy to show that the map \( H^3(\pi^{un}, \mathbb{Z}/n\mathbb{Z}) \to H^3_c(\pi, \mathbb{Z}/n\mathbb{Z}) \) given by

\[
[w] \mapsto [(\pi^{un, \infty}(w), (0)_{v \in X^{\infty}})]
\]

is well-defined and a group homomorphism. Now define the map \( j^3_{un} \) by

\[
j^3_{un} : H^3(\pi^{un}, \mathbb{Z}/n\mathbb{Z}) \to H^3_c(\pi, \mathbb{Z}/n\mathbb{Z}) \to H^3_c(U_S, \mathbb{Z}/n\mathbb{Z}) \to H^3(X, \mathbb{Z}/n\mathbb{Z}). \tag{2}
\]

Let \( A \) be a finite group, \( M(A) := \text{Hom}_{cont}(\pi^{un}, A)/A \) and fix a class \( c \in H^3(A, \mathbb{Z}/n\mathbb{Z}) \) for an integer \( n \geq 2 \). Define the arithmetic Chern-Simons action by a function

\[
CS_c : M(A) \to \mu_n(F)^D, \quad [\rho] \mapsto \text{inv}(j^3_{un}(\rho^*(c))).
\]

Since \( \rho^*(c) \) depends only on the class \([\rho] \), \( CS_c \) is well-defined.
Proposition 2.5. Let $m > 0$ be a divisor of $n$ such that $\mu_n(F) = \mu_m(F)$ (for example, $m = |\mu_n(F)|$). Let $\alpha : \mathbb{Z}/n\mathbb{Z} \to \mathbb{Z}/m\mathbb{Z}$ be a group homomorphism defined by $\alpha(1) = 1$ and $\alpha' = \alpha \cdot c \in H^1(A, \mathbb{Z}/m\mathbb{Z})$. Then $\text{CS}_c([\rho]) = \text{CS}_{\alpha'}([\rho])$ for every $[\rho] \in \mathcal{M}(A)$.

Proof. Let $\rho_{\mathcal{CS}} : H^1(A, \mathbb{Z}/n\mathbb{Z}) \xrightarrow{\alpha'} H^1(A, \mathbb{Z}/m\mathbb{Z}) \xrightarrow{\alpha} H^1(A, \mathbb{Z}/m\mathbb{Z}) \xrightarrow{\alpha} H^1(A, \mathbb{Z}/m\mathbb{Z})$ be the following commutative diagram.

\[
\begin{array}{cccc}
H^3(A, \mathbb{Z}/n\mathbb{Z}) & \xrightarrow{\alpha'} & H^3(A, \mathbb{Z}/n\mathbb{Z}) & \xrightarrow{\alpha} \\
\downarrow & & \downarrow & \\
H^3(A, \mathbb{Z}/m\mathbb{Z}) & \xrightarrow{\alpha'} & H^3(A, \mathbb{Z}/m\mathbb{Z}) & \xrightarrow{\alpha} \\
\end{array}
\]

By the proposition above, we may assume that $\mu_n(T) = \mu_n(F)$. $F$ is totally imaginary for $n \geq 3$ under the assumption, so the case $n = 2$ is the only case which [2] does not cover. From now on, we assume that $\mu_n(T) = \mu_n(F)$ and identify $\mu_n(F)^D$ with $\frac{1}{n}\mathbb{Z}/\mathbb{Z}$. The identification of $\mu_n(F)^D$ with $\frac{1}{n}\mathbb{Z}/\mathbb{Z}$, which is unique only up to Aut($\mathbb{Z}/n\mathbb{Z}$) will be fixed in Section 3.

2.4 Arithmetic Chern-Simons action with boundary

Let $S_n$ be any finite set of finite places of $F$ containing primes of $F$ above $n$. Denote $T = S_n \cup X_\infty$ and $T_f = S_n$. Note that $T = T_f = S_n$ for $n \geq 3$ due to the assumption $\mu_n(T) = \mu_n(F)$. For $T' \in \{T, T_f\}$, let

\[Y_{T'}(A) := \text{Hom}_{\text{cont}}(\pi_{T'}, A)\]

equipped with the conjugation action of $A$ and denote its action groupoid by $\mathcal{M}_{T'}(A)$. Similarly, let

\[Y^\text{loc}_{T'}(A) := \prod_{v \in T'} \text{Hom}_{\text{cont}}(\pi_v, A)\]

equipped with the conjugation action of $A^T := \prod_{v \in T'} A$ and denote its action groupoid by $\mathcal{M}^\text{loc}_{T'}(A)$. Define the functor $r_{T'} : \mathcal{M}_{T'}(A) \to \mathcal{M}^\text{loc}_{T'}(A)$ by

\[r_{T'}(\rho) = i_{T'}^\ast(\rho) := (\rho \circ i_v)_{v \in T'}\]

Let $C_T := \prod_{v \in T} C^\dagger(\pi_v, \mathbb{Z}/n\mathbb{Z})$, $Z_T := \prod_{v \in T} \mathbb{Z}^\dagger(\pi_v, \mathbb{Z}/n\mathbb{Z})$ and $B_T := \prod_{v \in T} B^\dagger(\pi_v, \mathbb{Z}/n\mathbb{Z})$ be the product of continuous cochains, cocycles and coboundaries for each $v \in T$ and $d_T := (d_v)_{v \in T} : C_T \to Z_T$. Let $\rho_T := (\rho_v)_{v \in T} \in Y^\text{loc}_{T'}(A)$, $c \circ \rho_T := (c \circ \rho_v)_{v \in T}$ and $c \circ A_{a_v} := (c \circ A_{a_v})_{v \in T}$ for $a = (a_v)_{v \in T} \in A^T$ where $A_{a_v} : A \to A$ is defined by $A_{a_v}(x) = a_v x a_v^{-1}$. For $H^2_T := \prod_{v \in T} H^2(\pi_v, \mathbb{Z}/n\mathbb{Z})$, $H(\rho_T) := d_T^{-1}(c \circ \rho_T)/B_T \subseteq C_T/B_T$ is a $H^2_T$-torsor.

By [11, Theorem 2.5.2], there is an isomorphism $i_v : H^2(\pi_v, \mathbb{Z}/n\mathbb{Z}) \to \frac{1}{n}\mathbb{Z}/\mathbb{Z}$ for all $v \in T$. By the Poitou-Tate exact sequence ( [10, 8.6.10(3)]), the sequence

\[H^2(\pi_T, \mathbb{Z}/n\mathbb{Z}) \to H^2_T \to H^0(\pi_T, \mathbb{Z}/n\mathbb{Z})^D \to 0\]

is exact. Denote the map $H^2_T \to H^0(\pi_T, \mathbb{Z}/n\mathbb{Z})^D$ by $\sum$ and let

\[L_T(\rho_T) := \sum(H(\rho_T))\]

be a $\frac{1}{n}\mathbb{Z}/\mathbb{Z}$-torsor defined by the pushout of a $H^2_T$-torsor $H(\rho_T)$ by $\sum$. Then $L_T$ can be extended to a functor from $\mathcal{M}^\text{loc}_{T'}(A)$ to the category of $\frac{1}{n}\mathbb{Z}/\mathbb{Z}$-torsors $\text{tors}(\frac{1}{n}\mathbb{Z}/\mathbb{Z})$ exactly as in [2, p. 6-7]. Denote

\[L_T^\text{glob} := L_T \circ r_T : \mathcal{M}_{T}(A) \to \text{tors}(\frac{1}{n}\mathbb{Z}/\mathbb{Z}).\]
Remark 2.6. The map $H_T^2 \to H^0(\pi_T, \mathbb{Z}/n\mathbb{Z})$ is the dual of $H^0(\pi_T, \mathbb{Z}/n\mathbb{Z}) \to \prod_{v \in T} H^0(\pi_v, \mathbb{Z}/n\mathbb{Z})$ induced by $i_v T$ for each $v \in T$ ([10, p. 495]). For each $v \in T$, the map $H^0(\pi_T, \mathbb{Z}/n\mathbb{Z}) \to H^0(\pi_v, \mathbb{Z}/n\mathbb{Z})$ is identified with an isomorphism $\mu_a(F) \to \mu_a(F_v)$ so the map $\sum$ is same as $\sum_{v \in T} \text{inv}_v$ and equals to the sum map $\sum$ of [2, p. 3].

Lemma 2.7. Let $\rho \in Y_T(A)$ and $a \in \text{Aut}(\rho)$ be a morphism in $\mathcal{M}_T(A)$. Then $L_T^{\text{glob}}(a) = \text{id}_{L_T^{\text{glob}}(\rho)}$.

