INDUCTION OF $\mathbb{Z}^2$-ACTIONS AND OF PARTITIONS OF THE 2-TORUS

SÉBASTIEN LABBÉ

Abstract. Sturmian sequences are the most simple aperiodic sequences. A result of Morse, Hedlund (1940) and Coven, Hedlund (1970) is that a biinfinite binary sequence is sturmian if and only if it is obtained as the coding of an irrational rotation on the circle $\mathbb{T} = \mathbb{R}/\mathbb{Z}$. The reason is that sturmian sequences and codings of rotations have the same substitutive structure. The proof is related to the continued fraction expansion of real numbers and is based on induced maps.

We consider a generalization of this result in the context of the most simple aperiodic two-dimensional sequences, namely Wang shifts defined by the fewest number of tiles. We prove that the Jeandel-Rao’s Wang shift, an aperiodic Wang shift defined by only 11 Wang tiles, has the same substitutive structure as the symbolic dynamical system defined by the action of some $\mathbb{Z}^2$-rotation and partition of the 2-torus. The proof is algorithmic and is based on the induction of $\mathbb{Z}^2$-rotations and partitions of the 2-torus.

As for continued fraction expansion of quadratic irrationals, the algorithm stops when it gets a partition and a $\mathbb{Z}^2$-action which is the same as in an earlier step up to some renormalization. This is what happens with the partition of the 2-torus coding Jeandel-Rao’s aperiodic tilings. After few induction steps that we may call preperiod, we obtain a self-induced Markov partition of $\mathbb{T}^2$ coding a self-similar Wang shift defined by 19 Wang tiles. The substitution of the self-similarity is the same as the one previously known and computed from the 19 Wang tiles using marker tiles.

1. Introduction

The most classic right-sided aperiodic sequence is certainly the Fibonacci word \cite{Ber80}

\[ F = abaababaabaababaabab\ldots \]

which is the unique right infinite word fixed by the morphism $a \mapsto ab, b \mapsto a$. We may check that it contains as factors (or subwords) one empty word $\varepsilon$, two letters $a, b$, three words $aa, ab, ba$ of length 2, four words $aab, aba, baa, bab$ of length 3 and in general $n + 1$ words of length $n$. The number $p(n)$ of distinct finite words of length $n$ appearing in a sequence $w \in \mathcal{A}^\mathbb{N} \cup \mathcal{A}^\mathbb{Z}$ over an alphabet $\mathcal{A}$ defines a function $p: \mathbb{N} \to \mathbb{N}$ called the factor complexity \cite{CN10}. There are two ways of extending the Fibonacci word to the left in order to preserve its factor complexity $p(n) = n + 1$, namely $\bar{F}abF$ and $\bar{F}baF$ where $\bar{F} = \ldots bababaababaabaababababa$ is the left-infinite word defined as the reversal of $F$.

A result of Morse and Hedlund says that either $w$ is eventually periodic or $p$ is strictly increasing. A direct consequence is that aperiodic sequences must contain at least $p(n) \geq n + 1$ words of length $n$ for each $n \in \mathbb{N}$. It turns out that sequences of complexity $p(n) = n + 1$ exist, the Fibonacci word being an example, and are known under the name of sturmian sequences \cite{MH40}. Sturmian sequences \cite[Chap. 2]{Lot02} are thus the most simple aperiodic sequences in terms of factor complexity. Note that Morse and Hedlund defined them in terms of another notion, namely balanced sequences, and the link with factor complexity was done later \cite{CH73}.

The main result of \cite{MH40} together with the contribution of Coven and Hedlund \cite{CH73} is that a sequence $w \in \{a, b\}^\mathbb{Z}$ is sturmian if and only if it is obtained as the coding of an irrational rotation $R_\alpha(x) = x + \alpha$ on the circle $\mathbb{T} = \mathbb{R}/\mathbb{Z}$ starting from some $x_0 \in \mathbb{T}$ where $\alpha \in \mathbb{R} \setminus \mathbb{Q}$ is the frequency of $a$’s in the sequence $w$. Moreover, the map $w \mapsto x_0$ is continuous and commutes the shift action $\sigma$ on sequences with the rotation $\mathbb{R}_\alpha$ on the circle. This entails that the symbolic dynamical system $(S_\alpha, \sigma)$ given by the shift action $\sigma$ on sturmian sequences of frequency $\alpha$ is measurably conjugate to the irrational rotation $(\mathbb{T}, R_\alpha)$ of angle $\alpha$ on the circle. Proving that codings of irrational rotations on the circle are sturmian sequences, that is, sequences of complexity $n + 1$, is the easy part. The proof of the converse is not trivial, takes some amount of work in \cite{Arn02} and is very interesting as it uses important tools from combinatorics, number theory, diophantine approximations, numeration systems and dynamical systems.

A generalization of the result of Morse and Hedlund was provided by Rauzy \cite{Rau82}. Based on the right-infinite sequence often called the Tribonacci word

\[ T = 12131211213121121312112131211213121\ldots \]

which is fixed by $1 \mapsto 12, 2 \mapsto 13, 3 \mapsto 1$, Rauzy proved that the system $(X_T, \sigma)$ is measurably conjugate to the toral rotation $(\mathbb{T}^2, x \mapsto x + (\beta^{-1}, \beta^{-2}))$ where $\beta$ is the real root of $x^3 - x^2 - x - 1$, the characteristic polynomial of the incidence matrix of the substitution. The coding of the toral
translation is made through the partition into three parts of a fundamental domain of $\mathbb{T}^2$ known as the Rauzy fractal \cite[§7.4]{Fog02}.

Finding further generalizations was coined the term of Rauzy program in \cite{BFZ05}, a survey divided into three parts: the good coding of $k$-interval exchange transformations (IET); the bad coding of a rotation on $\mathbb{T}^k$; and the ugly coding of two rotations on $\mathbb{T}^1$. The IET are the good part since they behave well with induced transformations and admit continued fraction algorithms \cite{Rau79,Vee82,Yoc06,AF07}. The bad part was much improved since then with various recent results using multidimensional continued fraction algorithms (MCFA) including Brun’s algorithm \cite{Bru58} which provides measurable-theoretic conjugacy with symbolic systems for almost every toral rotations on $\mathbb{T}^2$ \cite{BST14,Thu17}. As the authors wrote in \cite{BFZ05}, the term ugly “refers to some esthetic difficulties in building two-dimensional sequences by iteration of patterns”. Indeed, digital planes \cite{ABEI01,ABI02,BFZ05,Ber09,BBJS13} are typical objects that are described by the coding of two rotations on $\mathbb{T}^1$ and they are not built by rectangular shaped substitutions. In this contribution, we want to add some shine on the ugly part.

In some sense, there is another way to generalize the result of Morse, Hedlund and Coven to higher dimension. Instead of increasing the size of the alphabet (as for the IET and the MCFA), we may increase the dimension of the domain. Informally, our goal is to tackle the following question.

*If the most simple aperiodic sequences $\mathbb{Z} \to \mathcal{A}$ are coded by irrational rotations, what about the most simple aperiodic sequences $\mathbb{Z}^2 \to \mathcal{A}$?*

We now need to define what we mean by simple 2-dimensional aperiodic sequences which may have various interpretations. One option is to consider factor complexity as for the 1-dimensional case. But the simplicity of the threshold $p(n) \geq n + 1$ in one dimension becomes a very hard question in two dimensions. Indeed, an important open problem in symbolic dynamics known as Nivat’s conjecture is to show that sequences $w \in \mathcal{A}^{\mathbb{Z}^2}$ with factor complexity $p(m,n)$ counting the number of different rectangular patterns of shape $m \times n$ are periodic as soon as $p(m,n) \leq mn$ for some $m,n \geq 1$. Assuming the conjecture is true, on which progress has been done recently as summarized in \cite{Kar19}, one possibility is to consider sequences of complexity $p(m,n) = mn + 1$ or else $p(m,n) = mn + m + n + 1$ like done in \cite{BV00}. In this work, we do not consider the factor complexity approach and choose another point of view.

In symbolic dynamics, the one-dimensional setup is much different then that of the $d$-dimensional setup with $d \geq 2$. For example, nonempty 1-dimensional subshifts of finite type (SFT) necessarily contain a periodic sequence, whereas there exists $d$-dimensional SFTs that are aperiodic when $d \geq 2$ \cite{Ber66}. In this work, we consider the most simple 2-dimensional SFTs, more precisely Wang shifts given by the fewest number of Wang tiles. The first aperiodic Wang shift was given by Berger and the question of finding the Wang shift with the fewest number of tiles was open until recently. In 2015, Jeandel-Rao discovered an aperiodic set of 11 Wang tiles and they proved that no set of 10 or less Wang tiles is aperiodic \cite{JR15}. In that sense, Jeandel-Rao tilings are the most simple aperiodic sequences $\mathbb{Z}^2 \to \mathcal{A}$. Therefore, a natural question is whether Jeandel-Rao tilings are coded by irrational rotations.

In \cite{Lab19a} we proposed a way to construct Jeandel-Rao tilings as coding of $\mathbb{Z}^2$-rotations on a 2-dimensional torus using some polygonal partition of the 2-torus. As for sturmian sequences, once the partition is given, proving that codings of rotations give valid Wang tiling is the easy part. The most difficult part is to show that any tiling in the Jeandel-Rao Wang shift correspond to the coding with respect to the polygonal partition of the orbit under the $\mathbb{Z}^2$-rotation of some starting point on the 2-torus. The proof of this has to be inspired by the proof of the equivalent result for sturmian sequences.

Let us recall the main steps of the proof that any sturmian sequence is the coding of an irrational rotation \cite{Arn02}, see also the summary done in the first section of \cite{Thu17}. The strategy is to show
they both have a common substitutive structure involving the substitutions \( \tau_a = (a \mapsto a, b \mapsto ab) \), \( \tau_b = (a \mapsto ab, b \mapsto b) \) and the unsorted Farey map \( f(x) = \frac{x}{1-x} \) if \( 0 \leq x \leq \frac{1}{2} \) and \( f(x) = \frac{2x-1}{x} \) if \( \frac{1}{2} < x \leq 1 \) \( [AL18] \). More precisely,

1. Using combinatorial arguments based on factor complexity and balance, sturmian sequences \( S_\alpha \) of slope \( \alpha \) can be desubstituted indefinitely:

\[
S_\alpha \overset{\omega_0}{\leftarrow} S_{f(\alpha)} \overset{\omega_1}{\leftarrow} S_{f^2(\alpha)} \overset{\omega_2}{\leftarrow} S_{f^3(\alpha)} \overset{\omega_3}{\leftarrow} \ldots
\]

with \( \omega_i \in \{\tau_a, \tau_b\} \) for every \( i \) where \( f \) is the Farey map.

2. Using induced maps and Rauzy induction, coding \( C_\alpha \subset \{a, b\}^\mathbb{Z} \) of rotations \( R_\alpha \) on the circle \( \mathbb{R}/\mathbb{Z} \) can be desubstituted indefinitely:

\[
C_\alpha \overset{\omega_0}{\leftarrow} C_{f(\alpha)} \overset{\omega_1}{\leftarrow} C_{f^2(\alpha)} \overset{\omega_2}{\leftarrow} C_{f^3(\alpha)} \overset{\omega_3}{\leftarrow} \ldots
\]

with \( \omega_i \in \{\tau_a, \tau_b\} \) for every \( i \) where \( f \) is the Farey map.

3. The sequence of substitutions \( (\omega_i)_{i \in \mathbb{N}} = \tau_a^{\alpha_0} \tau_b^{\alpha_1} \ldots \) gives the continued fraction expansion of \( \alpha = [a_0; a_1, \ldots] \). The sequence of shifts done after each substitution gives the Ostrowski expansion of the starting point \( x_0 \in \mathbb{T} \) with respect to \( \alpha \) \( [Arn02, \text{Thm 6.4.23}] \).

We follow the same proof plan for Jeandel-Rao tilings. Due to the space needed to introduce various different tools, the proof was split. Part (1) of the proof was done in two previous publications. Using combinatorial arguments based on the definition of marker tiles, algorithms were proposed in \( \text{[Lab18b]} \) to describe the substitutive structure of Jeandel-Rao tilings. We obtained a sequence of 2-dimensional substitutions which is ultimately periodic with a quite long preperiod. The periodic part corresponds to a self-similar aperiodic Wang tile set of cardinality 19 described in \( \text{[Lab18a]} \).

This reminds of Lagrange’s theorem which states that \( \alpha \) is a quadratic irrational if and only if the continued fraction expansion of \( \alpha \) is ultimately periodic. In that case, the sequence of substitutions describing a sturmian sequence of slope \( \alpha \) is also ultimately periodic. This is what happens for the Fibonacci word but also as it turns out in the 2-dimensional setup for some Wang shifts including Jeandel-Rao tilings.

The next step is to follow part (2) of the proof for sturmian sequences and this is the goal of the current contribution. In this work, we define the notion of induced \( \mathbb{Z}^2 \)-actions and more importantly of partitions of the 2-torus induced by \( \mathbb{Z}^2 \)-actions. These 2-dimensional induced \( \mathbb{Z}^2 \)-actions and partitions admit renormalization schemes as in the classic 1-dimensional setting. We prove that the two partitions introduced in \( \text{[Lab19a]} \) are related through this induction and renormalization process. In particular, we prove that the partition of \( \mathbb{R}^2/\mathbb{Z}^2 \) into 19 atoms associated to the 19 Wang tile set is self-induced with the same substitution as the one computed in \( \text{[Lab18a]} \).

From the partition coding Jeandel-Rao tilings, the 2-dimensional induction process gives a sequence of substitutions here which is exactly the same as the sequence of substitutions computed in \( \text{[Lab18b]} \) from the Jeandel-Rao Wang tiles themselves. As for sturmian sequences, we have 2-dimensional Wang shifts and shifts defined as the coding of \( \mathbb{Z}^2 \)-rotations on the 2-torus which have the same substitutive structure. As a consequence, this shows that the minimal subshift \( X_0 \subseteq \Omega_0 \) constructed by substitutions in \( \text{[Lab18b]} \) is equal (or even topologically conjugate) to the symbolic dynamical system \( X_{\mathcal{P}_0, R_0} \) introduced in \( \text{[Lab19a]} \). In other words, we prove that any Jeandel-Rao Wang tiling in \( X_0 \subsetneq \Omega_0 \) is the coding under the partition \( \mathcal{P}_0 \) of the \( \mathbb{Z}^2 \)-rotation \( R_0 \) on the torus \( \mathbb{R}^2/\Gamma_0 \).

In this work, we define the induction of \( \mathbb{Z}^2 \)-actions and of induced partitions of the 2-torus and we concentrate our attention on Jeandel-Rao tilings and on its internal self-similar structure. It is worth noticing that there must exists other examples of simple aperiodic sequences \( \mathbb{Z}^2 \rightarrow \mathcal{A} \) where the method works and why not in larger dimensions. It could be the case that the most
simple aperiodic sequences $\mathbb{Z}^d \to \mathcal{A}$ are also coded by irrational $\mathbb{Z}^2$-rotations on $\mathbb{T}^d$. This calls for a general theory of $d$-dimensional subshifts of finite type coded by Markov partitions of the $d$-dimensional torus and admitting induced subsystems.

**Structure of the article.** The introduction is followed by a short section explaining informally and visually the classical 1-dimensional induction. The remaining of the article is divided into four parts. The first part gathers the preliminary notions. The second part introduces the notions of induction of $\mathbb{Z}^2$-actions, induced partitions of the 2-torus and renormalization schemes. The third proves that the Markov partition of $\mathbb{R}^2/\mathbb{Z}^2$ introduced in [Lab19a] is self-induced and that the corresponding substitution is the same as the one given in [Lab18a] to describe a self-similar Wang tile set of cardinality 19. In the fourth section, we induce the partition proposed in [Lab19a] to get a sequence of substitutions until we reach a self-induced partition. We show that the self-induced partition is isomorphic to the one presented in the third part and we prove that the substitutive structure obtained from the induction procedure is the same as the substitutive structure computed directly from the Jeandel-Rao Wang tiles in [Lab18b].

**Acknowledgements.** I am thankful to Vincent Delecroix for many helpful discussions at LaBRI in Bordeaux during the preparation of this article which allowed me to improve my knowledge on dynamical systems and Rauzy induction. I want to thank Nathalie Priebe Frank for her patience because it took me much longer than I thought to explain and write down what I meant by 'just induce' during a conversation at CIRM (Tiling and Recurrence, Marseille, December 2017, organized by Pierre Arnoux and Shigeki Akiyama).

I acknowledge financial support from the Laboratoire International Franco-Québécois de Recherche en Combinatoire (LIRCO), the Agence Nationale de la Recherche through the project CODYS (ANR-18-CE40-0007) and the Horizon 2020 European Research Infrastructure project OpenDreamKit (676541).

