An entire function connected with the approximation of the golden ratio

Anton A. Kutsenko

Abstract

In 1987, R. B. Paris uses the analytic function

\[ g(w) = \lim_{n \to \infty} (2\varphi)^n \left( \sqrt{1 + \sqrt{1 + \ldots \sqrt{1 + w - \varphi}}}_n \right), \quad \varphi = \frac{1 + \sqrt{5}}{2}, \quad (1) \]

to estimate the convergence of nested squares to the golden ratio. The function \( g \) is non-entire and, perhaps, can not be expressed in terms of some standard known functions. We show that \( f(z) := g^{-1}(z) \) is an entire function of an exponential type. We demonstrate also the relations between \( f(z) \) and Julia sets generated by the polynomial \( z^2 - 1 \). We derive some other expansions for \( f(z) \).

Keywords: Golden ratio

1. Introduction

In his nice and short paper \[1\], R. B. Paris investigated the convergence of nested squares to the golden ratio. He found \( \varphi - \varphi_n \sim \frac{2C}{(2\varphi)^n} \), where \( \varphi_1 = 1, \varphi_{n+1} = \sqrt{1 + \varphi_n} \). The value \( C \approx 1.098 \) admits explicit representation \( C = \varphi \tilde{g}(1/\varphi) \), where the analytic function \( \tilde{g} \) satisfying

\[ \tilde{g}(z) = 2\varphi \tilde{g}(\varphi - \sqrt{\varphi^2 - z}), \quad |z| < \varphi^2; \quad \tilde{g}(0) = 0, \quad \tilde{g}'(0) = 1, \]

see \[2\, 3\]. There is another form of this representation \( 2C = g(1) \), see \[1\]. The functions \( \tilde{g}, \, g \) are analytic in some domain, but non-entire. We show that \( f := g^{-1} \) admits extension to an entire function. We explore some properties of \( f \). Section \[2\] contains rigorous results, other sections are more experimental. Some interesting comments are available in \[1\], where
I opened the discussion about some of related results. Note that in the current paper I use only part of these results obtained by me.

2. Basic properties of $g$ and $g^{-1}$

Differentiating (1), we obtain the following expansion

$$g'(w) = \sqrt{1 + w} \cdot \frac{1}{\sqrt{1 + \sqrt{1 + w}}} \cdot \frac{1}{\sqrt{1 + \sqrt{1 + \sqrt{1 + w}}}} \cdots$$

(2)

Thus $g'(\varphi) = 1$, since $w = \varphi$ is a fixed point of the mapping $\sqrt{1 + w}$. Along with $g(\varphi) = 0$, we can state that there is an analytic function $f(z) = g^{-1}(z)$ defined in some neighborhood of $z = 0$. This function satisfies $f(0) = \varphi$, $f'(0) = 1$.

Definition (1) leads to the functional equation

$$g(w) = (2\varphi)g(\sqrt{1 + w}),$$

(3)

where, as above, the branch of square root satisfies $\sqrt{1 + \varphi} = \varphi$. Substituting $w = f^{-1}(z)$ into (3) and applying $f^{-1}$, we obtain

$$f(2\varphi z) = f(z)^2 - 1.$$  

(4)

Remark. It can be shown that the functional equation $f(az) = f(z)^2 - 1$, $f'(0) \neq 0$ admits an analytic solution if and only $a = 1 \pm \sqrt{5}$, see also [4].

Applying Leibnitz rule to (4), we get

$$(2\varphi)^n f^{(n)}(0) = \sum_{k=0}^{n} \binom{n}{k} f^{(k)}(0)f^{(n-k)}(0), \quad n \geq 2,$$

(5)

which with $f(0) = \varphi$ gives the recurrent formula

$$f^{(n)}(0) = \frac{\sum_{k=1}^{n-1} \binom{n}{k} f^{(k)}(0)f^{(n-k)}(0)}{(2\varphi)^n - 2\varphi}, \quad n \geq 2.$$  

(6)

