INTRODUCTION

At the ARTA VI Conference in Mexico celebrating Jose Antonio de la Peña’s 60th birthday, the second author presented his paper [2] defining “frieze varieties” of an acyclic quiver and, using a result of Jose Antonio de la Peña [3] on eigenvalues of the Coxeter matrix of the quiver, to prove the main result: The dimension of this frieze variety is equal to 0,1, or \( \geq 2 \) if and only if the representation type of the quiver is finite, tame, or wild, respectively. In particular, the dimension of the frieze variety is 1 if and only if \( Q \) is an extended Dynkin quiver.

2010 Mathematics Subject Classification. 13F60,16G20.

The second author was supported by the NSF grants DMS-1254567 and DMS-1800860 and by the University of Connecticut.
After the talk, the two authors discussed properties and examples of frieze varieties throughout the conference. This paper is a report on these discussions.

The basic idea was to generalize the notion of frieze varieties by allowing for arbitrary generic vectors \((b_1, b_2, \ldots, b_n)\) instead of the vector \((1, 1, \ldots, 1)\) as the initial condition for the defining recurrence. We show that, for any generic point \(a^*_i = (a_1, \ldots, a_n)\) in any component of the (generalized) frieze variety of positive dimension, the mutations of \(a^*_i\) will be contained as a dense subset of the variety. (Theorems 2.3, 3.4)

We also show that mutation cyclically permutes the components of the (generalized) frieze variety (Theorem 3.2). In nice examples, we can use this cyclic permutation to generate all polynomials which define all components of the generalized frieze variety out of a single rational function. (Proposition 4.2)

Finally, we also observe that a symmetry of a mutation of a quiver decreases the dimension of the frieze variety. (Proposition 6.2)

The authors wish to thank the organizers of the conference for a very enjoyable and productive event. We also wish to say a special “Happy Birthday” to José Antonio de la Peña and congratulations on his numerous achievements.

1. Preliminaries

We recall the main result of [2]. Let \(Q\) be a connected finite quiver without oriented cycles and label the vertices 1, 2, \ldots, \(n\) such that if there is an arrow \(i \to j\) then \(i > j\).

**Definition 1.1.** [2]

1. For every vertex \(i \in Q_0\) define positive rational numbers \(f_i(t)\) \((t \in \mathbb{Z}_{\geq 0})\) recursively by
   \[
   f_i(0) = 1 \quad \text{and} \quad f_i(t + 1) = 1 + \prod_{j \to i} f_j(t) \prod_{j \leftarrow i} f_j(t + 1) f_i(t).
   \]

2. For every \(t \geq 0\), define the point \(P_t = (f_1(t), \ldots, f_n(t)) \in \mathbb{C}^n\).

3. The **frieze variety** \(X(Q)\) of the quiver \(Q\) is the Zariski closure of the set of all points \(P_t\) \((t \in \mathbb{Z}_{\geq 0})\).

The main result in [2] is the following characterization of the finite–tame–wild trichotomy for acyclic quivers \(Q\) in terms of its frieze variety \(X(Q)\).

**Theorem 1.2.** [2] Let \(Q\) be an acyclic quiver.

(a) If \(Q\) is representation finite then the frieze variety \(X(Q)\) is of dimension 0.

(b) If \(Q\) is tame then the frieze variety \(X(Q)\) is of dimension 1.

(c) If \(Q\) is wild then the frieze variety \(X(Q)\) is of dimension at least 2.

2. Definitions and main result

Let \(Q\) be as in section 1. Let \(A(Q)\) be the cluster algebra of \(Q\) and let \(x = (x_1, \ldots, x_n)\) be the initial cluster in \(A(Q)\). Let \(\mu_k\) denote the mutation in direction \(k\) and let \(x'_k\) be the new cluster variable obtained by this mutation, thus \(\mu_k(x) = (x_1, \ldots, x_{k-1}, x'_k, x_{k+1}, \ldots, x_n)\). Define the mutation sequence

\[
\mu_* = \mu_n \circ \cdots \circ \mu_2 \circ \mu_1,
\]

where the order 1, 2, \ldots, \(n\) of the vertices is as in section 1. It is shown in [2] that the point \(P_t\) in Definition 1.1 is equal to the specialization of the cluster \(\mu_*'(x)\) at \(x_i = 1\).
For an arbitrary point \( a_\ast = (a_1, \cdots, a_n) \in \mathbb{C}^n \) with \( a_i \neq 0 \) and any \( 1 \leq k \leq n \), let
\[
\mu_k(a_1, \cdots, a_n) = (a_1, \cdots, a_{k-1}, a'_k, a_{k+1}, \cdots, a_n) \in \mathbb{C}^n
\]
where \( a'_k \) is obtained from the cluster variable \( x'_k \) by specializing the initial cluster variables \( x_i = a_i, i = 1, 2, \ldots, n \). For generic \( a_\ast \) we will have \( a'_k \neq 0 \), so mutation can be repeated. Let \( \mu_\ast(a_\ast) = \mu_n \circ \cdots \circ \mu_1(a_\ast) \).

We propose the following generalization of the frieze variety.

**Definition 2.1.**

(1) We say that \( a_\ast \in \mathbb{C}^n \) is a **generic specialization** of \( \mathbf{x} \) if all coordinates of \( \mu_t^k(a_\ast) \) are nonzero for all \( t \geq 0 \).

(2) We refer to the set of all \( \mu_t^k(a_\ast) \in \mathbb{C}^n \) for \( t \geq 0 \) as the \( \mu_\ast \)-orbit of \( a_\ast \).

(3) For any generic specialization \( a_\ast \) of \( \mathbf{x} \), the **generalized frieze variety** \( X(Q, a_\ast) \) is defined to be the Zariski closure in \( \mathbb{C}^n \) of the \( \mu_\ast \)-orbit of \( a_\ast \).