2. **One-dimensional induction**

A glyph from Sir Arthur Conan Doyle’s *The Adventure of the Dancing Men* is walking on a sidewalk made of alternating red bricks of size 1 and blue bricks of size $\alpha > 1$. It walks from left to right with step size 1 and uses its left foot on blue bricks and its right foot on red bricks, thus constructing a walking sequence, that is, a biinfinite binary sequence $w_0$ in $\{\blacklozenge, \blacktriangleleft\}^\mathbb{Z}$. If $\alpha = \frac{3}{110}\sqrt{5} + \frac{75}{22} \approx 3.47007$, the walking sequence may look like the following.

![Walking sequence diagram](image)

Such binary sequences are called mechanical sequences [MH40]. They are also obtained as the coding under the partition $[-1,0)$ and $[0,\alpha)$ of a rotation $x \mapsto x+1$ on the circle $\mathbb{R}/(1+\alpha)\mathbb{Z}$. A more recent treatment on mechanical sequences is this chapter from Lothaire’s book [Lot02, Chap. 2]. As noted by Morse and Hedlund, the structure of repetitions in these sequences is described by the continued fraction expansion of the number $\alpha \in \mathbb{R}$. In the simpler case when the origin of the walk is at the left-end side of a blue brick, the statement can be written as follows.
Theorem 1. [Arn02, § 6.4] Let \( \alpha \in \mathbb{R}_{>0} \setminus \mathbb{Q} \). Consider the partition of the circle \( \mathbb{R}/(1+\alpha)\mathbb{Z} \) into red bricks \([-1,0) + (1 + \alpha)\mathbb{Z} \) and blue bricks \([0,\alpha) + (1 + \alpha)\mathbb{Z} \). Let \( w : \mathbb{Z} \to \{\text{blue bricks}, \text{red bricks}\} \) be the walking sequence starting at 0 with step size 1 using the left foot on blue bricks and the right foot on red bricks. Then the substitutive structure of \( w \) is

\[
\lim_{n \to \infty} \tau_{a_0} \tau_{a_1} \ldots \tau_{a_{n-1}} (\text{blue bricks}, \text{red bricks})
\]

where

\[
(1) \quad \tau_{2n} = \begin{cases} 
\begin{array}{c}
\text{blue bricks} \\
\text{red bricks}
\end{array} & \quad \text{and } \tau_{2n+1} = \begin{cases} 
\begin{array}{c}
\text{red bricks} \\
\text{blue bricks}
\end{array}
\end{cases}
\end{cases}
\]

for all \( n \geq 0 \) and \( \alpha = [a_0; a_1, a_2, \ldots] \) is the continuous fraction expansion of \( \alpha \).

For general starting point on the circle, the walking sequence has the same substitutive structure as in the theorem but one must add a certain amount \( b_n \in \mathbb{N} \) of shifts after each substitution \( \tau_{a_n} \) with \( 0 \leq b_n \leq a_n \) and the sequence \( (b_n)_{n \in \mathbb{N}} \) of shifts is given by the expansion of the origin of the walk in the Ostrowski numeration system [Arn02, Theorem 6.4.21].

The proof of Theorem 1 is based on induced transformations (first return maps) of irrational rotations on the circle. In general, the first return map of a rotation to an interval is a 3-interval exchange transformation (IET) but for some particular values for the length of the interval, it may be a 2-IET which corresponds to a rotation [Rau77]. This allows to desubstitute a mechanical sequence and write it as the image of another mechanical sequence using a procedure known as Rauzy induction for general k-IETs.

Proof by the example of Theorem 1. Let \( \alpha = \frac{3}{119} \sqrt{5} + \frac{75}{22} \approx 3.47007 \) whose continued fraction expansion is

\[ \alpha = [3; 2, 7, (1, 5)^*] = 3 + \frac{1}{[2; 7, (1, 5)^*]} \]

It is one of the root of the polynomial \( p(x) = 55x^2 - 375x + 639 \). To understand the structure of the walking sequence of parameter \( \alpha \), we may do the following observation: each right foot step is preceded (and succeeded) by \( \lfloor \alpha \rfloor = 3 \) left foot steps. We may prove that it is always the case. Thus using the substitution

\[ \sigma_0 : \begin{array}{c}
\text{blue bricks} \\
\text{red bricks}
\end{array} \quad \text{and } \begin{array}{c}
\text{red bricks} \\
\text{blue bricks}
\end{array} \]

we may recover the original walking sequence if we forget the three left foot steps that precedes any right foot step.

The three removed left steps are always done on the last three unit size part of the blue bricks drawn in dashed white and any steps done on a white unit size brick belongs to some removed steps. Thus we may remove the white part of the side walk, glue the remaining blocks together and we get a new walk still of step size 1 but with a new value of \( \{\alpha\} = \alpha - \lfloor \alpha \rfloor \) for the length of the blue brick.
Now a less evident observation is that a walk with steps $+1$ from a given starting point is equivalent to a walk with steps $-\{\alpha\}$ from the same starting point. The reason is that we are basically walking on $\mathbb{R}/(1 + \{\alpha\})\mathbb{Z}$, that is, a circle of circumference $1 + \{\alpha\}$.

Therefore, we may rescale that negative size step walk going from right to left by the factor $-\frac{1}{\{\alpha\}}$ to get a walk with positive step size $+1$ on a sidewalk made of blue bricks of size 1 and red bricks of size $G(\alpha) = \frac{1}{\{\alpha\}}$.

We remark that it is the same sequence of steps as before the rescaling, the only difference being that colored bricks now correspond to left-open right-closed intervals of the real line $\mathbb{R}$ instead of left-closed right-open intervals. Thus this shows that the original walk $w_0 \in \{,\}^\mathbb{Z}$ corresponding to red bricks of size $\alpha$ can be written as the image under the substitution $\sigma_1$ of the newly created walk, that is,

$$w_0 = \sigma_0(w_1) = \tau_0^{[\alpha]}(w_1)$$

where $w_1$ is a walk on a side walk with red bricks of size $G(\alpha) > 1$ now larger than the blue bricks of size 1. The relation with the continued fraction expansion follows from the fact that

$$\alpha = [\alpha] + \frac{1}{G(\alpha)}.$$

We can iterate the process $n$ times to get

$$w_0 = \sigma_0\sigma_1 \ldots \sigma_{n-1}(w_n) = \tau_0^{a_n}\tau_1^{a_1} \ldots \tau_{n-1}^{a_{n-1}}(w_n)$$
for all \( n \geq 0 \) where \( \tau_{2n} \) and \( \tau_{2n+1} \) are as in Equation (1), \( w_n \) is a walk on a side walk with larger bricks of size \( G^n(\alpha) \) (of color red or blue depending on the parity of \( n \)) and \( \alpha = [a_0; a_1, a_2, \ldots] \) is the continuous fraction expansion of \( \alpha \).

Theorem [1] giving the substitutive structure of walking sequences is what allows to make the link between mechanical sequences and sturmian sequences defined as aperiodic sequences of factor complexity \( n + 1 \).

In this work, we consider 2-dimensional walking sequences \( w \in \mathcal{A}^{\mathbb{Z}^2} \) for some alphabet \( \mathcal{A} \) obtained from the coding of a \( \mathbb{Z}^2 \)-walk on a \( \Gamma \)-invariant partition of \( \mathbb{R}^2 \) for some lattice \( \Gamma \subset \mathbb{R}^2 \). After introducing the necessary notions in Part [1] we introduce the induction of \( \mathbb{Z}^2 \)-actions and partitions of a 2-torus in Part [2] which is inspired from the above proof of Theorem [1].

Part 1. Preliminaries

This part is divided into four sections on dynamical systems, subshifts and Wang tilings; two-dimensional words and morphisms; symbolic representation of \( \mathbb{Z}^2 \)-actions; and polygonal exchange transformations.

3. Dynamical systems, subshifts and Wang tilings

In this section, we introduce dynamical systems, subshifts, shifts of finite type, Wang tiles and Wang shifts. We denote by \( \mathbb{Z} = \{\ldots, -1, 0, 1, 2, \ldots\} \) the integers and by \( \mathbb{N} = \{0, 1, 2, \ldots\} \) the non-negative integers. If \( d \geq 1 \) is an integer and \( 1 \leq k \leq d \), we denote by \( e_k = (0, \ldots, 0, 1, 0, \ldots, 0) \in \mathbb{Z}^d \) the vector of the canonical basis of \( \mathbb{Z}^d \) with a 1 at position \( k \) and 0 elsewhere.

3.1. Topological dynamical systems. Most of the notions introduced here can be found in [Wal82]. A dynamical system is a triple \((X, G, T)\), where \( X \) is a topological space, \( G \) is a topological group and \( T \) is a continuous function \( G \times X \to X \) defining a left action of \( G \) on \( X \): if \( x \in X \), \( e \) is the identity element of \( G \) and \( g, h \in G \), then using additive notation for the operation in \( G \) we have \( T(e, x) = x \) and \( T(g + h, x) = T(g, T(h, x)) \). In other words, if one denotes the transformation \( x \mapsto T(g, x) \) by \( T^g \), then \( T^{g + h} = T^g T^h \). In this work, we consider the abelian group \( G = \mathbb{Z} \times \mathbb{Z} \).

If \( Y \subset X \), we denote the topological closure of \( Y \) as \( \overline{Y} \) and the \( T \)-closure of \( Y \) as \( \overline{Y}^T := \cup_{g \in G} T^g(Y) \). A subset \( Y \subset X \) is \( T \)-invariant if \( \overline{Y}^T = Y \). A dynamical system \((X, G, T)\) is called minimal if \( X \) does not contain any nonempty, proper, closed \( T \)-invariant subset. The left action of \( G \) on \( X \) is free if \( g = e \) whenever there exists \( x \in X \) such that \( T^g(x) = x \).

Let \((X, G, T)\) and \((Y, G, S)\) be two dynamical systems using the same topological group \( G \). A homomorphism \( \theta : (X, G, T) \to (Y, G, S) \) is a continuous function \( \theta : X \to Y \) satisfying the commuting property that \( T^g \circ \theta = \theta \circ S^g \) for every \( g \in G \). A homomorphism \( \theta : (X, G, T) \to (Y, G, S) \) is said to be an embedding if it is one-to-one, a factor map if it is onto, and a topological conjugacy if it is both one-to-one and onto and its inverse map is continuous. If \( \theta : (X, G, T) \to (Y, G, S) \) is a factor map, then \((Y, G, S)\) is called a factor of \((X, G, T)\) and \((X, G, T)\) is called an extension of \((Y, G, S)\). Two subshifts are topologically conjugate if there is a topological conjugacy between them.

A measure-preserving dynamical system is defined as a system \((X, G, T, \mu, \mathcal{B})\), where \( \mu \) is a probability measure defined on the \( \sigma \)-algebra \( \mathcal{B} \) of subsets of \( X \), and \( T^g : X \to X \) is a measurable map which preserves the measure \( \mu \) for all \( g \in G \), that is, \( \mu(T^g(B)) = \mu(B) \) for all \( B \in \mathcal{B} \). The measure \( \mu \) is said to be \( T \)-invariant.

The set of all \( T \)-invariant probability measures of a dynamical system \((X, G, T)\) is denoted \( \mathcal{M}^T(X) \). An invariant probability measure on \( X \) is said ergodic if for every set \( B \in \mathcal{B}, T^g(B) = B \) with \( g \in G \setminus \{e\} \) implies that \( B \) has either zero of full measure. A dynamical system \((X, G, T)\)
is **uniquely ergodic** if it has only one invariant probability measure, i.e., $|\mathcal{M}^T(X)| = 1$. A dynamical system $(X, G, T)$ is said **strictly ergodic** if it is uniquely ergodic and minimal.

Let $(X, T, \mu, \mathcal{B})$ and $(X', T', \mu', \mathcal{B}')$ be two measure-preserving dynamical systems. We say that the two systems are **isomorphic** if there exists measurable sets $X_0 \subset X$ and $X'_0 \subset X'$ of full measure (i.e., $\mu(X \setminus X_0) = 0$ and $\mu'(X' \setminus X'_0) = 0$) with $T(X_0) \subset X_0$, $T'(X'_0) \subset X'_0$, and there exists a map $\phi : X_0 \to X'_0$, called an **isomorphism**, that is one-to-one and onto and such that for all $A \in \mathcal{B}'(X'_0)$,

- $\phi^{-1}(A) \in \mathcal{B}(X_0)$,
- $\mu(\phi^{-1}(A)) = \mu'(A)$, and
- $\phi \circ T(x) = T' \circ \phi(x)$ for all $x \in X_0$.

The role of the set $X_0$ is to make precise the fact that the properties of the isomorphism need to hold only on a set of full measure.

### 3.2. Subshifts and shifts of finite type.

We follow the notations of [Sch01]. Let $\mathcal{A}$ be a finite set, $d \geq 1$, and let $\mathcal{A}^{\mathbb{Z}^d}$ be the set of all maps $x : \mathbb{Z}^d \to \mathcal{A}$, furnished with the compact product topology. We write a typical point $x \in \mathcal{A}^{\mathbb{Z}^d}$ as $x = (x_m) = (x_m : m \in \mathbb{Z}^d)$, where $x_m \in \mathcal{A}$ denotes the value of $x$ at $m$. The topology $\mathcal{A}^{\mathbb{Z}^d}$ is compatible with the metric $\delta$ defined for all colorings $x, x' \in \mathcal{A}^{\mathbb{Z}^d}$ by $\delta(x, x') = 2^{-\text{min}\{\|m\| : x_m \neq x'_m\}}$. The **shift action** $\sigma : n \mapsto \sigma^n$ of $\mathbb{Z}^d$ on $\mathcal{A}^{\mathbb{Z}^d}$ is defined by

$$\sigma^n(x)_m = x_{m+n}$$

for every $x = (x_m) \in \mathcal{A}^{\mathbb{Z}^d}$ and $n \in \mathbb{Z}^d$. If $X \subset \mathcal{A}^{\mathbb{Z}^d}$, we denote the topological closure of $X$ as $\overline{X}$ and the shift-closure of $X$ as $\sigma(X) = \{\sigma^n(x) \mid x \in X, n \in \mathbb{Z}^d\}$. A subset $X \subset \mathcal{A}^{\mathbb{Z}^d}$ is **shift-invariant** if $\sigma(X) = X$ and a closed, shift-invariant subset $X \subset \mathcal{A}^{\mathbb{Z}^d}$ is a **subshift**. If $X \subset \mathcal{A}^{\mathbb{Z}^d}$ is a subshift we write $\sigma = \sigma^X$ for the restriction of the shift-action (2) to $X$. If $X \subset \mathcal{A}^{\mathbb{Z}^d}$ is a subshift it will sometimes be helpful to specify the shift-action of $\mathbb{Z}^d$ explicitly and to write $(X, \sigma)$ instead of $X$. When $X$ is a subshift, the triple $(X, \mathbb{Z}^d, \sigma)$ is a dynamical system and the notions presented in the previous section hold. We say that a nonempty subshift $X$ is **aperiodic** if the shift-action $\sigma$ on $X$ is free.

For any subset $S \subset \mathbb{Z}^d$ we denote by $\pi_S : \mathcal{A}^{\mathbb{Z}^d} \to \mathcal{A}^S$ the projection map which restricts every $x \in \mathcal{A}^{\mathbb{Z}^d}$ to $S$. A **pattern** is a function $p : S \to \mathcal{A}$ for some finite subset $S \subset \mathbb{Z}^d$. To every pattern $p : S \to \mathcal{A}$ correspond a subset $\pi_S^{-1}(p) \subset \mathcal{A}^{\mathbb{Z}^d}$ called **cylinder**. A subshift $X \subset \mathcal{A}^{\mathbb{Z}^d}$ is a **shift of finite type** (SFT) if there exists a finite set $\mathcal{F}$ of **forbidden** patterns such that

$$X = \{x \in \mathcal{A}^{\mathbb{Z}^d} \mid \pi_S \cdot \sigma^n(x) \notin \mathcal{F} \text{ for every } n \in \mathbb{Z}^d \text{ and } S \subset \mathbb{Z}^d \}.$$  

In this case, we write $X = \text{SFT}(\mathcal{F})$. In this contribution, we consider tilings of $\mathbb{Z} \times \mathbb{Z}$, that is, the case $d = 2$.

### 3.3. Wang shifts.

A **Wang tile** $\tau = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$ is a unit square with colored edges formally represented as a tuple of four colors $(a, b, c, d) \in I \times J \times I \times J$ where $I$, $J$ are two finite sets (the vertical and horizontal colors respectively). For each Wang tile $\tau = (a, b, c, d)$, we denote by $\text{RIGHT}(\tau) = a$, $\text{TOP}(\tau) = b$, $\text{LEFT}(\tau) = c$, $\text{BOTTOM}(\tau) = d$ the colors of the right, top, left and bottom edges of $\tau$ [Wan61,Rob71].

