Introduction and Preliminaries
Chapter 1

Introduction

The present work on probability theory is an outgrowth of the constructive analysis in [Bishop 1967] and [Bishop and Bridges 1985].

Perhaps the simplest explanation of constructive mathematics is by way of focusing on the following two commonly used theorems. The first, the principle of finite search, states that, given a finite sequence of 0-or-1 integers, either all members of the sequence are equal to 0, or there exists a member which is equal to 1. We use this theorem without hesitation because, given the finite sequence, a finite search would determine the result.

The second theorem, which we may call the principle of infinite search, states that, given an infinite sequence of 0-or-1 integers, either all members of the sequence are equal to 0, or there exists a member which is equal to 1. The name “infinite search” is perhaps unfair, but it brings into sharp focus that the computational meaning of this theorem is not clear. The theorem is tantamount to an infinite loop in computer programming.

Most mathematicians acknowledge the important distinction between the two theorems, but regard the principle of infinite search as an expedient tool to prove theorems, with the belief that theorems so proved can then be specialized to constructive theorems, when necessary.

Contrary to this belief, many classical theorems proved directly or indirectly via the principle of infinite search are actually equivalent to the latter, and, as such, can never have a constructive proof. Oftentimes, not even the numerical meaning of the theorems in question is clear.

We believe that, for the constructive formulations and proofs of even the most abstract theorems, the easiest way is a disciplined and systematic approach, by using only finite searches and by quantifying mathematical objects and theorems at each and every step, with natural numbers as a starting point. The above cited references show that this approach is not only possible, but fruitful.

It should be emphasized that we do not claim that theorems whose proofs require the principle of infinite search are untrue or incorrect. They are certainly correct and consistent derivations from commonly accepted axioms. There is indeed no reason why we cannot discuss such classical theorems alongside their constructive counterparts. The term “non-constructive mathematics” is not meant to be pejorative. We will use,
in its place, the more positive term “classical mathematics”.

Moreover, it is a myth that constructivists use a different system of logic. The only logic we use is everyday logic; no formal language is needed. The present author considers himself a mathematician who is neither interested in, nor equipped to comment on, the formalization of mathematics, classical or constructive.

Since a constructively valid argument is also correct from the classical viewpoint, a reader of the classical persuasion should have no difficulties understanding our proofs. Proofs using only finite searches are surely agreeable to any reader who is accustomed to infinite searches.

Indeed, the author would consider the present book a success if the reader, but for this introduction and occasional remarks in the text, finishes reading without realizing that this is a constructive treatment. At the same time, we hope that a reader of the classical persuasion might consider the more disciplined approach of constructive mathematics for his or her own research an invitation to a challenge.

We hasten to add that we do not think that finite computations in constructive mathematics are the end. We would prefer a finite computation with \( n \) steps to one with \( n! \) steps. We would be happy to see a systematic and general development of mathematics which is not only constructive, but also computationally efficient. That admirable goal will however be left to abler hands.

Probability theory, rooted in applications, can naturally be expected to be constructive. Indeed, the crowning achievements of probability theory — the laws of large numbers, the central limit theorems, the analysis of Brownian motion processes and their stochastic integrals, and that of Levy processes, to name just a few — are exemplars of constructive mathematics. Kolmogorov, the grandfather of modern probability theory, actually took an interest in the formalization of general constructive mathematics.

On the other hand, many a theorem in modern probability actually implies the principle of infinite search. The present work attempts a systematic constructive development. Each existence theorem will be a construction. The input data, the construction procedure, and the output objects are the essence and integral parts of the theorem. Incidentally, by inspecting each step in the procedure, we can routinely observe how the output varies with the input. Thus a continuity theorem in epsilon-delta terms routinely follows an existence theorem. For example, we will construct a Markov process from a given semigroup, and prove that the resulting Markov process varies continuously with the semigroup, in epsilon-delta terms often derived from the Borell-Cantelli lemma.

The reader with the probability literature will notice that our constructions resemble Kolmogorov’s construction of the Brownian motion process, which is replete with Borel-Cantelli estimates and rates of convergence. This is in contrast to popular proofs of existence via Prokhorov’s Theorem. The reader can regard Part III of this book, Chapters 6-11, the part on stochastic processes, as an extension of Kolmogorov’s constructive methods to stochastic processes: Danielle-Kolmogorov-Skorokhod construction of random fields, measurable random fields, a.u. continuous processes, a.u. càdlàg processes, martingales, strong Markov processes, and Feller processes, all with locally compact state spaces.

Such a systematic, constructive, and general treatment of stochastic processes, we believe, has not previously been attempted.
The purpose of this book is twofold. A student with a general mathematics background can use it at the first-year graduate-school level can use it as an introduction to probability or to constructive mathematics, and an expert in probability can use it as a reference for further constructive development in his or her own research specialties.

Part II of this book, Chapters 3-5, is a re-packaging and expansion of the measure theory in [Bishop and Bridges 1985]. This is so we can have a self-contained probability theory in terms familiar to probabilists.

For expositions of constructive mathematics, see the first chapters of the last cited reference. See also [Richman 1982] and [Stolzenberg 1970]. We give a synopsis in the next chapter, along with basic notations and terminologies.
Chapter 2

Preliminaries

Natural numbers

We start with the natural numbers as known in elementary schools. All mathematical objects are constructed from natural numbers, every theorem ultimately a calculation on the natural numbers. From natural numbers are constructed the integers and the rational numbers, along with the arithmetical operations, in the manner taught in elementary schools.

We claim to have a natural number only when we have provided a finite method to calculate it, i.e., to find its decimal representation. This is the fundamental difference from classical mathematics, which requires no such finite method; an infinite procedure in a proof is considered just as good in classical mathematics.

The notion of a finite natural number is so simple and so immediate that no attempt is needed to define them in even simpler terms. A few examples would suffice as clarification: 1, 2, 3 are natural numbers. So are \(9^9\) and \(9^{9^9}\); the multiplication method will give, at least in principle, their decimal expansion in a finite number of steps. On the other hand, the “truth value” of a particular mathematical statement is a natural number only if a finite method has been supplied which, when carried out, would conclusively prove or disprove the statement.

Calculations and theorems

An algorithm or a calculation means any finite, step-by-step procedure. A mathematical object is defined when we specify the calculations that need to be done to produce this object. We say that we have proved a theorem if we have provided a step-by-step method that translates the calculations doable in the hypothesis to a calculation in the conclusion of the theorem. The statement of the theorem is merely a summary of the algorithm contained in the proof.

Although we do not, for good reasons, write mathematical proofs in a computer language, the reader would do well to compare constructive mathematics to the development of a large computer software library, successive objects and library functions
being built from previous ones, each with a guarantee to finish in a finite number of steps.

Proofs by contradiction

There is a trivial form of proofs by contradiction which is valid and useful in constructive mathematics. Suppose we have already proved that one of two given alternatives, \( A \) and \( B \), must hold, meaning that we have given a finite method, which, when unfolded, gives either a proof for \( A \) or a proof for \( B \). Suppose subsequently we also prove that \( A \) is impossible. Then we can conclude that we have a proof of \( B \); we need only exercise said finite method, and see that the resulting proof is for \( B \).

Recognizing non-constructive theorems

Consider the simple theorem “if \( a \) is a real number, then \( a \leq 0 \) or \( 0 < a \)”, which may be called the principle of excluded middle for real numbers. We can see that this theorem implies the principle of infinite search by the following argument. Let \( (x_i)_{i=1,2,...} \) be any given sequence of 0-or-1 integers. Define the real number \( a = \sum_{i=1}^{\infty} x_i 2^{-i} \). If \( a \leq 0 \), then all members of the given sequence are equal to 0; if \( 0 < a \), then some member is equal to 1. Thus the theorem implies the principle of infinite search, and therefore cannot be constructively valid.

Any theorem that implies this limited principle of excluded middle cannot have a constructive proof. This observation provides a quick way for the constructive analyst to recognize certain theorems as nonconstructive. Then we can proceed to find constructive substitutes.

For the aforementioned principle of excluded middle of real numbers itself, a useful constructive substitute is the theorem “if \( a \) is a real number, then, for arbitrarily small \( \varepsilon > 0 \), we have \( a < \varepsilon \) or \( 0 < a \)”. Heuristically, this is a recognition that a general real number \( a \) can be computed with arbitrarily small, but nonzero, error.

Prior knowledge

We assume that the reader of this book has familiarity of calculus and metric spaces, and has had an introductory course in probability theory at the level of [Feller I 1971] Feller or [Ross 2003] Ross. We recommend prior reading of the first four chapters of [Bishop and Bridges 1985], which contain the basic treatment of the real numbers, set theory, and metric spaces. We will also require some rudimentary knowledge of complex numbers and complex analysis.

The reader should have no difficulty in switching back and forth between constructive mathematics and classical mathematics, any more than in switching back and forth between classical mathematics and computer programming. Indeed, the reader is urged to read, concurrently with this book if not before, the many classical texts in probability.
**Notations and conventions**

If \( x, y \) are mathematical objects, we write \( x \equiv y \) to mean "\( x \) is defined as \( y \)". "\( x \), which is defined as \( y \)". "\( x \), which has been defined earlier as \( y \)". or any other grammatical variation depending on the context.

**Numbers**

Unless otherwise indicated, \( N, Q \), and \( R \) will denote the set of integers, the set of rational numbers in the decimal or binary system, and the set of real numbers respectively. We will also write \( \{1, 2, \cdots\} \) for the set of positive integers. The set \( R \) is equipped with the Euclidean metric. Suppose \( a, b, a_i \in R \) for \( i = m, m+1 \cdots \) for some \( m \in N \). We will write \( \lim_{i \to \infty} a_i \) for the limit of the sequence \( a_m, a_{m+1}, \cdots \) if it exists, without explicitly referring to \( m \). We will write \( a \lor b, a \land b, a_+, a_- \) for \( \max(a, b), \min(a, b), a \lor 0, a \land 0 \) respectively. The sum \( \sum_{i=m}^n a_i \equiv a_m + \cdots + a_n \) is understood to be 0 if \( n < m \). The product \( \prod_{i=m}^n a_i \equiv a_m \cdots a_n \) is understood to be 1 if \( n < m \). Suppose \( a_i \geq 0 \) for \( i = m, m+1 \cdots \). We write \( \sum_{i=m}^n a_i < \infty \) if and only if \( \sum_{i=m}^\infty |a_i| < \infty \), in which case \( \sum_{i=m}^n a_i \) is taken to be \( \lim_{n \to \infty} \sum_{i=m}^n a_i \). In other words, unless otherwise specified, convergence of a series of real numbers means absolute convergence.

**Sets and functions**

In general, a set is a collection of objects equipped with an equality relation. To define a set is to specify how to construct an element of the set, and how to prove that two elements are equal. A set is also called a family.

The usual set-theoretic notations are used. Let two subsets \( A \) and \( B \) of a set \( \Omega \) be given. We will write \( A \cup B \) for the union, and \( A \cap B \) or \( AB \) for the intersection. We write \( A \subset B \) if each member \( \omega \) of \( A \) is a member of \( B \). We write \( A \supset B \) for \( B \subset A \). The set-theoretic complement of a subset \( A \) of the set \( \Omega \) is defined as the set \( \{ \omega \in \Omega : \omega \notin A \} \). We write \( \omega \not\in A \) if \( \omega \in A \) implies a contradiction. The set \( \Omega \) is said to be discrete if, for each \( \omega, \omega' \in \Omega \) either (i) \( \omega = \omega' \) or (ii) the assumption that \( \omega = \omega' \) leads to a contradiction. Given a set \( \Omega \), the subset \( \emptyset \) defined as the set-theoretic complement of \( \Omega \) and is called the empty set. The notion of a set-theoretic complement is otherwise rarely used in the present book. Instead, we will use heavily the notions of a metric complement or a measure-theoretic complement, to be defined later.

Suppose \( A, B \) are sets. A finite, step by step, method \( X \) which produces an element \( X(x) \in B \) given any \( x \in A \) is called an operation on \( A \) to \( B \). The element \( X(x) \) need not be unique. Two different applications of the operation \( X \) with the same input element \( x \) can produce different outputs. An example of an operation is \( [x]_1 \), which assigns to each \( x \in R \) an integer \( [x]_1 \in (a, a+2) \). This operation is a substitute of the classical operation \( [\cdot]_1 \), and will be used frequently in the present work.

Suppose \( \Omega, \Omega' \) are sets. Suppose \( X \) is an operation which, for each \( \omega \) in some non-empty subset \( A \) of \( \Omega \), constructs a unique member \( X(\omega) \) in \( \Omega' \). Then the operation \( X \) is called a function from \( \Omega \) to \( \Omega' \), or simply a function on \( \Omega \). The subset \( A \) is called the domain of \( X \). A function is also called a mapping. We then write \( X : \Omega \to \Omega' \), and write \( \text{domain}(X) \) for the set \( A \). Thus a function \( X \) is an operation which has the additional
with domain \( Y \) there exists an operation \( \Omega \) on the set \( A \). Functions defined only almost everywhere, in a sense to be made precise later. Separately, we sometimes use the expression \( \omega \to X(\omega) \) for a function \( X \) whose domain is understood. For example, the expression \( \omega \to \omega^2 \) stands for the function \( X: R \to R \) defined by \( X(\omega) \equiv \omega^2 \) for each \( \omega \in R \).