(4) Let \( \tilde{X}(Q, a_\ast) \) be \( X(Q, a_\ast) \) with zero dimensional components removed. In particular, \( \tilde{X}(Q, a_\ast) \) is empty when \( Q \) has finite type.

**Remark 2.2.**

(1) By the well-known Laurent Phenomenon proved by Fomin and Zelevinsky in [1], the coordinates of \( \mu_t^k(a_\ast) \) for any integer \( t \) are given by Laurent polynomials in \( a_1, \cdots, a_n \). Therefore, \( \mu_t^k(a_\ast) \) is defined for all \( t \) as long as \( a_\ast \in (\mathbb{C}^\times)^n \), i.e. \( a_i \neq 0 \) for all \( i \).

Moreover, by the positivity theorem proved in [3], if \( a_\ast \) is a positive real vector, then all \( \mu_t^k(a_\ast) \) are positive real vectors. In particular, every positive real vector is a generic specialization.

(2) The frieze variety of \( Q \) is \( X(Q) = X(Q, (1, 1, \cdots, 1)) \).

We will show that the frieze variety is invariant under mutation in the following sense.

**Theorem 2.3.** If \( a_\ast \in \mathbb{C}^n \) is a generic point on the frieze variety, then \( a_\ast \) is a generic specialization of \( \mathbf{x} \) and \( X(Q, a_\ast) = \tilde{X}(Q) \). More precisely, for each component \( X_i \) of \( X(Q) \) of dimension \( \geq 1 \) there is a subset \( U_i \subset X_i \) given as a countable intersection of open subsets \( U_i^d \) so that, for any \( a_\ast \) in any \( U_i \) we have \( X(Q, a_\ast) = \tilde{X}(Q) \).

**Corollary 2.4.** If \( a_\ast \in X(Q) \) is a generic point then \( \mu_\ast(a_\ast) \in X(Q) \).

We note that frieze varieties often have nongeneric points. See, e.g., Remark 5.1 and the end of Example 5.7.

3. Proof of Theorem 2.3

We prove a more general result (Theorem 3.3 below) using the following lemmas.

**Lemma 3.1.** If \( b_\ast \) is a generic specialization of \( \mathbf{x} \) and \( a_\ast \in \tilde{X}(Q, b_\ast) \cap (\mathbb{C}^\times)^n \) then \( \mu_\ast(a_\ast) \in \tilde{X}(Q, b_\ast) \).

**Proof.** Since \( \tilde{X}(Q, b_\ast) \) contains all but finitely many elements of \( X(Q, b_\ast) \), \( \tilde{X}(Q, b_\ast) = X(Q, \mu_t^k(b_\ast)) \) for sufficiently large \( t > 0 \). Replacing \( b_\ast \) with \( \mu_t^k(b_\ast) \), we may therefore assume that \( \tilde{X}(Q, b_\ast) = X(Q, b_\ast) \) contains \( \mu_t^k(b_\ast) \) for all \( t \geq 0 \).

The variety \( X(Q, b_\ast) \) is given by a finite number of polynomials \( f_j \). For any \( a_\ast \in (\mathbb{C}^\times)^n \), \( \mu_\ast(a_\ast) \in \mathbb{C}^n \) is well-defined and lies in \( X(Q, b_\ast) \) if and only if \( f_j(\mu_t^k(a_\ast)) = 0 \) for all \( j \). Since the coordinates of \( \mu_\ast(a_\ast) \) are Laurent polynomials in \( x_1, \cdots, x_n \), each \( f_j(\mu_t^k(a_\ast)) \) is also a Laurent polynomial in the \( x_i \). So, there are monomials \( g_j(x_\ast) \) with the property that

\[
F_j(x_\ast) := f_j(\mu_t^k(x_\ast))g_j(x_\ast) \in \mathbb{C}[x_1, \cdots, x_n].
\]
The polynomials $F_j$ have the property that, for any $a_s \in (\mathbb{C}^* )^n$, $\mu_s(a_s) \in X(Q, b_s)$ if and only if $F_j(a_s) = 0$ for all $j$. Since $\mu^*_s(b_s) \in X(Q, b_s)$ for all $t \geq 0$, this implies that $F_j(\mu^*_s(b_s)) = 0$ for all $t \geq 0$. This implies that $F_j = 0$ on the Zariski closure of this set of points: $X(Q, b_s)$. Now let $a_s \in X(Q, b_s)$, then $F_j(a_s) = 0$ for all $j$, and by the above argument, $\mu_s(a_s) \in X(Q, b_s) = X_0(Q, b_s)$ as claimed. \hfill \square

In order to state the main result (Theorem 3.2) which will generalize Theorem 2.5, we need to consider the irreducible components of the variety $X_0(Q, b_s)$. We will show that the mutation $\mu$ cyclically permutes these components.

**Theorem 3.2.** Let $b_s$ be any generic specialization of the cluster $x$, for example, $b_s = (1, 1, \cdots, 1)$. Choose $t_0 \geq 0$ so that $\mu^*_s(b_s) \in X(Q, b_s)$ for all $t \geq t_0$. Then the components of $X_0(Q, b_s) = X(Q, \mu^*_s(b_s))$ can be numbered $X_1, \cdots, X_m$ with the following properties.

1. For each $t \geq t_0$, $\mu^*_s(b_s) \in X_t$ if and only if $t \equiv i \mod m$. In particular, for each $t \geq t_0$, $\mu^*_s(b_s)$ lies in exactly one $X_i$.

2. $X_i$ is the closure of the set of all $\mu^*_j(b_s)$ for all integers $j \geq t_0/m$.