Let $\mathcal{T}$ be a set of Wang tiles. A **tiling of $\mathbb{Z}^2$** by $\mathcal{T}$ is a function $x : \mathbb{Z}^2 \to \mathcal{T}$ which assigns tiles to each position of $\mathbb{Z}^2$ so that contiguous edges have the same color, that is,

- $\text{RIGHT}(x_n) = \text{LEFT}(x_{n+e_1})$
- $\text{TOP}(x_n) = \text{BOTTOM}(x_{n+e_2})$
for every \( n \in \mathbb{Z}^2 \). We denote by \( \Omega_T \subset \mathbb{T}^2 \) the set of all Wang tilings of \( \mathbb{Z}^2 \) by \( T \) and we call it the **Wang shift** of \( T \). Together with the shift action \( \sigma \) of \( \mathbb{Z}^2 \) on \( \mathbb{A}^2 \), it is a SFT of the form \( [3] \).

A set of Wang tiles \( T \) tiles the plane if \( \Omega_T \not= \emptyset \) and does not tile the plane if \( \Omega_T = \emptyset \). A tiling \( x \in \Omega_T \) is periodic if there is a nonzero period \( n \in \mathbb{Z}^2 \setminus \{(0,0)\} \) such that \( x = \sigma^n(x) \) and otherwise it is said nonperiodic. A set of Wang tiles \( T \) is periodic if there is a tiling \( x \in \Omega_T \) which is periodic. A Wang tile set \( T \) is aperiodic if the subshift \( \Omega_T \not= \emptyset \) is aperiodic.

### 4. Two-dimensional words and morphisms

In this section, we reuse the notations from [Lab18a] and [Lab18b] on \( d \)-dimensional words, morphisms and self-similar subshifts.

#### 4.1. \( d \)-dimensional word

In this section, we recall the definition of \( d \)-dimensional word that appeared in [CKR10] and we keep the notation \( u \circ_i v \) they proposed for the concatenation.

If \( i \leq j \) are integers, then \([i,j]\) denotes the interval of integers \( \{i,i+1,\ldots,j\}\). Let \( n = (n_1,\ldots,n_d) \in \mathbb{N}^d \) and \( A \) be an alphabet. We denote by \( A^n \) the set of functions \( u : [0,n_1-1] \times \cdots \times [0,n_d-1] \to A \).

An element \( u \in A^n \) is called a **\( d \)-dimensional word** \( u \) of shape \( n = (n_1,\ldots,n_d) \in \mathbb{N}^d \) on the alphabet \( A \). The set of all finite \( d \)-dimensional word is \( A^* = \{ A^n \mid n \in \mathbb{N}^d \} \). When the context is clear, we write \( A \) instead of \( A^{(1,\ldots,1)} \). When \( d = 2 \), we represent a \( d \)-dimensional word \( u \) of shape \((n_1,n_2)\) as a matrix with Cartesian coordinates:

\[
\begin{pmatrix}
u_{0,0} & \ldots & u_{0,n_2-1} \\
\ldots & \ldots & \ldots \\
u_{n_1-1,0} & \ldots & u_{n_1-1,n_2-1}
\end{pmatrix}
\]

Let \( n, m \in \mathbb{N}^d \) and \( u \in A^n \) and \( v \in A^m \). If there exists an index \( i \) such that the shapes \( n \) and \( m \) are equal except at index \( i \), then the **concatenation of \( u \) and \( v \) in the direction \( e_i \)** is well-defined: it is the \( d \)-dimensional word \( u \circ_i v \) of shape \((n_1,\ldots,n_{i-1},n_i+m_i,n_{i+1},\ldots,n_d) \in \mathbb{N}^d \) defined as

\[
(\circ_i u)(a) = \begin{cases} 
u(a) & \text{if } 0 \leq a_i < n_i, \\
u(a - n_i e_i) & \text{if } n_i \leq a_i < n_i + m_i.
\end{cases}
\]

If the shapes \( n \) and \( m \) are not equal except at index \( i \), we say that the concatenation of \( u \in A^n \) and \( v \in A^m \) in the direction \( e_i \) is **not well-defined**.

Let \( n, m \in \mathbb{N}^d \) and \( u \in A^n \) and \( v \in A^m \). We say that \( u \) occurs in \( v \) at position \( p \in \mathbb{N}^d \) if \( v \) is large enough, i.e., \( m - p + n \in \mathbb{N}^d \) and

\[
v(a+p) = u(a)
\]

for all \( a = (a_1,\ldots,a_d) \in \mathbb{N}^d \) such that \( 0 \leq a_i < n_i \) with \( 1 \leq i \leq d \). If \( u \) occurs in \( v \) at some position, then we say that \( u \) is a \( d \)-dimensional **subword** or **factor** of \( v \).

#### 4.2. \( d \)-dimensional morphisms

In this section, we generalize the definition of \( d \)-dimensional morphisms [CKR10] to the case where the domain and codomain are different, see also [Moz89].

Let \( A \) and \( B \) be two alphabets. Let \( X \subseteq A^d \). A function \( \omega : X \to B^d \) is a **\( d \)-dimensional morphism** if for every \( i \) with \( 1 \leq i \leq d \), and every \( u,v \in X \) such that \( u \circ_i v \in X \) is well-defined we have that the concatenation \( \omega(u) \circ_i \omega(v) \) in direction \( e_i \), is well-defined and

\[
\omega(u \circ_i v) = \omega(u) \circ_i \omega(v).
\]

When \( A = B \), we say that a \( d \)-dimensional morphism \( \omega : A \to A^d \) is **expansive** if for every \( a \in A \) and \( K \in \mathbb{N} \), there exists \( m \in \mathbb{N} \) such that \( \min(\text{SHAPE}(\omega^m(a)) > K \).

We say that \( \omega \) is **primitive** if there exists \( m \in \mathbb{N} \) such that for every \( a,b \in A \) the letter \( b \) occurs in \( \omega^m(a) \).
A \(d\)-dimensional morphism \(\omega : X \to \mathcal{B}^d\) with \(X \subseteq \mathcal{A}^d\) can be extended to a \(d\)-dimensional morphism \(\omega : Y \to \mathcal{B}^d\) on \(Y \subseteq \mathcal{A}^d\) with the principle that the origin of \(\omega(y) \in \mathcal{B}^d\) is at the origin of the word \(\omega(y_0)\).

4.3. Self-similar subshifts. In this section we consider subshifts defined from substitutions leading to self-similar structures. Given a \(d\)-dimensional morphism \(\omega : \mathcal{A} \to \mathcal{B}^d\) we define the image of a subshift \(X \subseteq \mathcal{A}^d\) under \(\omega\) as the subshift
\[
\omega(X)^\sigma = \{\sigma^k \omega(u) \mid k \in \mathbb{Z}^d, u \in X\} \subseteq \mathcal{B}^d.
\]

A subshift \(X \subseteq \mathcal{A}^d\) is \textit{self-similar} if there exists an expansive \(d\)-dimensional morphism \(\omega : \mathcal{A} \to \mathcal{A}^d\) such that \(X = \omega(X^\sigma)\).

Self-similar subshifts can be constructed by iterative application of the morphism \(\omega\) starting with the letters. The \textit{language} \(L_\omega\) defined by an expansive \(d\)-dimensional morphism \(\omega : \mathcal{A} \to \mathcal{A}^d\) is
\[L_\omega = \{u \in \mathcal{A}^d \mid u \text{ is a } d\text{-dimensional subword of } \omega^n(a) \text{ for some } a \in \mathcal{A} \text{ and } n \in \mathbb{N}\}.
\]
The \textit{substitutive shift} \(X_\omega\) defined as
\[X_\omega = \{w \in \mathcal{A}^d \mid u \in L_\omega \text{ for every subword of } w\}\]
is a self-similar subshift. If \(\omega\) is primitive, then \(X_\omega\) is the smallest nonempty subshift \(X \subseteq \mathcal{A}^d\) satisfying \(X = \omega(X^\sigma)\).

\[\text{Lemma 2. Let } \omega : \mathcal{A} \to \mathcal{A}^d \text{ be an expansive and primitive } d\text{-dimensional morphism. Let } X \subseteq \mathcal{A}^d \text{ be a self-similar subshift such that } X = \omega(X^\sigma). \text{ Then } X = X_\omega.\]

5. Symbolic representation of \(\mathbb{Z}^2\)-actions

This section follows the section [LM95, §6.5] on Markov partitions where we adapt it to the case of invertible \(\mathbb{Z}^2\)-actions. This section is the same as in [Lab9a] and hence every proof of this section are omitted.

A \textit{topological partition} of a metric space \(M\) is a finite collection \(\{P_0, P_1, ..., P_{r-1}\}\) of disjoint open sets whose closures \(\overline{P}_j\) together cover \(M\) in the sense that \(M = \overline{P}_0 \cup \overline{P}_1 \cup \cdots \cup \overline{P}_{r-1}\).

Suppose that \(M\) is a compact metric space, \((M, \mathbb{Z}^2, R)\) is an invertible dynamical system and that \(\mathcal{P} = \{P_0, P_1, ..., P_{r-1}\}\) is a topological partition of \(M\). Let \(\mathcal{A} = \{0, 1, \ldots, r - 1\}\) and \(S \subseteq \mathbb{Z}^2\) be a finite set. We say that a pattern \(w : S \to \mathcal{A}\) is \textit{allowed} for \(\mathcal{P}, R\) if
\[
\bigcap_{k \in S} R^{-k}(P_{w_k}) \neq \emptyset.
\]

Let \(L_{\mathcal{P}, R}\) be the collection of all allowed patterns for \(\mathcal{P}, R\). It can be checked that \(L_{\mathcal{P}, R}\) is the language of a subshift. Hence, using standard arguments [LM95, Prop. 1.3.4], there is a unique subshift \(X_{\mathcal{P}, R} \subseteq \mathcal{A}^d\) whose language is \(L_{\mathcal{P}, R}\). We call \(X_{\mathcal{P}, R}\) the \textit{symbolic dynamical system corresponding to} \(\mathcal{P}, R\). For each \(w \in X_{\mathcal{P}, R} \subseteq \mathcal{A}^d\) and \(n \geq 0\) there is a corresponding nonempty open set
\[D_n(w) = \bigcap_{\|k\| \leq n} R^{-k}(P_{w_k}) \subseteq M.
\]
The closures \(\overline{D}_n(w)\) of these sets are compact and decrease with \(n\), so that \(\overline{D}_0(w) \supseteq \overline{D}_1(w) \supseteq \overline{D}_2(w) \supseteq \ldots\). It follows that \(\bigcap_{n=0}^\infty \overline{D}_n(w) \neq \emptyset\). In order for points in \(X_{\mathcal{P}, R}\) to correspond to points in \(M\), this intersection should contain only one point. This leads to the following definition.

A topological partition \(\mathcal{P}\) of \(M\) gives a \textit{symbolic representation} of \((M, \mathbb{Z}^2, R)\) if for every \(w \in X_{\mathcal{P}, R}\) the intersection \(\bigcap_{n=0}^\infty \overline{D}_n(w)\) consists of exactly one point \(m \in M\). We call \(w\) a \textit{symbolic
representation of $m$. We call $\mathcal{P}$ a Markov partition for $(M, \mathbb{Z}^2, R)$ if $\mathcal{P}$ gives a symbolic representation of $(M, \mathbb{Z}^2, R)$ and furthermore $X_{\mathcal{P}, R}$ is a shift of finite type.

5.1. Symbolic representation of $\mathbb{Z}^2$-rotations on the torus. From now on, we assume that the compact metric space $M$ is a 2-torus. Let $T$ be a lattice in $\mathbb{R}^2$, i.e., a discrete subgroup of the additive group $\mathbb{R}^2$ such that the quotient space has finite invariant measure. This defines a 2-torus $T = \mathbb{R}^2 / T$. For some $\alpha, \beta \in T$, we consider the dynamical system $(T, \mathbb{Z}^2, R)$ where $R : \mathbb{Z}^2 \times T \to T$ is the action defined by

$$R^n(x) := R(n, x) = x + n_1 \alpha + n_2 \beta$$

for every $n = (n_1, n_2) \in \mathbb{Z}^2$. The map $R$ is a continuous $\mathbb{Z}^2$-action on $T$.

**Lemma 3.** Let $(T, \mathbb{Z}^2, R)$ be a minimal dynamical system and $\mathcal{P} = \{P_0, P_1, \ldots, P_r\}$ be a topological partition of $T$. If there exists an atom $P_i$ which is invariant only under the trivial translation in $T$, then $\mathcal{P}$ gives a symbolic representation of $(T, \mathbb{Z}^2, R)$.

The set

$$\Delta_{\mathcal{P}, R} := \bigcup_{n \in \mathbb{Z}^2} R^n \left( \bigcup_{a \in A} \partial P_a \right) \subset T$$

is the set of points whose orbit under the $\mathbb{Z}^2$-action of $R$ intersect the boundary of the topological partition $\mathcal{P} = \{P_a\}_{a \in A}$. From Baire Category Theorem [LM95, Theorem 6.1.24], the set $T \setminus \Delta_{\mathcal{P}, R}$ is dense in $T$. For every starting point $x \in T \setminus \Delta_{\mathcal{P}, R}$, the coding of its orbit under the $\mathbb{Z}^2$-action of $R$ is a well-defined 2-dimensional word:

$$\text{ORBIT}^{\mathcal{P}, R}_x : \mathbb{Z} \times \mathbb{Z} \to A$$

$$n \mapsto a \quad \text{if and only if} \quad R^n(x) \in P_a.$$  

**Lemma 4.** The symbolic dynamical system $X_{\mathcal{P}, R}$ corresponding to $\mathcal{P}, R$ is the topological closure of the set of orbits:

$$X_{\mathcal{P}, R} = \overline{\text{ORBIT}^{\mathcal{P}, R}_x \mid x \in T \setminus \Delta_{\mathcal{P}, R}}$$

**Lemma 5.** Let $\mathcal{P}$ gives a symbolic representation of the dynamical system $(T, \mathbb{Z}^2, R)$. Then

(i) if $(T, \mathbb{Z}^2, R)$ is minimal, then $(X_{\mathcal{P}, R}, \mathbb{Z}^2, \sigma)$ is minimal,

(ii) if $R$ is a free $\mathbb{Z}^2$-action on $T$, then $X_{\mathcal{P}, R}$ aperiodic.

6. Polygon exchange transformations

When the $\mathbb{Z}^2$-action $R$ is a $\mathbb{Z}^2$-rotation on the torus $T$, the maps $R^{e_1}$ and $R^{e_2}$ can be seen as polygon exchange transformations [Hoo13, Sch14] on a fundamental domain of $T$.

**Definition 6.** [AKY18] Let $X$ be a polygon together with two topological partitions of $X$ into polygons

$$X = \bigcup_{k=0}^{N} P_k = \bigcup_{k=0}^{N} Q_k$$

such that for each $k$, $P_k$ and $Q_k$ are translation equivalent, i.e., there exists $v_k \in \mathbb{R}^2$ such that $P_k = Q_k + v_k$. A polygon exchange transformation (PET) is the piecewise translation on $X$ defined for $x \in P_k$ by $T(x) = x + v_k$. The map is not defined for points $x \in \cup_{k=0}^{N} \partial P_k$.

The fact that a rotation on a circle can be seen as an exchange of two intervals is well-known as noticed for example in [Rau77]. It generalizes in higher dimension where a generic translation on a $d$-dimensional torus is a polyhedron exchange transformation defined by the exchange of at most $2^d$ pieces on a fundamental domain having for shape a $n$-dimensional parallelootope. We state a 2-dimensional version of this lemma restricted to the case of rectangular fundamental domain because
we use this connection several times in the following sections to prove that induced \( \mathbb{Z}^2 \)-actions are again \( \mathbb{Z}^2 \)-rotations on a torus.

**Lemma 7.** Let \( \Gamma = \ell_1 \mathbb{Z} \times \ell_2 \mathbb{Z} \) be a lattice in \( \mathbb{R}^2 \) and its rectangular fundamental domain \( D = [0, \ell_1) \times [0, \ell_2) \). For every \( \alpha = (\alpha_1, \alpha_2) \in D \), the dynamical system \((\mathbb{R}^2/\Gamma, \mathbb{Z}, x \mapsto x + \alpha)\) is measurably conjugate to the dynamical system \((D, \mathbb{Z}, T)\) where \( T: D \to D \) is the polygon exchange transformation shown in Figure 1.

**Figure 1.** The polygon exchange transformation \( T \) of the rectangle \([0, \ell_1) \times [0, \ell_2)\) as defined on the figure can be seen as a toral translation by the vector \((\alpha_1, \alpha_2)\) on the torus \( \mathbb{R}^2/(\ell_1 \mathbb{Z} \times \ell_2 \mathbb{Z}) \).

**Proof.** It follows from the fact that toral rotations and such polygon exchange transformations are the cartesian product of circle rotations and exchange of two intervals.

**Part 2. Induction of \( \mathbb{Z}^2 \)-actions and induced partitions of the 2-torus**

### 7. Induced \( \mathbb{Z}^2 \)-actions

Renormalization schemes also known as *Rauzy induction* were originally defined for dynamical system including interval exchange transformations (IET) \([\text{Rau79}]\). A natural way to generalize it to higher dimension is to consider polygon exchange transformations \([\text{Hoo13}, \text{AKY18}]\) or even polytope exchange transformations \([\text{Sch14}, \text{Sch16}]\) where only one map is considered. But more dimensions also allows to induce two or more (commuting) maps at the same time.