Let \( X: \Omega \to \Omega' \) be a function, and let \( A \) be a subset of \( \Omega \) such that \( A \cap \text{domain}(X) \) is non-empty. Then the \textit{restriction} \( X|A \) of \( X \) to \( A \) is defined as the function from \( A \) to \( \Omega' \) with \( \text{domain}(X|A) \equiv A \cap \text{domain}(X) \) and \( (X|A)(\omega) \) for each \( \omega \in \text{domain}(X|A) \). The set

\[
B \equiv \{ \omega' \in \Omega' : \omega' = X(\omega) \text{ for some } \omega \in \text{domain}(X) \}
\]

is called the \textit{range} of the function \( X \), and is denoted by \( \text{range}(X) \).

A function \( X: A \to B \) is called a \textit{surjection} if \( \text{range}(X) = B \); in that case, there exists an operation \( Y: B \to A \), not necessarily a function, such that \( X(Y(b)) = b \) for each \( b \in B \). The function \( X \) is called an \textit{injection} if for each \( a, a' \in \text{domain}(X) \) with \( X(a) = X(a') \) we have \( a = a' \). It is called a \textit{bijection} if \( \text{domain}(X) = A \) and if \( X \) is both a surjection and an injection.

Let \( X: B \to A \) be a surjection with \( \text{domain}(X) = B \). Then the triple \( (A, B, X) \) is called an \textit{indexed set}. In that case, we call \( X_b = X(b) \) for each \( b \in B \). We will, by abuse of notations, call \( A \) or \( \{X_b : b \in B\} \) an \textit{indexed set}, and write \( A \equiv \{X_b : b \in B\} \). We will call \( B \) the index set, and say that \( A \) is indexed by the members \( b \) of \( B \).

A set \( A \) is said to be \textit{finite} if there exists a bijection \( v: \{1, \ldots, n\} \to A \), for some \( n \geq 1 \), in which case we write \( |A| \equiv n \) and call it the \textit{size} of \( A \). We will then call \( v \) an \textit{enumeration} of the set \( A \), and call the pair \((A, v)\) an \textit{enumerated set}. When the enumeration \( v \) is understood from context, we will abuse notations and simply call the set \( A \equiv \{v_1, \ldots, v_n\} \) an enumerated set.

A set \( A \) is said to be \textit{countable} if there exists a surjection \( v: \{1, 2, \ldots\} \to A \). A set \( A \) is said to be \textit{countably infinite} if there exists a bijection \( v: \{1, 2, \ldots\} \to A \). We will then call \( v \) an \textit{enumeration} of the set \( A \), and call the pair \((A, v)\) an enumerated set. When the enumeration \( v \) is understood from context, we will abuse notations and simply call the set \( \{v_1, v_2, \ldots\} \) an enumerated set.

Suppose \( X: \Omega \to \Omega' \) and \( X': \Omega' \to \Omega'' \) are such that the set \( A \) defined by \( A = \{\omega \in \text{domain}(X') : X'(\omega) \in \text{domain}(X)\} \) is non-empty. Then the \textit{composite function} \( X' \circ X: \Omega \to \Omega'' \) is defined to have \( \text{domain}(X' \circ X) = A \) and \( (X' \circ X)(\omega) = X'(X(\omega)) \) for \( \omega' \in A \). The alternative notations \( X'(X) \) will also be used for \( X' \circ X \).

Henceforth, unless otherwise indicated, we write \( X(\omega) \) only with the implicit condition that \( \omega \in \text{domain}(X) \).

Two functions \( X, Y \) are considered equal, \( X = Y \) in symbols, if

\[
\text{domain}(X) = \text{domain}(Y)
\]

and \( X(\omega) = Y(\omega) \) for each \( \omega \in \text{domain}(X) \). When emphasis is needed, this equality will be referred to as the \textit{set-theoretic equality}, in contradistinction to almost everywhere equality, to be defined later.

Let \( \Omega \) be a set and let \( n \geq 1 \) be arbitrary integer. A function \( \omega: \{1, \cdots, n\} \to \Omega \) which assigns to each \( i \in \{1, \cdots, n\} \) an element \( \omega(i) \equiv \omega_i \in \Omega \) is called a \textit{finite}
sequence of elements in $\Omega$. A function $\omega : \{1, 2, \cdots, \} \to \Omega$ which assigns to each $i \in \{1, 2, \cdots, \}$ an element $\omega(i) \equiv \omega_i \in \Omega$ is called an infinite sequence of elements in $\Omega$. We will then write $\omega \equiv (\omega_1, \cdots, \omega_n) \equiv (\omega)_{i=1, \cdots, n}$, in the first case, and write $(\omega_1, \omega_2, \cdots)$ or $(\omega)_{i=1,2,\cdots}$, in the second case, for the sequence $\omega$. If, in addition, $j$ is a sequence of integers in domain($\omega$), with that $j_k < j_h$ for each $k < h$ in domain($j$), then the sequence $\omega \circ j : \text{domain}(j) \to \Omega$ is called a subsequence of $\omega$. Throughout this book, we will write a subscripted symbol $a_b$ interchangeably with $a(b)$ to lessen the burden on subscripts. Thus, $a_{b(c)}$ stands for of $a_{b_c}$. Similarly, $\omega_{j(k)} \equiv \omega(j(k))$ for each $k \in \text{domain}(j)$, and we write $(\omega(j_1), \omega(j_2), \cdots)$ or $(\omega(j_k))_{k=1,2,\cdots}$, or simply $(\omega(j))_k$, for the subsequence when the domain of $j$ is clear. If $(\omega_1, \cdots, \omega_n)$ is a sequence, we will write $\{\omega_1, \cdots, \omega_n\}$ for the range of $\omega$. Thus an element $\omega_0 \in \Omega$ is in $\{\omega_1, \cdots, \omega_n\}$ if and only if there exists $i = 1, \cdots, n$ such that $\omega_0 = \omega_i$.

Suppose $(\omega_i)_{i=1,2,\cdots}$ and $(\omega'_i)_{i=1,2,\cdots}$, are two infinite sequences. We will write $(\omega_i, \omega'_i)_{i=1,2,\cdots}$ for the merged sequence $(\omega, \omega', \omega_2, \cdots)$. Similar notations for several sequences.

Let $(\Omega_n)_{n=0,1,\cdots}$ be a sequence of non-empty sets. Consider any $0 \leq n \leq \infty$, i.e. $n$ is a non-negative integer or the symbol $\infty$. We will let $\Omega^{(n)}$ denote the Cartesian product $\prod_{j=0}^n \Omega_j$. Consider $0 \leq k < \infty$ with $k \leq n$. The coordinate function $\pi_k$ is the function with domain($\pi_k$) = $\Omega^{(n)}$ and $\pi_k(\omega_0, \omega_1, \cdots) = \omega_k$. If $\Omega_n = \Omega$ for each $n \geq 0$, then we will write $\Omega_k$ for $\Omega^{(n)}$ for each $n \geq 0$. Let $X$ be a function on $\Omega_k$ and let $Y$ be a function on $\Omega^{(n)}$. When confusion is unlikely, we will use the same symbol $X$ also for the function $X \circ \pi_k$ on $\Omega^{(n)}$, which depends only on the $k$-th coordinate. Likewise we will use $Y$ also for the function $Y \circ (\pi_0, \cdots, \pi_k)$ on $\Omega^{(n)}$, which depends only on the first $k + 1$ coordinates. Thus every function on $\Omega_k$ or $\Omega^{(n)}$ is identified with a function on $\Omega^{(n)}$. Accordingly, sets of functions on $\Omega_k, \Omega^{(n)}$ are regarded also as sets of functions on $\Omega^{(n)}$.

Let $M$ the family of all real-valued functions on $\Omega$, equipped with the set-theoretic equality for functions. Suppose $X, Y \in M$ and suppose $f$ is a function on $R \times R$ such that the set

$D \equiv \{ \omega \in \text{domain}(X) \cap \text{domain}(Y) : (X(\omega), Y(\omega)) \in \text{domain}(f) \}$

is non-empty. Then $f(X, Y)$ is defined as the function with domain($f(X, Y)$) $\equiv D$ and $f(X, Y)(\omega) \equiv f(X(\omega), Y(\omega))$ for each $\omega \in D$. The definition extends to a sequence of functions in the obvious manner. Suppose $(X_i)_{i=m, m+1, \cdots}$ is a sequence in $F$. Suppose the set

$D \equiv \{ \omega \in \bigcap_{i=m}^{\infty} \text{domain}(X_i) : \sum_{i=m}^{\infty} |X_i(\omega)| < \infty \}$

is non-empty, then $\sum_{i=m}^{\infty} X_i(\omega)$ is defined as the function with domain($\sum_{i=m}^{\infty} X_i$) $\equiv D$ and with value $\sum_{i=m}^{\infty} X_i(\omega)$ for each $\omega \in D$. Unless otherwise specified, convergence for series means absolute convergence.

Suppose $X, Y \in M$ and $A$ is a subset of $\Omega$, and suppose $a \in R$. We say $X \leq Y$ on $A$ if (i) $A \cap \text{domain}(X) = A \cap \text{domain}(Y)$ and (ii) $X(\omega) \leq Y(\omega)$ for each $\omega \in A \cap \text{domain}(X)$. If $X \leq Y$ on $\Omega$ we will simply write $X \leq Y$. Thus $X \leq Y$ implies $\text{domain}(X) = \text{domain}(Y)$. We write $X \leq a$ if $X(\omega) \leq a$ for each $\omega \in \text{domain}(X)$. We will write

$(X \leq a) \equiv \{ \omega \in \text{domain}(X) : X(\omega) \leq a \}$. 

Yuen-Kwok Chan 17 Constructive Probability
We make similar definitions when the relation $\leq$ is replaced by $<, \geq, >$, or =. We say $X$ is non-negative if $X \geq 0$.

Suppose $a \in R$. We will abuse notations and write $a$ also for the constant function $X$ with domain $(X) = \Omega$ and with $X(\omega) = a$ for each $\omega \in domain(X)$.

Let $X$ be a function on the product set $\Omega' \times \Omega''$. Let $\omega' \in \Omega'$ be such that $(\omega', \omega'') \in domain(X)$ for some $\omega'' \in \Omega''$. Define the function $X(\omega', \cdot)$ on $\Omega''$ by

$$domain(X(\omega', \cdot)) \equiv \{ \omega'' \in \Omega'' : (\omega', \omega'') \in domain(X) \}$$

and $X(\cdot, \omega'')(\omega') \equiv X(\omega', \omega'')$. Similarly, let $\omega'' \in \Omega''$ be such that $(\omega', \omega'') \in domain(X)$ for some $\omega' \in \Omega'$. Define the function $X(\cdot, \omega'')$ on $\Omega'$ by

$$domain(X(\cdot, \omega'')) \equiv \{ \omega' \in \Omega' : (\omega', \omega'') \in domain(X) \} \cdot \{ \omega' \in \Omega' : (\omega', \omega'') \in domain(X) \} \cdot$$

and $X(\cdot, \omega'')(\omega') \equiv X(\omega', \omega'')$. Given a function $X$ on the Cartesian product $\Omega' \times \Omega'' \times \cdots \times \Omega^{(n)}$, for each $(\omega', \omega'', \cdots, \omega^{(n)}) \in domain(X)$, we define similarly the functions $X(\cdot, \omega'', \cdots, \omega^{(n)})(\omega'), X'(\cdot, \omega', \omega''', \cdots, \omega^{(n-1)}), \cdots, X(\omega', \omega'', \cdots, \omega^{(n-1)}, \cdots)$ on the sets $\Omega', \Omega'', \cdots, \Omega^{(n)}$ respectively.

Let $M', M''$ denote the families of all real-valued functions on two sets $\Omega', \Omega''$ respectively, and let $L''$ be a subset of $M''$. Suppose

$$T : \Omega' \times L'' \rightarrow R$$

is a real-valued function. We can define a function

$$T^+ : L'' \rightarrow M'$$

with

$$domain(T^+) \equiv \{ X'' \in L'' : domain(T(\cdot, X'')) \text{ is non-empty} \}$$

and by $T^+(X'') \equiv T(\cdot, X'')$. When there is no risk of confusion, we write $T$ also for the function $T$, $TX''$ for $T(\cdot, X'')$, and write

$$T : L'' \rightarrow M'$$

interchangeably with the expression (2.0.1). Thus the duality

$$T(\cdot, X'')(\omega') \equiv T(\omega', X'') \equiv T(\omega', \cdot)(X'').$$

(2.0.2)

**Metric spaces**

We recommend prior reading of the first four chapters of [Bishop and Bridges 1985], which contain the basic treatment of the real numbers, set theory, and metric spaces. We will use without comment theorems about metric spaces and continuous functions from these chapters. The definitions and notations, with few exceptions, are familiar to readers of classical texts. A summary of these definitions follows.