3. For any $a_s \in X_i \cap (\mathbb{C}^* )^n$ we have $\mu_s(a_s) \in X_{i+1}$ (or $X_1$ if $i = m$).

**Proof.** By replacing $b_s$ with $\mu^*_a(b_s)$ we may assume that $t_0 = 0$ and $X_0(Q, b_s) = X(Q, b_s)$.

Let $X_1, \cdots, X_m$ be the components of $X(Q, b_s)$.

Consider the polynomials $f_j$ which define the component $X_j$. As in (3.3), there are polynomials $F_{jk}$ with the property that, for any $a_s \in (\mathbb{C}^* )^n$, $\mu_s(a_s) \in X_j$ if and only if $F_{jk}(a_s) = 0$ for all $k$. Then the polynomials $F_{jk}$ and $f_p$ define a subvariety $X_{ij}$ of $X_j$ which contains all $a_s \in (\mathbb{C}^* )^n \cap X_j$ so that $\mu_s(a_s) \in X_j$. By Lemma 3.1 $\mu_s(a_s) \in X_0(Q, b_s) = \cup X_j$, for all $a_s \in (\mathbb{C}^* )^n \cap X_i$. Therefore, $X_i$ is the union of the subvarieties $X_{ij}$. Since $X_i$ is irreducible, $X_i = X_{ij}$ for some $j$. In fact $j$ is uniquely determined by $i$, but we don’t need to verify this.

The equation $X_i = X_{ij}$ implies that, for any $a_s \in X_i \cap (\mathbb{C}^* )^n$, $\mu_s(a_s) \in X_j$. For each $i$, choose one such $j$. Then $\pi(i) = j$ defines a mapping of the set $\{1, 2, \cdots, m\}$ to itself.

Statement (3) will follow from this after we show that $\pi$ is a cyclic permutation.

**Claim 1:** $\pi$ is a permutation which is transitive, i.e. $\pi$ is an $m$-cycle.

Proof: Since $b_s \in X(Q, b_s)$, it must lie in one of the components; suppose that $b_s \in X_1$. Then $\mu_s(b_s) \in X_{\pi(i)}$ and $\mu^*_s(b_s) \in X_{\pi^*(i)}$. Thus, the $\mu_\pi$-orbit of $b_s$ lies in the union of all $X_j$ where $j$ is in the $\pi$-orbit of $i$. But the closure of the $\mu_\pi$-orbit of $b_s$ is the union of all the $X_j$. So $\pi$ must be transitive, which also implies $\pi$ is a permutation and, in particular, an $m$-cycle.

Since $\pi$ is an $m$-cycle, we may reindex the sets $X_i$ so that $\pi(i) = i + 1$ for $i < m$ and $\pi(m) = 1$ and so that $b_s \in X_m$.

**Claim 2:** For each $t \geq 0$, $\mu^*_s(b_s)$ lies in only one $X_j$: the one where $i \equiv t \mod m$.

Proof: Suppose not. Then $\mu^*_s(b_s) \in X_i \cap X_j \subset X_j$ where $j \neq i$. By the division algorithm, any $s \geq t$ can be written as $s = p + km$ where $1 \leq p < m$. If $p = i$, then $\mu^*_s(b_s) \in X_p$. If $p \neq i$ then $\mu^*_s(b_s) \in X_j$. So, the set of all $\mu^*_s(b_s)$ for all $s \geq t$ lies in the union of all $X_p$ for $p \neq i$ which is a contradiction.

These claims prove Statement (1). Statement (2) follows from the definition of $X_i$. \hfill \square

**Lemma 3.3.** For every component $X_i$ of $X_0(Q, b_s)$ and every integer $d > 0$, there is a $p_d > d$ and a dense open subset $U_d^i$ of $X_i$ so that, for every $a_s \in U_d^i$, we have the following.

1. For every $0 \leq t \leq p_d$, the coordinates of $\mu_s^*(a_s)$ are nonzero.
Therefore, $P_d \leq F$ \text{ numerator of this polynomial. Then for each $i$ for some $j$ for some $k$ consisting of matrix of rank $k$}

For example, when $n, d$ defined (Condition (1)) and has maximum rank. This will be the desired set.

By (1) in Lemma 3.3, every element of $U_i^\infty$ is a generic specialization of $x$. By Lemma 3.1, the entire $\mu_\ast$-orbit of $a_\ast$ lies in $\bar{X}(Q, b_\ast)$. So, $X(Q, a_\ast) \subset \bar{X}(Q, b_\ast)$.

If $X(Q, a_\ast) \neq \bar{X}(Q, b_\ast)$ there must be a polynomial $f$ which is zero on the $\mu_\ast$-orbit of $a_\ast$ but nonzero on $\bar{X}(Q, b_\ast)$. Let $d = \text{deg } f$. Given that $f$ is zero on the $\mu_\ast$-orbit of $a_\ast \in U_i^\infty \subset U_i^d$, we conclude by (2) in Lemma 3.3 that $f$ is zero on $\bar{X}(Q, b_\ast)$. This contradiction proves the theorem. $\square$

Remark 3.5. Theorem 2.3 follows from Theorem 3.4 by choosing $b_\ast = (1, 1, \ldots, 1)$.

It remains to prove the lemma:

Proof of Lemma 3.3 By replacing $b_\ast$ with $\mu_\ast^0(b_\ast)$ we may assume that $t_0 = 0$ in Theorem 3.2 and $\bar{X}(Q, b_\ast) = X(Q, b_\ast) = X_0 \cup \cdots \cup X_{m-1}$. By (1) in Theorem 3.2 we have that $\mu_\ast^0(b_\ast) \in X_i$. Since $\bar{X}(Q, b_\ast) = X(Q, b_\ast)$, a polynomial $f$ will be zero on $X(Q, b_\ast)$ if and only if $f(\mu_\ast^0(b_\ast)) = 0$ for all $t \geq i$. The key point of the proof is to show that, for $f$ of degree $\leq d$, we only need to check this condition for $t \leq p_d$ for some fixed $p_d > 0$. This is a linear condition on the coefficients of $f$. Since the rank of a linear system is a lower semi-continuous function, there will be an open subset $U_i^d$ of $X_i$ on which this system is defined (Condition (1)) and has maximum rank. This will be the desired set.