It is clear that $|f'(0)| = 1$, $|f''(0)| = ((2\varphi)^2 - 2\varphi)^{-1} \leq 1$. Suppose that we already proved $|f^{(k)}(0)| \leq 1$ for all $k = 1, ..., n - 1$. Then, by (6), we have

$$|f^{(n)}(0)| \leq \frac{\sum_{k=1}^{n-1} \binom{n}{k} |f^{(k)}(0)||f^{(n-k)}(0)|}{(2\varphi)^n - 2\varphi} \leq \frac{\sum_{k=1}^{n-1} \binom{n}{k}}{(2\varphi)^n - 2\varphi} = \frac{2^n - 2}{(2\varphi)^n - 2\varphi} \leq 1, \quad n \geq 2.$$

Hence, all $|f^{(n)}(0)| \leq 1$ and the coefficients in Taylor expansion $|f^{(n)}(0)/n!| \leq 1/n!$. We obtain

Theorem 2.1. The function $f$ can be extended to an entire function of an exponential type. Its order does not exceed 1.
Remark. Due to (6), we conclude that all \( f^{(n)}(0) > 0 \). Thus, \( f \) is strictly increasing function for \( z > 0 \). It is easy to check that there are negative zeros of \( f \). Let \( c < 0 \) be the first zero \( f(c) = 0 \). Then the values
\[
f((2\varphi)^{-n}c) = \sqrt{1 + \cdots + \sqrt{1}} > 0, \quad n \geq 1
\]
completely determine the entire function \( f \). In particular, \( f((2\varphi)^{-1}c) = 1 \) and, hence, the Paris constant \( 2C = (2\varphi)^{-1}c \), see Section 3.

3. Zeros of \( f \) and polynomial dynamics

The well-known identity \( \cos 2z = 2(\cos z)^2 - 1 \) is similar to (4). It generates the scaled Chebyshev polynomials
\[
\cos(2^n z) = \tilde{T}_{2^n}(\cos z), \quad \tilde{T}_{2^n}(z) = (2z^2 - 1) \circ \cdots \circ (2z^2 - 1) = (2z^2 - 1)^{\circ n}.
\]
Identity (4) also generates the polynomials
\[
f((2\varphi)^n z) = P_n(f(z)), \quad P_n(z) = (z^2 - 1)^{\circ n}. \tag{7}
\]
Differentiating (4), we obtain
\[
f'(z) = \varphi^{-1} f((2\varphi)^{-1} z) f'((2\varphi)^{-1} z) = \cdots = \varphi^{-n} f((2\varphi)^{-1} z) f((2\varphi)^{-2} z) \cdots f((2\varphi)^{-n} z) f'((2\varphi)^{-n} z)
\]
which gives us
\[
f'(z) = \prod_{n=1}^{\infty} \varphi^{-1} f((2\varphi)^{-n} z), \tag{8}
\]
since \( f'((2\varphi)^{-n} z) \to f'(0) = 1 \). This is an analog of the Euler formula
\[
\sin x = x \prod_{n=1}^{\infty} \cos \frac{x}{2^n}.
\]
For the rest, the function \( f \) and \( f' \) are more complex than \( \cos \) and \( \sin \). One of the reason is that \( P_n \) can have many complex zeros. Recall that zeros of the Chebyshev polynomials are real. Using
\[
f((2\varphi)^2 z) = P_2(f(z)) = f(z)^2(f(z)^2 - 2), \tag{9}
\]
we obtain the following
Proposition. If \( z_0 \) is a zero of \( f \) of multiplicity \( m \) then \((2\varphi)^2 z_0 \) is a zero of \( f \) of multiplicity \( 2m \).

Moreover, from (8) it is seen that \( z_0 \) is a simple zero of \( f \) if and only if \( f((2\varphi)^{-n} z_0) \neq 0 \) for all \( n > 1 \). Let \( z_0 \) be some simple zero of \( f \). Then
\[
0 = f(z_0) = P_n(f((2\varphi)^{-n} z_0)), \tag{10}
\]
where \( n \in \mathbb{N} \). It means that \( f((2\varphi)^{-n}z_0) \) is a primitive zero of \( P_n \). We call zero \( y_0 \) of \( P_n \) primitive if \( P_k(y_0) \neq 0 \) for all \( k < n \). All primitive zeros \( y \) of \( P_n, n \geq 3 \) have the form

\[
y(s) = s_1 \sqrt{1 + s_2 \sqrt{1 + \ldots + s_{n-2} \sqrt{2}}}.
\]