Let $(S, d)$ be a metric space. If $J$ is a subset of $S$, its metric complement is the set $\{ x \in S : d(x, y) > 0 \}$ for all $y \in J$. Unless otherwise specified, $J^c$ will denote the metric complement of $J$. A condition is said to hold for all but countably many members of $S$. 

Yuen-Kwok Chan 18 Constructive Probability
if it holds for each member in the metric complement \( J_c \) of some countable subset \( J \) of \( S \). We will say that two elements \( x, y \in S \) are unequal, and write \( x \neq y \), if \( d(x, y) > 0 \).

We will call a subset \( A \) of \( S \) metrically discrete if, for each \( x, y \in A \) we have \( x = y \) or \( d(x, y) > 0 \). Classically each subset \( A \) of \( S \) is metrically discrete.

Let \( (f_n)_{n=1, 2, \ldots} \) be a sequence of functions from a set \( \Omega \) to \( S \) such that the set

\[
D \equiv \{ \omega \in \bigcup_{n=1}^{\infty} \bigcap_{i=1}^{n} \text{domain}(f_i) : \lim_{i \to \infty} f_i(\omega) \text{ exists in } S \}
\]

is non-empty, then \( \lim_{i \to \infty} f_i \) is defined as the function with \( \text{domain}(\lim_{i \to \infty} f_i) \equiv D \) and with value \( \lim_{i \to \infty} f_i(\omega) \) for each \( \omega \in D \). We emphasize that \( \lim_{i \to \infty} f_i \) is well defined only if it can be shown that \( D \) is non-empty. Note that for each \( \omega \in D \), the value \( f_i(\omega) \) is defined in \( S \) for each \( i \geq n \) for some \( n \geq 1 \), but not necessary for any \( i < n \).

A function \( f: S \to S' \) is said to be uniformly continuous on a subset \( A \subset \text{domain}(f) \), relative to the metrics \( d, d' \) on \( S, S' \) respectively, if there exists an operation \( \delta: (0, \infty) \to (0, \infty) \) such that \( d'(f(x), f(y)) < \delta \) for each \( x, y \in A \) with \( d(x, y) < \delta(\epsilon) \). When there is need to be precise as to the metrics \( d, d' \), we will say that \( f: (S, d) \to (S', d') \) is uniformly continuous on \( A \). The operation \( \delta \) is called a modulus of continuity of \( f \) on \( A \). If there exists a coefficient \( c \geq 0 \) such that \( d'(f(x), f(y)) \leq cd(x, y) \) for all \( x, y \in A \), then the function \( f \) is said to be Lipschitz continuous on \( A \), and the constant \( c \) is then called a Lipschitz constant of \( f \) on \( A \). In that case, we will say simply that \( f \) has Lipschitz constant \( c \).

A metric space \( (S, d) \) is said to be totally bounded if, for each \( \epsilon > 0 \), there exists a finite subset \( A \subset S \) such that for each \( x \in S \) there exists \( y \in A \) with \( d(x, y) < \epsilon \). The subset \( A \) is then called an \( \epsilon \)-approximation of \( S \). A compact metric space \( K \) is defined as a complete and totally bounded metric space.

A subset \( A \subset S \) is said to be bounded if there exists \( x \in S \) and \( a > 0 \) such that \( A \subset (d(\cdot, x) \leq a) \). A subset \( S' \subset S \) is said to be locally compact if every bounded subset of \( S' \) is contained in some compact subset. The metric space \( (S, d) \) is said to be locally compact if the subset \( S \) is locally compact. A function \( f: (S, d) \to (S', d') \) is said to be continuous if \( \text{domain}(f) = S \) and if it is uniformly continuous on each compact subset \( K \) of \( S \).

Suppose \( (S_n, d_n)_{n=1, 2, \ldots} \) is a sequence of metric spaces. For each integer \( n \geq 1 \), define

\[
d^{(n)}(x, y) \equiv (\bigotimes_{i=1}^{n} d_i)(x, y) \equiv (d_1 \otimes \cdots \otimes d_n)(x, y) \equiv \bigvee_{i=1}^{n} d_i(x_i, y_i)
\]

for each \( x, y \in \prod_{i=1}^{n} S_i \). Then \( (S^{(n)}, d^{(n)}) \equiv \bigotimes_{i=1}^{n} (S_i, d_i) \equiv (\prod_{i=1}^{n} S_i, \otimes_{i=1}^{n} d_i) \) is a metric space called the product metric space of \( S_1, \ldots, S_n \). Define the infinite product metric \( \bigotimes_{i=1}^{\infty} d_i \) on \( \prod_{i=1}^{\infty} S_i \) by

\[
d^{(\infty)}(x, y) \equiv (\bigotimes_{i=1}^{\infty} d_i)(x, y) \equiv \bigvee_{i=1}^{\infty} 2^{-1}(1 \wedge d_i(x_i, y_i))
\]

for each \( x, y \in \prod_{i=1}^{\infty} S_i \). Define the infinite product metric space

\[
(S^{(\infty)}, d^{(\infty)}) \equiv \bigotimes_{i=1}^{\infty} (S_i, d_i) \equiv \bigotimes_{i=1}^{\infty} S_i, \otimes_{i=1}^{\infty} d_i)
\]
CHAPTER 2. PRELIMINARIES

Suppose, in addition, \((S_n, d_n)\) is a copy of the same metric space \((S, d)\) for each \(n \geq 1\). Then we simply write \((S^n, d^n) \equiv (S^{(n)}, d^{(n)})\) and \((S^n, d^n) \equiv (S^{(\infty)}, d^{(\infty)})\). Thus, in this case,

\[
d(x, y) \equiv \sqrt[n]{\sum_{i=1}^{n} d(x_i, y_i)}
\]

for each \(x = (x_1, \cdots, x_n), y = (y_1, \cdots, y_n) \in S^n\), and

\[
d^{(\infty)}(x, y) \equiv \sum_{i=1}^{\infty} 2^{-i} (1 \wedge d_i(x_i, y_i)).
\]

for each \(x = (x_1, x_2, \cdots), y = (y_1, y_2, \cdots) \in S^{\infty}.

If, in addition, \((S_n, d_n)\) is locally compact for each \(n \geq 1\), then the finite product space \((S^n, d^{(n)})\) is locally compact for each \(n \geq 1\), while the infinite product space \((S^{(\infty)}, d^{(\infty)})\) is complete but not necessarily locally compact. If \((S_n, d_n)\) is a compact for each \(n \geq 1\), then both the finite and infinite product spaces are compact.

Suppose \((S, d)\) is a metric space. We will write \(C_u(S, d)\), or simply \(C_u(S)\), for the space of real-valued functions functions on \((S, d)\) with domain \(f = S\) which are uniformly continuous on each bounded subset of \(S\). We will write \(C_{ab}(S, d)\), or simply \(C_{ab}(S)\), for the subspace of \(C_u(S)\) whose members are bounded. Let \(x_o\) be an arbitrary, but fixed, reference point in \((S, d)\). A continuous function \(f\) on \((S, d)\) is then said to vanish at infinity if, for each \(\epsilon > 0\), there exists \(a > 0\) such that \(|f| \leq \epsilon\) for each \(x \in S\) with \(d(x, x_o) > a\). Write \(C_0(S, d)\), or simply \(C_0(S)\), for the space of continuous functions on \((S, d)\) which vanish at infinity. A real-valued function \(f\) on \(S\) is said to have a subset \(A \subset S\) as support if \(x \in domain(f)\) and \(|f(x)| > 0\) together imply \(x \in A\). Then we also say that \(f\) is supported by \(A\), or that \(A\) supports \(f\). We will write \(C(S, d)\), or simply \(C(S)\), for the subspace of \(C_{ab}(S, d)\) whose members have bounded supports. In the case where \((S, d)\) is locally compact, \(C(S)\) consists of continuous functions on \((S, d)\) with compact supports. Summing up,

\[
C(S) \subset C_0(S) \subset C_{ab}(S) \subset C_{u}(S).
\]

Suppose a subset \(A\) of \(R\) is nonempty. A number \(b \in R\) is called a lower bound of \(A\), and \(A\) said to bounded from below, if \(b \leq a\) for each \(a \in A\). A lower bound \(b\) of \(A\) is called the greatest lower bound, or infimum, of \(A\) if \(b \geq b'\) for each lower bound \(b'\) of \(A\). In that case, we write \(\inf A \equiv b\).

Similarly, a number \(b \in R\) is called an upper bound of \(A\), and \(A\) said to be bounded from above, if \(b \geq a\) for each \(a \in A\). An upper bound \(b\) of \(A\) is called the least upper bound, or supremum, of \(A\) if \(b \leq b'\) for each upper bound \(b'\) of \(A\). In that case, we write \(\sup A \equiv b\).

There is no constructive general proof for the existence of an infimum for an subset of \(R\) that is bounded from below. Existence needs to be proved before each usage for each special case, much as in the case of limits. In that regard, [Bishop and Bridges 1985] proves that, if a non-empty subset \(A\) of \(R\) is totally bounded, then both \(\inf A\) and \(\sup A\) exist.

Suppose \(f\) is a continuous function on a compact metric space \((K, d)\). Then the last cited text proves that \(\inf_K f \equiv \inf\{f(x) : x \in K\}\) and \(\sup_K f \equiv \sup\{f(x) : x \in K\}\) exist.
Miscellaneous

The symbols \( \Rightarrow, \Leftarrow, \text{ and } \Leftrightarrow \) will in general stand for “only if”, “if”, and “if and only if” respectively. An exception will be made where the symbol \( \Rightarrow \) is used for weak convergence, defined later. The intended meaning will be clear from context.

We will often write “\( x, y, \cdots, z \in A \)” as an abbreviation for “\( \{ x, y, \cdots, z \} \subset A \)”.

Unless it is otherwise indicated by context, the symbols \( i, j, k, m, n, p \) will denote integers, the symbols \( a, b \) will denote real numbers, and the symbols \( \varepsilon, \delta \) positive real numbers. For example the statement “for each \( i \geq 1 \)” will mean “for each integer \( i \geq 1 \)”.

Suppose \( (a_n)_{n=1}^{2} \ldots \) is a sequence of real numbers. Then \( a_n \to a \) stands for \( \lim_{n \to \infty} a_n = a \). We write \( a_n \uparrow a \) if \( (a_n) \) is a nondecreasing sequence and \( a_n \to a \). Similarly, we write \( a_n \downarrow a \) if \( (a_n) \) is a nonincreasing sequence and \( a_n \to a \). More generally, suppose \( f \) is a function on some subset \( A \subset \mathbb{R} \). Then \( f(x) \to a \) stands for \( \lim_{x \to x_0} f(x) = a \) where \( x_0 \) can stand for a real number or for one of the symbols \( \infty \) or \( -\infty \).

We use the common “big \( O \)” and “small \( o \)” notation. Suppose \( f \) and \( g \) are functions on some subset \( A \subset \mathbb{R} \). Let \( x_0 \) stand for a real number or for one of the symbols \( \infty \) or \( -\infty \). If for some \( c > 0 \), we have \( |f(x)| \leq c|g(x)| \) for all \( x \in A \) in some neighborhood \( B \) of \( x_0 \), then we write \( f(x) = O(g(x)) \). If for each \( c > 0 \), we have \( |f(x)| \leq c|g(x)| \) for each \( x \in A \) in some neighborhood \( B \) of \( x_0 \), then we write \( f(x) = o(g(x)) \). A subset \( B \subset \mathbb{R} \) is a neighborhood of \( x_0 \) if there exists an open interval \( (a, b) \) such that either (i) \( x_0 \in (a, b) \), (ii) \( b = x_0 = \infty \), or (iii) \( a = x_0 = -\infty \).

Finally, we use the symbol \( \square \) to mark the end of a proof or a definition.
Part II

Probability Theory
Chapter 3

Partitions of Unity

In the Introduction, we summarized the basic concepts and theorems about metric spaces from [Bishop and Bridges 1985]. Locally compact metric spaces were introduced. They can be regarded as a simple, but wide ranging, generalization of the real line. Most, if not all, metric spaces in the present book are locally compact.

In the present chapter, we will define binary approximations and partitions of unity for a locally compact metric space $(S, d)$. Roughly speaking, a binary approximation is a digitization of $(S, d)$, a generalization of the binary numbers which digitize the space $\mathbb{R}$ of real numbers. A partition of unity is then a sequence in $C(S, d)$ which serves as a basis for $C(S, d)$ in the sense that each $f \in C(S, d)$ can be approximated by linear combinations of members in the partition of unity.