We now construct the linear system. With $n, d$ fixed, consider the polynomial mapping

$$P_d : \mathbb{C}^n \to \mathbb{C}^{\binom{n+d}{n}}$$

which sends $x_\ast = (x_1, \ldots, x_n) \in \mathbb{C}^n$ to the sequence of all monomials in $x_j$ of degree $\leq d$. For example, when $n = 2, d = 3$, we have:

$$P_3(x, y) = (1, x, y, x^2, xy, y^2, x^3, x^2y, xy^2, y^3).$$

Then any polynomial function $f$ on $\mathbb{C}^n$ of degree $\leq d$ is given as the composition of $P_d$ with a linear mapping $f_* : \mathbb{C}^{\binom{n+d}{n}} \to \mathbb{C}$.

Let $B_d \subset \mathbb{C}^{\binom{n+d}{n}}$ be the vector space span of all $P_d(\mu_\ast^i(b_\ast))$ for all $i \geq m$. Then a polynomial $f$ of degree $\leq d$ is zero on $X(Q, \mu_\ast^m(b_\ast)) = X(Q, b_\ast)$ if and only if $f_*(B_d) = 0$. So, $P_d(\mu_\ast(a_\ast)) \in B_d$ for all $a_\ast \in X(Q, b_\ast)$. Let $k$ be the dimension of $B_d$. Then $B_d$ has a basis consisting of $P_d(\mu_\ast^i(b_\ast))$ for some $m \leq t_1 < t_2 < \cdots < t_k$. These vectors form a $\binom{n+d}{n}$ matrix of rank $k$. So, there is some $k \times k$ minor $M$ of this matrix which is nonzero. Since $t_j \geq m \geq i$, the entries of the matrix, being monomials in the coordinates of $\mu_\ast^{-i}(\mu_\ast^i(b_\ast))$ for some $j$, are given as Laurent polynomials in the coordinates of $\mu_\ast^i(b_\ast) \in X_i$. Therefore, for each $i$, the minor $M$ is a Laurent polynomial in the coordinates of $\mu_\ast^i(b_\ast)$. Let $F_i$ be the numerator of this polynomial. Then $F_i(\mu_\ast^i(b_\ast)) \neq 0$.

Let $p_d = t_k - i$ and let $V_i^d$ be the subset of $X_i$ of all points $a_\ast$ so that $\mu_\ast^i(a_\ast)$ is defined with nonzero coordinates for $0 \leq t \leq p_d$. Since this is an open condition and $\mu_\ast^i(b_\ast) \in V_i^d$, $V_i^d$ is a dense open subset of $X_i$. By Lemma 3.1, $\mu_\ast^i(a_\ast) \in X(Q, b_\ast)$ for all $0 \leq t \leq p_d$. Therefore, $P_d(\mu_\ast^i(a_\ast)) \in B_d$ for all $0 \leq t \leq p_d$. The condition that the vectors $P_d(\mu_\ast^i(a_\ast))$,
for $0 \leq t \leq p_d$ span $B_d$ is an open condition which holds for $a_s = \mu^t_s(b_s) \in X_i \cap V^d_i$. Therefore, it holds on some Zariski open neighborhood of $\mu^t_s(b_s)$ in $X_i \cap V^d_i$. In fact, this condition will hold on the open subset $U^d_i$ of $X_i \cap V^d_i$ on which $F_i \neq 0$.

Since $U^d_i \subset V^d_i$, then $a_s \in U^d_i$ will satisfy Condition (1). For any polynomial $f$ of degree $\leq d$ which is zero on $\mu^t_s(a_s)$ for all $0 \leq t \leq p_d$, the corresponding linear map $f_*$ will vanish on the vector $P_d(\mu^t_s(a_s))$ for all $0 \leq t \leq p_d$. Since these vectors span $B_d$, $f_*(B_d) = 0$. This implies that $f$ is zero on the set $X(Q, b_s)$, proving Condition (2) and concluding the proof of Lemma 3.3. Theorems 3.4 and 2.3.

We illustrate some of the concepts in the proof of Lemma 3.3 with two examples.

**Example 3.6.** Consider the $A_2$ quiver

\[
Q : \quad 1 \leftarrow 2.
\]

Then $X(Q)$ has only five points $\mu^t_s(b_s) = (1, 1), (2, 3), (2, 1), (1, 2), (3, 2)$ for $i = 0, 1, 2, 3, 4$. Thus $m = 5$ and each $X_i$ consists of one point. For $d = 2$, $\binom{n+d}{n} = 6$. So, the five vectors $P_2(\mu^t_s(b_s))$ do not span $C^6$. These five vectors are the rows of the following $5 \times 6$ matrix.

(The proof of Lemma 3.3 uses the transpose of this matrix.)

<table>
<thead>
<tr>
<th>$b_s$</th>
<th>1</th>
<th>$x$</th>
<th>$y$</th>
<th>$x^2$</th>
<th>$xy$</th>
<th>$y^2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>$\mu^1_s(b_s)$</td>
<td>1</td>
<td>2</td>
<td>3</td>

</tbody>
</table>

The span of these five vectors is $B_2 \subset C^6$. This is a hyperplane perpendicular to the vector $(3, -2, -2, 1, -1, 1)$. Dot product with this vector gives a linear map $f_* : C^6 \to C$, composing with $P_2$ gives

\[
f(x, y) = f_*(P_2(x, y)) = x^2 - xy + y^2 - 2x - 2y + 3.
\]

This is the only quadratic polynomial which vanishes on the frieze variety $X(Q)$. The real points form an ellipse centered at $(2, 2)$ with major axis going from $(1, 1)$ to $(3, 3)$.