In this section, we define the induction of \( \mathbb{Z}^2 \)-actions on a subdomain. We consider the torus \( T = \mathbb{R}^2/\Gamma \) where \( \Gamma \) is a lattice in \( \mathbb{R}^2 \). Let \( \alpha_1, \alpha_2 \in \mathbb{R}^2 \) and consider the \( \mathbb{Z}^2 \)-action \( R: \mathbb{Z}^2 \times T \to T \) defined by

\[
R^n(x) := R(n, x) = x + n_1 \alpha_1 + n_2 \alpha_2
\]

for every \( n = (n_1, n_2) \in \mathbb{Z}^2 \). We assume that \( R \) is a minimal action on \( T \). For every \( n \in \mathbb{Z}^2 \), the toral translation \( R^n \) can be seen as polygon exchange transformations on a fundamental domain of \( T \).

The set of return times of \( x \in T \) to a window \( W \subset T \) under the action \( R \) is the subset of \( \mathbb{Z} \times \mathbb{Z} \) defined as:

\[
\delta_W(x) = \{ n \in \mathbb{Z} \times \mathbb{Z} \mid R^n(x) \in W \}.
\]

We say that the \( \mathbb{Z}^2 \)-action \( R \) is cartesian on a window \( W \subset T \) if for all \( x \in T \) there exists two strictly increasing sequences \( r_x^{(1)}, r_x^{(2)}: \mathbb{Z} \to \mathbb{Z} \) such that the set of return times is the cartesian product of their ranges, i.e.,

\[
\delta_W(x) = r_x^{(1)}(\mathbb{Z}) \times r_x^{(2)}(\mathbb{Z}).
\]

We always assume that the sequences are shifted in such a way that

\[
r_x^{(i)}(n) \geq 0 \iff n \geq 0 \quad \text{for } i \in \{1, 2\}.
\]

In particular, if \( x \in W \), then \((0, 0) \in \delta_W(x)\), so that \( r_x^{(1)}(0) = r_x^{(2)}(0) = 0 \).
When the $\mathbb{Z}^2$-action $R$ is cartesian on a window $W \subset T$, we say that the tuple
\[ (r_x^{(1)}(1), r_x^{(2)}(1)) \]
is the first return time of a starting point $x \in T$ to a window $W \subset T$ under the action $R$.

When the $\mathbb{Z}^2$-action $R$ is cartesian on a window $W \subset T$, we may consider its return map on $W$ and we prove in the next lemma that this gives a $\mathbb{Z}^2$-action on $W$. More precisely, we define the induced $\mathbb{Z}^2$-action $\hat{R}|_W : \mathbb{Z}^2 \times W \to W$ by
\[ (\hat{R}|_W)^n(x) := \hat{R}|_W(n, x) = R^{(r_x^{(1)}(n_1), r_x^{(2)}(n_2))}(x) \]
for every $n = (n_1, n_2) \in \mathbb{Z}^2$.

**Lemma 8.** If the $\mathbb{Z}^2$-action $R$ is cartesian on a window $W \subset T$, then $\hat{R}|_W : \mathbb{Z}^2 \times W \to W$ is a well-defined $\mathbb{Z}^2$-action.

**Proof.** Let $x \in W$. We have that
\[ \hat{R}|_W(0, x) = R^{(r_x^{(1)}(0), r_x^{(2)}(0))}(x) = R^{(0,0)}(x) = x. \]

Firstly, using
\[ r_x^{(i)}(k + n) = r_{R^{(0,0)}(x)}^{(i)}(k) + r_x^{(i)}(n), \]
and skipping few details, we get
\[ \hat{R}|_W(k \mathbf{e}_i + n \mathbf{e}_i, x) = \hat{R}|_W(k \mathbf{e}_i, \left(\hat{R}|_W(n \mathbf{e}_i, x)\right)). \]
Secondly, using the fact that
\[ r_x^{(1)}(k_1) = r_y^{(1)}(k_1) \]
whenever $y = R^{(0,r_x^{(2)}(k_2))}x = \hat{R}|_W(k_2 \mathbf{e}_2, x)$, we obtain
\[ \hat{R}|_W(k, x) = R^{(r_x^{(1)}(k_1), r_x^{(2)}(k_2))}(x) = R^{(r_x^{(1)}(k_1), 0)}R^{(0,r_x^{(2)}(k_2))}(x) = R^{(r_x^{(1)}(k_1), 0)}\hat{R}|_W(k_2 \mathbf{e}_2, x) = \hat{R}|_W(k_1 \mathbf{e}_1, \hat{R}|_W(k_2 \mathbf{e}_2, x)). \]
Therefore, for every $k, n \in \mathbb{Z}^2$, we have
\[ (\hat{R}|_W)^{k+n}(x) = (\hat{R}|_W)^{(k_1+n_1)\mathbf{e}_1}(\hat{R}|_W)^{(k_2+n_2)\mathbf{e}_2}(x) = (\hat{R}|_W)^{k_1\mathbf{e}_1}(\hat{R}|_W)^{n_1\mathbf{e}_1}(\hat{R}|_W)^{k_2\mathbf{e}_2}(\hat{R}|_W)^{n_2\mathbf{e}_2}(x) = (\hat{R}|_W)^{k_1\mathbf{e}_1}(\hat{R}|_W)^{n_1\mathbf{e}_1}(\hat{R}|_W)^{k_2\mathbf{e}_2}(\hat{R}|_W)^{n_2\mathbf{e}_2}(x) = (\hat{R}|_W)^{k}(\hat{R}|_W)^{n}(x), \]
which shows that $\hat{R}|_W$ is a $\mathbb{Z}^2$-action on $W$. $\square$

A consequence of the lemma is that the $\mathbb{Z}^2$-action $\hat{R}|_W$ is generated by two commutative maps
\[ (\hat{R}|_W)^{e_1}(x) = R^{(r_x^{(1)}(0), 0)}(x) \quad \text{and} \quad (\hat{R}|_W)^{e_2}(x) = R^{(0,r_x^{(2)}(0))}(x) \]
which are the first return maps of $R^{e_1}$ and $R^{e_2}$ to $W$:
\[ (\hat{R}|_W)^{e_1}(x) = \hat{R}|_W(e_1(x)) \quad \text{and} \quad (\hat{R}|_W)^{e_2}(x) = \hat{R}|_W(e_2(x)). \]
Recall that the first return map $\hat{T}|_W$ of a dynamical system $(X, T)$ maps a point $x \in W \subset X$ to the first point in the forward orbit of $T$ lying in $W$, i.e.
\[ \hat{T}|_W(x) = T^{r(x)}(x) \quad \text{where} \quad r(x) = \min\{k \in \mathbb{Z}_{>0} : T^k(x) \in W\}. \]
From Poincaré’s recurrence theorem, if \( \mu \) is a finite \( T \)-invariant measure on \( X \), then the first return map \( T|_W \) is well defined for \( \mu \)-almost all \( x \in W \). When \( T \) is a translation on a torus, if the subset \( W \) is open, then the first return map is well-defined for every point \( x \in W \). Moreover if \( W \) is a polygon, then the first return map \( T|_W \) is a polygon exchange transformation.

8. Partitions of the torus induced by \( \mathbb{Z}^2 \)-actions

For IETs, the interval on which we define the Rauzy induction is usually given by one of the atom of the partition which defines the IET itself. In our setting, it is not the case. The partition that we use carries more information than the natural partition which allows to define the \( \mathbb{Z}^2 \)-action \( R \) as a pair of polygon exchange transformations. The partition is a refinement of the natural partition involving well-chosen sloped lines.

Let \( \mathcal{P} = \{P_a\}_{a \in A} \) be a topological partition of \( T \) together with its coding map
\[
\text{Code} : \ T \setminus (\bigcup_{a \in A} \partial P_a) \to A
\]
\[
x \mapsto a \quad \text{if and only if} \quad x \in P_a.
\]
For every starting point \( x \in T \setminus \Delta_{\mathcal{P}, R} \), the coding of its orbit under the \( \mathbb{Z}^2 \)-action of \( R \) defines a 2-dimensional word
\[
\text{Orbit}^{\mathcal{P}, R}_x : \ \mathbb{Z} \times \mathbb{Z} \to A
\]
\[
n \mapsto \text{Code}(R^n(x)).
\]
If the \( \mathbb{Z}^2 \)-action \( R \) is cartesian on a window \( W \subset T \), then we define the return word map as
\[
\text{ReturnWord} : \ W \to A^*^2
\]
\[
x \mapsto \left( \begin{array}{ccc}
\text{Code}(R^{0,s-1}(x)) & \cdots & \text{Code}(R^{(r-1,s-1)}(x)) \\
\cdots & \cdots & \cdots \\
\text{Code}(R^{0,0}(x)) & \cdots & \text{Code}(R^{(r-1,0)}(x))
\end{array} \right),
\]
in which we use \( r = r_1(x) \) and \( s = r_2(x) \) to simplify the notations.

The image \( \mathcal{L} = \text{ReturnWord}(W) \subset A^*^2 \) is a language called the set of return words. When the return time to \( W \) is bounded, the set of return words \( \mathcal{L} \) is finite. Let \( \mathcal{L} = \{w_b\}_{b \in \mathcal{B}} \) be an enumeration of \( \mathcal{L} \) for some finite set \( \mathcal{B} \). The induced partition of \( \mathcal{P} \) by the action of \( R \) on the subdomain \( W \) is a topological partition of \( W \) defined as the set of preimage sets under \( \text{ReturnWord} \):
\[
\tilde{\mathcal{P}}|_W = \{\text{ReturnWord}^{-1}(w_b)\}_{b \in \mathcal{B}}.
\]
This yields the induced coding on \( W \)
\[
\text{Code}|_W : \ W \to \mathcal{B}
\]
\[
y \mapsto b \quad \text{if and only if} \quad y \in \text{ReturnWord}^{-1}(w_b).
\]
A natural substitution comes out of this induction procedure:
\[
\omega : \ \mathcal{B} \to A^*^2
\]
\[
b \mapsto w_b.
\]

The partition \( \tilde{\mathcal{P}}|_W \) of \( W \) can be effectively computed by refining the partition \( \mathcal{P} \) with the window \( W \) with several copies of \( \mathcal{P} \) under action \( R \). We do not provide a formula for this here. The next result shows that it is possible to write the coding of the orbit under the \( \mathbb{Z}^2 \)-action \( R \) as the image under the 2-dimensional substitution \( \omega \) of the coding of the orbit under the \( \mathbb{Z}^2 \)-action \( \tilde{R}|_W \).

\[\text{In practice, the way the enumeration is done is important for instance in the case of self-induced systems. When the words are 1-dimensional, we order by default the words } w_b \in \mathcal{L} \text{ by length and then lexicographically.}\]
Lemma 9. If the $\mathbb{Z}^2$-action $R$ is cartesian on a window $W \subset T$, then $\omega$ is a 2-dimensional morphism, and for every $x \in W$ we have

$$\text{Orbit}^{\mathcal{P}, R}_x = \omega \left( \text{Orbit}^{\mathcal{P}|_W, \hat{R}|_W}_x \right).$$

Proof. Let $x \in W$. By hypothesis, there exists $P, Q \subset \mathbb{Z}$ such that the set of returns times satisfies $\delta_W(x) = P \times Q$ and we may write $P = \{r_i\}_{i \in \mathbb{Z}}$ and $Q = \{s_j\}_{j \in \mathbb{Z}}$ as increasing sequences such that $r_0 = s_0 = 0$. Therefore, $\text{Orbit}^{\mathcal{P}, R}_x$ may be decomposed into a lattice of rectangular blocks. More precisely, for every $i, j \in \mathbb{Z}$, the following block is the image of a letter under $\omega$:

$$\left( \text{Code}(R^{(r_i, s_j+1)}x) \cdots \text{Code}(R^{(r_i+1, s_j+1)}x) \right) = \text{ReturnWord}(R^{(r_i, s_j)}x) = w_{i,j} = \omega(b_{i,j})$$

for some letter $b_{i,j} \in \mathcal{B}$. Moreover,

$$b_{i,j} = \text{Code}|_W(R^{(r_i, s_j)}x) = \text{Code}|_W \left( (\hat{R}|_W)^{(i,j)}x \right).$$

Since the adjacent blocks have matching dimensions, for every $i, j \in \mathbb{Z}$, the following concatenations

$$\omega \left( b_{i,j} \circ 1 b_{(i+1),j} \right) = \omega \left( b_{i,j} \right) \circ 1 \omega \left( b_{(i+1),j} \right) \quad \text{and} \quad \omega \left( b_{i,j} \circ 2 b_{i,(j+1)} \right) = \omega \left( b_{i,j} \right) \circ 2 \omega \left( b_{i,(j+1)} \right)$$

are well defined. Thus $\omega$ is a 2-dimensional morphism on the set $\{ \text{Orbit}^{\mathcal{P}|_W, \hat{R}|_W}_x \mid x \in W \}$ and we have

$$\text{Orbit}^{\mathcal{P}, R}_x = \omega \left( \text{Orbit}^{\mathcal{P}|_W, \hat{R}|_W}_x \right)$$

which ends the proof. Note that the domain of $\omega$ can be extended to its topological closure.

\[ \square \]

Proposition 10. Let $\mathcal{P}$ be a topological partition of $T$. If the $\mathbb{Z}^2$-action $R$ is cartesian on a window $W \subset T$, then $\chi_{\mathcal{P}, R} = \omega(\chi_{\mathcal{P}|_W, \hat{R}|_W})$.

Proof. Let

$$Y = \left\{ \text{Orbit}^{\mathcal{P}, R}_x \mid x \in T \right\} \quad \text{and} \quad Z = \left\{ \text{Orbit}^{\mathcal{P}|_W, \hat{R}|_W}_x \mid x \in W \right\},$$

$(\supseteq)$. Let $x \in W$. From Lemma 9, $\omega \left( \text{Orbit}^{\mathcal{P}|_W, \hat{R}|_W}_x \right) = \text{Orbit}^{\mathcal{P}, R}_x$ with $x \in W \subset T$. $(\subseteq)$. Let $x \in T$. There exists $k_1, k_2 \in \mathbb{N}$ such that $x' = R^{-(k_1, k_2)}(x) \in W$. Therefore, we have $x = R^{(k_1, k_2)}(x')$ where $0 \leq k_1 < r(x')$ and $0 \leq k_2 < s(x')$. Thus the shift $k = (k_1, k_2) \in \mathbb{Z}^2$ is bounded by the maximal return time of $R^{e_1}$ and $R^{e_2}$ to $W$. We have

$$\text{Orbit}^{\mathcal{P}, R}_x = \text{Orbit}^{\mathcal{P}, R}_{R^k x'} = \sigma^k \circ \text{Orbit}^{\mathcal{P}, R}_{x'} = \sigma^k \circ \omega \left( \text{Orbit}^{\mathcal{P}|_W, \hat{R}|_W}_{x'} \right)$$

where we used Lemma 9 with $x' \in W$. We conclude that $Y = \overline{\omega(Z)}$. The result follows from Lemma 4 by taking the topological closure on both sides.

\[ \square \]

Including the first vs the last letter. We finish with a remark on the definition of the return word map. There is a choice to be made in its definition whether we include the first or the last letter of the orbit that comes back to the window (vertically and horizontally). For example, another option is to define return words that includes the last letter instead of the first letter. In general, for each value of $\epsilon_1, \epsilon_2 \in \{0, 1\}$, we may define

$$\text{ReturnWord}_{\epsilon_1, \epsilon_2} : W \rightarrow \mathcal{A}^2$$

$$x \mapsto \left( \text{Code}(R^{(\epsilon_1, \epsilon_2, s-1)}x) \cdots \text{Code}(R^{(\epsilon_1+r-1, \epsilon_2+s-1)}x) \right)$$

where $\mathcal{A}^2 = \mathcal{A} \times \mathcal{A}$. This map allows for a different choice of endpoints in the definition of return words, giving rise to a variant of the return word map that includes the last letter of the orbit instead of the first.
where \(r = r_x^{(1)}(x)\) and \(s = r_x^{(2)}(x)\). An alternative is to consider ReturnWord for the \(\mathbb{Z}^2\)-actions \(R^{(-n_1,n_2)}, R^{(n_1,-n_2)}\) or \(R^{(-n_1,-n_2)}\) and taking horizontal and/or vertical mirror images of the obtained return words.

9. Renormalization schemes

In what follows, we define a renormalization scheme on a topological partition of the domain \(X\) together with a dynamical systems \((X, \mathbb{Z}^2, R)\) defined by a \(\mathbb{Z}^2\)-action \(R\) on \(X\).