(11)

where \( s = (s_k) \in \{\pm 1\}^{n-2} \). There seems to be \( 2^{n-2} \) distinct primitive zeros of \( P_n, n \geq 3 \). Formula (11) can be easily implemented for numerical experiments. Using (10), and \( f(0) = \varphi, f'(0) = 1 \), we conclude that

\[
(2\varphi)^{-n}z_0 = y(s) - \varphi + O(z_0^2(2\varphi)^{-2n}),
\]

(12)

for some \( s \in \{\pm 1\}^{n-2} \). Denote the ring \( S_n := \{z : (2\varphi)^n < |z| \leq (2\varphi)^{n+1}\} \). If \( z_0 \) belongs to the ring \( S_{n-n_1} \) for some \( n, n_1 \in \mathbb{N}, \) then

\[
z_0 = (2\varphi)^n(y(s) - \varphi) + O((2\varphi)^{n-2n_1+2}).
\]

(13)

Moreover, any primitive zero \( y(s) \) of \( P_n \) lying in \( \varphi + S_{-n_1} \), generates by (13) a simple zero \( z_0 \) of \( f \) lying in the relative vicinity (of order \( O((2\varphi)^{-n_1+2}) \)) of \( S_n \), when \( n_1 \) is large. Since such primitive zeros of \( P_n \) approximate a Julia set, we obtain that large simple zeros of \( f \) also create the structure similar to the Julia set. In Fig. 1 we draw approximate position of simple zeroes of \( f \), using primitive zeros of \( P_{28} \) and \( n_1 = 11, 12, 13 \).

![Image](image_url)

Figure 1: Approximate position of simple zeros of \( f \) located in (a) \( S_{16} \), (b) \( S_{17} \cup S_{16} \cup S_{15} \).
4. Weierstrass-Hadamard expansion of $f$ and related formulas

Let $\{z_n\}$ be all simple zeros of $f$. Denote $H(z) = \prod_n (1 - z/z_n)$. Numerical experiments show that $H$ is well defined, since the number of primitive zeros located in $S_n$ grows up approximately as $A2^n (A > 0)$, while the radius of $S_n$ is $(2\varphi)^n+1$. The order of grows $A2^n$ is also confirmed by the exact order of $f$, see below. Recall that each simple zero $z_n$ generates zeros $(2\varphi)^k z_n$ of multiplicity $2^k$, $k \geq 1$. Then, since $f$ is an entire function of the order at most 1, it admits the Weierstrass-Hadamard expansion

$$f(z) = \varphi e^{d z} \prod_{n=0}^\infty H\left(\frac{z}{(2\varphi)^{2n}}\right)^{2^n}$$

with some constant $d$. In fact, $d = 0$, since the order of $f$ does not exceed $\rho = \ln 2/\ln(2\varphi) < 1$. The value $\rho$ can be obtained by substituting $e^{B|z|^p}$ into (4) which leads to $e^{(2\varphi)^p B|z|^p} = e^{2B|z|^p}$ or $(2\varphi)^p = 2$. The exact value $\rho$ first appeared in comments, see [4]. Thus

$$f(z) = \varphi \prod_{n=0}^\infty H\left(\frac{z}{(2\varphi)^{2n}}\right)^{2^n} \quad (14)$$

Substituting (14) into (9), we obtain another formula for $f$ containing simple zeros only

$$f(z) = \sqrt{2 + \varphi^{-1} H((2\varphi)^2 z)}. \quad (15)$$

Finally, substituting (14) into (8), we obtain the formula for derivative

$$f'(z) = \prod_{n=1}^\infty H\left(\frac{z}{(2\varphi)^{2n}}\right)^{2^n-1} \prod_{n=1}^\infty H\left(\frac{z}{(2\varphi)^{2n-1}}\right)^{2^{n-1}}. \quad (16)$$

Let us simplify (15) writing

$$f(2\varphi z)^2 - 1 = 1 + \varphi^{-1} H((2\varphi)^3 z)$$

or, by (4),

$$f(z) = 1 + \frac{H(2\varphi z)}{\varphi}. \quad (17)$$