Here is another example which explains the minor $M$ and numerator $F$.

**Example 3.7.** Consider the Kronecker quiver

\[
Q : \quad 1 \iff 2.
\]

Consider the frieze variety $X(Q)$. The first three points are $b_* = (1, 1), \mu_s(b_s) = (2, 5), \mu^2_s(b_s) = (13, 34)$.

Take $d = 1$. Then $\binom{n+d}{n} = 3$. In order to span $C^3$ we need three vectors: $P_1(\mu^t_s(b_s))$ for $t = 0, 1, 2$. These are the rows of the following matrix.

<table>
<thead>
<tr>
<th>$b_s$</th>

<td>34</td>
</tr>
</tbody>
</table>

Since this has full rank, the determinant of this matrix (which is $-15$) is the maximal minor. However we need the minor as a Laurent polynomial in the coordinates of $\mu^t_s(b_s)$. Take
We are looking for points $a_\ast = (a_1, a_2)$ close to $\mu_1^t(b_\ast) = (2, 5)$. What we have already calculated is: $M(2, 5) = -15$.

Using invariant rational functions, the generalized frieze variety $X(Q, b_\ast)$ can be given as follows. The rational function

$$h(x) = \frac{x_1^2 + x_2^2 + 1}{x_1 x_2}$$

is equal, as an element of $\mathbb{C}(x)$, on all mutations of the cluster $x$. At $b_\ast = (1, 1)$ it takes the value $h(1, 1) = 3$. This makes

$$x_1^2 + x_2^2 + 1 = 3x_1 x_2$$

at all points in $X(Q)$. Note that equation (3.2) is a specialization of the Markov equation $x_1^2 + x_2^2 + x_3^2 = 3x_1 x_2 x_3$.

Using this equation we can see that the value of $M$ at any point $(y_1, y_2)$ in $X(Q)$ is equal to $-15$. So, $F = -15y_1^2 y_2^2$. The set $U_1^d$ for $d = 1$ is given by $F(\mu_1^t(a_\ast)) \neq 0$ for three values of $t$, namely $t = -1, 0, 1$ since we are thinking of $a_\ast$ as a specialization of $(y_1, y_2) = (x_1^t, x_2^t)$. This makes $U_1^1 = V_1^d$ the complement in $X(Q)$ of the 12 points consisting of $\mu_\ast^{-t}$, for $t = -1, 0, 1$, applied to the points $(0, \pm \sqrt{-1}), (\pm \sqrt{-1}, 0)$.

4. Construction from invariant rational functions

For any $k \geq 0$, the coordinates of $\mu_1^k(x)$ are Laurent polynomials in $x$. Furthermore, each coordinate of $x$ is given as a Laurent polynomial in $\mu_k^t(x)$. So, the set of values of $\mu_k^t(x)$ is not contained in any hypersurface in $\mathbb{C}^n$. So, for any rational function $h(x) \in \mathbb{C}(x)$ and any $t \geq 0$, we have another rational function $h(\mu_1^t(x)) \in \mathbb{C}(x)$ since the denominator of $h(\mu_1^t(x))$ cannot be identically zero. Suppose, furthermore, that $h(x)$ is a Laurent polynomial in $x$ and $a_\ast \in \mathbb{C}^n$ is a generic specialization of $x$. Then $h(\mu_1^t(a_\ast))$ is a well-defined complex number for any $t \geq 0$. This is particularly useful when $h(x)$ is periodic in the following sense.

**Definition 4.1.** We say that a rational function $h(x)$ is **invariant under $\mu_1^k$** if:

$$h(\mu_1^k(x)) = h(x)$$

as an element of $\mathbb{C}(x)$. If $k > 0$ is minimal and $h(x)$ is Laurent, we say that $h(x)$ is an **invariant Laurent polynomial for $Q$ of period $k$**. For each $t \geq 0$ we will use the notation:

$$h(\mu_1^t(x)) = \frac{f_t(x)}{g_t(x)}$$

Note that $f_t, g_t \in \mathbb{C}[x]$ depend only on the residue class of $t$ modulo the period $k$. 

Proposition 4.2. Let $h(x)$ be an invariant Laurent polynomial of period $k$. Let $a_*$ be a generic specialization of $x$. For each $t \geq 0$, let $c_t = h(\mu_*^t(a_*))$ and let $f_t(x), g_t(x)$ be as in (4.2). For $0 \leq t < k$, let
\[ F_{j,t}(x) := f_t(x) - c_{t+j}g_t(x) \]
be the numerator of the rational function $h(\mu_*^t(x)) - h(\mu_*^{j+t}(a_*))$, and let $X_j$ be the intersection of the $k$ hypersurfaces given by $F_{j,t}(x) = 0$, for $0 \leq j < k$.

Then the generalized quiver variety $X(Q, a_*)$ is contained in the union $X_0 \cup X_1 \cup \cdots \cup X_{k-1}$.