Sometimes, when \(R\) is a \(\mathbb{Z}^2\)-action on \(X\), the induced \(\mathbb{Z}^2\)-action \(R|_W\) can be renormalized as a \(\mathbb{Z}^2\)-action on the original domain \(X\). This leads to the definition of renormalization schemes. The following definition is inspired from [AKY18] and adapted to the case dynamical systems defined by \(\mathbb{Z}^2\)-actions.

Definition 11. A dynamical system \((X, \mathbb{Z}^2, R)\) has a renormalization scheme if there exists a proper subset \(W \subset X\), a homeomorphism \(\phi : W \to X\), a renormalized dynamical system \((X, \mathbb{Z}^2, R')\) such that

\[
(R')^n = \phi \circ (R|_W)^n \circ \phi^{-1}
\]

for all \(n \in \mathbb{Z}^2\), meaning that the following diagram commute:

\[
\begin{array}{ccc}
W & \xrightarrow{\phi} & X \\
\downarrow & & \downarrow \\
(R|_W)^n & \xrightarrow{\phi} & (R')^n \\
W & \xrightarrow{\phi} & X
\end{array}
\]

The dynamical system \((X, \mathbb{Z}^2, R)\) is self-induced if it is equal to the renormalized one, that is, if \(R = R'\).

Now we define the renormalization of a topological partition \(\mathcal{P} = \{P_a\}_{a \in A}\) of \(X\). If a dynamical system \((X, \mathbb{Z}^2, R)\) has a renormalization scheme with the same notations as above, then the induced partition \(\mathcal{P}|_W = \{Q_b\}_{b \in B}\) of \(W\) can be renormalized as a partition

\[
\phi(\mathcal{P}|_W) = \{\phi(Q_b)\}_{b \in B}
\]

of \(X\). If the dynamical system \((X, \mathbb{Z}^2, R)\) is self-induced and \(A = B\) and \(\mathcal{P} = \phi(\mathcal{P}|_W)\), then we say that the topological partition \(\mathcal{P}\) of \(X\) is self-induced.

Proposition 12. Let \(\mathcal{P}\) be a topological partition of \(T\) and suppose that the \(\mathbb{Z}^2\)-action \(R\) is cartesian on a window \(W \subset T\). If \(\mathcal{P}\) is self-induced, then \(\chi_{\mathcal{P}, R}\) is self-similar satisfying \(\chi_{\mathcal{P}, R} = \omega(\chi_{\mathcal{P}, R}^\sigma)\)

where \(\omega\) is the 2-dimensional morphism defined in Eq. (4).

Proof. From Proposition 10, we have \(\chi_{\mathcal{P}, R} = \omega(\chi_{\mathcal{P}|_W, R|_W})^\sigma\). It remains to show \(\chi_{\mathcal{P}, R} = \chi_{\mathcal{P}|_W, R|_W}\).

Since \(\mathcal{P}\) is self-induced, we have CODE\(_{|_W} = CODE \circ \phi\). Thus for every \(m, n \in \mathbb{Z}\) and every \(x \in W\), we have

\[
\text{ORBIT}^{\mathcal{P}|_W, R|_W}_x(n) = \text{CODE}_{|_W} \circ (R|_W)^n(x) = \text{CODE} \circ \phi \circ (R|_W)^n(x) = \text{CODE} \circ (R)^n \circ \phi(x) = \text{ORBIT}^{\mathcal{P}, R}_{\phi(x)}(n).
\]

Since \(\phi : W \to T\) is a homeomorphism, we obtain

\[
\chi_{\mathcal{P}, R} = \left\{\text{ORBIT}^{\mathcal{P}, R}_x \mid x \in T\right\} = \left\{\text{ORBIT}^{\mathcal{P}, R}_{\phi(x)} \mid x \in W\right\} = \left\{\text{ORBIT}^{\mathcal{P}|_W, R|_W}_x \mid x \in W\right\} = \chi_{\mathcal{P}|_W, R|_W}
\]

and the conclusion follows. \(\square\)
Part 3. A self-induced partition of $\mathbb{T}^2$

Whenever $i \leq j$ are integers, then $[i, j]$ denotes the interval of integers $\{i, i + 1, \ldots, j\}$.

10. Inducing the $\mathbb{Z}^2$-action $R_\mathcal{U}$ and the partition $\mathcal{P}_\mathcal{U}$ of $\mathbb{T}^2$

In this section, we present an example of a self-induced partition of the torus $\mathbb{T}^2 = (\mathbb{R}/\mathbb{Z})^2$. We consider the dynamical system $(\mathbb{T}^2, \mathbb{Z}^2, R_\mathcal{U})$ defined by the $\mathbb{Z}^2$-action

$$R_\mathcal{U} : \mathbb{Z}^2 \times \mathbb{T}^2 \rightarrow \mathbb{T}^2$$

$$(n, x) \mapsto x + \varphi^{-2}n$$

where $\varphi = \frac{1 + \sqrt{5}}{2}$. We consider the Markov partition $\mathcal{P}_\mathcal{U} = \{P_a\}_{a \in [0, 18]}$ for the dynamical system $(\mathbb{T}^2, \mathbb{Z}^2, R_\mathcal{U})$ that was introduced in [Lab19a]. It is illustrated in Figure 2. The topological partition $\mathcal{P}_\mathcal{U}$ defines a coding map $\text{Code}_{\mathcal{U}} : \mathbb{T}^2 \rightarrow [0, 18]$.

![Figure 2. The topological partition $\mathcal{P}_\mathcal{U}$ of $\mathbb{T}^2$ using alphabet $[0, 18]$ for the atoms.](image)

**Theorem 13.** The topological partition $\mathcal{P}_\mathcal{U}$ is self-induced and the set $\mathcal{X}_{\mathcal{P}_\mathcal{U}, R_\mathcal{U}}$ is self-similar satisfying $\mathcal{X}_{\mathcal{P}_\mathcal{U}, R_\mathcal{U}} = \beta_\mathcal{U}(\mathcal{X}_{\mathcal{P}_\mathcal{U}, R_\mathcal{U}})^2$ where $\beta_\mathcal{U} : [0, 18] \rightarrow [0, 18]^2$ is defined as

$$\beta_\mathcal{U} : \begin{cases} 0 \mapsto (17) , & 1 \mapsto (16) , & 2 \mapsto (15, 11) , & 3 \mapsto (13, 9) , \\ 4 \mapsto (17, 8) , & 5 \mapsto (16, 8) , & 6 \mapsto (15, 8) , & 7 \mapsto (14, 8) , \\ 8 \mapsto \left(\frac{6}{14}, \frac{3}{17}\right) , & 9 \mapsto \left(\frac{3}{17}, \frac{16}{2}\right) , & 10 \mapsto \left(\frac{3}{16}, \frac{2}{14}\right) , & 11 \mapsto \left(\frac{2}{14}, \frac{1}{2}\right) , \\ 12 \mapsto \left(\frac{7}{15}, \frac{1}{11}\right) , & 13 \mapsto \left(\frac{1}{11}, \frac{13}{9}\right) , & 14 \mapsto \left(\frac{13}{9}, \frac{6}{12}\right) , & 15 \mapsto \left(\frac{6}{12}, \frac{1}{2}\right) , \\ 16 \mapsto \left(\frac{5}{18}, \frac{1}{13}\right) , & 17 \mapsto \left(\frac{1}{13}, \frac{8}{14}\right) , & 18 \mapsto \left(\frac{8}{14}, \frac{2}{0}\right) . \end{cases}$$

**Proof.** Let $x \in \mathbb{T}^2$ and consider $\text{Orbit}^\mathcal{P_\mathcal{U}}_{\mathcal{X}} : \mathbb{Z}^2 \rightarrow [0, 18]$ obtained as the coding under $\text{Code}_{\mathcal{U}}$ of the orbit of the starting point $x \in \mathbb{T}^2$ under the $\mathbb{Z}^2$-action $R_\mathcal{U}$. Let $W = [0, \varphi^{-1}] \times [0, \varphi^{-1}]$. The first return time to $W$ under both the maps $R^1_\mathcal{U}$ and $R^2_\mathcal{U}$ is 1 or 2. The values for the first return time under the $\mathbb{Z}^2$-action $R_\mathcal{U}$ yield a topological partition $\{\mathcal{A}, \mathcal{B}, \mathcal{C}, \mathcal{D}\}$ of $W$ defined as

$$\begin{align*} \mathcal{A} &= (0, \varphi^{-3}) \times (0, \varphi^{-3}) , & \mathcal{B} &= (\varphi^{-3}, \varphi^{-1}) \times (0, \varphi^{-3}) , \\ \mathcal{C} &= (0, \varphi^{-3}) \times (\varphi^{-3}, \varphi^{-1}) , & \mathcal{D} &= (\varphi^{-3}, \varphi^{-1}) \times (\varphi^{-3}, \varphi^{-1}) . \end{align*}$$
The first return return time of $A$ under $R_U$ is $(1, 1)$. The first return return time of $B$ under $R_U$ is $(2, 1)$. The first return return time of $C$ under $R_U$ is $(1, 2)$. The first return return time of $D$ under $R_U$ is $(2, 2)$. The partition is shown in Figure 3 together with the images of the atoms under $R_U$ until it returns to $W$. 

\begin{figure}[h]
\centering
\begin{tabular}{|c|c|c|}
\hline
\$\frac{1}{\varphi^3}$ & $A$ & $B$ \\
\hline
\$\frac{1}{\varphi}$ & $\mathcal{R}_U^{(1,0)}(B)$ & \$\mathcal{R}_U^{(1,1)}(D)$ \\
\hline
\$1$ & $\mathcal{R}_U^{(0,1)}(D)$ & $\mathcal{R}_U^{(1,1)}(D)$ \\
\hline
\end{tabular}
\end{figure}

\begin{figure}[h]
\centering
\begin{tabular}{|c|c|c|}
\hline
\$\frac{1}{\varphi^3}$ & $\mathcal{R}_U^{(2,1)}(D)$ & $\mathcal{R}_U^{(1,1)}(D)$ \\
\hline
\$\frac{1}{\varphi}$ & $\mathcal{R}_U^{(2,1)}(B)$ & $\mathcal{R}_U^{(1,1)}(B)$ \\
\hline
$1$ & $\mathcal{R}_U^{(2,2)}(D)$ & $\mathcal{R}_U^{(2,1)}(D)$ \\
\hline
\end{tabular}
\end{figure}

**Figure 3.** The set \{A, B, C, D\} forms a partition of the rectangle W. We consider the first return to W. The orbit of A, B, C and D under $R_U$ before it returns to W yields two partitions of $\mathbb{T}^2$.

The $\mathbb{Z}^2$-action $R_U$ is cartesian on the window $W$. Thus from Lemma 8, the induced $\mathbb{Z}^2$-action $\overline{R_U}|_W : \mathbb{Z}^2 \times W \to W$ given by

$$ (\overline{R_U}|_W)^n(x) = (\overline{R_U}|_W)^{n_1} \circ (\overline{R_U}|_W)^{n_2}(x), $$

for every $n = (n_1, n_2) \in \mathbb{Z}^2$, is well-defined.

Both first return maps $\overline{R_U}^1|_W$ and $\overline{R_U}^2|_W$ are defined as exchanges of rectangles among \{A, B, C, D\}. Thus using Lemma 7, we may identify $W$ with the torus $(\mathbb{R}/\mathbb{Z})^2$ and define the induced $\mathbb{Z}^2$-action as toral rotations on $(\mathbb{R}/\mathbb{Z})^2$:

$$ (\overline{R_U}|_W)^n(x) = x - \varphi^{-3}n \mod \left(\frac{1}{\varphi}\mathbb{Z}\right)^2 $$

Thus we have that the return word function is

**ReturnWord**: $W \to [0, 18]^2$

$$ x \mapsto \begin{cases} 
\text{CODE}_U(x) & \text{if } x \in A, \\
\left(\text{CODE}_U(x), \text{CODE}_U(R_U^{(1,0)}x)\right) & \text{if } x \in B, \\
\left(\text{CODE}_U(R_U^{(0,1)}x)\right) & \text{if } x \in C, \\
\left(\text{CODE}_U(R_U^{(0,1)}x), \text{CODE}_U(R_U^{(1,1)}x)\right) & \text{if } x \in D.
\end{cases} $$
We get the set of return words \( \mathcal{L} = \text{ReturnWord}(W) \) with
\[
\mathcal{L} = \left\{ \begin{array}{llllll}
  w_0 = (17), & w_1 = (16), & w_2 = (15, 11), & w_3 = (13, 9), \\
  w_4 = (17, 8), & w_5 = (16, 8), & w_6 = (15, 8), & w_7 = (14, 8), \\
  w_8 = \left( \begin{array}{c}
  6 \\
  14
\end{array} \right), & w_9 = \left( \begin{array}{c}
  3 \\
  17
\end{array} \right), & w_{10} = \left( \begin{array}{c}
  3 \\
  16
\end{array} \right), & w_{11} = \left( \begin{array}{c}
  2 \\
  14
\end{array} \right), \\
  w_{12} = \left( \begin{array}{c}
  7 \\
  15 \\
  11
\end{array} \right), & w_{13} = \left( \begin{array}{c}
  6 \\
  14 \\
  11
\end{array} \right), & w_{14} = \left( \begin{array}{c}
  7 \\
  13 \\
  9
\end{array} \right), & w_{15} = \left( \begin{array}{c}
  6 \\
  12 \\
  9
\end{array} \right), \\
  w_{16} = \left( \begin{array}{c}
  5 \\
  18 \\
  10
\end{array} \right), & w_{17} = \left( \begin{array}{c}
  4 \\
  13 \\
  9
\end{array} \right), & w_{18} = \left( \begin{array}{c}
  2 \\
  14 \\
  8
\end{array} \right).
\end{array} \right.
\]

The induced partition to \( W \) by \( R_\mathcal{U} \) is
\[
\widetilde{\mathcal{P}}_\mathcal{U}|_W = \{\text{ReturnWord}^{-1}(w_b)\}_{b \in [0,18]}
\]
which is a topological partition of \( W \) made of 19 atoms, see Figure 4. The induced coding is
\[
\text{CODE}_\mathcal{U}|_W : \ W \rightarrow [0,18] \quad y \mapsto b \quad \text{if and only if} \quad y \in \text{ReturnWord}^{-1}(w_b).
\]

![Figure 4. The induced topological partition \( \widetilde{\mathcal{P}}_\mathcal{U}|_W \) of \( \mathbb{R}/\mathbb{Z}^2 \).](image)

A natural substitution comes out of this construction:
\[
\beta_\mathcal{U} : \ [0,18] \rightarrow [0,18]^* \\
\ b \mapsto w_b
\]
which corresponds to the one defined in Equation (5).

As shown in Figures 2 and 4, the partitions defined by the preimages of CODE_\mathcal{U} and CODE_\mathcal{U}|_W are the same up to homothety by \(-\varphi\). Moreover the action \( R_\mathcal{U} \) on \( \mathbb{T}^2 \) correspond to the action \( \widetilde{R}_\mathcal{U}|_W \) on \( W \). We now formalize these observations. Let \( h : (\mathbb{R}/\varphi^{-1}\mathbb{Z})^2 \rightarrow (\mathbb{R}/\mathbb{Z})^2 \) be the homeomorphism defined by \( h(x) = -\varphi x \). We may verify that the following diagram commute:
\[
\begin{array}{ccc}
(\mathbb{R}/\varphi^{-1}\mathbb{Z})^2 & \xrightarrow{h} & (\mathbb{R}/\mathbb{Z})^2 \\
(\widetilde{R}|_W)^n \downarrow & & \downarrow h^n \\
(\mathbb{R}/\varphi^{-1}\mathbb{Z})^2 & \xrightarrow{h} & (\mathbb{R}/\mathbb{Z})^2
\end{array}
\]
for every \( n \in \mathbb{Z}^2 \). Therefore, the dynamical system \((\mathbb{T}^2, \mathbb{Z}^2, R_\mathcal{U})\) is self-induced.

Moreover \( \mathcal{A} = [0,18] = \mathcal{B} \) and \( \mathcal{P}_\mathcal{U} = h(\widetilde{\mathcal{P}}_\mathcal{U}|_W) \), so that \( \mathcal{P}_\mathcal{U} \) is self-induced. From Proposition 12, we conclude that \( \mathcal{X}_{\mathcal{P}_\mathcal{U}, R_\mathcal{U}} \) is self-similar satisfying \( \mathcal{X}_{\mathcal{P}_\mathcal{U}, R_\mathcal{U}} = \beta_\mathcal{U}(\mathcal{X}_{\mathcal{P}_\mathcal{U}, R_\mathcal{U}})^\theta \).
As a consequence the symbolic dynamical system $X_{P_U,R_U}$ is exactly equal to the substitutive subshift $X_{\beta_U}$.

**Corollary 14.** $X_{\beta_U} = X_{P_U,R_U}$

**Proof.** From Theorem 13, we have $X_{P_U,R_U}$ is self-similar satisfying $X_{P_U,R_U} = \beta_U(X_{P_U,R_U})^\sigma$. The 2-dimensional morphism $\beta_U$ is expansive and primitive. From Lemma 2 we deduce that $X_{\beta_U} \subseteq X_{P_U,R_U}$.