We first cite a theorem from [Bishop and Bridges 1985] which guarantees an abundance of compact subsets.

**Theorem 3.0.1. (Abundance of compact sets).** Let $f : K \to \mathbb{R}$ be a continuous function on a compact metric space $(K, d)$ with domain $(f) = K$. Then, for all but countably many real numbers $\alpha > \inf_K f$, the set $(f \leq \alpha) \equiv \{ x \in K : f(x) \leq \alpha \}$ is compact.

**Proof.** See Theorem (4.9) in Chapter 4 of [Bishop and Bridges 1985].

Classically, the set $(f \leq \alpha)$ is compact for each $\alpha \geq \inf_K f$, without exception. Such a general statement would however imply the principle of infinite search, and is therefore nonconstructive. Theorem [3.0.1] above is sufficient for all our purposes.

**Definition 3.0.2. (Convention for compact sets $(f \leq a)$).** We hereby adopt the convention that, if the compactness of the set $(f \leq \alpha)$ is required in a discussion, compactness has been explicitly or implicitly verified, usually by proper prior selection of the constant $\alpha$, enabled by Theorem [3.0.1].

The following corollary guarantees an abundance of compact neighborhoods of a compact set.

**Corollary 3.0.3. (Abundance of compact neighborhoods).** Let $(S, d)$ be a locally compact metric space, and let $K$ be a compact subset of $S$. Then the subset $K_r \equiv (d(\cdot, K) \leq r) \equiv \{ x \in S : d(x, K) \leq r \}$
is compact for all but countably many \( r > 0 \).

**Proof.** Let \( n \geq 1 \) be arbitrary. Then \( K_n \equiv (d(\cdot, K) \leq n) \) is a bounded set. Since \((S, d)\) is locally compact, there exists a compact set \( S_n \) such that \( K_n \subset S_n \subset S \). The continuous function \( f \) on \((S, d)\) defined by \( f \equiv d(\cdot, K) \) has infimum 0. Hence, by Theorem 3.0.1, the set \( \{ x \in S_n : d(x, K) \leq r \} \) is compact for all but countably many \( r > 0 \). On the other hand, for all \( r < n \) we have

\[
K_r = K_r \cap K_n S_n = \{ x \in S_n : d(x, K) \leq r \}.
\]

Thus \( K_r \) is compact for all \( r \in (0, n) \cap A_n \), where \( A_n \) contains all but countably many \( r > 0 \). Define \( A = \bigcap_{n=1}^\infty A_n \). Then \( A \) contains all but countably many \( r > 0 \). Now let \( r \in (0, \infty) \cap A \) be arbitrary. Then \( r \in (0, n) \cap A_n \) for some \( n \geq 1 \), whence \( K_r \) is compact.

Separately, the next elementary metric space lemma will be convenient.

**Lemma 3.0.4. (If \((S, d)\) is compact, then the subspace of \( C(S^n, d^m) \) whose members depend on finitely many coordinates is dense).** Suppose \((S, d)\) is a compact metric space.

Let \( n \geq 1 \) be arbitrary. Define the truncation function \( j_n^* : S^n \to S^n \) by

\[
j_n^*(x_1, x_2, \cdots) = (x_1, x_2, \cdots, x_n, x_0, x_0, \cdots)
\]

for each \((x_1, x_2, \cdots) \in S^n \). Then \( j_n^* \circ j_m^* = j_n^* \) for each \( m \geq n \). Let

\[
L_{0,n}^\circ \equiv \{ f \in C(S^n, d^m) : f = f \circ j_n^* \}.
\]

Let \( L_{0,\infty}^\circ \equiv \bigcup_{n=1}^\infty L_{0,n}^\circ \). Then \( L_{0,n}^\circ \subset L_{0,n+1}^\circ \). Moreover, the following holds.

1. \( L_{0,n}^\circ \) and \( L_{0,\infty}^\circ \) are linear subspaces of \( C(S^n, d^m) \), and consist of functions which depend, respectively, on the first \( n \) and on finitely many coordinates.

2. The subspace \( L_{0,\infty}^\circ \) is dense in \( C(S^n, d^m) \) relative to the supremum norm \( \| \cdot \| \). Specifically, let \( f \in C(S^n, d^m) \) be arbitrary, with a modulus of continuity \( \delta_f \). Then \( f \circ j_n^* \in L_{0,n}^\circ \). Moreover, for each \( \epsilon > 0 \) we have \( \| f - f \circ j_n^* \| \leq \epsilon \) if \( n > -\log_2(\delta_f(\epsilon)) \).

In particular, if \( f \) has Lipschitz constant \( c > 0 \), then \( \| f - f \circ j_n^* \| \leq \epsilon \) if \( n > \log_2(ce^{-1}) \).

**Proof.** Let \( m \geq n \geq 1 \) and \( w \in S^n \) be arbitrary. Then, for each \((x_1, x_2, \cdots) \in S^n \), we have

\[
j_n^*(j_m^*(x_1, x_2, \cdots)) = j_n^*(x_1, x_2, \cdots, x_m, x_0, x_0, \cdots)
\]

\[
= (x_1, x_2, \cdots, x_n, x_0, x_0, \cdots) = j_n^*(x_1, x_2, \cdots).
\]

Hence \( j_n^* \circ j_m^* = j_n^* \).

1. It is clear from the defining equality \[3.0.1\] that \( L_{0,n}^\circ \) is a linear subspace of \( C(S^n, d^m) \). Let \( f \in L_{0,n}^\circ \) be arbitrary. Then \( f = f \circ j_n^* = f \circ j_n^* \circ j_m^* = f \circ j_m^* \). Hence \( f \in L_{0,m}^\circ \). Thus \( L_{0,n}^\circ \subset L_{0,m}^\circ \). Consequently, \( L_{0,\infty}^\circ \equiv \bigcup_{n=1}^\infty L_{0,n}^\circ \) is a union of a nonincreasing sequence of linear subspaces of \( C(S^n, d^m) \), and is therefore also a linear subspace of \( C(S^n, d^m) \).
2. Let \( f \in C(S^n, d^n) \) be arbitrary, with a modulus of continuity \( \delta_f \). Let \( \varepsilon > 0 \) be arbitrary. Suppose \( n > -\log_2(\delta_f(\varepsilon)) \). Then \( 2^{-n} < \delta_f(\varepsilon) \). Let \((x_1, x_2, \cdots) \in S^n\) be arbitrary. Then

\[
\begin{align*}
    d^n((x_1, x_2, \cdots), j^n_n(x_1, x_2, \cdots)) \\
    = d^n((x_1, x_2, \cdots), (x_1, x_2, \cdots, x_n, x_0, \cdots)) \\
    \equiv \sum_{k=1}^{n} 2^{-k} d(x_k, x_k) + \sum_{k=n+1}^{\infty} 2^{-k} \tilde{d}(x_k, x_0) \leq 0 + 2^{-n} < \delta_f(\varepsilon),
\end{align*}
\]

where \( \tilde{d} \equiv 1 \land d \). Hence

\[
|f(x_1, x_2, \cdots) - f \circ j^n_n(x_1, x_2, \cdots)| < \varepsilon,
\]

where \((x_1, x_2, \cdots) \in S^n\) is arbitrary. We conclude that \( \|f - f \circ j^n_n\| \leq \varepsilon \), as alleged. \( \square \)

### 3.1 Binary Approximations

Let \((S, d)\) be an arbitrary locally compact metric space. Then \( S \) has a countable dense subset. A binary approximation, defined below in this section, is a structured and well-quantified countable dense subset.

Recall that (i) \( |A| \) denotes the number of elements in an arbitrary finite set \( A \), (ii) a subset \( A \) of \( S \) is said to be metrically discrete if, for each \( y, z \in A \), either \( y = z \) or \( d(y, z) > 0 \), and (iii) a finite subset \( A \) of \( K \subset S \) is called an \( \varepsilon \)-approximation of \( K \) if for each \( x \in K \) there exists \( y \in A \) with that \( d(x, y) < \varepsilon \). Classically, each subset of \((S, d)\) is metrically discrete.

\( \square \)

**Definition 3.1.1. (Binary approximation and modulus of local compactness).** Let \((S, d)\) be a locally compact metric space, with an arbitrary, but fixed, reference point \( x_0 \). Let \( A_0 = \{ x_0 \} \subset A_1 \subset A_2 \subset \cdots \) be a sequence of metrically discrete and finite subsets of \( S \). For each \( n \geq 1 \), let \( \kappa_n \equiv |A_n| \). Suppose

\[
(d(\cdot, x_0) \leq 2^n) \subset \bigcup_{x \in A(n)} (d(\cdot, x) \leq 2^{-n}) \tag{3.1.1}
\]

and

\[
\bigcup_{x \in A(n)} (d(\cdot, x) \leq 2^{-n+1}) \subset (d(\cdot, x_0) \leq 2^{n+1}) \tag{3.1.2}
\]

for each \( n \geq 1 \). Then the sequence \( \xi \equiv \{A_n\}_{n=1,2,\cdots} \) of subsets is called a binary approximation for \((S, d)\) relative to \( x_0 \), and the sequence of integers

\[
\|\xi\| \equiv \{\kappa_n\}_{n=1,2,\cdots} \equiv \{ |A_n| \}_{n=1,2,\cdots}
\]

is called the modulus of local compactness of \((S, d)\) corresponding to \( \xi \).

Thus a binary approximation is an expanding sequence of \( 2^{-n} \)-approximation for \((d(\cdot, x_0) \leq 2^n) \) as \( n \to \infty \). The next proposition shows that the definition is not vacuous. \( \square \)
First note that \( \bigcup_{n=1}^{m} A_n \) is dense in \((S,d)\) in view of relation [3.1.1]. In the case where \((S,d)\) is compact, for \( n \geq 1 \) so large that \( S = (d(\cdot,x_0 \leq 2^n)) \), relation [3.1.1] says that we need at most \( \kappa_n \) points to make a \( 2^{-n} \)-approximation of \( S \). The number \( \log \kappa_n \) is thus a bound for Kolmogorov’s \( 2^{-n} \)-entropy of the compact metric space \((S,d)\), which represents the informational content in a \( 2^{-n} \)-approximation of \( S \). (See [Lorentz 1966] for a definition of \( \varepsilon \)-entropy).

**Lemma 3.1.2. (Existence of metrically discrete \( \varepsilon \)-approximations).** Let \( K \) be a compact subset of the locally compact metric space \((S,d)\). Let \( A_0 \) be a metrically discrete finite subset of \( K \). Let \( \varepsilon > 0 \) be arbitrary. Then the following holds:

1. There exists a metrically discrete finite subset \( A_1 \) of \( K \) such that (i) \( A_0 \subset A_1 \) and (ii) \( A_1 \) is an \( \varepsilon \)-approximation of \( K \).

2. In particular, there exists a metrically discrete finite set \( A_1 \) which is an \( \varepsilon \)-approximation of \( K \).

**Proof.** 1. Let \( A \equiv \{ y_1, \cdots, y_m \} \) be an \( \varepsilon \)-approximation of \( K \). We apply a weeding procedure on \( A \). Successively examine each \( y_i \in A \). Either (i) \( d(y_i,x) > 0 \) for each \( x \in A_0 \), and \( d(y_i,y_j) > 0 \) for each \( j \) with \( 1 \leq j \leq i - 1 \), or (ii) \( d(y_i,x) < \varepsilon \) for some \( x \in A_0 \) or \( d(y_i,y_j) < \varepsilon \) for some \( j \) with \( 1 \leq j \leq i - 1 \). In case (ii), discard the point \( y_i \) from \( A \), decrease \( m \) by 1, relabel the thus-far surviving points as \( y_1, \cdots, y_m \), redefine \( A \equiv \{ y_1, \cdots, y_m \} \), and repeat the procedure. Observe that, after at most \( m \) steps, each surviving member in the set \( A \), if any, is of positive distance to each member of \( A_0 \), and is of positive distance to any other surviving member of \( A \). Now define \( A_1 \equiv A_0 \cup A \). In view of the above observation, the set \( A_0 \cup A \) is metrically discrete. In other words, \( A_1 \) is metrically discrete.

Let \( B \) be the set of discarded points. Let \( y \in K \) be arbitrary. Since \( A \cup B \) is equal to the original \( \varepsilon \)-approximation of \( K \), we see that \( y \) is of distance less than \( \varepsilon \) to some member of \( A \), or it is of distance less than \( \varepsilon \) to some member of \( B \). At the same time, each member of \( B \) is of distance less than \( \varepsilon \) to some members of \( A_0 \cup A \), according to condition (ii). Hence, in either case, \( y \) is of distance less than \( 2 \varepsilon \) to some members of \( A_0 \cup A \), thanks to the triangle inequality. We conclude that \( A_1 \equiv A_0 \cup A \) is a \( 2 \varepsilon \)-approximation of \( K \). Assertion 1 has been proved.