Proof. For any $0 \leq j < k$ and $s \geq 0$, let $b_s = \mu_*^{j+ks}(a_*)$. Then, for any $t \geq 0$, we have $h(\mu_*^t(b_s)) = h(\mu_*^{j+t}(a_*)) = c_{j+t}$. Since $F_{j,t}(x)$ is the numerator of $h(\mu_*^t(x)) - h(\mu_*^{j+t}(a_*))$, we get $F_{j,t}(b_s) = 0$. Therefore, $b_s = \mu_*^{j+ks}(a_*)$ lies in $X_j$ for all $s \geq 0$ and the union of the $X_j$ contains the entire $\mu_*$-orbit of $a_*$. So, $X(Q, a_*) \subset \bigcup X_j$. \qed

Remark 4.3. Thus, the single Laurent polynomial $h(x)$ generates $k^2$ polynomials $F_{j,t}(x)$ giving $k$ varieties $X_j$ whose union contains $X(Q, a_*)$ and, in many cases, is equal to $X(Q, a_*)$ as shown in several examples below. In these examples, all of the rational functions $h(\mu_*^t(x)) = f_t(x)/g_t(x)$ are Laurent polynomials with positive integer coefficients. This is reflected in the fact that the monomials in the polynomials $F_{j,t}(x) = f_t(x) - c_{j+t}g_t(x)$ have the same sign except for one: $-c_{j+t}g_t(x)$. We note that this is not a general phenomenon since, e.g., when $Q$ has finite type, $\mu_*^k(x) = x$ for some $k$ and, therefore, every Laurent polynomial will be invariant with period dividing $k$.

5. Examples

To illustrate Proposition 4.2, we give two examples, both tame, where a single invariant Laurent polynomial $h(x)$ whose period $k$ is one less than the number of vertices of $Q$ gives the complete decomposition of $X(Q)$ as a union of $k$ curves.

5.1. The affine quiver $\tilde{A}_2$. Let $Q$ be the quiver:

```
  2
 /\n 1 ← 3
```

This quiver has the property that $\mu_1Q \cong Q$ after renumbering the vertices. In terms of the cluster variables $(x, y, z)$, after one mutation, we get back the same quiver with new variables $(y, z, x')$ where $x' = \frac{1}{y}(yz + 1)$. For any rational function $h(x, y, z)$ let
\[ h'(x, y, z) := h(y, z, x'), \]
where $x'$ is the cluster variable obtained from the cluster $(x, y, z)$ by mutation in $x$. We also use the notation $h' = h \circ \tilde{\mu}$ where
\[ (5.1) \quad \tilde{\mu}(x, y, z) := (y, z, x'). \]

Note that $h^{(3)}(x, y, z) = h''(x, y, z) = h(\mu_2(x, y, z))$.

For example, let $h(x)$ be the Laurent polynomial
\[ h(x, y, z) = \frac{x + z}{y} \]
Then $h'$, $h''$ are given by
\[ h'(x, y, z) = h(y, z, x') = \frac{y + x'}{z} = \frac{xy + yz + 1}{xz}, \]
\[ h''(x, y, z) = h'(y, z, x') = \frac{z + y'}{x} = \frac{yz + yx + 1}{zx}, \]
\[ h'''(x, y, z) = h''(y, z, x') = \frac{x + z'}{y} = \frac{xy + xz + 1}{yz}, \]
\[ h''''(x, y, z) = h'''(y, z, x') = \frac{y + z'}{x} = \frac{yz + yx + 1}{zx}. \]
FRIEZE VARIETIES ARE INVARIANT UNDER MUTATION

\[ h''(x, y, z) = h'(y, z, x') = h(z, x', y') = \frac{z + y'}{x'} \]

Observe that

\[ \frac{h}{h''} = \frac{(x + z)x'}{y(z + y')} = \frac{yz + 1 + zx'}{yz + 1 + zx'} = 1 \]

and thus \( h'' = h \) and, consequently, \( h^{(a)} = h \) if \( a \) is even, and \( h^{(a)} = h' \) if \( a \) is odd. Therefore \( h \) and \( h' \) are invariant under \( \mu_2^* \):

\[ h(\mu_2^*(x, y, z)) = h^{(6)}(x, y, z) = h(x, y, z), \]

and similarly, \( h' \circ \mu_2^* = h^{(7)} = h' \).

Thus, \( h(x) \) is an invariant Laurent polynomial for \( Q \) of period 2. So, Proposition 4.2 applies with

\[ c_0 = h(1, 1, 1) = 2 \]
\[ c_1 = h'(1, 1, 1) = 3. \]

So, \( X(Q) \) is contained in the union of two curves \( X_0 \cup X_1 \) where \( X_0 \) is given by the polynomial equations \( F_{00} = F_{01} = 0 \) where

\[ F_{00}(x, y, z) = \text{Num}(h(x, y, z) - c_0) = x + z - 2y \]
\[ F_{01}(x, y, z) = \text{Num}(h'(x, y, z) - c_1) = xy + yz + 1 - 3xz \]

and \( X_1 \) is given by \( F_{11} = F_{12} = 0 \) where

\[ F_{10}(x, y, z) = \text{Num}(h(x, y, z) - c_1) = x + z - 3y \]
\[ F_{11}(x, y, z) = \text{Num}(h'(x, y, z) - c_0) = xy + yz + 1 - 2xz. \]

From these equations it is easy to verify the observation from \([2]\) that \( X_0 \) is a nonsingular degree 2 curve. Indeed the equation \( F_{00} = 0 \) is equivalent to the linear equation \( z = 2y - x \) which reduced the second equation to \( F_{01}(x, y, z) = F_{01}(x, y, 2y - x) = 0 \) which is a nondegenerate quadratic in two variables. Thus \( X_0 \) is a nonsingular curve in \( \mathbb{C}^3 \) containing the infinite set of points \( \mu_{2k}^*(1, 1, 1) \) for \( k \geq 0 \). So, it must be the closure of this set. Similarly, the curve \( X_1 \) must be the closure of the set of all \( \mu_{2k+1}^*(1, 1, 1) \). We therefore see that the frieze variety \( X(Q) \) has two components given by the above four polynomials.

These polynomials come from an example worked out in \([2]\), but here all four polynomials come from the same Laurent polynomial \( h \).