From Lemma 3 the partition $P_U$ gives a symbolic representation of the dynamical system $(\mathbb{T}^2, \mathbb{Z}^2, R_U)$. The dynamical system $(\mathbb{T}, \mathbb{Z}^2, R)$ is minimal. Thus from Lemma 5 $(X_{P_U,R_U}, \mathbb{Z}^2, \sigma)$ is minimal. The equality $X_{\beta_U} = X_{P_U,R_U}$ follows from the minimality of $X_{P_U,R_U}$. \(\square\)

We observe that Corollary 14 was proved and the 2-dimensional morphism $\beta_U$ was computed exclusively from the partition $P_U$ and the induction of the $\mathbb{Z}^2$-action $R_U$ on $\mathbb{T}^2$.

### Part 4. Substitutive structure of $X_{P_0,R_0}$: just induce!

In this part, we start with the partition associated to Jeandel-Rao Wang tilings and construct a sequence of induced partition until the induction process loops. The proof can be verified with a computer. The Sage code to reproduce the computations of all induced $\mathbb{Z}^2$-actions and induced partitions is in the appendix.
12. Inducing the $\mathbb{Z}^2$-action $R_0$ and the partition $\mathcal{P}_0$ to get $\mathcal{X}_{P_1,R_1}$

Let $\Gamma_0 = \langle (\varphi,0), (1,\varphi+3) \rangle_\mathbb{Z}$ be a lattice with $\varphi = \frac{1+\sqrt{5}}{2}$. We consider the dynamical system $(\mathbb{R}^2/\Gamma_0, \mathbb{Z}^2, R_0)$ defined by the $\mathbb{Z}^2$-action

$$R_0 : \mathbb{Z}^2 \times \mathbb{R}^2/\Gamma_0 \to \mathbb{R}^2/\Gamma_0$$

$$(n, x) \mapsto x + n.$$

We consider the topological partition $\mathcal{P}_0$ of $\mathbb{R}^2/\Gamma_0$ illustrated in Figure 5 on a fundamental domain where each atom is associated to a letter in the alphabet $A_0 = [0,10]$. The partition $\mathcal{P}_0$ defines a coding map $\text{Code}_0 : \mathbb{R}^2/\Gamma_0 \to A_0$ and it was proved in [Lab19a] that the coding of orbits under the $\mathbb{Z}^2$-action $R_0$ are valid Wang tilings using the 11 Wang tiles from Jeandel-Rao tile set.

![Figure 5](image_url)

**Figure 5.** The partition $\mathcal{P}_0$ of $\mathbb{R}^2/\Gamma_0$ into atoms associated to letters in $A_0$ illustrated on a rectangular fundamental domain.

**Proposition 18.** Let $(\mathbb{R}^2/\Gamma_1, \mathbb{Z}^2, R_1)$ be a dynamical system with lattice $\Gamma_1 = \varphi \mathbb{Z} \times \mathbb{Z}$ and $\mathbb{Z}^2$-action

$$R_1 : \mathbb{Z}^2 \times \mathbb{R}^2/\Gamma_1 \to \mathbb{R}^2/\Gamma_1$$

$$(n, x) \mapsto x + n_1 e_1 + n_2 (\varphi^{-1}, \varphi^{-2}).$$

Let $\mathcal{P}_1$ be the topological partition illustrated in Figure 8 where each atom is associated to a letter in $A_1 = [0,27]$. Then $\mathcal{X}_{P_0,R_0} = \beta_0(\mathcal{X}_{P_1,R_1})^\sigma$ where $\beta_0 : A_1^{\mathbb{Z}^2} \to A_0^{\mathbb{Z}^2}$ is the 2-dimensional morphism.
defined by

\[
\begin{align*}
0 &\mapsto (7, 3, 9, 0), & 1 &\mapsto (7, 9, 0, 0), & 2 &\mapsto (4, 10, 9, 1), & 3 &\mapsto (7, 3, 9, 1), & 4 &\mapsto (6, 3, 9, 1), & 5 &\mapsto (8, 3, 9, 1), & 6 &\mapsto (2, 7, 9, 1), \\
7 &\mapsto (5, 7, 1), & 8 &\mapsto (5, 7, 1), & 9 &\mapsto (7, 5, 1), & 10 &\mapsto (4, 10, 8, 1), & 11 &\mapsto (5, 4, 10, 1), & 12 &\mapsto (4, 10, 1, 1), & 13 &\mapsto (3, 9, 1, 1).
\end{align*}
\]

(6) \ \beta_0 : 

\[
\begin{align*}
14 &\mapsto (6, 7, 8, 9), & 15 &\mapsto (3, 7, 8, 9), & 16 &\mapsto (7, 5, 6, 0), & 17 &\mapsto (2, 6, 5, 0), & 18 &\mapsto (7, 9, 9, 0), & 19 &\mapsto (7, 9, 9, 0), & 20 &\mapsto (8, 7, 9, 0), \\
21 &\mapsto (8, 9, 9, 0), & 22 &\mapsto (10, 7, 7, 1), & 23 &\mapsto (3, 24, 7, 1), & 24 &\mapsto (8, 7, 7, 1), & 25 &\mapsto (2, 10, 7, 1), & 26 &\mapsto (10, 27, 7, 1), & 27 &\mapsto (4, 5, 1).
\end{align*}
\]

Proof. Let \( W = (0, \varphi) \times (0, 1) \). The \( \mathbb{Z}^2 \)-action \( R_0 \) is cartesian on the window \( W \). Thus from Lemma 8, the induced \( \mathbb{Z}^2 \)-action \( \tilde{R}_0 \) is well-defined. The first return time to \( W \) under \( R_0 \) is \((1, 4)\) or \((1, 5)\). The orbits of points in \( W \) until the first return to \( W \) under \( \tilde{R}_0 \) is shown in Figure 6.

The maximal subsets of \( W \) on which the first return map \( \tilde{R}_0^e \) is continuous yield a partition \( \{A, B, C, D\} \) of \( W \) defined as

\[
\begin{align*}
A &= (0, 1) \times (\varphi^{-1}, 1), & B &= (1, \varphi) \times (\varphi^{-1}, 1), \\
C &= (0, 1) \times (0, \varphi^{-1}), & D &= (1, \varphi) \times (0, \varphi^{-1}).
\end{align*}
\]

The return time of \( A \cup B \) to \( W \) under \( \tilde{R}_0^e \) is 4. The return time of \( C \cup D \) to \( W \) under \( \tilde{R}_0^e \) is 5. The first return maps \( \tilde{R}_0^e \) is defined as exchanges of rectangles \( \{A, B, C, D\} \) which, from Lemma 7, is equivalent to a toral translation by \((\varphi^{-1}, \varphi^{-2})\) on \( \mathbb{R}^2/\Gamma_1 \).

The first return map \( \tilde{R}_0^e \) is defined as an exchange of two rectangles, see Figure 7, which, from Lemma 7, is equivalent to a toral translation by \( e_1 \) on \( \mathbb{R}^2/\Gamma_1 \). Thus, we may identify \( W \) with the torus \( \mathbb{R}^2/\Gamma_1 \) and define the induced \( \mathbb{Z}^2 \)-action as toral rotations on \( \mathbb{R}^2/\Gamma_1 \):

\[
(\tilde{R}_0)(x)^n(x) = x + n_1 e_1 + n_2(\varphi^{-1}, \varphi^{-2}) \mod \Gamma_1.
\]

We observe that \( R_1 = \tilde{R}_0 \).

Thus we have that the return word function \( \text{RETURNWORD} : W \to \{0, 10\}^{\mathbb{Z}^2} \) is

\[
\begin{align*}
x \mapsto \begin{cases}
\text{CODE}_0(R_0^{(0,3)}(x)) & \text{if } x \in A \cup B \\
\text{CODE}_0(R_0^{(0,2)}(x)) & \text{if } x \in C \cup D.
\end{cases}
\end{align*}
\]
The set \( \{A, B, C, D\} \) forms a partition of the rectangle \( W = (0, \varphi) \times (0, 1) \). The return time to \( W \) under the map \( R_0^e \) is 4 or 5. The orbit of \( A, B, C \) and \( D \) under \( R_0^e \) before it returns to \( W \) yields a partitions of \( \mathbb{R}^2/\Gamma_0 \). The first return map \( \widehat{R}_0^e|_W \) is equivalent to a toral translation by the vector \( (\frac{1}{\varphi}, \frac{1}{\varphi^2}) \) on \( \mathbb{R}^2/\Gamma_1 \).

We get the set of return words \( \mathcal{L} = \{w_b\}_{b \in [0,27]} = \text{ReturnWord}(W) \) as listed in \([6]\). The partition induced by \( R_0 \) on \( W \) is

\[
\mathcal{P}_1 := \widehat{\mathcal{P}}_0|_W = \{\text{ReturnWord}^{-1}(w_b)\}_{b \in [0,27]}
\]

which is a topological partition of \( W \) made of 28 atoms (the atoms \( \text{ReturnWord}^{-1}(w_{21}) \) and \( \text{ReturnWord}^{-1}(w_{25}) \) are both the union of two triangles), see Figure 8.

The induced coding is

\[
\text{Code}_1 := \text{Code}_0|_W : \quad W \rightarrow [0, 27]
\]

\[
y \mapsto b \quad \text{if and only if} \quad y \in \text{ReturnWord}^{-1}(w_b).
\]
A natural substitution comes out of this construction:

\[ \beta_0 : [0, 27] \to [0, 10]^* \]

which corresponds to the one defined in Equation (6). From Proposition 10, we have \( X_{\mathcal{P}_0, R_0} = \beta_0(\mathcal{X}_{\mathcal{P}_1, R_1})^\sigma \) which ends the proof.

The meaning of the substitution \( \beta_0 \) in terms of rectangular patterns \( 5 \times 1 \) and \( 4 \times 1 \) of Wang tiles is illustrated in Figure 11 in the appendix.

13. Changing the base of the \( \mathbb{Z}^2 \)-action to get \( X_{\mathcal{P}_2, R_2} \)

Recall that \( \Gamma_1 = \varphi \mathbb{Z} \times \mathbb{Z} \) and that the coding on the torus \( \mathbb{R}^2 / \Gamma_1 \) is given by the \( \mathbb{Z}^2 \)-action \( R_1 \) of \( (n, x) \mapsto x + n_1 e_1 + n_2 (\varphi^{-1}, \varphi^{-2}) \). We remark that \( R_1^{e_1} \) is a horizontal translation while \( R_1^{e_2} \) is not. But we observe that \( R_1^{e_1+e_2} = R_1^{e_1} \circ R_1^{e_2} \) is a vertical translation \( x \mapsto x + (0, \varphi^{-2}) \). So it is natural to change the base of the \( \mathbb{Z}^2 \)-action \( R_1 \) by using \( R_1^{e_1+e_2} \) instead of \( R_1^{e_2} \). Therefore we let

\[ R_2^{(n_1, n_2)}(x) = R_1^{(n_1 + n_2, n_2)}(x) = x + n_1 e_1 + \varphi^{-2} n_2 e_2 \]

for every \( n = (n_1, n_2) \in \mathbb{Z}^2 \) which defines an action \( \mathbb{Z}^2 \times \mathbb{R}^2 / \Gamma_2 \to \mathbb{R}^2 / \Gamma_2 \) where \( \Gamma_2 = \Gamma_1 \). We keep the rest as is, that is \( \Gamma_2 = \Gamma_1 \), \( \mathcal{A}_2 = \mathcal{A}_1 \), and \( \text{CODE}_2 = \text{CODE}_1 \). We get the setup illustrated in Figure 9.
In general we have the following result.

**Lemma 19.** For every $M \in \text{SL}_2(\mathbb{Z})$, the map

$$p_M : A^{\mathbb{Z}^2} \rightarrow A^{\mathbb{Z}^2}$$
$$w \mapsto (n \mapsto w_{Mn})$$

is a homeomorphism.

**Proof.** The map $p_M$ is continuous and admits an inverse $p_{M^{-1}}$ which is also continuous. \qed

**Lemma 20.** There exists a homeomorphism $\beta_1 : \mathcal{X}_{\mathcal{P}_2,R_2} \rightarrow \mathcal{X}_{\mathcal{P}_1,R_1}$.

**Proof.** Let $M = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}$ and $\beta_1 = p_M$ be the homeomorphism defined in Lemma 19. For every $x \in \mathbb{R}^2/\Gamma_1 = \mathbb{R}^2/\Gamma_2$ and $m, n \in \mathbb{Z}$, we have

$$\text{ Orbit}^{\mathcal{P}_1,R_1}_{x}(m, n) = \text{ CODE}_1(R_1^{(m,n)}(x)) = \text{ CODE}_2(R_2^{(m-n,n)}(x)) = \text{ Orbit}^{\mathcal{P}_2,R_2}_{x}(m-n, n) = \beta_1 \left( \text{ Orbit}^{\mathcal{P}_2,R_2}_{x}(m, n) \right)$$

Therefore $\beta_1(\mathcal{X}_{\mathcal{P}_2,R_2}) = \mathcal{X}_{\mathcal{P}_1,R_1}$. \qed

**Remark 21.** The fact that $R_2^{\mathbb{Z}^2}$ is a vertical rotation by $\varphi^{-2}$ on $\mathbb{T}$ implies that the language $\mathcal{L} \subset \{4, 5\}^{\mathbb{Z}}$ of the sequences of horizontal strips of height 4 or 5 in $\mathcal{X}_{\mathcal{P}_0, R_0} \subset \Omega_0$ is the language of the Fibonacci word, the fixed point of $4 \mapsto 5, 5 \mapsto 54$. The height 4 or 5 refers to the rectangular patches shown in Figure 11. This fact for all tilings of $\Omega_0$ was used by Jeandel and Rao to prove aperiodicity of their Wang tile set [JR15], see also [Lab18b, Prop 21].

14. **Inducing the symbolic dynamical system $\mathcal{X}_{\mathcal{P}_2,R_2}$ to get $\mathcal{X}_{\mathcal{P}_k,R_k}$ and $\mathcal{X}_{\mathcal{P}_l,R_l}$**

In this section, we induce the topological partition $\mathcal{P}_2$ until we reach a partition which is self-induced.

**Proposition 22.** For every $i$ with $2 \leq i \leq 7$, there exist a lattice $\Gamma_{i+1}$, an alphabet $\mathcal{A}_{i+1}$, a $\mathbb{Z}^2$-action $R_{i+1} : \mathbb{Z}^2 \times \mathbb{R}^2/\Gamma_{i+1} \rightarrow \mathbb{R}^2/\Gamma_{i+1}$, a topological partition $\mathcal{P}_{i+1}$ of $\mathbb{R}^2/\Gamma_{i+1}$ and substitutions $\beta_i : \mathcal{A}_{i+1} \rightarrow \mathcal{A}_i^{\mathbb{Z}^2}$ such that

$$\mathcal{X}_{\mathcal{P}_i,R_i} = \beta_i(\mathcal{X}_{\mathcal{P}_{i+1},R_{i+1}}).$$

**Proof.** We proceed as in the proof of Theorem 13 and Prop. 18 by making use of Proposition 10 many times. We use again and again the same induction process by producing at each step a new partition until we reach a partition which is self-induced.

We start with the lattice $\Gamma_2 = \langle (\varphi, 0), (0, 1) \rangle_{\mathbb{Z}}$, the partition $\mathcal{P}_2$, the coding map $\text{ CODE}_2 : \mathbb{R}^2/\Gamma_2 \rightarrow \mathcal{A}_2$, the alphabet $\mathcal{A}_2 = [0, 27]$ and $\mathbb{Z}^2$-action $R_2$ defined on $\mathbb{R}^2/\Gamma_2$ as in Figure 9.