Proof. By the definition of the action groupoid $\mathcal{M}_T(A)$, $\text{Ad}_a \circ \rho = \rho$. By [2, Lemma A.2], there is $h_a \in C^2(A, \mathbb{Z}/n\mathbb{Z})/B^2(A, \mathbb{Z}/n\mathbb{Z})$ such that

$$c \circ \text{Ad}_a = c + dh_a,$$

so $dh_a \circ \rho = d(h_a \circ \rho) = 0$ and $h_a \circ \rho \in H^2(\pi_T, \mathbb{Z}/n\mathbb{Z})$. $L_T^{\text{glob}}(a)$ maps an element of $L_T^{\text{glob}}(\rho)$ represented by $(f, x) \in H(\pi_T(\rho)) \times \frac{1}{n} \mathbb{Z}/\mathbb{Z}$ to an element represented by $(f + (h_a \circ \rho \circ i_v)v \in T, x)$, or equivalently, $(f, x + \sum((h_a \circ \rho \circ i_v)v \in T))$. By the Poitou-Tate exact sequence, $\sum((h_a \circ \rho \circ i_v)v \in T) = 0$ so $L_T^{\text{glob}}(a)$ is an identity map on $L_T^{\text{glob}}(\rho)$.

By the above lemma, there is a $\frac{1}{n} \mathbb{Z}/\mathbb{Z}$-torsor $L_T^{\text{inv}}([\rho])$ of invariant sections for the functor $L_T^{\text{glob}}$ which depends only on the orbit $[\rho] \in Y_T(A)/A$. Explicitly,

$$L_T^{\text{inv}}([\rho]) = \lim_{\rho' \to [\rho]} L_T^{\text{glob}}(\rho') = \{(x, \rho' \in \prod_{\rho' \to [\rho]} L_T^{\text{glob}}(\rho') \mid \forall a \in \text{Hom}(\rho_1, \rho_2) L_T^{\text{glob}}(a)(x, \rho_1) = x, \rho_2\}.$$

By [10, Proposition 8.3.18] and [10, Theorem 10.6.1], $H^3(\pi_T, \mathbb{Z}/n\mathbb{Z}) = 0$ so for $\rho \in Y_T(A)$, $c \circ \rho = d\beta$ for some $\beta \in C^2(\pi_T, \mathbb{Z}/n\mathbb{Z})$. Then $c \circ \rho \circ pt = d(\beta \circ pt)$ and $d(i_T^*(\beta \circ pt)) = c \circ i_T^*(\rho \circ pr)$. By the Poitou-Tate exact sequence, $\sum((i_T^*(\beta \circ pt)) = 0$ by the Poitou-Tate exact sequence, so $C_{S_T,j,c}$ is well-defined.

3 Decomposition formula

An explicit computation of the arithmetic Chern-Simons invariant relies on the decomposition formula, which expresses the arithmetic Chern-Simons invariant as the difference of a ramified global trivialization and an unramified local trivialization. In this section, we prove the decomposition formula. The proof is done in several steps.

(1) By [10, 8.6.10(ii)], $H^3(\pi_T, \mathbb{Z}/n\mathbb{Z}) \cong \prod_{v \in T} H^3(\pi_v, \mathbb{Z}/n\mathbb{Z})$ so the top row of the following diagram is exact. Its bottom row is exact by Poitou-Tate exact sequence and Remark 2.6.

$$
\begin{array}{c}
H^2(\pi_T, \mathbb{Z}/n\mathbb{Z}) \\
\downarrow \\
H^2(\pi_T, \mathbb{Z}/n\mathbb{Z})
\end{array}
\begin{array}{c}
\rightarrow \\
\rightarrow \\
\rightarrow
\end{array}
\begin{array}{c}
\prod_{v \in T} H^2(\pi_v, \mathbb{Z}/n\mathbb{Z}) \\
\rightarrow \\
\rightarrow \\
\rightarrow
\end{array}
\begin{array}{c}
H^3(\pi_T, \mathbb{Z}/n\mathbb{Z}) \\
\sum_{v \in T} \text{inv}_v \\
\rightarrow \\
\rightarrow \\
\rightarrow
\end{array}
\begin{array}{c}
\mathbb{Z}/\mathbb{Z} \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow
\end{array}
\begin{array}{c}
0
\end{array}
$$

From the diagram above, we obtain an isomorphism $\text{inv}_T' : H^3(\pi_T, \mathbb{Z}/n\mathbb{Z}) \to \frac{1}{n} \mathbb{Z}/\mathbb{Z}$ which makes the diagram commute.
(2) By [11, Proposition 2.18], \( H^3(\pi_v/I_v, Z/nZ) = H^3(\pi_v/I_v, Z/nZ) = 0 \) for every \( v \in T \). Let \( T_1 \subset T_2 \) be finite sets of primes of \( F \) which may or may not contain real places and denote the projection \( \pi_{T_2} \to \pi_{T_1} \) by \( \kappa_{T_1,T_2} \). The map \( H^3_c(\pi_{T_1}, Z/nZ) \to H^3_c(\pi_{T_2}, Z/nZ) \) can be described as follows.

Choose an element \([((a_v, b_v)_v) \in H^3_c(\pi_{T_1}, Z/nZ)\). For \( v \in T_2 \setminus T_1, \kappa_v \) factors through \( \pi_v/I_v \) so \( \kappa_v(a) \) can be restricted to \( \pi_v(a) |_{\pi_v/I_v} \in Z^3(\pi_v/I_v, Z/nZ) = B^3(\pi_v/I_v, Z/nZ) \). Now there is a canonical

\[
\tilde{b}_v \in C^2(\pi_v/I_v, Z/nZ)/B^2(\pi_v/I_v, Z/nZ) \quad (v \in T_2 \setminus T_1)
\]
such that \( d\tilde{b}_v = \kappa_v(a) |_{\pi_v/I_v} \). This can be lifted to a canonical class \( b_v \in C^2(\pi_v, Z/nZ)/B^2(\pi_v, Z/nZ) \).

(Note that \( b_v = 0 \) if \( v \in X_{\infty} \).) Now \([[(\kappa_{T_1,T_2})_v(a_v, b_v)_v)] \) is an element of \( H^3_c(\pi_{T_2}, Z/nZ) \) and it is independent of the choice of \( b_v \) because \( H^2(\pi_v/I_v, Z/nZ) = 0 \). The canonical map

\[
H^3_c(\pi_{T_1}, Z/nZ) \to H^3_c(\pi_{T_2}, Z/nZ) \quad \left( \left[ (a_v, b_v)_v \right] \mapsto \left[ (\kappa_{T_1,T_2})_v(a_v, b_v)_v \right] \right)
\]
is a group homomorphism. For \( X_{\infty} \subset T_1 \subset T_2 \), the map \( H^3_c(U_{T_1}, Z/nZ) \to H^3_c(U_{T_2}, Z/nZ) \) is defined in exactly the same way.

(3) Let \( j : U_T \hookrightarrow X \) be an open immersion and \( i : Z \to X \) be its complement. Then the following diagram commutes, where \( \alpha \) and \( \gamma \) are given as (2) and \( \beta(f) = f |_{U_T} \).

\[
\begin{array}{ccc}
H^3_c(X, Z/nZ) & \times & \text{Hom}_X(Z/nZ, G_m,X) \\
\downarrow & & \downarrow \\
H^3_c(U_T, Z/nZ) & \times & \text{Hom}_{U_T}(Z/nZ, G_m,U_T)
\end{array}
\]

(4) \( 0 \to j_*j^*G_m \to G_m \to i_*i^*G_m \to 0 \) is exact by [6, Proposition 5.4.2] and \( H^r(X, i_*i^*G_m) \cong H^r(Z, i^*G_m) = 0 \) for \( r \geq 1 \) by [9, Proposition 2.2.3(c)] and [9, Lemma 2.2.7], so the map \( H^3_c(X, j_*j^*G_m) \to H^3_c(X, G_m) \) is an isomorphism. Now the composition

\[
H^3_c(X, j_*j^*G_m) \to H^3_c(X, G_m) \to H^3_c(U_T, G_m)
\]
is given by

\[
(a_v, b_v)_v \mapsto (g_v a_v, (g_v b_v)_v)_{v \in X_{\infty}} \mapsto (j^*g_v a_v, (c_v)_v)_{v \in T}
\]
where \( g : j_*j^*G_m \to G_m \) and \( c_v = g_v b_v \) for \( v \in X_{\infty} \). Since \( j^*g \) is an identity, \( j^*g a = (j^*g)_* (j^*a) = j^*a \) and \( b_v \in C^2(\text{Spec } F_v, \kappa_v j^*G_m) \) so \( b_v = 0 \) for all \( v \in X_{\infty} \). Now the composition map is given by \( (a, 0) \in X_{\infty} \mapsto (j^*a, (c_v)_v)_{v \in T} \) and it is same as the isomorphism given by [9, Proposition 2.2.3(d)].

(This is clear from the proof of [9, Proposition 2.2.3(d)].) Thus \( \gamma \) is an isomorphism and by Artin-Verdier duality, \( \alpha \) is also an isomorphism. For a fixed map \( \text{inv} \), we may assume that \( \text{inv}_{U_T} = \text{inv} \circ \alpha^{-1} \).