2. Assertion 2 is a special case of Assertion 1 by taking \( A_0 \equiv \emptyset \). \( \square \)

**Proposition 3.1.3. (Existence of binary approximations).** Each locally compact metric space \((S,d)\) has a binary approximation.

**Proof.** Let \( x_0 \in S \) be an arbitrary, but fixed, reference point. Proceed inductively on \( n \geq 1 \) to construct a metrically discrete and finite subset \( A_n \) of \( S \) to satisfy relations [3.1.1] and [3.1.2].

Let \( n \geq 0 \) be arbitrary. Let \( A_0 \equiv \{ x_0 \} \). Suppose the set \( A_n \) has been constructed for some \( n \geq 0 \), such that, if \( n \geq 1 \), then (i) \( A_n \) is metrically discrete and finite, and (ii) relations [3.1.1] and [3.1.2] are satisfied. Proceed to construct \( A_{n+1} \).

To that end, write \( \varepsilon \equiv 2^{-n-2} \), and take any \( r \in [2^n+1,2^{n+1}+\varepsilon) \) such that

\[
K \equiv (d(\cdot,x_0) \leq r)
\]
is compact. This is possible in view of Corollary 3.0.3 If \( n = 0 \), then \( A_n \equiv \emptyset \subset K \) trivially. If \( n \geq 1 \), then, according to the induction hypothesis, \( A_n \) is metrically discrete, and by relation 3.1.2 we have
\[
A_n \subset \bigcup_{x \in A(n)} (d(\cdot, x) \leq 2^{-n+1}) \subset (d(\cdot, x_0) \leq 2^{n+1}) \subset K.
\]
Hence we can apply Lemma 3.1.2 to construct a \( 2^{-n-1} \) approximation \( A_{n+1} \) of \( K \) which is metrically discrete and finite. We conclude that
\[
(d(\cdot, x_0) \leq 2^{n+1}) \subset K \subset \bigcup_{x \in A(n+1)} (d(\cdot, x) \leq 2^{-n-1})
\]
proving relation 3.1.1 for \( n + 1 \).

Now let
\[
y \in \bigcup_{x \in A(n+1)} (d(\cdot, x) \leq 2^{-n})
\]
be arbitrary. Then \( d(y, x) \leq 2^{-n} \) for some \( x \in A_{n+1} \equiv A_n \cup A \subset K \). Therefore
\[
d(x, x_0) \leq r < 2^{n+1} + \epsilon.
\]
Consequently
\[
d(y, x_0) \leq 2^{-n} + 2^{n+1} + \epsilon = 2^{-n} + 2^{n+1} + 2^{-n-2} \leq 2^{n+2}.
\]
Thus
\[
\bigcup_{x \in A(n+1)} (d(\cdot, x) \leq 2^{-n}) \subset (d(\cdot, x_0) \leq 2^{n+2}),
\]
proving relation 3.1.2 for \( n + 1 \). Induction is completed. Thus the sequence \( \xi \equiv (A_n)_{n=1,2,...} \) satisfies all the conditions in Definition 3.1.1 to be a binary approximation of \((S, d)\).

**Definition 3.1.4. (Finite product and power of binary approximations).** Let \( n \geq 1 \) be arbitrary. For each \( i = 1, \cdots, n \), let \((S_i, d_i)\) be a locally compact metric space, with a reference point \( x_{i,0} \in S_i \) and with a binary approximation \( \xi_i = (A_{p})_{p=1,2,...} \) relative to \( x_{i,0} \). Let \((S(n), d(n)) = (\prod_{i=1}^{n} S_i, \otimes_{i=1}^{n} d_i)\) be the product metric space, with \( x_{0}(n) = (x_{1,0}, \cdots, x_{n,0}) \) designated as the reference point in \((S(n), d(n))\).

For each \( p \geq 1 \), let \( A_{p} = A_{1,p} \times \cdots \times A_{n,p} \). The next lemma proves that \((A_{p})_{p=1,2,...}\) is a binary approximation of \((S(n), d(n))\) relative to \( x_{0}(n) \). We will call \( \xi(n) = (A_{p})_{p=1,2,...} \) the product binary approximation of \( \xi_1, \cdots, \xi_n \), and write \( \xi(p) = \xi_1 \otimes \cdots \otimes \xi_n \). If \((S, d)\) for some locally compact metric space, with \( x_{i,0} = x_0 \) and \( \xi_i = \xi \) for each \( i = 1, \cdots, n \), we will call \( \xi(n) \) the \( n \)-th power of \( \xi \), and write \( \xi^{n} = \xi(n) \).

**Lemma 3.1.5. (Finite product binary approximation is indeed a binary approximation).** Use the assumptions and notations in Definition 3.1.2. Then \( \xi(n) \) is indeed a binary approximation of \((S(n), d(n))\) relative to \( x_{0}(n) \). Let \( \|\xi_i\| = (K_i, p)_{p=1,2,...} \equiv
Thus relation 3.1.1 has been verified for the sequence $\xi$. For each $i = 1, \cdots, n$. Let $\|\xi^{(n)}\|$ be the modulus of local compactness of $(S, d)$. Then $\|\xi^{(n)}\| = (\prod_{i=1}^{n} \kappa_{q})_{p=1,2,\cdots}$.

In particular, if $\xi_i \equiv \xi$ for each $i = 1, \cdots, n$, for some binary approximation $\xi$ of some locally compact metric space $(S,d)$, then $\|\xi^{(n)}\| = (\kappa_{q})_{p=1,2,\cdots}$.

Proof. Recall that $A_{p}^{(n)} \equiv A_{1,p} \times \cdots \times A_{n,p}$ for each $p \geq 1$. Hence $A_{1}^{(n)} \subset A_{2}^{(n)} \subset \cdots$. Let $p \geq 1$ be arbitrary. Let

$x \equiv (x_1, \cdots, x_n), y \equiv (y_1, \cdots, y_n) \in A_{p}^{(n)} \equiv A_{1,p} \times \cdots \times A_{n,p}$

be arbitrary. For each $i = 1, \cdots, n$, because $(A_{i,q})_{q=1,2,\cdots}$ is a binary approximation, the set $A_{i,p}$ is metrically discrete. Hence either (i) $x_i = y_i$ for each $i = 1, \cdots, n$, or (ii) $d_i(x_i, y_i) > 0$ for some $i = 1, \cdots, n$. In case (i) we have $x = y$. In case (ii) we have

$$d^{(n)}(x,y) = \sqrt{\sum_{j=1}^{n} d_j(x_j, y_j)} \geq d_i(x_i, y_i) > 0.$$  

Thus $A_{p}^{(n)}$ is metrically discrete.

2. Next note that

$$(d^{(n)}(\cdot, x^{(n)}_{\circ}) \leq 2^p) \equiv \{ (y_1, \cdots, y_n) \in S^{(n)} : \sum_{i=1}^{n} d_i(y_i, x_{i,\circ}) \leq 2^p \} = \bigcap_{i=1}^{n} \{ (y_1, \cdots, y_n) \in S^{(n)} : d_i(y_i, x_{i,\circ}) \leq 2^p \} \subset C \equiv \bigcap_{i=1}^{n} \bigcup_{z \equiv (z(1), \cdots, z(n)) \in A_{i,1}(p) \times \cdots \times A_{i,n}(p)} \{ (y_1, \cdots, y_n) \in S^{(n)} : d_i(y_i, z_{i}) \leq 2^{-p} \}, \quad (3.1.3)$$

where the last inclusion is due to relation 3.1.1 applied to the binary approximation $(A_{i,q})_{q=1,2,\cdots}$. Basic Boolean operations yield

$$C = \bigcup_{(z(1), \cdots, z(n)) \in A_{1}(p) \times \cdots \times A_{n}(p)} \{ (y_1, \cdots, y_n) \in S^{(n)} : d_i(y_i, z_{i}) \leq 2^{-p} \} \subset C = \bigcup_{(z(1), \cdots, z(n)) \in A_{1}(p) \times \cdots \times A_{n}(p)} \{ (y_1, \cdots, y_n) \in S^{(n)} : \sqrt{\sum_{i=1}^{n} d_i(y_i, z_{i})} \leq 2^{-p} \}, \quad (3.1.4)$$

Thus relation 3.1.1 has been verified for the sequence $\xi^{(n)} \equiv (A_{q}^{(n)})_{q=1,2,\cdots}$.
Reversing direction, we have, similarly,
\[
\bigcup_{x \in A_p^{(n)}} (d^{(n)}(\cdot, x) \leq 2^{-p+1})
\]
\[
= \bigcap_{i=1}^{n} \bigcup_{(i,p) \in A(i,p)} \{(y_1, \ldots, y_n) \in S^{(n)} : d_i(y_i, z_i) \leq 2^{p+1}\}
\subset \bigcap_{i=1}^{n}\{ (y_1, \ldots, y_n) \in S^{(n)} : d_i(y_i, x_{i,\circ}) \leq 2^{p+1}\}
\]
\[
= \{ (y_1, \ldots, y_n) \in S^{(n)} : \bigvee_{i=1}^{n} d_i(y_i, x_{i,\circ}) \leq 2^{p+1}\}
\]
\[
= (d^{(n)}(\cdot, x_{\circ}^{(n)}) \leq 2^{p+1}),
\]
which verifies relation 3.1.2 for the sequence \(\xi^{(n)} \equiv (A_q^{(n)})_{q=1,2,\ldots}\). Thus all the conditions in Definition 3.1.7 have been proved for the sequence \(\xi^{(n)}\) to be a binary approximation of \((S^{(n)}, d^{(n)})\) relative to \(x_{\circ}^{(n)}\). Moreover
\[
\|\xi^{(n)}\| \equiv (|A_q^{(n)}|)_{q=1,2,\ldots} = \{ \prod_{i=1}^{n} |A_{i,q}| \}_{q=1,2,\ldots} \equiv (\prod_{i=1}^{n} \kappa_{i,q})_{1,2,\ldots}.
\]

We now extend the construction of product binary approximations to the infinite product space \((S^\infty, d^\infty)\) in the case where \((S,d)\) is compact. As usual, \(\bar{d} \equiv 1 \wedge d\).

**Definition 3.1.6. (Countable product of binary approximation for compact space).** Suppose \((S,d)\) is a compact metric space, with a reference point \(x_0 \in S\), and with a binary approximation \(\xi \equiv (A_n)_{n=1,2,\ldots}\) relative to \(x_0\). Let \((S^\infty, d^\infty)\) be the countable power of metric space \((S,d)\), with \(x_0^\infty \equiv (x_0, x_0, \cdots)\) designated as the reference point in \((S^\infty, d^\infty)\).

For each \(n \geq 1\), define the subset
\[
B_n \equiv A_{n+1}^{\infty+1} \times \{x_0^\infty\} = \{ (x_1, \ldots, x_{n+1}, x_0, x_0, \cdots) : x_i \in A_{n+1} \text{ for each } i = 1, \ldots, n+1 \}.
\]
The next lemma proves that \(\xi^\infty \equiv (B_n)_{n=1,2,\ldots}\) is a binary approximation of \((S^\infty, d^\infty)\) relative to \(x_0^\infty\). We will call \(\xi^\infty\) the countable \textit{power of the binary approximation} \(\xi\).

**Lemma 3.1.7. (Countable product binary approximation for infinite product of compact metric spaces is indeed a binary approximation).** Suppose \((S,d)\) is a compact metric space, with a reference point \(x_0 \in S\), and with a binary approximation \(\xi \equiv (A_n)_{n=1,2,\ldots}\) relative to \(x_0\). Without loss of generality, assume that \(d \leq 1\). Then the sequence \(\xi^\infty \equiv (B_n)_{n=1,2,\ldots}\) in Definition 3.1.7 is indeed a binary approximation of \((S^\infty, d^\infty)\) relative to \(x_0^\infty\).

Let \(\|\xi\| \equiv (\kappa_n)_{n=1,2,\ldots} \equiv (|A_n|)_{n=1,2,\ldots}\) denote the modulus of local compactness of \((S,d)\) corresponding to \(\xi\). Then the modulus of local compactness of \((S^\infty, d^\infty)\) corresponding to \(\xi^\infty\) is given by
\[
\|\xi^\infty\| \equiv (\kappa_{n+1}^{\infty+1})_{n=1,2,\ldots}.
\]
CHAPTER 3. PARTITIONS OF UNITY

Proof. Let $n \geq 1$ be arbitrary.

1. Let

$$x \equiv (x_1, \cdots, x_{n+1}, x_0, x_0, \cdots), y \equiv (y_1, \cdots, y_{n+1}, x_0, x_0, \cdots) \in B_n$$

be arbitrary. Since $A_{n+1}$ is metrically discrete we have either (i) $x_i = y_i$ for each $i = 1, \cdots, n+1$, or (ii) $d(x_i, y_i) > 0$ for some $i = 1, \cdots, n+1$. In case (i) we have $x = y$. In case (ii) we have

$$d^w(x, y) \equiv \sum_{j=1}^{n+1} 2^{-j} \hat{d}(x_j, y_j) \geq 2^{-j} \hat{d}(x_i, y_i) > 0.$$ 

Thus we see that $B_n$ is metrically discrete.