We consider the window $W_2 = (0, 1) \times (0, 1)$ as a subset of $\mathbb{R}^2/\Gamma_2$. The action $R_2$ is cartesian on $W_2$. Thus from Lemma 8 $R_3 := \widetilde{R}_2|_{W_2} : \mathbb{Z}^2 \times W_2 \rightarrow W_2$ is a well-defined $\mathbb{Z}^2$-action. From Lemma 7 the $\mathbb{Z}^2$-action $R_3$ can be seen as toral translation on $\mathbb{R}^2/\Gamma_3$ with $\Gamma_3 = \mathbb{Z}^2$. Let $\mathcal{P}_3 = \widetilde{R}_2|_{W_2}$ be the induced partition. From Proposition 10 then $\mathcal{X}_{\mathcal{P}_2,R_2} = \beta_2(\mathcal{X}_{\mathcal{P}_3,R_3})$. The partition $\mathcal{P}_3$, the action
We consider the window $W_3 = (0, \varphi^{-1}) \times (0, 1)$ as a subset of $\mathbb{R}^2 / \Gamma_3$. The action $\mathcal{R}_3$ is cartesian on $W_3$. Thus from Lemma 8, $R_4 := \mathcal{R}_3|_{W_3} : \mathbb{Z}^2 \times W_3 \to W_3$ is a well-defined $\mathbb{Z}^2$-action. From Lemma 7, the $\mathbb{Z}^2$-action $\mathcal{R}_4$ can be seen as toral translation on $\mathbb{R}^2 / \Gamma_4$ with $\Gamma_4 = (\varphi^{-1} \mathbb{Z}) \times \mathbb{Z}$. Let $\mathcal{P}_4 = \mathcal{P}_3|_{W_3}$ be the induced partition. From Proposition 10, then $\mathcal{X}_{\mathcal{P}_3, \mathcal{R}_3} = \beta_3(\mathcal{X}_{\mathcal{P}_4, \mathcal{R}_4})$. The partition $\mathcal{P}_4$, the action $\mathcal{R}_4$ and substitution $\beta_3$ are given below with alphabet $\mathcal{A}_4 = [0, 19]$:

Now we consider the window $W_4 = (0, \varphi^{-1}) \times (0, \varphi^{-1})$ as a subset of $\mathbb{R}^2 / \Gamma_4$. The action $\mathcal{R}_4$ is cartesian on $W_4$. Thus from Lemma 8, $R_5 := \mathcal{R}_4|_{W_4} : \mathbb{Z}^2 \times W_4 \to W_4$ is a well-defined $\mathbb{Z}^2$-action. From Lemma 7, the $\mathbb{Z}^2$-action $\mathcal{R}_5$ can be seen as toral translation on $\mathbb{R}^2 / \Gamma_5$ with $\Gamma_5 = (\varphi^{-1} \mathbb{Z}) \times (\varphi^{-1} \mathbb{Z})$. Let $\mathcal{P}_5 = \mathcal{P}_4|_{W_4}$ be the induced partition. From Proposition 10, then $\mathcal{X}_{\mathcal{P}_4, \mathcal{R}_4} = \beta_4(\mathcal{X}_{\mathcal{P}_5, \mathcal{R}_5})$. The partition $\mathcal{P}_5$, the action $\mathcal{R}_5$ and substitution $\beta_4$ are given below with alphabet $\mathcal{A}_5 = [0, 21]$:

Now it is appropriate to rescale the partition $\mathcal{P}_5$ by the factor $-\varphi$. Doing so, the new obtained action $\mathcal{R}_5'$ is the same as two steps before, that is, $R_3$ on $\mathbb{R}^2 / \mathbb{Z}^2$. More formally, let $h : (\mathbb{R} / \varphi^{-1} \mathbb{Z})^2 \to (\mathbb{R} / \mathbb{Z})^2$ be the homeomorphism defined by $h(x) = -\varphi x$. We define $\mathcal{P}_5' = h(\mathcal{P}_5)$, $\text{CODE}_5' = \beta_4(\mathcal{X}_{\mathcal{P}_5', \mathcal{R}_5'})$.

CODE₅ ∘ h⁻¹, (R₅')ⁿ = h ∘ (R₅)ⁿ ∘ h⁻¹ as shown below:

By construction, the following diagrams commute:

$$\begin{align*}
(\mathbb{R}/\varphi^{-1}\mathbb{Z})^2 & \xrightarrow{h} (\mathbb{R}/\mathbb{Z})^2 \\
\mathbb{R}/\varphi^{-1}\mathbb{Z})^2 & \xrightarrow{h} (\mathbb{R}/\mathbb{Z})^2
\end{align*}$$

Using the above commutative properties, for every y ∈ \mathbb{R}²/Γ₅ and m, n ∈ \mathbb{Z}, we have

$$\textit{ORBIT}_y^{P₅,R₅}(n) = \text{CODE}_5(R₅^n(y)) = \text{CODE}_5'(n) ∘ h(R₅^n(y))$$

$$= \text{CODE}_5'(n) ∘ (R₅')^n(h(y))) = \textit{ORBIT}_y^{P₅,R₅'}(n).$$

Thus \(\mathcal{X}_{P₅,R₅} = \mathcal{X}_{P₅,R₅'}\). Now we consider the window \(W₅ = (0, \varphi^{-1}) \times (0, 1)\) as a subset of \(\mathbb{R}²/\Gamma₅\). The action \(R₅\) is cartesian on \(W₅\). Thus from Lemma 8, \(R₆ := R₅|_{W₅} : \mathbb{Z}² × W₅ → W₅\) is a well-defined \(\mathbb{Z}²\)-action. From Lemma 7, the \(\mathbb{Z}²\)-action \(R₆\) can be seen as toral translation on \(\mathbb{R}²/\Gamma₆\) with \(Γ₆ = (\varphi^{-1}\mathbb{Z}) × \mathbb{Z}\). Let \(P₆ = P₅|_{W₅}\) be the induced partition. From Proposition 10, then \(\mathcal{X}_{P₅,R₅} = β₅(\mathcal{X}_{P₅,R₅})\). The partition \(P₆\), the action \(R₆\) and substitution \(β₅\) are given below with alphabet \(A₆ = [0, 17]\):

Now we consider the window \(W₆ = (0, \varphi^{-1}) \times (0, 1)\) as a subset of \(\mathbb{R}²/\Gamma₆\). The action \(R₆\) is cartesian on \(W₆\). Thus from Lemma 8, \(R₇ := R₆|_{W₆} : \mathbb{Z}² × W₆ → W₆\) is a well-defined \(\mathbb{Z}²\)-action. From Lemma 7, the \(\mathbb{Z}²\)-action \(R₇\) can be seen as toral translation on \(\mathbb{R}²/\Gamma₇\) with \(Γ₇ = (\varphi^{-1}\mathbb{Z}) × (\varphi^{-1}\mathbb{Z})\). Let \(P₇ = P₆|_{W₆}\) be the induced partition. From Proposition 10, then \(\mathcal{X}_{P₆,R₆} = β₆(\mathcal{X}_{P₆,R₆})\).
The partition $\mathcal{P}_7$, the action $R_7$ and substitution $\beta_7$ are given below with alphabet $\mathcal{A}_7 = [0, 20]$:

$$
\mathcal{P}_7 = \begin{array}{c}
\begin{array}{cccccccccc}
& \frac{1}{\varphi} & & & & & & & & \\
\end{array}
\begin{array}{cccccccccc}
11 & 12 & 13 & & & & & & & \\
14 & 15 & 16 & 17 & 18 & 19 & 20 \\
\end{array}
\end{array}
$$

$$
R_7^n(x) = x - \varphi^{-3}n
$$

Again it is appropriate to rescale the partition $\mathcal{P}_7$ by the factor $-\varphi$. We use the homeomorphism $h : (\mathbb{R}/\varphi^{-1}\mathbb{Z})^2 \to (\mathbb{R}/\mathbb{Z})^2$ defined previously by $h(x) = -\varphi x$. We define $\mathcal{P}'_7 = h(\mathcal{P}_7)$, $\text{CODE}'_7 = \text{CODE}_7 \circ h^{-1}$, $(R_7')^n = h \circ (R_7)^n \circ h^{-1}$ as shown below:

$$
\mathcal{P}'_7 = \begin{array}{c}
\begin{array}{cccccccccc}
& \frac{1}{\varphi} & & & & & & & & \\
\end{array}
\begin{array}{cccccccccc}
8 & 5 & 3 & 7 & 1 & 0 & 2 \\
14 & 13 & 12 & 17 & 16 & 15 & 11 \\
\end{array}
\end{array}
$$

$$
(R_7')^n(x) = x + \varphi^{-2}n
$$

Using the above commutative properties, for every $y \in \mathbb{R}^2/\Gamma_7$ and $m, n \in \mathbb{Z}$, we have

$$
\text{ORBIT}_{\mathcal{P}'_7,R_7'}(n) = \text{CODE}_7(R_7^n(y)) = \text{CODE}_7 \circ h(R_7^n(y)) = \text{CODE}_7 \circ (R_7')^n(h(y))) = \text{ORBIT}_{\mathcal{P}_7,R_7}(n).
$$

Thus $\mathcal{X}_{\mathcal{P}_7,R_7} = \mathcal{X}_{\mathcal{P}'_7,R_7'}$. Now we consider the window $W_7 = (0, \varphi^{-1}) \times (0, 1)$ as a subset of $\mathbb{R}^2/\mathbb{Z}^2$. The action $R_7'$ is cartesian on $W_7$. Thus from Lemma 8, $R_8 := R_7'|_{W_7} : \mathbb{Z}^2 \times W_7 \to W_7$ is a well-defined $\mathbb{Z}^2$-action. From Lemma 7, the $\mathbb{Z}^2$-action $R_8$ can be seen as toral translation on $\mathbb{R}^2/\Gamma_8$ with $\Gamma_8 = (\varphi^{-1}\mathbb{Z}) \times \mathbb{Z}$. Let $\mathcal{P}_8 = \mathcal{P}_7|_{W_7}$ be the induced partition. From Proposition 10, then $\mathcal{X}_{\mathcal{P}_7,R_7} = \beta_7(\mathcal{X}_{\mathcal{P}_8,R_8})$. The partition $\mathcal{P}_8$, the action $R_8$ and substitution $\beta_7$ are given below with alphabet $\mathcal{A}_8 = [0, 18]$:

$$
\mathcal{P}_8 = \begin{array}{c}
\begin{array}{cccccccccc}
& \frac{1}{\varphi} & & & & & & & & \\
\end{array}
\begin{array}{cccccccccc}
1 & 11 & 10 & 6 & 7 & 0 & 9 \\
5 & 15 & 8 & 4 & 14 & 16 & 12 \\
\end{array}
\end{array}
$$

$$
R_8^n(x) = x + (-\varphi^{-3}, 0)n_1 + (0, \varphi^{-2})n_2
$$

$$
\beta_7 : \mathcal{A}_8 \to \mathcal{A}_7^2
$$

$$
\begin{array}{cccccccccc}
0 \mapsto (5), & 1 \mapsto (8), & 2 \mapsto (14), & 3 \mapsto (15), & 4 \mapsto (18), & 5 \mapsto (20), & 6 \mapsto (3, 1), & 7 \mapsto (4, 2), & 8 \mapsto (5, 1), & 9 \mapsto (6, 0), & 10 \mapsto (7, 1), & 11 \mapsto (8, 1), & 12 \mapsto (12, 11), & 13 \mapsto (13, 11), & 14 \mapsto (14, 9), & 15 \mapsto (15, 10), & 16 \mapsto (16, 11), & 17 \mapsto (17, 11), & 18 \mapsto (19, 9).
\end{array}
$$
This completes the proof. □

What happens if we do two more steps in the previous proof is illustrated in the appendix where we compute $\mathcal{P}_9$ and $\mathcal{P}_{10}$ where $\mathcal{P}_{10}$ is the same as $\mathcal{P}_8$ up to a permutation of the alphabet. We do not do these steps here because we show instead that the topological partition $\mathcal{P}_8$ is equivalent to $\mathcal{P}_U$ thus is self-induced.

**Lemma 23.** $\mathcal{X}_{\mathcal{P}_s,R_s}$ and $\mathcal{X}_{\mathcal{P}_u,R_u}$ are topologically conjugate. More precisely, $\mathcal{X}_{\mathcal{P}_s,R_s} = \rho(\mathcal{X}_{\mathcal{P}_u,R_u})$, where $\rho : [0,18]^2 \rightarrow [0,18]^2$ is the 2-dimensional morphism defined by the following letter-to-letter permutation:

$$
\rho : \begin{cases}
0 \mapsto 0, & 1 \mapsto 1, & 2 \mapsto 9, & 3 \mapsto 7, & 4 \mapsto 8, \\
5 \mapsto 11, & 6 \mapsto 10, & 7 \mapsto 6, & 8 \mapsto 2, & 9 \mapsto 4, \\
10 \mapsto 5, & 11 \mapsto 3, & 12 \mapsto 18, & 13 \mapsto 14, & 14 \mapsto 16, \\
15 \mapsto 13, & 16 \mapsto 12, & 17 \mapsto 17, & 18 \mapsto 15.
\end{cases}
$$

**Proof.** Recall from Theorem 13 that $R^u_{\mathcal{P}_u}(x) = x + \varphi^{-2}n$. Let $g : \mathbb{R}^2/\Gamma_8 \rightarrow \mathbb{T}^2$ be the homeomorphism defined by $(x,y) \mapsto (-\varphi x,y)$. We observe that $g(\mathcal{P}_8)$ is equal to $\mathcal{P}_U$ after permuting the coding alphabet of $\mathcal{P}_U$ by $\rho$. In other words, $\text{CODE}_8 = \rho \circ \text{CODE}_U \circ g$. Also $g \circ R^u_{\mathcal{P}_u} = R^u_{\mathcal{P}_u} \circ g$. Thus for every $x \in \mathbb{R}^2/\Gamma_8$ and $n \in \mathbb{Z}^2$, we have

$$
\text{ORBIT}_{x,\text{CODE}_8}(n) = \text{CODE}_8 \circ R^u_{\mathcal{P}_u}(x) = \rho \circ \text{CODE}_U \circ g \circ R^u_{\mathcal{P}_u}(x) = \rho \left( \text{ORBIT}_{g(x),\text{CODE}_U}(n) \right).
$$

Thus we conclude $\mathcal{X}_{\mathcal{P}_s,R_s} = \rho(\mathcal{X}_{\mathcal{P}_u,R_u})$. □

15. **Geometric representation of Jeandel-Rao tilings in $X_0 \subseteq \Omega_0$**

In [Lab19a], it was shown that the symbolic dynamical system $\mathcal{X}_{\mathcal{P}_0,R_0}$ corresponding to the partition $\mathcal{P}_0$ and $\mathbb{Z}^2$-action $R_0$ is a minimal subshift of Jeandel-Rao aperiodic tilings $\Omega_0$. Thus it provides a efficient way to construct valid Wang tilings by coding $\mathbb{Z}^2$-actions on a torus. An natural question is whether all Jeandel-Rao tilings can be constructed in such a way. The answer is no as it was shown in [Lab18b] that $\Omega_0$ is not minimal. But then this asks for the description of the elements in the set $\Omega_0 \setminus \mathcal{X}_{\mathcal{P}_0,R_0}$ and how big is this set. We believe that $\Omega_0 \setminus \mathcal{X}_{\mathcal{P}_0,R_0}$ is of measure 0 for any shift-invariant probability measure $\mu$ on $\Omega_0$ but this is an open question.

$$
\mathcal{X}_{\mathcal{P}_0,R_0} \nleftarrow \mathcal{X}_{\mathcal{P}_1,R_1} \nleftarrow \mathcal{X}_{\mathcal{P}_2,R_2} \nleftarrow \mathcal{X}_{\mathcal{P}_3,R_3} \nleftarrow \mathcal{X}_{\mathcal{P}_4,R_4} \nleftarrow \mathcal{X}_{\mathcal{P}_5,R_5} \nleftarrow \mathcal{X}_{\mathcal{P}_6,R_6} \nleftarrow \mathcal{X}_{\mathcal{P}_7,R_7} \nleftarrow \mathcal{X}_{\mathcal{P}_8,R_8} \nleftarrow \mathcal{X}_{\mathcal{P}_U,R_U}
$$

**Figure 10.** The substitutive structure of $\mathcal{X}_{\mathcal{P}_0,R_0}$.

In [Lab19a], we proved $\mathcal{X}_{\mathcal{P}_0,R_0} \subseteq \Omega_0$. What remains to be done is $\mathcal{X}_{\mathcal{P}_0,R_0} \supseteq \Omega_0 \mod \mu$. In other words, for $\mu$-almost any tiling $t$ in $\Omega_0$, we would like to show that it is the coding of the $\mathbb{Z}^2$-action $R_0$ under the partition $\mathcal{P}_0$ of some starting point in $\mathbb{R}^2/\Gamma_0$. To tackle this question, as for sturmian sequences, the strategy is to describe tilings in $\Omega_0$ by their substitutive structure [Lab18b] as recalled by Theorem 24 below. In the previous sections, we described the substitutive structure of $\mathcal{X}_{\mathcal{P}_0,R_0}$ (summarized in Figure 10) and it turns out that it matches exactly the substitutive structure of a minimal subshift $X_0$ of $\Omega_0$ as shown below in Theorem 26. As a consequence, if the tiling $t$ belongs to $X_0$, then it belongs also to $\mathcal{X}_{\mathcal{P}_0,R_0}$, i.e., it is the coding of a $\mathbb{Z}^2$-action on a 2-torus.

**Theorem 24.** [Lab18b] Let $\mathcal{T}_0$ be the Jeandel-Rao 11 tiles and $\Omega_0$ be its Wang shift. There exist sets of Wang tiles $\{\mathcal{T}_i\}_{1 \leq i \leq 12}$ together with their associated Wang shifts $\{\Omega_i\}_{1 \leq i \leq 12}$ that provide the substitutive structure of Jeandel-Rao tilings. More precisely,
(i) There exists a sequence of recognizable 2-dimensional morphisms:

\[ \Omega_0 \overset{\omega_0}{\rightarrow} \Omega_1 \overset{\omega_1}{\rightarrow} \Omega_2 \overset{\omega_2}{\rightarrow} \Omega_3 \overset{\omega_3}{\rightarrow} \Omega_4 \]

that are onto up to a shift, i.e., \( (\Omega_i+1) = \Omega_i \) for each \( i \in \{0, 1, 2, 3\} \).