(5) By [9, Proposition 2.2.9], \( j^\beta : H^3_c(\pi_{T}, Z/nZ) \to H^3_c(U_{T}, Z/nZ) \) is an isomorphism. Now we can choose an isomorphism \( \mu_n(F)^D \to \frac{1}{n}Z/Z \) which makes the following diagram commute. Two maps \( H^3_c(\pi_{T}, Z/nZ) \to H^3_c(\pi_{T}, Z/nZ) \) and \( \alpha \) are defined in the same way so they commute with \( j^\beta \).

\[
\begin{array}{ccc}
H^3_c(\pi_{T}, Z/nZ) & \to & H^3_c(\pi_{T}, Z/nZ) \\
\downarrow & & \downarrow \\
H^3_c(\pi_{T}, Z/nZ) & \to & H^3_c(\pi_{T}, Z/nZ)
\end{array}
\]

\[
\begin{array}{ccc}
H^3_c(\pi_{T}, Z/nZ) & \to & H^3_c(\pi_{T}, Z/nZ) \\
\downarrow & & \downarrow \\
H^3_c(\pi_{T}, Z/nZ) & \to & H^3_c(\pi_{T}, Z/nZ)
\end{array}
\]

\[
\begin{array}{ccc}
H^3_c(\pi_{T}, Z/nZ) & \to & H^3_c(\pi_{T}, Z/nZ) \\
\downarrow & & \downarrow \\
H^3_c(\pi_{T}, Z/nZ) & \to & H^3_c(\pi_{T}, Z/nZ)
\end{array}
\]
(6) Let \( w \) be a cocycle representing \( \rho^\ast(c) \in H^3(p_{\text{un}}, \mathbb{Z}/n\mathbb{Z}) \). By the vanishing of \( H^3(p_{\text{Tr}}, \mathbb{Z}/n\mathbb{Z}) \), we can find a global cochain \( b'_+ \in C^2(p_{\text{Tr}}, \mathbb{Z}/n\mathbb{Z}) \) such that \( \kappa_{\text{Tr}}^\ast(w) = db'_+ \). Denote \( b_+ := b'_+ \circ p_{\text{Tr}} \in C^2(p_{\text{Tr}}, \mathbb{Z}/n\mathbb{Z}) \) and \( b_{+,v} := \tau_v(b_+) \in C^2(\pi_v, \mathbb{Z}/n\mathbb{Z}) \).

From the discussion at (2), the image of \( \rho^\ast(c) \) is \( [w] \) in \( H^3(p_{\text{Tr}}, \mathbb{Z}/n\mathbb{Z}) \) is \( [(\kappa_{\text{Tr}}^\ast(w), (b_{-,v})_{v\in T})] \), where \( b_{-,v} \) is a lift of \( b_{-,v} \in C^2(\pi_v/I_v, \mathbb{Z}/n\mathbb{Z}) \) such that \( \kappa_{\text{Tr}}^\ast(w)|_{\pi_v/I_v} = db_{-,v} \). Now

\[
[(\kappa_{\text{Tr}}^\ast(w), (b_{-,v})_{v\in T})] = [(db_{+,v}, (b_{-,v})_{v\in T})] = [(0, (b_{-,v} - b_{+,v})_{v\in T})]
\]

and by the diagram in (5) and the fact that \( b_{-,v} = b_{+,v} = 0 \) for \( v \in X_\infty \),

\[
CS_c([\rho]) = \text{inv}_T^\ast([(0, (b_{-,v} - b_{+,v})_{v\in T})]) = \sum_{v\in T} \text{inv}_v([b_{-,v} - b_{+,v}]).
\]

**Theorem 3.1.** Let \( F \) be a number field and \( n \geq 2 \) be an integer. For any finite set \( T_f \) of finite primes of \( F \) containing all primes dividing \( n \) and a non-cyclic gauge group \( G \), the arithmetic Chern-Simons invariants associated to the gauge group \( \rho : G \times \mathbb{Z}/n\mathbb{Z} \) are non-vanishing, which generalizes the result of [1].

**4 Examples**

In this section, we provide some examples of computation of \( CS_c([\rho]) \). In first subsection, we prove that for all \( n \geq 2 \) and a finite group \( G \), there are infinitely many number fields \( F \) whose arithmetic Chern-Simons invariants associated to the gauge group \( A = G \times \mathbb{Z}/n\mathbb{Z} \) (the semidirect product of \( G \) by \( \mathbb{Z}/n\mathbb{Z} \)) are non-vanishing, which generalizes the result of [1]. In the next two subsections, we concentrate on the case \( n = 2 \) and provide some explicit examples of computation of \( CS_c([\rho]) \).

**4.1 Non-vanishing examples with general \( n \) and non-abelian gauge group**

In this subsection, \( F \) is always totally imaginary. In [1], the following is proved.

**Theorem 4.1.** ([1, Theorem 1.2]) Let \( n > 1 \) be an integer and \( c \) be a fixed generator of \( H^3(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/n\mathbb{Z}) \). Then, there are infinitely many totally imaginary number fields \( F \) with a cyclic unramified Kummer extension \( K/F \) of degree \( n \) such that for a natural map \( \rho : \pi \to \text{Gal}(K/F) \cong \mathbb{Z}/n\mathbb{Z} \),

\[
CS_c([\rho]) \neq 0.
\]

For \( n \geq 3 \) and a non-cyclic gauge group \( A \), nothing was known about the non-triviality of \( CS_c \). Based on the theorem above, we prove for a large family of finite groups, there are infinitely many totally imaginary number fields \( F \) such that \( CS_c([\rho]) \neq 0 \) for some \( \rho \) and \( c \).

**Lemma 4.2.** Let \( \varphi : B \to A \) be a homomorphism of finite groups, \( \rho \in \text{Hom}_{\text{cont}}(\pi, B) \) and \( c \in H^3(A, \mathbb{Z}/n\mathbb{Z}) \). For \( \rho' = \varphi \circ \rho : \pi \to A \) and \( c' = \varphi^\ast(c) \in H^3(B, \mathbb{Z}/n\mathbb{Z}) \),

\[
CS_c([\rho']) = CS_c([\rho]),
\]

**Proof.** \((\rho')^\ast(c) = (\varphi \circ \rho)^\ast(c) = \rho^\ast \varphi^\ast(c) = \rho^\ast(c')\). \(\qed\)
Let $A$ be a finite group and $\varphi : \mathbb{Z}/n\mathbb{Z} \to A$ be a group homomorphism. If there exists $c \in H^3(A, \mathbb{Z}/n\mathbb{Z})$ such that $\varphi^*(c)$ is a generator of $H^3(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/n\mathbb{Z})$, then by Theorem 4.1 and Lemma 4.2,

$$CS_\varphi([\varphi \circ \rho]) = CS_{\varphi^*(c)}([\rho]) \neq 0$$

for infinitely many number fields $F$ with some $\rho \in \text{Hom}_{\text{cont}}(\pi, \mathbb{Z}/n\mathbb{Z})$. For any finite group $G$, let

$$\delta : H^1(G, \mathbb{Z}/n\mathbb{Z}) \to H^2(G, \mathbb{Z}/n\mathbb{Z})$$

be a Bockstein homomorphism coming from the exact sequence $0 \to \mathbb{Z}/n\mathbb{Z} \to \mathbb{Z}/n^2\mathbb{Z} \to \mathbb{Z}/n\mathbb{Z} \to 0$. For an identity map $Id \in \text{Hom}(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/n\mathbb{Z}) = H^1(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/n\mathbb{Z})$, $Id \cup \delta(Id) \in H^3(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/n\mathbb{Z})$ is a generator of the group $H^3(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/n\mathbb{Z})$ ([3, p. 11]). Suppose that there is $\psi \in \text{Hom}(A, \mathbb{Z}/n\mathbb{Z})$ such that $\psi \circ \varphi = Id$ and denote $c = \psi \cup \delta(\psi) \in H^3(A, \mathbb{Z}/n\mathbb{Z})$.

$$H^1(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/n\mathbb{Z}) \xrightarrow{\varphi^*} H^2(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/n\mathbb{Z})$$

$$H^1(A, \mathbb{Z}/n\mathbb{Z}) \xrightarrow{\delta} H^2(A, \mathbb{Z}/n\mathbb{Z})$$

Since the diagram above commutes,

$$\varphi^*(c) = \varphi^*(\psi) \cup \varphi^*(\delta(\psi)) = \varphi^*(\psi) \cup \delta(\varphi^*(\psi)) = Id \cup \delta(Id)$$

so $\varphi^*(c)$ is a generator of $H^3(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/n\mathbb{Z})$.

**Theorem 4.3.** Let $G$ be a finite group, $\alpha : \mathbb{Z}/n\mathbb{Z} \to \text{Aut}(G)$ a group homomorphism and $A = G \rtimes_{\alpha} \mathbb{Z}/n\mathbb{Z}$ the semidirect product of $G$ by $\mathbb{Z}/n\mathbb{Z}$ with respect to $\alpha$. Then there are infinitely many totally imaginary number fields $F$ such that

$$CS_\varphi([\rho]) \neq 0$$

for some $\rho \in \text{Hom}_{\text{cont}}(\pi, A)$ and $c \in H^3(A, \mathbb{Z}/n\mathbb{Z})$.