2. Next, let $y \equiv (y_1, y_2, \cdots) \in S^\infty$ be arbitrary. Let $j = 1, \cdots, n+1$ be arbitrary. Then

$$y_j \in (d(\cdot, x_0) \leq 2^{n+1}) \subset \bigcup_{z \in A(n+1)} (d(\cdot, z) \leq 2^{-n-1}),$$

where the first containment relation is a trivial consequence of the hypothesis that $d \leq 1$, and the second is an application of relation \[3.1.1\]. Hence there exists some $u_j \in A_{n+1}$ with $d(y_j, u_j) \leq 2^{-n-1}$. It follows that

$$u \equiv (u_1, \cdots, u_{n+1}, x_0, x_0, \cdots) \in B_n,$$

and

$$d^w(y, u) \leq \sum_{j=1}^{n+1} 2^{-j} \hat{d}(y_j, u_j) + \sum_{j=n+2}^{\infty} 2^{-j} \leq \sum_{j=1}^{n+1} 2^{-j} 2^{-n-1} + 2^{-n-1} < 2^{-n-1} + 2^{-n-1} = 2^{-n}.$$

We conclude that

$$(d^w(\cdot, x^\infty_0) \leq 2^n) = S^\infty \subset \bigcup_{u \in B(n)} (d^w(\cdot, u) \leq 2^{-n}).$$

where the equality is trivial because $d^w \leq 1$. Thus relation \[3.1.1\] is verified for the sequence $(B_n)_{n=1, 2, \cdots}$. At the same time, we have trivially

$$\bigcup_{u \in B(n)} (d^w(\cdot, u) \leq 2^{-n+1}) \subset S^\infty = (d^w(\cdot, x^\infty_0) \leq 2^{n+1}).$$

Thus all the conditions in Definition \[3.1.1\] have been verified for the sequence $\xi^\infty \equiv (B_n)_{n=1, 2, \cdots}$ to be a binary approximation of $(S^\infty, d^w)$ relative to $x^\infty_0$. Moreover,

$$\|\xi^\infty\| \equiv (|B_n|)_{n=1, 2, \cdots} = (|A_{n+1}^\infty|)_{n=1, 2, \cdots} = (k^\infty_{n+1})_{n=1, 2, \cdots}.$$
3.2 Partitions of Unity

In this section, we define and construct a partition of unity determined by a binary approximation of a locally compact metric space. Versions of partitions of unity abound in the literature, providing approximate linear bases in the analysis of linear spaces of functions. The present version, roughly speaking, furnishes an approximate linear basis for \( C(S) \), the space of continuous functions with compact supports on a locally compact metric space.

First we list, without proof, an elementary lemma for ease of later reference.

**Lemma 3.2.1. (Elementary lemma for Lipschitz continuous functions).** Let \( (S,d) \) be an arbitrary metric space. A real-valued function \( f \) on \( S \) is said to be Lipschitz continuous, with Lipschitz constant \( c \geq 0 \) if \( |f(x) - f(y)| \leq cd(x,y) \) for each \( x, y \in S \).

We will then also say simply that the function has Lipschitz constant \( c \).

Let \( x_0 \in S \) be an arbitrary, but fixed, reference point. Let \( f, g \) be real-valued functions with Lipschitz constants \( a, b \) respectively on \( S \). Then the following holds.

1. \( d(\cdot, x_0) \) has Lipschitz constant \( 1 \).
2. \( \alpha f + \beta g \) has Lipschitz constant \( |\alpha|a + |\beta|b \) for each \( \alpha, \beta \in \mathbb{R} \).
3. \( f \vee g \) and \( f \wedge g \) have Lipschitz constant \( a \vee b \).
4. \( 1 \wedge (1 - cd(\cdot, x_0))_+ \) has Lipschitz constant \( c \) for each \( c > 0 \).
5. If \( \|f\|, \|g\| \leq 1 \) then \( fg \) has Lipschitz constant \( a + b \).
6. Suppose \( (S', d') \) is a locally compact metric space. Suppose \( f' \) is a real-valued functions on \( S' \), with Lipschitz constant \( a' > 0 \). Suppose \( \|f'\|, \|f'\| \leq 1 \). Then \( f \otimes f' : S \times S' \to \mathbb{R} \) has Lipschitz constant \( a + a' \) where \( S \times S' \) is equipped with the product metric \( d \equiv d \otimes d' \), and where \( f \otimes f'(x, x') \equiv f(x)f'(x') \) for each \( (x, x') \in S \times S' \).

7. Assertion 6 above can be generalized to a \( p \)-fold product \( f \otimes f' \otimes \cdots \otimes f^{(p)} \).

The next definition and proposition are essentially Proposition 6.15 in [Bishop and Bridges 1985].

**Definition 3.2.2. (\( \varepsilon \)-partition of unity).** Let \( A \) be an arbitrary metrically discrete and finite subset of a locally compact metric space \( (S, d) \). Because the set \( A \) is finite, we can write \( A = \{x_1, \ldots, x_\kappa\} \) for some sequence \( x \equiv (x_1, \ldots, x_\kappa) \) where \( x : \{1, \ldots, \kappa\} \to A \) is an enumeration of the finite set \( A \). Thus \( |A| \equiv \kappa \). Let \( \varepsilon > 0 \) be arbitrary. Define, for each \( k = 1, \ldots, \kappa \),

\[
\eta_k \equiv 1 \wedge (2 - \varepsilon^{-1}d(\cdot, v_k))_+ \in C(S), \tag{3.2.1}
\]

and

\[
g^+_k \equiv \eta_1 \vee \cdots \vee \eta_k \in C(S). \tag{3.2.2}
\]

In addition, define \( g^+_0 \equiv 0 \) and, for each \( k = 1, \ldots, \kappa \), define

\[
g_{\nu(k)} \equiv g^+_k - g^+_{k-1}. \tag{3.2.3}
\]

Then the subset \( \{g_x : x \in A\} \) of \( C(S) \) is called the \( \varepsilon \)-partition of unity of \( (S, d) \), determined by the enumerated set \( A \). The members of \( \{g_x : x \in A\} \) are called the basis functions of the \( \varepsilon \)-partition of unity.
CHAPTER 3. PARTITIONS OF UNITY

Proposition 3.2.3. (Properties of \(\varepsilon\)-partition of unity). Let \(A = \{x_1, \cdots, x_\kappa\}\) be an arbitrary metrically discrete and enumerated finite subset of a locally compact metric space \((S, d)\). Let \(\varepsilon > 0\) be arbitrary. Let \(\{g_x : x \in A\}\) be the \(\varepsilon\)-partition of unity determined by the enumerated set \(A\). Then the following holds.

1. \(g_x\) has values in \([0, 1]\) and has \((d(\cdot, x) < 2\varepsilon)\) as support, for each \(x \in A\).
2. \(\sum_{x \in A} g_x \leq 1\) on \(S\).
3. \(\sum_{x \in A} g_x = 1\) on \(\bigcup_{x \in A} (d(\cdot, x) \leq \varepsilon)\).
4. For each \(x \in A\), the functions \(g_x\), \(\sum_{y \in A^\smallsetminus \{x\}} g_y\), and \(\sum_{y \in A} g_y\) have Lipschitz constant \(2\varepsilon^{-1}\). Here \(y < x\) means \(y = x_i\) and \(x = x_j\) for some \(i, j \in \{1, \cdots, \kappa\}\) with \(i < j\).

Proof. 1. Use the notations in Definition 3.2.2. Let \(k = 1, \cdots, \kappa\) be arbitrary. Suppose \(y \in S\) is such that \(g_{v(k)}(y) > 0\). By the defining equality \[3.2.3\] it follows that \(g^+_k(y) > g^{+}_{k-1}(y)\). Hence \(\eta_k(y) > 0\) by equality \[3.2.2\]. Equality \[3.2.1\] then implies that \(d(y, v_k) < 2\varepsilon\). In short \(g_{v(k)}(d(\cdot, v_k) < 2\varepsilon)\) as support. In general \(g_{v(k)} \geq 0\) in view of equalities \[3.2.1\] \[3.2.2\] and \[3.2.3\].

2. \(\sum_{x \in A} g_x = g^+_k \equiv \eta_1 \lor \cdots \lor \eta_\kappa \leq 1\). Condition 2 is verified. Consequently \(g_x \leq 1\) for each \(x \in A\).

3. Suppose \(y \in S\) is such that \(d(y, v_k) \leq \varepsilon\) for some \(k = 1, \cdots, \kappa\). Then \(\eta_k(y) = 1\) according to equality \[3.2.1\]. Hence \(\sum_{x \in A} g_x(y) = g^+_k(y) = 1\) by equality \[3.2.2\].

4. Now let \(k = 1, \cdots, \kappa\) be arbitrary. Refer to Exercise 3.2.4 for basic operations of Lipschitz constants. Then, in view of the defining equality \[3.2.1\] the function \(\eta_k\) has Lipschitz constant \(\varepsilon^{-1}\). Hence \(g^+_k \equiv \eta_0 \lor \cdots \lor \eta_k\) has Lipschitz constant \(\varepsilon^{-1}\). In particular, \(\sum_{y \in A} g_y \equiv g^+_k\) has Lipschitz constant \(\varepsilon^{-1}\). Moreover, for each \(k = 1, \cdots, \kappa\), the function
\[
\sum_{y \in A^\smallsetminus \{v(k)\}} g_y \equiv \sum_{i=1}^{k-1} g_{v(i)} \equiv g^+_k
\]
have Lipschitz constant \(\varepsilon^{-1}\) whence \(g_{v(k)} \equiv g^+_k - g^+_{k-1}\) has Lipschitz constant \(2\varepsilon^{-1}\). In other words, for each \(x \in A\), the functions \(\sum_{y \in A} g_y\), \(\sum_{y \in A^\smallsetminus \{x\}} g_y\), and \(g_x\) have Lipschitz constant \(c = 2\varepsilon^{-1}\). \(\square\)

Recall that if \(f \in C(S)\) then \(\sup_{x \in S} |f(x)|\) exists and is denoted by \(\|f\|\).

Definition 3.2.4. (Partition of unity of locally compact metric space). Let \((S, d)\) be a locally compact metric space, with a reference point \(x_0 \in S\). Let the nondecreasing sequence \(\xi \equiv (A_n)_{n=1,2,\cdots}\) of enumerated finite subsets of \((S, d)\) be a binary approximation of \((S, d)\) relative to \(x_0\).

For each \(n \geq 1\), let \(\{g_{n,x} : x \in A_n\}\) be the \(2^{-n}\)-partition of unity of \((S, d)\) determined by \(A_n\). Then the sequence \(\pi \equiv (\{g_{n,x} : x \in A_n\})_{n=1,2,\cdots}\) is called a partition of unity of \((S, d)\) determined by the binary approximation \(\xi\). \(\square\)

Proposition 3.2.5. (Properties of partition of unity). Let \(\xi \equiv (A_n)_{n=1,2,\cdots}\) be a binary approximation of the locally compact metric space \((S, d)\) relative to a reference point \(x_0\). Let \(\pi \equiv (\{g_{n,x} : x \in A_n\})_{n=1,2,\cdots}\) be the partition of unity determined by \(\xi\). Let \(n \geq 1\) be arbitrary. Then the following holds.

Yuen-Kwok Chan 34 Constructive Probability
1. $g_{n,x} \in C(S)$ has values in $[0, 1]$ and has support $(d(\cdot, x) \leq 2^{-n+1})$, for each $x \in A_n$.

2. $\sum_{y \in A(n)} g_{n,x} \leq 1$ on $S$.

3. $\sum_{y \in A(n)} g_{n,x} = 1$ on $\bigcup_{y \in A(n)} (d(\cdot, x) \leq 2^{-n})$.

4. For each $x \in A_n$, the functions $g_{n,x}, \sum_{y \in A(n); y < x} g_{n,y}$, and $\sum_{y \in A(n)} g_{n,y}$ have Lipschitz constant $2^{n+1}$.

5. For each $x \in A_n$,

$$g_{n,x} = \sum_{y \in A(n+1)} g_{n,x}g_{n+1,y} \quad (3.2.4)$$

on $S$.

Proof. Assertions 1-4 are restatements of their counterparts in Proposition 3.2.3 for the case $\varepsilon \equiv 2^{-n}$.