Remark 5.1. We note that frieze varieties often have nongeneric points. For example, the first component \( X_0 \) of the frieze variety discussed above contains the point \((0, \sqrt{2}i/2, \sqrt{2}i)\). Mutation at the first vertex gives \( x' = (yz + 1)/x = 0/0 \) which is undefined. However, \( \tilde{\mu} \) (defined in (5.1) above) sends the 0-component of \( X(Q) \) to the 1-component \( X_1 \). So, the value of \( x' \) can be computed from the linear equation \( F_{10}(y, z, x') = 0: \)

\[ x' = 3z - y = \frac{5}{2}\sqrt{2}i. \]
5.2. The affine quiver $\tilde{A}_n$. More generally, consider the quiver:

$$Q: \begin{array}{cccc}
1 & 2 & \cdots & n-1 \\
\downarrow & & & \leftarrow \\
0 & & & n
\end{array}$$

for $n \geq 3$. Let $h$ be the Laurent polynomial:

$$h(x_0, x_1, \cdots, x_n) = \frac{x_{n-2} + x_n}{x_{n-1}}.$$ 

Mutation gives:

$$h'(x_0, \cdots, x_n) := h(x_1, x_2, \cdots, x_n, x_0) = \frac{x_{n-1} + x'_0}{x_n} = \frac{x_{n-1}x_0 + x_1x_n + 1}{x_0x_n}.$$ 

Mutating $k$ times for $3 \leq k \leq n$ ($k = 2$ is given in (5.2) below) gives

$$h^{(k)}(x_0, x_1, \cdots, x_n) = h(x_{k}, x_{k+1}, \cdots, x_n, x'_0, \cdots, x'_{k-1}) = \frac{x'_{k-3} + x'_{k-1}}{x'_{k-2}}.$$ 

For $k = n$, $h^{(n)} = h$ since the quotient is:

$$\frac{h}{h^{(n)}} = \frac{(x_{n-2} + x_n)x'_{n-2}}{x_{n-1}(x'_{n-3} + x'_{n-1})} = \frac{x_{n-1}x'_{n-3} + 1 + x_nx'_{n-2}}{x_{n-1}x'_{n-3} + 1 + x_nx'_{n-2}} = 1.$$ 

This gives us a cleaner formula for $h^{(k)}$ for $2 \leq k \leq n$ using $2 - n \leq k - n \leq 0$:

$$h^{(k)}(x) = h^{(k-n)}(x) = h(x'_{k+1}, \cdots, x'_n, x_0, x_1, \cdots, x_k) = \frac{x'_{k-2} + x_k}{x'_{k-1}}.$$ 

The equation $h = h^{(n)}$ also implies that $h^{(nk)} = h$, for all $k \geq 0$. So,

$$h(\mu^*_a(x)) = h^{(n+1)}(x) = h^{(k)}(x).$$

In particular $h(\mu^*_a(x)) = h^{(n)}(x) = h(x)$. So, $h(x)$ is an invariant Laurent polynomial for $Q$ of period dividing $n$. To see that the period of $h$ is exactly $n$ we compute $c_k$:

$$c_k = h^{(k)}(1, 1, \cdots, 1) = h(1, 1, \cdots, 1, 2, 3, \cdots, k + 1) = \begin{cases} 3 & \text{if } k = 1; \\ 2 & \text{if } 2 \leq k \leq n. \end{cases}$$

Also, $h^{(k)}$ is invariant under $\mu^*_a$, for all $k \geq 0$, since $h^{(k)}(\mu^*_a(x)) = h^{(k+n)}(x) = h^{(k)}(x)$. So, for generic $a_*$, the frieze variety $X(Q, a_*)$ has $n$ components

$$X(Q, a_*) = X_0 \cup X_1 \cup \cdots \cup X_{n-1};$$

the first component $X_0$, containing the $\mu^*_a$-orbit of $a_* = (1, 1, \cdots, 1)$, is given by the $n$ polynomials $F_{01}, \cdots, F_{0n-1}, F_{0n} = F_{00}$ where

$$F_{01} = \text{Num}(h'(x) - c_1) = x_0x_{n-1} + x_1x_n + 1 - 3x_0x_n,$$

by Proposition 4.2 and (5.3); and for $2 \leq k \leq n$

$$F_{0k} = \text{Num}(h^{(k)}(x) - c_k) = x_{k-2} + x_k - 2x_{k-1},$$

by Proposition 4.2, (5.2) and (5.3).
Remark 5.2. Note that, for any point in $X_0$, the equations $F_{0k} = 0$ for $2 \leq k \leq n$ express the coordinates $x_2, x_3, \cdots, x_n$ as linear combinations of $x_0, x_1$. Thus, points in $X_0$ are determined by their first two coordinates. Since $X_0$ contains the 3 points $(1, 1, \cdots, 1), (1, 2, \cdots, 1), (n + 1, 2n + 3, \cdots)$ and their negatives (where we ignore all but the first two coordinates) and does not contain $(0, 0, \cdots)$, linear algebra in $\mathbb{C}^2$ shows $X_0$ cannot be a union of two straight lines. So, $X_0$ is an irreducible degree 2 curve containing the $\mu_n^2$-orbit of the point $a_1 = (1, 1, \cdots, 1)$. Since no two distinct curves can have an infinite intersection, $X_0$ is the Zariski closure of this set.

By Proposition 4.2, $X_1$ is given by the $n$ polynomial equations $F_{1t} = 0$ for $0 < t \leq n$

$$F_{1n} = \text{Num}(h(x) - c_1) = x_{n-2} + x_n - 3x_{n-1}$$

$$F_{11} = \text{Num}(h'(x) - c_2) = x_0x_{n-1} + x_1x_n + 1 - 2x_0x_n$$

$$F_{1k} = F_{0k}, \text{ for } k = 2, \cdots, n - 1.$$  

The other polynomials $F_{jt}$ are similar. As in the case of $\tilde{A}_2$, all polynomials $F_{jk}$ are given by the single Laurent polynomial $h$ and its $n - 1$ mutations $h^{(k)}$ for $1 \leq k < n$.