**Proof.** By the discussion above, it is enough to show that there are group homomorphisms $\varphi : \mathbb{Z}/n\mathbb{Z} \to A$ and $\psi : A \to \mathbb{Z}/n\mathbb{Z}$ such that $\psi \circ \varphi = Id$. Since $A$ is a semidirect product of $G$ by $\mathbb{Z}/n\mathbb{Z}$, there are $\psi \in \text{Hom}(A, \mathbb{Z}/n\mathbb{Z})$ and $\varphi \in \text{Hom}(\mathbb{Z}/n\mathbb{Z}, A)$ such that $\psi \circ \varphi = Id$. \qed

**Example 4.4.** For $d \geq 3$, the Heisenberg group

$$H_d(\mathbb{Z}/n\mathbb{Z}) := \left\{ \begin{array}{c}
1 & a & c \\
0 & I_{d-2} & b \\
0 & 0 & 1
\end{array} \right\} \in M_d(\mathbb{Z}/n\mathbb{Z}) : a \in M_{1,d-2}(\mathbb{Z}/n\mathbb{Z}), b \in M_{d-2,1}(\mathbb{Z}/n\mathbb{Z}), c \in \mathbb{Z}/n\mathbb{Z}$$

(together with matrix multiplication) can be represented as a semidirect product

$$((\mathbb{Z}/n\mathbb{Z})^{d-1} \times (\mathbb{Z}/n\mathbb{Z})^{d-3}) \rtimes (\mathbb{Z}/n\mathbb{Z}),$$

so Theorem 4.3 can be applied to the case $A = H_d(\mathbb{Z}/n\mathbb{Z})$.

**Example 4.5.** Let $F_q$ be a finite field of order $q = p^k \geq 3$ and $r$ be a positive integer. Then the general linear group $\text{GL}(r, F_q)$ can be represented as a semidirect product $\text{SL}(r, F_q) \rtimes (F_q)^\times$ and $(F_q)^\times$ is a cyclic group of order $q - 1$, so Theorem 4.3 can be applied to $n = q - 1$ and $A = \text{GL}(r, F_q)$.

**Example 4.6.** Let $p$ be a prime. If $p$ is odd, there are two non-abelian groups of order $p^3 : H_3(\mathbb{Z}/p\mathbb{Z})$ and $\mathbb{Z}/p^2\mathbb{Z} \rtimes \mathbb{Z}/p\mathbb{Z}$. Theorem 4.3 can be applied to both groups. If $p = 2$, then non-abelian groups of order 8 are $D_4 \cong \mathbb{Z}/4\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z}$ and $Q_8$. Since $Q_8$ is not a semidirect product of its proper subgroups, Theorem 4.3 cannot be applied.
4.2 The totally real analogue with \( n = 2 \)

Since most of the results in this subsection are analogues to section 5 of [2], proofs are generally omitted here. Under the assumption \( \mu_n(F) = \mu_n(F) \), (5.1)-(5.5) of [2] can be extended to every number field \( F \). Since we use \( \pi^u \) rather than \( \pi \), Assumption 5.7 and 5.9 of [2] should be refined by adding conditions about unramifiedness at real places.

**Assumption 4.7.** (1) \( e = \alpha \cup \epsilon \in \mathbb{H}^3(A, \mathbb{Z}/2\mathbb{Z}) \) with surjective \( \alpha : A \to \mathbb{Z}/2\mathbb{Z} \), and \( \epsilon \in \mathbb{H}^3(A, \mathbb{Z}/2\mathbb{Z}) \) corresponding to a central extension

\[ E : 0 \to \mathbb{Z}/2\mathbb{Z} \to \Gamma \to A \to 1. \]

(2) There are Galois extensions of \( F \):

\[ F \subset F^o \subset F^- \subset F^+ \]

such that \( \text{Gal}(F^-/F) \cong A \), \( \text{Gal}(F^+/F) \cong \Gamma \), \( F^-/F \) is unramified at all primes (including real primes) and \( F^+/F \) is unramified at the primes above \( 2 \).

(3) \( F^o \) is the fixed field of the kernel of the composition \( \text{Gal}(F^-/F) \cong A \to \mathbb{Z}/2\mathbb{Z} \).

(4) \( \rho : \pi^u \to A \) is given by the composition \( \pi^u \to \text{Gal}(F^-/F) \cong A \), where \( \pi^u \to \text{Gal}(F^-/F) \) is the natural projection map.

**Remark 4.8.** Let \( B = \{ F_1, \cdots, F_m \} \) be the set of subfields of \( F^- \) which are quadratic extensions of \( F \). Then \( B \) is bijective to the set of surjective homomorphisms \( \text{Gal}(F^-/F) \to \mathbb{Z}/2\mathbb{Z} \). So for each \( F_i \in B \), there is a unique surjective homomorphism \( \alpha_i : \text{Gal}(F^-/F) \to \mathbb{Z}/2\mathbb{Z} \) such that \( F^{\alpha_i} = F_i \).

Let \( S_f \) be the set of finite primes of \( F \) ramified in \( F^+ \), \( S_2 \) be the set of primes of \( F \) above \( 2 \) \((S_f \cap S_2 = \phi \) by the assumption\) and \( T_f := S_f \cup S_2 \). Denote the map \( \gamma \) of [2, Lemma 5.2] for the settings (a), (b) below by \( \gamma_v \) and \( \gamma_{-v} \) (for each \( v \in T_f \)), respectively.

(a) \( \tilde{A} = \pi_T, f = \rho \circ \kappa_T, \tilde{f} : \pi_T \to \text{Gal}(F^-/F) \cong \Gamma \), where \( \pi_T \to \text{Gal}(F^+/F) \) is the projection.

(b) \( \tilde{A} = \pi_v, f = \rho \circ \kappa_v, \tilde{f} : \pi_v \to \pi_v/I_v \tilde{f} \to \Gamma \) for \( f' \) satisfying \( \phi \circ f' = (\rho \circ \kappa_v) |_{\pi_v/I_v} \in \text{Hom}(\pi_v/I_v, A) \).

Denote \( \gamma_{+v} := \gamma_{+v} \circ \kappa_v \in \text{Hom}(\pi_e, \mathbb{Z}/2\mathbb{Z}) \) and \( \psi_v := \gamma_{+v} - \gamma_{-v} \) for each \( v \in T_f \). Note that \( \gamma_{-v} \) is unramified since it factors through \( \pi_v/I_v \). For \( v \in X^\infty, \kappa_v = 0 \) so \( \text{inv}_v(\rho_v(\alpha) \cup \psi_v) = 0 \) for \( \rho_v := \rho \circ \kappa_v \).

**Theorem 4.9.** Suppose \( \alpha, \epsilon \) are in Assumption 4.7. Then,

\[ CS_r(\rho) = \sum_{v \in T_f} \text{inv}_v(\rho_v^*(\alpha) \cup \psi_v) \equiv \frac{r}{2} \mod \mathbb{Z} \]

where \( r \) is the number of primes in \( S_f \) which are inert in \( F^o \).

**Assumption 4.10.** \( K \subset L \) and \( E \) are number fields, \( D > 1 \) is a squarefree integer such that

(1) \( \text{Gal}(L/Q) \cong \Gamma \) and \( d_L \) is odd.

(2) \( \text{Gal}(K/Q) \cong A \) and \( K \) is totally real.

(3) \( |E : Q| \) is odd and \( E \cap L = Q \).

(4) \( D \) divides \( d_K \), \( Q(\sqrt{D}) \subset K \) and \( K/Q(\sqrt{D}) \) is unramified at all primes.

**Proposition 4.11.** Let \( t > 1 \) be a squarefree integer prime to \( D \) and \( F = Q(\sqrt{D})E \) satisfies \( Q(\sqrt{D}) \cap L = Q \). Then \( F^- = KF \) and \( F^+ = LF \) satisfy Assumption 4.7.
For each real prime can be proved exactly as in [2, Proposition 5.10]. Now we give explicit computations of CS.

Proof. We use Theorem 4.9. Following the proof of [2, Theorem 5.13], we can deduce that EL \cap E′L = L is a contradiction. Thus.

Now suppose that Fα = F(\sqrt{M}) \subset F− for some divisor M > 0 of D. Denote Q1 = Q(\sqrt{M}), Q2 = Q(\sqrt{N}) for N = Dt/M and DL/K := NmK/Q(\Delta L/K) = dL/d2.

**Theorem 4.12.** Suppose we are in Assumption 4.10 and choose C \subset Fα \subset F− \subset F+ as above, ρ and c as Assumption 4.7. Then,

\[ CS_c([\rho]) \equiv \frac{s}{2} \pmod{\mathbb{Z}} \]

where s is the number of prime divisors of (Dl/K, D) which are inert either in Q1 or in Q2.

Proof. We use Theorem 4.9. Following the proof of [2, Theorem 5.13], we can deduce that

\[ S_f = \{ p \in \text{Spec}(O_F) : p \mid DL/K, p \nmid t \} \]

Let F0 = Q(\sqrt{Di}), p ∈ Sf be a prime above p and p0 = p ∩ F0 be a prime of F0. Suppose p does not divide D. If p splits in F0, then pO_F = p1 \cdots pm for some even integer m and p1 are all inert or all split in Fα, so they do not change the parity of r of Theorem 4.9. If p is inert in F0, then p0 splits in F0(\sqrt{M}) by [2, Lemma 5.12] and [F : F0] = [E : Q] is odd so p also splits in Fα. (Note that E ∩ F0 = Q.) Now suppose that p divides D. Then p is the only prime of F above p. Since [F : F0] is odd, p is inert in Fα if and only if p0 is inert in F0(\sqrt{M}). This is equivalent to the fact that p is inert either in Q1 or in Q2.