5. Now let $x \in A_n$ be arbitrary. By Assertion 1,

$$(g_{n,x} > 0) \subset (d(\cdot, x) \leq 2^{-n+1}).$$

At the same time

$$(d(\cdot, x) \leq 2^{-n+1}) \subset (d(\cdot, x_0) \leq 2^{n+1})$$

$$\subset \bigcup_{y \in A(n+1)} (d(\cdot, y) \leq 2^{-n-1}) \subset (\sum_{y \in A(n+1)} g_{n+1,y} = 1)$$

where the first inclusion is by relation 3.1.2, the second by relation 3.1.1 applied to $n+1$, and the third by Assertion 3 applied to $n+1$. Combining,

$$(g_{n,x} > 0) \subset (\sum_{y \in A(n+1)} g_{n+1,y} = 1).$$

The desired equality $3.2.4$ in Assert 5 follows. $\square$

Proposition 3.2.6. (Approximation by interpolation). Let $A$ be an arbitrary metrically discrete enumerated finite subset of a locally compact metric space $(S, d)$. Let $\varepsilon > 0$ be arbitrary. Let $\{g_x : x \in A\}$ be an $\varepsilon$-partition of unity corresponding to $A$.

Let $f \in C(S)$ be arbitrary, with a modulus of continuity $\delta_f$ and with $\bigcup_{x \in A} (d(\cdot, x) \leq \varepsilon)$ as support. Let $\alpha > 0$ be arbitrary. Suppose $\varepsilon < \frac{1}{2}\delta_f(\frac{1}{\alpha})$. Then

$$\left\|f - \sum_{x \in A} f(x)g_x \right\| \leq \alpha \quad (3.2.5)$$

on $S$.

Proof. For abbreviation, write $h \equiv \sum_{x \in A} f(x)g_x$. Let $y \in S$ be arbitrary.

1. Suppose $g_x(y) > 0$ for some $x \in A$. Since $g_x$ has $(d(\cdot, x) < 2\varepsilon)$ as support, it follows that $d(y, x) < 2\varepsilon < \delta_f(\frac{1}{\alpha})$. Hence

$$|f(y) - f(x)|g_x(y) < \frac{1}{3}\alpha g_x(y). \quad (3.2.6)$$
CHAPTER 3. PARTITIONS OF UNITY

2. Suppose \(|f(y) - f(x)|g_x(y) > \frac{1}{3}\alpha g_x(y)|\) for some \(x \in A\). Then \(g_x(y) > 0\), leading to inequality \(3.2.6\) by Step 1, a contradiction. Hence

\[
|f(y) - f(x)|g_x(y) \leq \frac{1}{3}\alpha g_x(y) \tag{3.2.7}
\]

for each \(x \in A\).

3. Either \(|f(y)| > 0\) or \(|f(y)| < \frac{1}{3}\alpha\). First suppose \(|f(y)| > 0\). Then \(y \in \bigcup_{x \in A} (d(\cdot, x) \leq \varepsilon)\) since the latter set supports \(f\), by hypothesis. Hence \(\sum_{x \in A} g_x(y) = 1\) by Condition 3 of Definition \(3.2.2\).

4. Now suppose \(|f(y)| < \frac{1}{3}\alpha\). Then

\[
|f(y) - h(y)| < \frac{1}{3}\alpha + \sum_{x \in A} |f(x)|g_x(y).
\]

Suppose the summand corresponding to some \(x \in A\) is greater than 0. Then \(g_x(y) > 0\). Hence inequality \(3.2.6\) in Step 1 holds. Consequently

\[
|f(y) - f(x)|g_x(y) < \frac{1}{3}\alpha g_x(y) \tag{3.2.8}
\]

\[
|f(y) - h(y)| < \frac{1}{3}\alpha + \sum_{x \in A} |f(x)|g_x(y)
\]

\[
\leq \frac{1}{3}\alpha + \sum_{x \in A} (|f(y)| + \frac{1}{3}\alpha)g_x(y) \leq \frac{1}{3}\alpha + \frac{2}{3}\alpha \sum_{x \in A} g_x(y) \leq \alpha.
\]

Combining, we see that \(|f(y) - h(y)| \leq \alpha\) for arbitrary \(x \in S\). \(\square\)

Proposition 3.2.7. (Approximation by Lipschitz continuous function). Let \(\xi \equiv (A_n)_{n=1,2,\ldots}\) be a binary approximation of the locally compact metric space \((S,d)\) relative to a reference point \(x_0\). Let \(\pi \equiv (\{g_{n,x} : x \in A_n\})_{n=1,2,\ldots}\) be the partition of unity determined by \(\xi\). Let \(f \in C(S)\) be a arbitrary, with a modulus of continuity \(\delta_f\), and with \(||f|| \leq 1\).

Let \(\alpha > 0\) be arbitrary. Let \(n \geq 1\) be so large that (i) \(f\) has the set \((d(\cdot, x_0) \leq 2^n)\) as support, and (ii) \(2^{-n} \leq \frac{1}{2}\delta_f(\frac{1}{3}\alpha)\). Then there exists \(g \in C(S)\) with Lipschitz constant \(2^{n+1}|A_n|\), such that \(||f - g|| \leq \alpha\). Specifically, we can take

\[
g \equiv \sum_{x \in A(n)} f(x)g_{n,x}.
\]
3.3. One-point Compactification

Proof. By the definition of a partition of unity, the set \( A_n \) is a \( 2^{-n} \)-partition of unity of \((S,d)\). By hypothesis, the function \( f \in C(S) \) has support

\[
(d(\cdot, x_0) \leq 2^n) \subset \bigcup_{x \in A(n)} (d(\cdot, x) \leq 2^{-n}),
\]

where the displayed relation is according to Proposition 3.2.3. At the same time, \( 2^{-n} < \frac{1}{2} \delta_f(\frac{1}{2} \alpha) \) by hypothesis. Hence Proposition 3.2.6 implies that \( \|f - g\| \leq \alpha \), where

\[
g \equiv \sum_{x \in A(n)} f(x) g_x \in C(S)
\]

Again, according to Proposition 3.2.3 each of the functions \( g_x \) in the last sum has Lipschitz constant \( 2^{n+1} \), while \( f(x) \) is bounded by 1 by hypothesis. Hence, using basic properties of Lipschitz constants in Exercise 3.2.1 we conclude that the function \( g \) has Lipschitz constant \( \sum_{x \in A(n)} |f(x)|2^{n+1} \leq 2^{n+1}|A_n| \), as desired. \( \square \)

3.3 One-point Compactification

The infinite product of a locally compact metric space is not necessarily locally compact, while the infinite product of a compact metric space remains compact. For that reason, we will find it sometimes useful to embed a locally compact metric space into a compact metric space such that, while the metric is not preserved, the continuous functions are. This is made precise in the present section as a first application of partitions of unity.

The next definition is essentially from [Bishop and Bridges 1985].

Definition 3.3.1. (One-point compactification). A one-point compactification of a locally compact metric space \((S,d)\) is a metric space \((\overline{S},\overline{d})\) with an element \( \Delta \), called the point at infinity, such that the following five conditions hold.

1. \( \overline{S} \equiv S \cup \{\Delta\} \) is dense in \((\overline{S},\overline{d})\). Moreover, \( \overline{d} \leq 1 \).

2. For each compact subset \( K \) of \((S,d)\), there exists \( c > 0 \) such that \( \overline{d}(x, \Delta) \geq c \) for each \( x \in K \).

3. Let \( K \) be an arbitrary compact subset of \((S,d)\). Let \( \varepsilon > 0 \) be arbitrary. Then there exists \( \delta_K(\varepsilon) > 0 \) such that for each \( y \in K \) and \( z \in S \) with \( \overline{d}(y,z) < \delta_K(\varepsilon) \), we have \( d(y,z) < \varepsilon \). In particular, the identity mapping \( \overline{1} : (\overline{S},\overline{d}) \to (S,d) \) is uniformly continuous on each compact subset of \( S \).

4. The identity mapping \( \overline{1} : (S,d) \to (\overline{S},\overline{d}) \), defined by \( \overline{1}(x) \equiv x \) for each \( x \in S \), is uniformly continuous on \((S,d)\). In other words, for each \( \varepsilon > 0 \), there exists \( \delta_{\overline{d}}(\varepsilon) > 0 \) such that \( \overline{d}(x,y) < \varepsilon \) for each \( x,y \in S \) with \( d(x,y) < \delta_{\overline{d}}(\varepsilon) \).

5. For each \( n \geq 1 \), we have

\[
(d(\cdot, x_0) > 2^{n+1}) \subset (\overline{d}(\cdot, \Delta) \leq 2^{-n}).
\]

Thus, as a point \( x \in S \) moves away from \( x_0 \) relative to \( d \), it converges to the point \( \Delta \) at infinity relative to \( \overline{d} \). \( \square \)
CHAPTER 3. PARTITIONS OF UNITY

The next proposition clarifies the relation between continuous functions on \((S,d)\) and continuous functions on \((\overline{S},\overline{d})\). First some notations.

**Definition 3.3.2. (Restriction of a family of functions).** Let \(A,A'\) be arbitrary sets and let \(B\) be an arbitrary subset of \(A\). Recall that the restriction of a function \(f : A \to A'\) to a subset \(B \subset A\) is denoted by \(f|B\). Suppose \(F\) is a family of functions from \(A\) to \(A'\) and suppose \(B \subset A\). Then we call the family

\[
F|B \equiv \{ f|B : f \in F \}
\]

the restriction of \(F\) to \(B\).

\[ \square \]

Recall that \(C_{ub}(S,d)\) denotes the space of bounded and uniformly continuous functions on a locally compact metric space \((S,d)\).

**Proposition 3.3.3. (Continuous functions on \((S,d)\) and continuous functions on \((\overline{S},\overline{d})\)).** Let \((S,d)\) be a locally compact metric space, with a fixed reference point \(x_0 \in S\). Let \((\overline{S},\overline{d})\) be a one-point compactification of \((S,d)\). Then the following holds.

1. Each compact subset \(K\) of \((S,d)\) is also a compact subset of \((\overline{S},\overline{d})\).
2. \(C(S,d) \subset C(\overline{S},\overline{d})\). \(S \subset C_{ub}(S,d)\). Moreover, if \(f \in C(\overline{S},\overline{d})\) has a modulus of continuity \(\overline{\delta}\), then \(\overline{f}|S \in C_{ub}(S,d)\) has the same modulus of continuity \(\overline{\delta}\).

**Proof.**

1. Suppose \(K\) is a compact subset of \((S,d)\). By Conditions 3 and 4 of Definition 3.3.1, the identity mapping \(i : (K,d) \to (K,\overline{d})\) and its inverse \(\overline{i} : (K,\overline{d}) \to (K,d)\) are uniformly continuous. Hence, since by assumption \((K,d)\) is compact, so is \((K,\overline{d})\).

2. First consider each \(f \in C(S,d)\). Let the compact subset \(K\) of \((S,d)\) be a support of \(f\). Extend \(f\) to a function \(\tilde{f}\) on \(\overline{S} = S \cup \{ \Delta \}\) by defining \(\tilde{f}(\Delta) \equiv 0\) and \(\tilde{f}(x) \equiv x\) for each \(x \in S\). We will show that \(\tilde{f}\) is uniformly continuous on \((\overline{S},\overline{d})\). To that end, let \(\varepsilon > 0\) be arbitrary. Let \(\delta > 0\) be so small that \(|\tilde{f}(x) - \tilde{f}(y)| < \varepsilon\) for each \(x,y \in S\) with \(d(x,y) < \delta\). Then, by Condition 2 in Definition 3.3.1, we have \(\overline{\delta} \equiv \delta \wedge \overline{d}(K,\Delta) > 0\).

Now consider each \(x,y \in S\) with \(\overline{d}(x,y) < \overline{\delta}\). Suppose, for the sake of a contradiction, that \(|\tilde{f}(x) - \tilde{f}(y)| > \varepsilon\). Either (i) \(x = \Delta\) or (ii) \(x \in S\). Consider case (i). Then \(\tilde{f}(x) = 0\).

Hence \(|\tilde{f}(y)| > 0\). Therefore \(y \in S\) and \(|\tilde{f}(y)| \equiv |\tilde{f}(\Delta)| > 0\). Since \(K\) is a support of \(f\) we see that \(y \in K\). Combining, \(\overline{d}(y,x) \geq \overline{d}(K,\Delta) \geq \overline{\delta}\), a contraction. Thus \(x \in S\). Similarly \(y \in S\). Therefore, by the definition of \(\overline{\delta}\), we have \(|f(x) - f(y)| < \varepsilon\), again a contradiction. Summing up, we see that \(|f(x) - f(y)| \leq \varepsilon\).

Since \(\varepsilon > 0\) and \(x,y \in S\) with \(\overline{d}(x,y) < \overline{\delta}\) are arbitrary, \(\tilde{f}\) is a uniformly continuous function on \((\overline{S},\overline{d})\). As such \(\tilde{f}\) can be extended by continuity to a function \(\overline{f} \in C(\overline{S},\overline{d})\), thanks to the denseness of \(\overline{S}\) in \((\overline{S},\overline{d})\). Since \(f \in C(S,d)\) is arbitrary and since \(\tilde{f} = \overline{f}|S\), we have proved that \(C(S,d) \subset C(\overline{S},\overline{d})\).