(ii) There exists a one-to-one and continuous map \( \pi : \Omega_5 \rightarrow \Omega_4 \).

(iii) There exists a topological conjugacy \( \eta : \Omega_6 \rightarrow \Omega_5 \) which shears Wang tilings by the action of the matrix \((\frac{1}{1} \frac{1}{1})\).

(iv) There exists a sequence of recognizable 2-dimensional morphisms:

\[ \Omega_6 \overset{\omega_6}{\rightarrow} \Omega_7 \overset{\omega_7}{\rightarrow} \Omega_8 \overset{\omega_8}{\rightarrow} \Omega_9 \overset{\omega_9}{\rightarrow} \Omega_{10} \overset{\omega_{10}}{\rightarrow} \Omega_{11} \overset{\omega_{11}}{\rightarrow} \Omega_{12} \]

that are onto up to a shift, i.e., \( (\Omega_{i+1}) = \Omega_i \) for each \( i \in \{6, 7, 8, 9, 10, 11\} \).

(v) The Wang shift \( \Omega_{12} \) is equivalent to \( \Omega_{12} \), thus is self-similar, aperiodic and minimal.

(vi) \( X_0 = \omega_0 \omega_1 \omega_2 \omega_3 \pi (\Omega_5) \subseteq \Omega_6 \) is an aperiodic and minimal subshift of Jeandel-Rao tilings \( \Omega_0 \).

The substitutions \( \omega_i \), \( \pi \) and \( \eta \) were computed from algorithms on Wang tiles based on marker tiles. Surprisingly, they are the same as the substitutions constructed here in previous sections using 2-dimensional Rauzy induction on toral partitions! More precisely, we make the following observation.

**Remark 25.** The reader may check that the following equalities hold:

\[ (8) \quad \omega_0 \omega_1 \omega_2 \omega_3 = \beta_0, \quad \pi \eta \omega_6 = \beta_1 \beta_2, \quad \omega_7 = \beta_3, \quad \omega_8 = \beta_4, \quad \omega_9 = \beta_5, \quad \omega_{10} = \beta_6 \quad \text{and} \quad \omega_{11} = \beta_7. \]

To obtain the equalities, we use a common convention here for the \( \beta_i \) and in \([Lab18b]\) for the \( \omega_i \), i.e., when constructing the substitutions, we sort the images of letters first by length and then lexicographically.

We now show the equality between the minimal subshift \( X_0 \) of Jeandel-Rao aperiodic tilings defined by its substitutive structure and the symbolic dynamical system \( X_{P_0, R_0} \).

**Theorem 26.** We have \( X_{P_0, R_0} = X_0 \) and similar equalities for intermediate subshifts:

\[ X_{P_7, R_7} = \Omega_{11}, \quad X_{P_6, R_6} = \Omega_{10}, \quad X_{P_5, R_5} = \Omega_9, \quad X_{P_4, R_4} = \Omega_8, \quad X_{P_3, R_3} = \Omega_7 \quad \text{and} \quad X_{P_2, R_2} = \pi (\Omega_5). \]

**Proof.** From Lemma 23 we have \( X_{P_8, R_8} = \rho (\Omega_{P_7, R_7}) \). From Corollary 17, we have \( X_{P_1, R_1} = \Omega_{12} \). Moreover in \([Lab18b]\), it was shown that \( \rho (\Omega_{12}) = \Omega_{12} \), where \( \rho \) is the same letter-to-letter bijection as in Lemma 23. Thus

\[ X_{P_8, R_8} = \rho (\Omega_{P_7, R_7}) = \rho (\Omega_{12}) = \Omega_{12}. \]

From Proposition 18, Lemma 20 and Proposition 22, \( X_{P_1, R_1} = \beta_1 (X_{P_{1+1}, R_{1+1}}) \) for each \( i \in \{0, 1, \ldots, 7\} \). Thus using Theorem 24 and Remark 25, we obtain

\[ X_{P_0, R_0} = \beta_0 \beta_1 \beta_2 \beta_3 \beta_4 \beta_5 \beta_6 \beta_7 (X_{P_8, R_8}) = \omega_0 \omega_1 \omega_2 \omega_3 \pi \eta \omega_6 \omega_7 \omega_8 \omega_9 \omega_{10} \omega_{11} (\Omega_{12}) = X_0 \subset \Omega_0. \]

Similarly for intermediate subshifts, we have

\[ X_{P_1, R_1} = \beta_1 \beta_2 \beta_3 \beta_4 \beta_5 \beta_6 \beta_7 (X_{P_8, R_8}) = \pi \eta \omega_6 \omega_7 \omega_8 \omega_9 \omega_{10} \omega_{11} (\Omega_{12}) = \pi (\Omega_5) \subset \Omega_4 \]

\[ X_{P_3, R_3} = \beta_3 \beta_4 \beta_5 \beta_6 \beta_7 (X_{P_8, R_8}) = \omega_7 \omega_8 \omega_9 \omega_{10} \omega_{11} (\Omega_{12}) = \Omega_7 \]

\[ X_{P_4, R_4} = \beta_4 \beta_5 \beta_6 \beta_7 (X_{P_8, R_8}) = \omega_8 \omega_9 \omega_{10} \omega_{11} (\Omega_{12}) = \Omega_8 \]

\[ X_{P_5, R_5} = \beta_5 \beta_6 \beta_7 (X_{P_8, R_8}) = \omega_9 \omega_{10} \omega_{11} (\Omega_{12}) = \Omega_9 \]

\[ X_{P_6, R_6} = \beta_6 \beta_7 (X_{P_8, R_8}) = \omega_{10} \omega_{11} (\Omega_{12}) = \Omega_{10} \]

\[ X_{P_7, R_7} = \beta_7 (X_{P_8, R_8}) = \omega_{11} (\Omega_{12}) = \Omega_{11} \]

which ends the proof. \( \square \)
The fact that $X_0$ and $X_{P_0, R_0}$ have the same substitutive structure implies the following corollary which can be seen as a generalization of what happens for Sturmian sequences.

**Corollary 27.** The dynamical system $(X_0, \mathbb{Z}^2, \sigma)$ is strictly ergodic and the measure-preserving dynamical system $(X_0, \mathbb{Z}^2, \sigma, \nu)$ is isomorphic to the toral $\mathbb{Z}^2$-rotation $(\mathbb{R}^2 / \Gamma_0, \mathbb{Z}^2, R_0, \lambda)$ where $\nu$ is the unique shift-invariant probability measure on $X_0$ and $\lambda$ is the Haar measure on $\mathbb{R}^2 / \Gamma_0$.

**Proof.** The same statement was proved in [Lab19a] for $X_{P_0, R_0}$ and we proved in Theorem 26 that $X_0 = X_{P_0, R_0}$. \hfill \Box

Although Jeandel-Rao tilings $\Omega_0$ is not minimal as it contains the proper minimal subshift $X_{P_0, R_0} = X_0$, we believe that it is uniquely ergodic.

**Conjecture 28.** The Jeandel-Rao subshift $\Omega_0$ is uniquely ergodic.

That conjecture is equivalent to prove that $\Omega_0 \setminus X_0$ has measure 0 for any shift-invariant probability measure on $\Omega_0$ which was stated as a conjecture in [Lab18] and where some progress was done. That would also imply the existence of an isomorphism of measure-preserving dynamical systems between Jeandel-Rao Wang shift $(\Omega_0, \mathbb{Z}^2, \sigma, \nu)$ and $(\mathbb{R}^2 / \Gamma_0, \mathbb{Z}^2, R_0, \lambda)$ where $\nu$ would be the unique shift-invariant probability measure on $\Omega_0$ and $\lambda$ is the Haar measure on $\mathbb{R}^2 / \Gamma_0$.

APPENDIX: The next two steps in the proof of Proposition 22

We need two more steps in the proof of Proposition 22 until the induction procedure loops. We obtain the partitions and substitutions below. We may observe that \( \mathcal{P}_{10} \) is the same as \( \mathcal{P}_8 \) up to a permutation \( \eta \) of letters and thus the induction procedure loops with self-similarity \( \beta_8 \beta_8 \eta \). Moreover \( \rho^{-1} \beta_8 \beta_8 \eta \rho \) is equal to the 2-dimensional morphism \( \beta_U \) computed in Theorem 13 and in [Lab18a] where \( \rho \) is defined in Lemma 23. Below are the coding maps and involved substitutions.

\[
\mathcal{P}_9 = \begin{array}{|c|c|c|c|}
\hline
\frac{1}{\varphi} & 1 & \frac{1}{\varphi^2} & \frac{1}{\varphi^3} \\
\hline
\end{array}
\]

\[
\rho_{9}(x) = x - \varphi^{-3}n
\]

\[
\mathcal{P}'_9 = \begin{array}{|c|c|c|c|c|}
\hline
\frac{1}{\varphi} & 1 & \frac{1}{\varphi^2} & \frac{1}{\varphi^3} & \frac{1}{\varphi^4} \\
\hline
\end{array}
\]

\[
(R'_9)^n(x) = x + \varphi^{-2}n
\]

\[
\mathcal{P}_{10} = \begin{array}{|c|c|c|c|c|}
\hline
\frac{1}{\varphi} & 1 & \frac{1}{\varphi^2} & \frac{1}{\varphi^3} & \frac{1}{\varphi^4} \\
\hline
\end{array}
\]

\[
R_{10}^n(x) = x + (-\varphi^{-3}, 0)n_1 + (0, \varphi^{-2})n_2
\]

\[
\beta_8 : \mathcal{A}_9 \to \mathcal{A}_9^2
\]

\[
\begin{align*}
0 & \mapsto (2), \quad 1 \mapsto (3), \quad 2 \mapsto (4), \quad 3 \mapsto (12), \\
4 & \mapsto (13), \quad 5 \mapsto (14), \quad 6 \mapsto (16), \quad 7 \mapsto (17), \\
8 & \mapsto (0), \quad 9 \mapsto (1), \quad 10 \mapsto (11), \quad 11 \mapsto \frac{1}{5}, \\
12 & \mapsto (7), \quad 13 \mapsto (6), \quad 14 \mapsto (5), \quad 15 \mapsto (8), \\
16 & \mapsto (11), \quad 17 \mapsto (10), \quad 18 \mapsto (7), \quad 19 \mapsto (17), \\
20 & \mapsto (18).
\end{align*}
\]

\[
\beta_9 : \mathcal{A}_{10} \to \mathcal{A}_{10}^2
\]

\[

15 & \mapsto (16, 11), \quad 16 \mapsto (17, 8), \quad 17 \mapsto (18, 9), \\
18 & \mapsto (20, 10).
\end{align*}
\]

\[
\eta : \mathcal{A}_8 \to \mathcal{A}_8^2
\]

\[
\begin{align*}
0 & \mapsto (1), \quad 1 \mapsto (0), \quad 2 \mapsto (4), \quad 3 \mapsto (3), \quad 4 \mapsto (5), \quad 5 \mapsto (2), \quad 6 \mapsto (10), \quad 7 \mapsto (9), \\
8 & \mapsto (11), \quad 9 \mapsto (8), \quad 10 \mapsto (7), \quad 11 \mapsto (6), \quad 12 \mapsto (15), \quad 13 \mapsto (18), \quad 14 \mapsto (17), \quad 15 \mapsto (16), \quad 16 \mapsto (13), \quad 17 \mapsto (14), \quad 18 \mapsto (12).
\end{align*}
\]
\[ \beta_5 \beta_6 \eta : \mathcal{A}_8 \to \mathcal{A}_8^2 \]

\[ \begin{aligned}
0 & \mapsto (17), & 1 & \mapsto (12), & 2 & \mapsto \binom{10}{16}, & 3 & \mapsto \binom{9}{16}, & 4 & \mapsto \binom{7}{17}, & 5 & \mapsto \binom{7}{12}, \\
6 & \mapsto (16, 2), & 7 & \mapsto (14, 4), & 8 & \mapsto (17, 2), & 9 & \mapsto (13, 3), & 10 & \mapsto (13, 2), & 11 & \mapsto (12, 2), \\
12 & \mapsto \binom{11}{15 5}, & 13 & \mapsto \binom{10 1}{18 4}, & 14 & \mapsto \binom{10 1}{16 3}, & 15 & \mapsto \binom{9 0}{16 2}, & 16 & \mapsto \binom{6 1}{14 4}, & 17 & \mapsto \binom{8 1}{14 4}, \\
18 & \mapsto \binom{6 1}{13 3}.
\end{aligned} \]

**Appendix: The partition $\mathcal{P}_1$ with Wang tiles**

![Diagram of the partition $\mathcal{P}_1$ with Wang tiles]

**Figure 11.** Each part of the topological partition $\mathcal{P}_1$ of $\mathbb{R}^2/\Gamma_1$ can be associated to a rectangular patch of Jeandel-Rao tiles of height 4 or 5 and width 1.
Appendix: Sage code

Polyhedron exchange transformations and induction of polyhedron partitions are implemented in Sage [Sag19] with the optional package slabbe [Lab19b].

```sage
sage: from slabbe import PolyhedronPartition
sage: from slabbe import PolyhedronExchangeTransformation as PET
```

The following allows to define the partition $P_0$ of $\mathbb{R}^2/\Gamma_0$, compute the induced partition $P_1$ of $\mathbb{R}^2/\Gamma_1$, the substitution $\beta_0$ and to reproduce the proof of Proposition 18.

```sage
sage: z = polygen(QQ, 'z')
sage: K = NumberField(z**2-z-1, 'phi', embedding=RR(1.6))
sage: phi = K.gen()
sage: P0 = PolyhedronPartition.jeandel_rao_tilings_partition()
sage: Gamma0 = matrix.column([(phi,0), (1,phi+3)])
sage: fundamental_domain = polytopes.parallelotope([(phi,0), (0,phi+3)])
sage: y_le_1 = [1, 0, -1] # syntax for the inequality y <= 1
sage: P1,beta0 = R0e2.induced_partition(y_le_1, P0, substitution_type='column')
```

The following allows to reproduce the proof of Proposition 22, that is, to construct the partitions $P_2$, $P_3$, $P_4$, $P_5$, $P_6$, $P_7$, $P_8$, $P_9$, $P_{10}$ and show that $P_8$ and $P_{10}$ are equivalent.

```sage
sage: x_le_1 = [1, -1, 0] # x <= 1
sage: Gamma2 = Gamma1 = matrix.column([(phi,0), (0,1)])
sage: P2 = P1
sage: R2e1 = PET.toral_translation(Gamma2, vector((1,0)))
sage: P3,beta2 = R2e1.induced_partition(x_le_1, P2, substitution_type='row')
sage: Gamma3 = matrix.column([(1,0), (0,1)])
sage: Gamma4 = matrix.column([(phi^-1,0), (0,1)])
sage: R9e1 = R7e1 = R5e1 = R3e1 = PET.toral_translation(Gamma3, vector((phi^-2,0)))
sage: R8e2 = R6e2 = R4e2 = PET.toral_translation(Gamma4, vector((0,phi^-2)))
sage: x_le_phi_inv = [phi^-1, -1, 0] # x <= phi^-1
sage: y_le_phi_inv = [phi^-1, 0, -1] # y <= phi^-1
sage: P4,beta3 = R3e1.induced_partition(x_le_phi_inv, P3, substitution_type='row')
sage: P5,beta4 = R4e2.induced_partition(y_le_phi_inv, P4, substitution_type='column')
sage: P5_scaled = (-phi*P5).translation((1,1))
sage: P6,beta5 = R5e1.induced_partition(x_le_phi_inv, P5_scaled, substitution_type='row')
sage: P7,beta6 = R6e2.induced_partition(y_le_phi_inv, P6, substitution_type='column')
sage: P7_scaled = (-phi*P7).translation((1,1))
sage: P8,beta7 = R7e1.induced_partition(x_le_phi_inv, P7_scaled, substitution_type='row')
sage: P9,beta8 = R8e2.induced_partition(y_le_phi_inv, P8, substitution_type='column')
sage: P9_scaled = (-phi*P9).translation((1,1))
sage: P10,beta9 = R9e1.induced_partition(x_le_phi_inv, P9_scaled, substitution_type='row')
sage: P8 == P10
```

We may check that the self-similarity for $P_8$ satisfies $\rho^{-1}\beta_8\beta_9\eta\rho = \beta_U$.

```sage
sage: rho = Substitution2d.from_permutation({0:0, 1:1, 2:9, 3:7, 4:8, 5:11, 6:10, 7:11, 8:2, 9:4, 10:5, 11:3, 12:18, 13:14, 14:16, 15:13, 16:12, 17:17, 18:15})
sage: view(rho.inverse()*beta8*beta9*eta*rho) # == betaU
```

To visualize the partitions and substitutions computed above, do as follows.

```sage
sage: P1.plot()
sage: view(beta0) # etc.
```