**Remark 4.13.** In Proposition 5.10 of [2], F = Q(\sqrt{|D|/t}) can be generalized to F = Q(\sqrt{|D|\cdot t})E for every number field E of odd degree such that E ∩ F = Q.

Now we give explicit computations of CS_c for A = Z/2Z, A = Z/2Z x Z/2Z and A = S4.

**Case I.** A = Z/2Z: Let A = Z/2Z, Γ = Z/2Z and p be a prime congruent to 1 modulo 4. Then K = Q(\sqrt{p}), the degree 4 subfield L of Q(\mu_p) and D = p satisfy Assumption 4.10. Let F = Q(\sqrt{p})E for a squarefree integer t > 1 prime to p and a number field E of odd degree.

**Proposition 4.14.** Let Fα = F− = FK, F+ = LF and ρ and c be chosen as above. Then,

\[ CS_c([\rho]) = \frac{1}{2} \iff \left( \frac{t}{p} \right) = -1. \]

**Case II.** A = Z/2Z x Z/2Z: Let A = Z/2Z x Z/2Z, Γ = Q8 (the quaternion group) and d1, d2 > 1 be squarefree integers such that d1 \equiv d2 \equiv 1 (mod 4) and (d1, d2) = 1. Suppose that there is a number field L containing Q(\sqrt{d1}, \sqrt{d2}) such that Gal(L/Q) ≃ Q8 and dL is odd. Then K = Q(\sqrt{d1}, \sqrt{d2}), L and D = d1d2 satisfy Assumption 4.10. By [2, Proposition 5.15], a prime p divides (D, DL/K) if and only if p divides D. Let F = Q(\sqrt{d1d2})E (t > 1 is a squarefree integer prime to d1d2, E is a number field of odd degree) and

\[ F_1 = F(\sqrt{d1}), F_2 = F(\sqrt{d2}), F_3 = F(\sqrt{d1d2}). \]

Since Hom(A, Z/2Z) is of order 4, these are all quadratic subfields of FK over F. Suppose that Q(\sqrt{d1d2}) \cap L \neq Q. Then \sqrt{d1d2} \in L so L = Q(\sqrt{d1}, \sqrt{d2}, \sqrt{d1d2}) = Q(\sqrt{d1}, \sqrt{d2}, \sqrt{t}) and Gal(L/Q) ≃ (Z/2Z)^3, which is a contradiction. Thus Q(\sqrt{d1d2} \cdot t) \cap L = Q.
Proposition 4.15. Let $F^\alpha_i = F_i$, $F^- = FK$, $F^+ = FL$ and $\rho$ and $c_i = \alpha_i \cup \epsilon$ be chosen as above. Then,

\[ CS_{c_i}([\rho]) = \frac{1}{2} \Leftrightarrow \prod_{p | d_i} \left( \frac{d_i}{p} \right) \cdot \prod_{p | d_2} \left( \frac{d_2}{p} \right) = -1. \]

Two examples of $L, K$ for $A = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, $\Gamma = \mathbb{Q}_8$ in [2, p. 21] can be used in our situation. Let

\[ g(x) = x^8 \cdot x^7 + 98x^6 \cdot 105x^5 + 3191x^4 + 1665x^3 + 44072x^2 + 47933x + 328171 \]

(LMFDB [13]) be an irreducible polynomial over $\mathbb{Q}$ and $\beta$ be a root of $g(x)$. Also let

\[ L = \mathbb{Q}(\beta), K = \mathbb{Q}(\sqrt[4]{5}, \sqrt{29}) \text{ and } D = 5 \cdot 29. \]

Then $K \subset L$, $\text{Gal}(L/\mathbb{Q}) \cong \mathbb{Q}_8$ and $d_L = 3^4 \cdot 5^6 \cdot 29^6$ is odd. Let $F = \mathbb{Q}(\sqrt[4]{145-t})E$, where $t > 1$ is a squarefree integer prime to 145 and $E$ is a number field of odd degree.

Corollary 4.16. Let $\rho$ and $c_i = \alpha_i \cup \epsilon$ be chosen as above. Then,

\[ CS_{c_i}([\rho]) = \frac{1}{2} \Leftrightarrow \left( \frac{t}{5} \right) = -1 \Leftrightarrow t \equiv \pm 2 \pmod{5}. \]

Let

\[ g(x) = x^8 - x^7 - 34x^6 + 29x^5 + 361x^4 - 305x^3 - 1090x^2 + 1345x - 395 \]

(LMFDB [14]) be an irreducible polynomial over $\mathbb{Q}$ and $\beta$ be a root of $g(x)$. Also let

\[ L = \mathbb{Q}(\beta), K = \mathbb{Q}(\sqrt[4]{5}, \sqrt{2t}), D = 5 \cdot 21 \]

and $F = \mathbb{Q}(\sqrt[4]{105-t})E$, where $t > 1$ is a squarefree integer prime to 105 and $E$ is a number field of odd degree.

Corollary 4.17. Let $\rho$ and $c_i = \alpha_i \cup \epsilon$ be chosen as above. Then,

\[ CS_{c_i}([\rho]) = \frac{1}{2} \Leftrightarrow \left( \frac{t}{3} \right) = -1 \Leftrightarrow t \equiv \pm 2 \pmod{5}. \]

Now let $A = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ and $\Gamma = D_4$, the dihedral group of order 8. Since $K$ is totally imaginary in the example in [2], we have to find a new example. Let

\[ g(x) = x^8 - x^6 + 4x^4 - 16x^2 + 256 \]

(LMFDB [15]) be an irreducible polynomial over $\mathbb{Q}$ and $\beta$ be a root of $g(x)$. Also let

\[ L = \mathbb{Q}(\beta), K = \mathbb{Q}(\sqrt[4]{5}, \sqrt{29}) \text{ and } D = 5 \cdot 29. \]
Then $K$, $L$ and $D$ satisfy Assumption 4.10 and $D_{L/K} = 5^2$. Let $F = \mathbb{Q}(\sqrt{145} \cdot t)E$ ($t > 1$ is a squarefree integer prime to 145 and $E$ is a number field of odd degree), $F_1 = F(\sqrt{5})$, $F_2 = F(\sqrt{29})$ and $F_3 = F(\sqrt{145})$. We can check that $\mathbb{Q}(\sqrt{145} \cdot t) \cap L = \mathbb{Q}$ as before.

**Proposition 4.18.** Let $F^{\alpha} = F_1$, $F^{-} = FK$, $F^{+} = FL$ and $\rho$ and $c = \alpha \cup \epsilon$ be chosen as above. Then,
\[
CS_c([\rho]) = \frac{1}{2} \iff t \equiv \pm 2 \pmod{5}.
\]
\[
CS_{c_1}([\rho]) = 0.
\]
\[
CS_{c_2}([\rho]) = \frac{1}{2} \iff t \equiv \pm 2 \pmod{5}.
\]

**Case III.** $A = S_4$: Let $A = S_4$, the symmetric group of degree 4. There is a unique surjective map $\alpha : A \to \mathbb{Z}/2\mathbb{Z}$ and three nontrivial central extensions $\Gamma_i (1 \leq i \leq 3)$ of $A$ by $\mathbb{Z}/2\mathbb{Z}$:
\[
\Gamma_1 = \text{GL}(2, \mathbb{F}_3), \quad \Gamma_2 = \text{the transitive group '16T65' in [19]} \quad \text{and} \quad \Gamma_3 = \text{SL}(2, \mathbb{Z}/4\mathbb{Z}).
\]
Let $\Gamma = \Gamma_1$ and suppose that $\mathbb{Q} \subset \mathbb{Q}(\sqrt{D}) \subset K \subset L$ and $E$ satisfy Assumption 4.10. Let $F = \mathbb{Q}(\sqrt{D})E$, where $t > 1$ is a squarefree integer prime to $D$. Since $\Gamma_1$ has a unique subgroup of order 24 and $\mathbb{Q}(\sqrt{D}) \neq \mathbb{Q}(\sqrt{D})$, $\mathbb{Q}(\sqrt{D}) \cap L = \mathbb{Q}$.

**Proposition 4.19.** Let $F^{\alpha} = F(\sqrt{D})$, $F^{-} = FK$, $F^{+} = FL$ and $\rho$ and $c = \alpha \cup \epsilon$ as above. Then,
\[
CS_c([\rho]) = 0.
\]
Let
\[
g_1(x) = x^8 - x^7 - 52x^5 - 66x^3 + 561x^4 + 1153x^3 - 851x^2 - 1857x + 876
\]
\[
g_2(x) = x^4 - x^3 - 5x^2 + 4x + 3
\]
(LMFDB [16], [17]) be irreducible polynomials over $\mathbb{Q}$, $D = 7537$ and $L$ and $K$ be the splitting fields of $g_1(x)$ and $g_2(x)$, respectively. Then $\text{Gal}(L/\mathbb{Q}) \cong \Gamma$, $\text{Gal}(K/\mathbb{Q}) \cong A$ and $K$ is totally real. Also $d_K = 7537^{12}$ and $d_L = 3^{24} \cdot 7537^{24}$ ($d_K$ and $d_L$ can be calculated from the datas of [16], [17] by using conductor-discriminant formula), so $D_{L/K} = 3^{24}$ and $D_{K/\mathbb{Q}(\sqrt{D})} = 1$. Thus $\mathbb{Q} \subset \mathbb{Q}(\sqrt{D}) \subset K \subset L$ and $E$ satisfy Assumption 4.10 for a number field $E$ of odd degree such that $E \cap L = \mathbb{Q}$. Let $F = \mathbb{Q}(\sqrt{7537} \cdot t)E$, where $t > 1$ is a squarefree integer prime to 7537.