6. Symmetry

One easy observation [2] is that, if a permutation $\sigma$ of $\{1, 2, \cdots, n\}$ leaves the quiver $Q$ invariant, then the frieze variety $X(Q)$ satisfies $x_k = x_{\sigma(k)}$ for all $k$. In terms of invariant rational functions, $h = x_{\sigma(k)}/x_k$ is invariant under $\mu_2^2$ since $\mu_2$ inverts $h$.

A similar result holds true if a mutation of $Q$ has symmetry. For example,

$$Q : 1 \leftrightarrow 2 \leftrightarrow 3$$

becomes symmetric after one mutation:

$$\mu_1(Q) : 1' \Rightarrow 2 \leftrightarrow 3$$

This implies that

$$h = \frac{x_1'}{x_3} = \frac{x_2^2 + 1}{x_1x_3}$$

is invariant under $\mu_2^2$. Since $c_0 = h(1, 1, 1) = 2$ and $c_1 = 1/c_0 = 1/2$, the frieze variety of $Q$ is $X(Q) = X_0 \cup X_1$, where $X_0$ is the hypersurface given by $F_0 = 0$, where

$$F_0 = \text{Num}(h(x) - c_0) = x_2^2 + 1 - 2x_1x_3$$

and $X_1$ is the hypersurface given by $F_1 = 0$, where

$$F_1 = \text{Num} \left( h(\mu_2^2(x)) - \frac{1}{2} \right) = \text{Num} \left( \frac{2}{h(x)} - 1 \right) = 2x_2^2 + 2 - x_1x_3.$$  

Remark 6.1. The hypersurface $X_0$ contains the $\mu_2^2$-orbit of the point $(1, 1, \cdots, 1)$. Since this set is not contained in any curve by Theorem 1.2, there cannot be a smaller variety containing this set. So, $X_0$ is the Zariski closure of the $\mu_2^2$ orbit of $(1, 1, \cdots, 1)$ and similarly for $X_1$.

More generally we have the following.
Proposition 6.2. Suppose that $i$ is a sink in the quiver $Q$ and $j$ is a source so that, for any other vertex $k$, the number $n_k$ of arrows from $k$ to $i$ is equal to the number of arrows from $j$ to $k$. Then, the frieze variety $X(Q)$ is contained in the union of two hyperplanes $X_0, X_1$ given by the equations $F_0 = 0$ and $F_1 = 0$, where

$$F_0 = 1 - 2x_ix_j + \prod_k x_k^{n_k}$$
$$F_1 = 2 - x_ix_j + 2\prod_k x_k^{n_k}.$$

Proof. After the mutation $\mu_\ast = \mu_n \circ \cdots \circ \mu_1$, we will have $x_\ast$ where

$$x_i' = \frac{1+\prod x_k^{n_k}}{x_i}, \quad x_j' = \frac{1+\prod (x_k')^{n_k}}{x_j}.$$

So, the rational function $h(x) = x_i'/x_j$ will mutate to

$$h(\mu_\ast(x)) = \left(\frac{x_j'}{x_j}\right) = \frac{x_j'}{1+\prod (x_k')^{n_k}} = \frac{x_j}{h(x)}.$$

So, $h(x)$ is $\mu_\ast^2$ invariant. Since $h(x) = f(x)/g(x)$ where $f(x) = 1 + \prod x_k^{n_k}$ and $g(x) = x_ix_j$, $c_0 = h(1,1,\cdots,1) = 2$, $c_1 = 1/c_0 = 1/2$, the numerator of $h(x) - c_0$ is $F_0$ and the numerator of $h(\mu_\ast(x)) - c_1$ is $F_1$. By Proposition 4.2, the $\mu_\ast^2$ orbit of $(1,1,\cdots,1)$ satisfies $F_0 = 0$ and the $\mu_\ast^2$ orbit of $\mu_\ast(1,1,\cdots,1)$ satisfies $F_1 = 0$. \hfill \Box

7. Questions

There are a few questions which we leave unanswered.

(1) In the tame case, does an invariant Laurent polynomial $h(x)$ always exist?
(2) Can $h(x)$ be chosen to have positive integer coefficients?
(3) Can $h(x)$ be chosen such that all mutations $h(\mu_\ast^t(x))$ have positive integer coefficients?
(4) Is the period of the invariant Laurent polynomial always equal to the number of components of $X(Q,a_\ast)$?

Another question which might arise is whether the number of components is always one less than the number of vertices. This is true in all of the cases we discussed above. However, it is not true in the following case:

\[
\begin{align*}
Q : & \quad 1 \quad 2 \\
& \quad \quad 3 \\
& \quad \quad 4
\end{align*}
\]

The frieze variety has two components each given by three polynomials. These are given by three invariant Laurent polynomials $h_1, h_2, h_3$ of period 2 where $h_1 = x_2/x_3$, Proposition 6.2 gives

$$h_2(x) = \frac{1 + x_2x_3}{x_1x_4}$$

and $h_3$ is given by

$$h_3(x) = \frac{x_1 + x_4}{x_2}.$$
We already know that mutation inverts \( h_1 \) and \( h_2 \), so they are periodic of period 2. Mutation of \( h_3 \) gives

\[
h_3(\mu_+(x)) = \frac{(x_1 + x_4)(x_2x_3 + 1)}{x_3x_1x_4} = \frac{x_1 + x_4}{x_3} h_2(x)
\]

So,

\[
h_3(\mu_+^2(x)) = \frac{x_1 + x_4}{x_2} h_2(x) h_2(\mu_+(x)) = h(x).
\]

Therefore, \( X(Q, a_+) \) has two components for any generic \( a_+ \) and mutation transposes these components.