**Corollary 4.20.** Let $F^{\alpha} = F(\sqrt{7537})$, $F^{-} = FK$, $F^{+} = FL$ and $\rho$ and $c$ be chosen as above. Then,
\[
CS_c([\rho]) = 0.
\]
Now let $\Gamma = \Gamma_2$,
\[
g_1(x) = x^{16} + 5x^{15} - 790x^{14} - 4654x^{13} + 234254x^{12} + 1612152x^{11} - 33235504x^{10}
\]
\[-263221982x^9 + 2331584048x^8 + 21321377994x^7 - 74566280958x^6 - 825209618478x^5
\]
\[+922238608476x^4 + 1379007068536x^3 - 6704962888135x^2 - 80794234036917x + 87192014930816
\]
(LMFDB [19]) and
\[
g_2(x) = x^4 - x^3 - 5x^2 + 4x + 2
\]
(LMFDB [18]) be irreducible polynomials over $\mathbb{Q}$, $D = 2777$ and $L$ and $K$ be the splitting fields of $g_1(x)$ and $g_2(x)$, respectively. Then by [2, Lemma 5.22] and the fact that $K$ is totally real, $\mathbb{Q} \subset \mathbb{Q}(\sqrt{D}) \subset K \subset L$ and $E$ satisfy Assumption 4.10 for a number field $E$ of odd degree such that $E \cap L = \mathbb{Q}$ and $\mathbb{Q}(\sqrt{2777} \cdot t) \cap L = \mathbb{Q}$ for squarefree $t > 1$ prime to 2777. Let $F = \mathbb{Q}(\sqrt{2777} \cdot t)E$, where $t > 1$ is a squarefree integer prime to 2777.
Proposition 4.21. Let $F^α = F(\sqrt[2]{2777})$, $F^− = FK$, $F^+ = FL$ and $ρ$ and $c$ be chosen as above. Then,
\[ CS_c([ρ]) = \frac{1}{2} ⇔ \left( \frac{t}{2777} \right) = -1. \]

Remark 4.22. Let $F = \mathbb{Q}(\sqrt[2]{2777}, \sqrt[1]{7537})$ and $c_1, c_2 ∈ H^3(S_4, \mathbb{Z}/2\mathbb{Z})$ are given by $c$ of Proposition 4.19 and 4.21, respectively. Then,
\[ CS_{c_3}([ρ]) = 0 \text{ and } \left( \frac{7537}{2777} \right) = -1 \Rightarrow CS_{c_3}([ρ]) = \frac{1}{2}, \]
so $CS_c([ρ])$ can be different when both the number field $F$ and the gauge group $A$ are same.

4.3 Biquadratic fields with $n = 2$

In this subsection, we provide an analogue of Theorem 4.12 for compositums of a biquadratic field and a number field of odd degree. Unfortunately, $CS_c([ρ])$ is always zero in this case.

Assumption 4.23. $K ⊂ L$ and $E$ are number fields, $D_1, D_2 ≠ 1$ are squarefree integers such that
(1) $Gal(L/\mathbb{Q}) ≈ Γ$ and $d_L$ is odd.
(2) $Gal(K/\mathbb{Q}) ≈ A$ and $K$ is totally real when both $D_1$ and $D_2$ are positive.
(3) $[E : \mathbb{Q}]$ is odd and $E ∩ L = \mathbb{Q}$.
(4) $(D_1, D_2) = 1$ and $D_1D_2$ divides $d_K$.
(5) $\mathbb{Q}(\sqrt{D_1}, \sqrt{D_2}) ⊂ K$ and $K/\mathbb{Q}(\sqrt{D_1}, \sqrt{D_2})$ is unramified at all primes.

Let $F = \mathbb{Q}(\sqrt{D_1t_1}, \sqrt{D_2t_2})E$, where $t_1, t_2 > 1$ are squarefree integers such that $D_1, D_2, t_1, t_2$ are pairwise coprime. Denote $F_0 = \mathbb{Q}(\sqrt{D_1t_1}, \sqrt{D_2t_2})$ and suppose that $F_0 ∩ L = \mathbb{Q}$. Then we can prove $F ∩ L = \mathbb{Q}$ exactly as the proof of Proposition 4.11.

Proposition 4.24. Let $K$, $L$, $D_1$, $D_2$ and $E$ satisfy Assumption 4.23 and $F$ is given as above (with the assumption $F_0 ∩ L = \mathbb{Q}$). Then $F^- = KF$ and $F^+ = LF$ satisfy Assumption 4.7.

Now suppose that $F^α = F(\sqrt[4]{M}) ⊂ F^−$ for some $M ≠ 1$ dividing $D_1D_2$. Denote $Q_1 = \mathbb{Q}(\sqrt[4]{M})$ and $Q_2 = \mathbb{Q}(\sqrt[4]{N})$ for $N = D_1D_2t_1t_2/M$.

Theorem 4.25. Suppose we are in Assumption 4.23 and choose $F ⊂ F^α ⊂ F^− ⊂ F^+$ as above, $ρ$ and $c$ as Assumption 4.7. Then,
\[ CS_c([ρ]) = 0. \]

Proof. We can prove that
\[ S_f = \{ p ∈ \text{Spec}(O_F) : p | D_{L/K}, p | t_1t_2 \} \]
by using Abhyankar’s lemma as in the proof of [2, Theorem 5.13]. By Theorem 4.9, $CS_c([ρ]) ≡ \frac{r}{2} (mod \mathbb{Z})$ where $r$ is the number of primes in $S_f$ which are inert in $F^α$. Let $p ∈ S_f$ be a prime above $p$ and $p_0 = p∩F_0$. For primes of $F$ above $p$, they are all inert or all split in $F^α$. Thus if $p$ splits into two or four primes in $F_0$, these do not change the parity of $r$, so we do not need to consider them.

Now suppose that $p_0$ is the only prime of $F_0$ above $p$. If $p$ is unramified in $F_0/\mathbb{Q}$, then its inertia degree in $F_0/\mathbb{Q}$ is 4 so
\[ \left( \frac{D_1t_1}{p} \right) = \left( \frac{D_2t_2}{p} \right) = \left( \frac{D_1D_2t_1t_2}{p} \right) = -1, \]
a contradiction. Suppose that each the ramification index and the inertia degree of $p$ in $F_0/\mathbb{Q}$ is 2. One can choose
\[ F_1 \in \{ \mathbb{Q}(\sqrt{D_1t_1}, \sqrt{M}), \mathbb{Q}(\sqrt{D_1t_1}, \sqrt{N}), \mathbb{Q}(\sqrt{D_2t_2}, \sqrt{M}), \mathbb{Q}(\sqrt{D_2t_2}, \sqrt{N}) \} \]
which is unramified at $p$. Since $[F : F_0] = [E : \mathbb{Q}]$ is odd, $F^\alpha / F$ is inert at $p$ if and only if $F_0(\sqrt{M})/F_0$ is inert at $p_0$. In this case, the inertia degree of $p$ in $F_0(\sqrt{M})/\mathbb{Q}$ is 4 and $F_0(\sqrt{M})/F_1$ is ramified at $p$ so the inertia degree of $p$ in $F_1/\mathbb{Q}$ is also 4, which is also a contradiction. 

\section{Completed étale cohomology of number fields}

In this section, we review the method of Zink [12] and Conrad-Masullo [4] of generalizing the étale cohomology of $X = \text{Spec}(\mathcal{O}_F)$ for totally imaginary number fields $F$, which was studied by Mazur [8], to arbitrary number fields. Also we give an alternative viewpoint of the arithmetic Chern-Simons theory by using this generalized étale cohomology. We closely follow the exposition of [4].

\subsection{Completed small étale sites}

Let $\eta : \text{Spec}(F) \to X$ be a generic point of $X$ and denote its image in $X$ also by $\eta$. For a scheme $Y$ and a group $G$, denote the category of abelian étale sheaves on $Y$ by $\text{Ab}_Y$ and the category of $G$-modules by $\text{Mod}_G$. For $F \in \text{Ab}_X$, $\eta^*(F) \in \text{Ab}_{\text{Spec}(F)}$ and the functor $\text{Ab}_{\text{Spec}(F)} \to \text{Mod}_{G_F}$ ($G \mapsto \lim_{\mathcal{L} \in \text{L}_{F/F}} G(\text{Spec}(L)))$ is an equivalence of categories ( [6, Proposition 5.7.8]) so $\eta^*(F)$ corresponds to a $G_F$-module. (Denote by $\mathcal{F}_\eta$)

Let $X_\infty = \{v_1, \ldots, v_r\}$ be the set of all real places of $F$ and $\overline{X} : = X \cup X_\infty$. We endow $\overline{X}$ with the topology whose closed sets are finite subsets of $\overline{X} \setminus \{\eta\}$. Denote an open set of $\overline{X}$ by $U$ and define $U_\infty : = \hat{U} \cap X_\infty$ and $U : = \hat{U} \cap X$. For an open subset $U \subset X$, define $\overline{U} : = U \cup X_\infty$. For each real place $v$ of $F$, let $\mathfrak{p}$ be a fixed extension of $v$ to $\overline{F}$ and denote the decomposition group and inertia group of $\mathfrak{p}$ by $D_v$ and $I_v$, respectively.

Since $v$ is a real place, $I_v = D_v = \text{Gal}(\overline{F}_v/F_v) \cong \mathbb{Z}/2\mathbb{Z}$. For $F \in \text{Ab}_U$, $I_v$ acts on $\mathcal{F}_\eta \in \text{Mod}_{G_F}$ via a natural homomorphism $I_v \to G_F$. For $x \in X \setminus \{\eta\}$, its decomposition group and inertia group is given by $D_x : = \text{Gal}(\overline{F}_x/F_x)$ and $I_x : = \text{Gal}(\overline{F}_x/F^\text{un}_x)$, where $F^\text{un}_x$ is the maximal unramified extension of $F_x$ in $\overline{F}_x$.

\begin{definition}
An abelian sheaf $\mathcal{F}$ on a non-empty open subset $\hat{U} \subset \overline{X}$ is a triple
\begin{equation}
\mathcal{F} : = (\{\mathcal{F}_\mathfrak{v}\}, \mathcal{F}, \{\varphi_\mathfrak{v}\})
\end{equation}
where $\mathfrak{v}$ varies through $U_\infty$, $\mathcal{F}_\mathfrak{v}$ are abelian groups, $\mathcal{F}$ is an abelian étale sheaf on $U$ and $\varphi_\mathfrak{v} : \mathcal{F}_\mathfrak{v} \to \mathcal{F}_\eta^\mathfrak{v}$ are group homomorphisms. We call $\mathcal{F}_\mathfrak{v}$ the stalk of $\mathcal{F}$ at $\mathfrak{v}$, and we also denote the stalk $\mathcal{F}_x$ at any $x \in U$ by $\mathcal{F}_x$. $\mathcal{F}$ is called constructible if $\mathcal{F}$ is constructible and $\mathcal{F}_\mathfrak{v}$ is finite for each $\mathfrak{v} \in U_\infty$.
\end{definition}

\begin{definition}
Let $\tilde{\mathcal{F}} : = (\{\tilde{\mathcal{F}}_\mathfrak{v}\}, \tilde{\mathcal{F}}, \{\tilde{\varphi}_\mathfrak{v}\})$ and $\tilde{\mathcal{G}} : = (\{\tilde{\mathcal{G}}_\mathfrak{v}\}, \tilde{\mathcal{G}}, \{\tilde{\psi}_\mathfrak{v}\})$ be abelian sheaves on $\tilde{U}$. A morphism $\tilde{f} : \tilde{\mathcal{F}} \to \tilde{\mathcal{G}}$ of abelian sheaves on $\tilde{U}$ is a triple $f : = ((\tilde{f}_\mathfrak{v}), f)$ such that $f : \mathcal{F} \to \mathcal{G}$ is a morphism of sheaves and for each $\mathfrak{v} \in U_\infty$, $\tilde{f}_\mathfrak{v} : \mathcal{F}_\mathfrak{v} \to \mathcal{G}_\mathfrak{v}$ is a group homomorphism and $f_\eta \circ \varphi_\mathfrak{v} = \psi_\mathfrak{v} \circ \tilde{f}_\mathfrak{v}$. The kernel and cokernel of $\tilde{f}$ is defined by $\ker(\tilde{f}) := (\{\ker(\tilde{f}_\mathfrak{v})\}, \ker(f), \{\varphi_\mathfrak{v}\})$ and $\coker(\tilde{f}) := (\{\coker(\tilde{f}_\mathfrak{v})\}, \coker(f), \{\psi_\mathfrak{v}\})$ for canonical group homomorphisms $\varphi_\mathfrak{v}$ and $\psi_\mathfrak{v}$.

Denote the category of abelian sheaves on $\tilde{U}$ by $\text{Ab}_{\tilde{G}}$. To develop a cohomology theory on $\tilde{U}$, we need to construct an étale site on which the category of abelian sheaves is $\text{Ab}_{\tilde{G}}$. For any scheme $Y$, define $Y(\mathbb{R}) := \text{Hom}(\text{Spec}(\mathbb{R}), Y)$. A morphism of schemes $f : Y \to Y'$ induces a map $f^\mathbb{R} : Y(\mathbb{R}) \to Y'(\mathbb{R})$ and $X(\mathbb{R})$ can be identified with $X_\infty$. Let $\text{Sch}_X$ be the category whose objects are pairs $\tilde{Y} = (Y, Y_\infty)$ for an étale $X$-scheme $Y$ and a subset $Y_\infty \subset Y(\mathbb{R})$, and morphisms $\tilde{g} : \tilde{Y} \to \tilde{Y}'$ are morphisms $g : Y \to Y'$ of $X$-schemes such that $g^\mathbb{R}(\overline{Y}_\infty) \subset \overline{Y}'_\infty$.

Now let $\text{Et}_{\tilde{G}}$ be the category whose objects are the morphisms $\tilde{Y} \to \tilde{U}$ in $\text{Sch}_X$ and morphisms are defined over $\tilde{U}$ in the evident manner. A covering in $\text{Et}_{\tilde{G}}$ is a family of morphisms $\{\tilde{f}_i : \tilde{Y}_i \to \tilde{Y}\}$ such
that \( \{ f_i : Y_i \to Y \} \) is a covering in \( \mathbf{Et}_U \) (so \( \bigcup_{i \in I} f_i(Y_i) = Y \)) and \( \bigcup_{i \in I} \tilde{f}_i(Y_i) = \tilde{Y}_\infty \). These coverings define the étale topology on \( \tilde{U} \), so they define the small étale site \( \tilde{U}_{et} \). Denote the category of abelian sheaves on \( \tilde{U}_{et} \) by \( \mathbf{Ab}_{\tilde{U}} \).

**Proposition A.3.** ([4, Theorem 2.4.3]) The categories \( \mathbf{Ab}_U \) and \( \mathbf{Ab}_{\tilde{U}} \) are equivalent.

For an abelian group \( A \), let \( A_{\tilde{U}} \) be the constant sheaf on \( \tilde{U}_{et} \) defined by \( A \). From the proof of the above proposition in [4], \( A_{\tilde{U}} \) corresponds to \( \{ (A)_v, A_U, \{ id_A \}_v \} \in \mathbf{Ab}_{\tilde{U}} \). Denote this element also by \( A_{\tilde{U}} \).

We may omit the subscript \( \tilde{U} \) of \( A_{\tilde{U}} \) when the context is clear. Even though the cohomology of \( \mathbf{Ab}_U \) is known, we only state the result for the case \( \mathbf{Ab}_{\tilde{U}} \).

A.2 Cohomology theory

Since \( \Gamma(\tilde{U}, \cdot) \) is left-exact, its right derived functor \( H^p(\tilde{U}, \cdot) := R^p \Gamma(\tilde{U}, \cdot) \) is well-defined for each \( p \geq 0 \). Let \( \tilde{V} \subset \tilde{U} \) be non-empty open subsets of \( \tilde{x} \) and \( \tilde{S} = \tilde{U} \setminus \tilde{V} \). Then \( \tilde{S} = S_f \cup S_\infty \) for \( S_f = U \setminus \tilde{V} \) and \( S_\infty = \tilde{U}_\infty \setminus \tilde{V}_\infty \). Define \( \Gamma_{\tilde{S}}(\tilde{U}, \tilde{F}) := \ker(\tilde{F}(\tilde{U}) \to \ker(\tilde{F}(\tilde{V}))) \) and \( H^p_{\tilde{S}}(\tilde{U}, \tilde{F}) := R^p \Gamma_{\tilde{S}}(\tilde{U}, \tilde{F}) \). Denote \( \Gamma_{\tilde{S}}(\tilde{U}, \tilde{F}) \) by \( \Gamma_v(\tilde{U}, \tilde{F}) \) and \( H^p_{\tilde{S}}(\tilde{U}, \tilde{F}) \) by \( H^p_v(\tilde{U}, \tilde{F}) \) when \( \tilde{S} = \{ x \} \).

From now on we identify two categories \( \mathbf{Ab}_{\tilde{U}} \) and \( \mathbf{Ab}_{\tilde{U}} \), and denote them without distinction.

**Lemma A.4.** ([4, Lemma 3.2.3]) For \( \tilde{F} = \{ (\tilde{F}_v), \{ \varphi_v \} \} \in \mathbf{Ab}_{\tilde{U}} \) and \( \tilde{v} \in \tilde{U}_\infty \),

\[
H^p_v(\tilde{U}, \tilde{F}) = \begin{cases} 
\ker(\varphi_v) & (p = 0) \\
\operatorname{coker}(\varphi_v) & (p = 1) \\
H^{p-1}(\tilde{U}, \tilde{F}) & (p \geq 2)
\end{cases}
\]

Let \( U \subset X \) be a non-empty open subscheme. For each \( v \in X_\infty = \overline{U}_\infty \), denote the algebraic closure of \( F \) in its completion \( F_v \cong \mathbb{R} \) by \( F^{alg}_v \). Its positive part, which corresponds to \( \mathbb{R}_{>0} \) by isomorphism is denoted by \( F^{alg,+}_v \). Denote the inclusion of groups \( F^{alg,+}_v \hookrightarrow F^{alg,\times}_v \) by \( \iota_v \). From the formula

\[
G_{m,U,\eta} = \lim_{\overset{F \subseteq L \subseteq \overline{T}, [L:F] < \infty}{F \subseteq L \subseteq \overline{T}, [L:F] < \infty}} G_{m,U}(\operatorname{Spec}(L)) = \lim_{\overset{F \subseteq L \subseteq \overline{T}, [L:F] < \infty}{F \subseteq L \subseteq \overline{T}, [L:F] < \infty}} L^{\times} \cong \overline{T}^{\times},
\]

\[
G_{m,U,\eta}^{I_v} = F^{alg,\times}_v
\]

and the following definition is well-defined. For the motivation of the definition below, see Example A.8.

**Definition A.5.** The sheaf \( G_{m,U} \in \mathbf{Ab}_{\overline{U}} = \mathbf{Ab}_{\overline{U}} \) is defined by the triple

\[
\{ (F^{alg,+}_v)_{v \in X_\infty}, G_{m,U}, \{ \iota_v \}_{v \in X_\infty} \}.
\]

Define the sheaf \( \mu_{n,U} \in \mathbf{Ab}_{\overline{U}} \) by \( \mu_{n,U} := \ker(G_{m,U} \rightarrow G_{m,U}) \). Since there is an injection \( F^{alg,+}_v \hookrightarrow \mathbb{R}_{>0} \), \( \ker(F^{alg,+} \rightarrow F^{alg,+}_v) = 0 \) and \( \mu_{n,U} = \{ 0 \}_{v \in X_\infty} \). We may omit the subscript \( U \) of \( G_{m,U} \) and \( \mu_{n,U} \) when the context is clear. Even though the cohomology of \( G_{m,U} \) for an arbitrary non-empty open subset \( U \) of \( X \) is known, we only state the result for the case \( U = X \) because this is the only case that we use later. Let \( C_{F}^{+} \) be the group of totally positive units of \( F \), and \( CL^+(F) \) be the narrow class group of \( F \).
Proposition A.6. ([12, Proposition 2.5.9])

\[ H^0(X, \mathbb{G}_m, \mathcal{X}) = \mathcal{O}_F^{\times}, \quad H^1(X, \mathbb{G}_m, \mathcal{X}) = Cl(F), \quad H^2(X, \mathbb{G}_m, \mathcal{X}) = 0, \quad H^3(X, \mathbb{G}_m, \mathcal{X}) = \mathbb{Q}/\mathbb{Z}. \]

The cohomology of $\mu_n | \mathcal{X}$ and $\mathbb{Z}/n\mathbb{Z} | \mathcal{X}$ will be given in the next subsection. To compute these, we should use Artin-Verdier duality for an arbitrary number field.

A.3 Artin-Verdier duality

Let $\mathcal{F} \in \text{Ab}_U$ for a non-empty open subset $U$ of $X$. For each $v \in X_\infty$, $\mathcal{F}_v$ is an $I_v$-module and the norm map $N_v$ induces a map $N_v : H_0(I_v, \mathcal{F}_v) \to H_0(I_v, \mathcal{F}_v)$.

Definition A.7. The modified sheaf of $\mathcal{F} \in \text{Ab}_U$ is defined by

\[ \tilde{\mathcal{F}} := \{ (H_0(I_v, \mathcal{F}_v))_{v \in X_\infty} : \mathcal{F}, (H_0(I_v, \mathcal{F}_v) \xrightarrow{N_v} H_0(I_v, \mathcal{F}_v))_{v \in X_\infty}) \in \text{Ab}_U. \]

Example A.8. (1) Since $\mathbb{G}_{m,U,\eta} = \mathcal{F}^\times$ and the image of $N_v : \mathbb{G}_{m,U,\eta} \to \mathbb{G}_{m,U,\eta}$ is $F_v^{alg,+}$,

\[ H_0(I_v, \mathbb{G}_{m,U,\eta}) \xrightarrow{N_v} F_v^{alg,+} \]

and $N_v : H_0(I_v, \mathbb{G}_{m,U,\eta}) \to H_0(I_v, \mathbb{G}_{m,U,\eta})$ is identified with the inclusion map $F_v^{alg,+} \hookrightarrow F_v^{alg,\times}$. Thus $\mathbb{G}_{m,U} = \mathbb{G}_{m,U}$.

(2) Let $A$ be an abelian group. It is easy to show that $\hat{A}_U = (\{ A \}, A_U, \{ A \to A \}) \in \text{Ab}_U$, which is not equal to $A_U$ in general. However, there is a natural morphism $\tilde{f} = (\{ A \to A \}, \text{id}_{A_U}) : \hat{A}_U \to A_U$ and it induces an isomorphism $H^p(\mathcal{U}, \hat{A}_U) \to H^p(\mathcal{U}, A_U)$ for each $p \geq 1$ by the following lemma.

Lemma A.9. Let $\mathcal{F} = (\{ \tilde{\mathcal{F}}_v \}, \mathcal{F}, \{ \varphi_v \})$ and $\mathcal{G} = (\{ \tilde{\mathcal{G}}_v \}, \mathcal{G}, \{ \psi_v \})$ be abelian sheaves on $\mathcal{U}$ and $\tilde{f} : \tilde{\mathcal{F}} \to \tilde{\mathcal{G}}$ be a morphism in $\text{Ab}_U$ whose kernel and cokernel are supported at real points. (Equivalently, $f : \mathcal{F} \to \mathcal{G}$ is an isomorphism in $\text{Ab}_U$.) Then for each $p \geq 1$, the map $H^p(\mathcal{U}, \tilde{\mathcal{F}}) \to H^p(\mathcal{U}, \tilde{\mathcal{G}})$ induced by $\tilde{f}$ is an isomorphism.

Definition A.10. Let $\mathcal{F} \in \text{Ab}_U$, $f : U \to X$ be an open immersion, $X_\infty = \{ v_1, \cdots, v_r \}$, $p \in \mathbb{Z}$ and $H^p_T$ denotes the $p$-th Tate cohomology.

(1) The $p$-th modified étale cohomology groups of $\mathcal{F}$ are

\[ \hat{H}^p(U, \mathcal{F}) := \left\{ \begin{array}{ll} H^p(\mathcal{U}, \mathcal{F}) & (p \geq 0) \\ \bigoplus_{k=1}^r H^p_{T^{-1}}(I_{v_k}, \mathcal{F}_v) & (p < 0) \end{array} \right. . \]

(2) The $p$-th compactly supported cohomology groups of $\mathcal{F}$ are $H^p_c(U, \mathcal{F}) := \hat{H}^p(X, j_! \mathcal{F})$.

Example A.11. ([4, Example 5.4.2]) A natural morphism $j_! \mathbb{G}_{m,U} \to \mathbb{G}_{m,\mathcal{X}}$ in $\text{Ab}_U$ induces an isomorphism $H^3_c(U, \mathbb{G}_{m,U}) \cong H^3(\mathcal{X}, j_! \mathbb{G}_{m,\mathcal{X}}) \cong H^3(\mathcal{X}, \mathbb{G}_{m,\mathcal{X}}) \cong \mathbb{Q}/\mathbb{Z}$.

Theorem A.12. ([4, Theorem 5.4.4]: Artin-Verdier duality) Let $\mathcal{F}$ be a constructible abelian étale sheaf on a dense open subset $U$ of $X$. The Yoneda pairing

\[ H^i_p(U, \mathcal{F}) \times \text{Ext}^{i-3}_U(\mathcal{F}, \mathbb{G}_{m,U}) \to H^3_c(U, \mathbb{G}_{m,U}) \cong \mathbb{Q}/\mathbb{Z} \]

is a perfect pairing of finite abelian groups for all $p \in \mathbb{Z}$. ($\text{Ext}^i_U$ is defined to be 0 for $i < 0$, so $H^p(U, \mathcal{F}) = 0$ if $p > 3$.)
By Theorem 2.3 and Theorem A.12, two different definitions of compactly supported étale cohomology in Section 2 and Appendix A are naturally identified. For an isomorphism

\[
\text{inv} : H^3(\mathbb{X}, \mathbb{Z}/n\mathbb{Z}) \xrightarrow{\sim} H^3_c(\mathbb{X}, \mathbb{Z}/n\mathbb{Z}) \xrightarrow{\sim} \mu_n(F)^D
\]

and a map

\[
j^3 : H^3(\pi_{an}, \mathbb{Z}/n\mathbb{Z}) \xrightarrow{j^3} H^3_c(\mathbb{X}, \mathbb{Z}/n\mathbb{Z}) \xrightarrow{\sim} H^3(\mathbb{X}, \mathbb{Z}/n\mathbb{Z}),
\]

the arithmetic Chern-Simons action can be expressed as

\[
CS_c([\rho]) = \text{inv}(j^3(\rho^*(c))).
\]