Now consider each \(\overline{f} \in C(\overline{S},\overline{d})\), with a modulus of continuity \(\overline{\delta}\). Then \(\overline{f}\) is bounded since \(C(\overline{S},\overline{d})\) is compact. Let \(\varepsilon > 0\) and \(x,y \in S\) be arbitrary with \(\overline{d}(x,y) < \overline{\delta}(\varepsilon)\). Then, by condition 4 in Definition 3.3.1, we have \(\overline{d}(x,y) < \varepsilon \wedge \overline{d}(x,y) < \overline{\delta}(\varepsilon)\). Hence \(|\overline{f}(x) - \overline{f}(y)| < \varepsilon\). Since \(\varepsilon > 0\) is arbitrary, we conclude that \(\tilde{f}|S \in C_{ub}(S,d)\), with modulus of continuity also given by \(\overline{\delta}\). Summing up, we have proved that \(C(\overline{S},\overline{d})|S \subset C_{ub}(S,d)\).
3.3. ONE-POINT COMPACTIFICATION

The next theorem constructs a one-point compactification. The proof follows the lines of Theorem 6.8 in Chapter 4 of [Bishop and Bridges 1985].

**Theorem 3.3.4. (Construction of a one-point compactification from a binary approximation).** Let \((S, d)\) be a locally compact metric space. Let the sequence \(\xi \equiv (A_n)_{n=1,2,\ldots}\) of subsets be a binary approximation of \((S, d)\) relative to \(x_0\). Then there exists a one-point compactification \((\overline{S}, \overline{d})\) of \((S, d)\), such that the following conditions hold.

(i). For each \(p \geq 1\) and for each \(y, z \in S\) with
\[
d(y, z) < p^{-1}2^{-p-1},
\]
we have
\[
\overline{d}(y, z) < 2^{-p+1}.
\]

(ii). For each \(n \geq 1\) and for each \(y \in (d(\cdot, x_0) \leq 2^n)\) and for each \(z \in S\) with
\[
\overline{d}(y, z) < 2^{-n-1}|A_n|^{-2},
\]
we have
\[
d(y, z) < 2^{-n+2}.
\]

The one-point compactification \((\overline{S}, \overline{d})\) constructed in the proof is said to be determined by the binary approximation \(\xi\).

**Proof.** Let \(\pi \equiv \{(g_{n,z} : x \in A_n)\}_{n=1,2,\ldots}\) be the partition of unity of \((S, d)\) determined by \(\xi\). Let \(n \geq 1\) be arbitrary. Then \(\{g_{n,z} : x \in A_n\}\) is a \(2^{-n}\)-partition of unity corresponding to the metrically discrete and enumerated finite set \(A_n\). Moreover, by Proposition 3.2.5, \(g_{n,x}\) has Lipschitz constant \(2^{n+1}\) for each \(x \in A_n\).

1. Define
\[
\overline{S} \equiv \{(x, i) \in S \times \{0, 1\} : i = 0 \text{ or } (x, i) = (x_0, 1)\}
\]
and define \(\Delta \equiv (x_0, 1)\). Identify each \(x \in S\) with \(\overline{x} \equiv (x, 0) \in \overline{S}\). Thus \(\overline{S} = S \cup \{\Delta\}\).

Extend each function \(f \in C(S)\) to a function on \(\overline{S}\) by defining \(f(\Delta) \equiv 0\). In particular \(g_{n,x}(\Delta) \equiv 0\) for each \(x \in A_n\). Define
\[
\overline{d}(y, z) \equiv \sum_{n=1}^{m} 2^{-n}|A_n|^{-1} \sum_{x \in A(n)} |g_{n,z}(y) - g_{n,x}(z)| \tag{3.3.1}
\]
for each \(y, z \in \overline{S}\). Then \(\overline{d}(y, y) = 0\) for each \(y \in \overline{S}\). Symmetry and triangle inequality of the function \(\overline{d}\) are immediate consequences of equality (3.3.1). Moreover, \(\overline{d} \leq 1\) since the functions \(g_{n,x}\) have values in \([0, 1]\).

2. Let \(y \in \overline{S}\) be arbitrary, and let \(K\) be an arbitrary compact subset of \((S, d)\). Suppose \(y \in K\). Let \(n \geq 1\) be so large that
\[
y \in K \subset (d(\cdot, x_0) \leq 2^n).
\]

Then
\[
y \in \bigcup_{x \in A(n)} (d(\cdot, x) \leq 2^{-n}) \subset (\sum_{x \in A(n)} g_{n,x} = 1).
\]
where the membership relation of on the left-hand side is by expression [3.3.1] in Definition [3.1.1] and where the inclusion on the right-hand side is according to Assertion 3 of Proposition [3.2.2]. Hence the defining equality [3.3.1] yields

$$\mathcal{d}(y, \Delta) \geq 2^{-n}|A_n|^{-1} \sum_{x \in A(n)} g_{n,x}(y) = 2^{-n}|A_n|^{-1},$$

establishing Condition 2 in Definition [3.3.1].

3. Let \( n \geq 1 \) be arbitrary. Let \( y \in (d(\cdot, x_0) \leq 2^n) \) and \( z \in S \) be arbitrary such that

$$\mathcal{d}(y, z) < \delta_{\xi,n} \equiv 2^{-n-1}|A_n|^{-2}.$$

As seen in Step 2,

$$\sum_{x \in A(n)} g_{n,x}(y) = 1.$$

Hence there exists \( x \in A_n \) such that

$$g_{n,x}(y) > \frac{1}{2}|A_n|^{-1} > 0.$$

At the same time,

$$|g_{n,x}(y) - g_{n,x}(z)| \leq \sum_{x \in A(n)} |g_{n,u}(y) - g_{n,u}(z)|$$

$$\leq 2^n|A_n|\mathcal{d}(y, z) < 2^n|A_n|\delta_{\xi,n} \equiv \frac{1}{2}|A_n|^{-1}.$$ 

Hence inequality [3.3.3] implies that \( g_{n,x}(z) > 0 \). Consequently, \( y, z \in (d(\cdot, x) < 2^{-n+1}) \). Thus \( d(y, z) < 2^{-n+2} \). This establishes Assertion (ii) of the theorem.

Now let \( K \) be an arbitrary compact subset of \((S, d)\) and let \( \varepsilon > 0 \) be arbitrary. Let \( n \geq 1 \) be so large that \( K \subset (d(\cdot, x_0) \leq 2^n) \) and that \( 2^{-n+2} < \varepsilon \). Let \( \delta_K(\varepsilon) \equiv \delta_{\xi,n} \). Then, by the preceding paragraph, for each \( y \in K \) and \( z \in S \) with \( \mathcal{d}(y, z) < \delta_K(\varepsilon) \equiv \delta_{\xi,n} \), we have \( d(y, z) < \varepsilon \). Condition 3 in Definition [3.3.1] has been verified.

In particular, suppose \( y, z \in S \) are such that \( \mathcal{d}(y, z) = 0 \). Then either \( y = z = \Delta \) or \( y, z \in S \), in view of inequality [3.3.2]. Suppose \( y, z \in S \). Then the preceding paragraph applied to the compact set \( K \equiv \{y, z\} \), implies that \( d(y, z) = 0 \). Since \((S, d)\) is a metric space, we conclude that \( y = z \). In view of the last paragraph of Step 1 above, \((S, \mathcal{d})\) is a metric space.

4. Recall that \( g_{n,x} \) has values in \([0, 1]\), and, as remarked above, has Lipschitz constant \( 2^{n+1} \), for each \( x \in A_n \), for each \( n \geq 1 \). Let \( p \geq 2 \) be arbitrary. Let \( y, z \in S \) be such that \( d(y, z) < p^{-2} - p^{-1} \). Then

$$\mathcal{d}(y, z) \equiv \sum_{n=1}^{\infty} 2^{-n}|A_n|^{-1} \sum_{x \in A(n)} |g_{n,x}(y) - g_{n,x}(z)|$$

$$\leq \sum_{n=1}^{\infty} 2^{-n}2^{n+1}d(y, z) + 2^{-p}$$

Yuen-Kwok Chan

Constructive Probability
3.3. ONE-POINT COMPACTIFICATION

\[ < p 2p^{-1}2^{-p-1} + 2^{-p} = 2^{-p} + 2^{-p} = 2^{-p+1}. \] (3.3.4)

Since \(2^{-p+1}\) is arbitrarily small, we see that the identity mapping \(\iota: (S, d) \to (\bar{S}, \bar{d})\) is uniformly continuous. This establishes Condition 4 in Definition 3.3.1.

5. Let \(n \geq 1\) be arbitrary. Consider each \(y \in (d(\cdot, x_0) > 2^{n+1})\). Let \(m \geq n\) be arbitrary. Then

\[ y \in (d(\cdot, x_0) > 2^{m+1}) \subset \bigcap_{x \in \bar{A}(m)} (d(\cdot, x) \geq 2^{-m+1}) \]

by relation 3.1.2 in Definition 3.1.1 of a binary approximation. For each \(x \in \bar{A}_m\), since \(g_{m,x}\) has support \((d(\cdot, x) \geq 2^{-m+1})\), we infer \(g_{m,x}(y) = 0\). Hence the defining equality 3.3.1 reduces to

\[ \bar{d}(y, \Delta) = \sum_{m=1}^{\infty} 2^{-m} |A_m|^{-1} \sum_{x \in \bar{A}(m)} g_{m,x}(y) \]

\[ = \sum_{m=n+1}^{\infty} 2^{-m} |A_m|^{-1} \sum_{x \in \bar{A}(m)} g_{m,x}(y) \]

\[ \leq \sum_{m=n+1}^{\infty} 2^{-m} = 2^{-n}. \] (3.3.5)

Since \(y \in (d(\cdot, x_0) > 2^{n+1})\) is arbitrary, we conclude that

\[ (d(\cdot, x_0) > 2^{n+1}) \subset (\bar{d}(\cdot, \Delta) \leq 2^{-n}). \] (3.3.6)

This proves Condition 5 in Definition 3.3.1.

6. We will prove next that \((\bar{S}, \bar{d})\) is totally bounded. To that end, let \(p \geq 1\) be arbitrary. Let \(m \equiv m_p \equiv \lceil (p+2) + \log_2 p \rceil\). Recall here that \(\lceil \cdot \rceil_1\) is the operation which assigns to each \(a \in [0, \infty)\) and integer \([a]_1\) in \((a, a+2)\). Then

\[ 2^{-m} < \bar{d}_p \equiv p^{-1}2^{-p-2}. \]

Note that

\[ \bar{S} \equiv S \cup \{\Delta\} \subset (d(\cdot, x_0) < 2^m) \cup (d(\cdot, x_0) > 2^{m-1}) \cup \{\Delta\} \]

\[ \subset \bigcup_{x \in \bar{A}(m)} (d(\cdot, x) \leq 2^{-m}) \cup (\bar{d}(\cdot, \Delta) \leq 2^{-m+2}) \cup \{\Delta\} \]

where the second inclusion is due to relation 3.1.1 and to relation 3.3.6 applied to \(m - 2\). Continuing,

\[ \bar{S} \subset \bigcup_{x \in \bar{A}(m)} (d(\cdot, x) \leq \bar{d}_p) \cup (\bar{d}(\cdot, \Delta) < p^{-1}2^{-p}) \cup \{\Delta\}, \]

\[ \subset \bigcup_{x \in \bar{A}(m)} (\bar{d}(\cdot, x) < 2^{-p}) \cup (\bar{d}(\cdot, \Delta) < 2^{-p}) \cup \{\Delta\}, \]

thanks to the inequality 3.3.4 in Step 4. Consequently, the set

\[ \bar{A}_p \equiv A_{m|p} \cup \{\Delta\} \]
is a metrically discrete $2^{-p}$-approximation of $(\overline{S}, \overline{d})$. Since $2^{-p}$ is arbitrarily small, the metric space $(\overline{S}, \overline{d})$ is totally bounded. Hence its completion $(\overline{S}, \overline{d})$ is compact, and $\overline{S}$ is dense in $(\overline{S}, \overline{d})$, proving Condition 1 in Definition 3.3.1. Note that, since $\overline{S} \equiv S \cup \{ \Delta \}$ is a dense subset of $(\overline{S}, \overline{d})$, the sequence $A_p$ is a $2^{-p}$-approximation of $(\overline{S}, \overline{d})$.

Summing up, $(\overline{S}, \overline{d})$ satisfies all the conditions in Definition 3.3.1 to be a one-point compactification of $(S, d)$.

Proposition 3.3.3 established the relation of continuity on $(S^n, d^n)$ to continuity on $C(\overline{S}^n, \overline{d}^n)$ in the case $n = 1$. The next lemma generalizes to the case where $n \geq 1$.

**Corollary 3.3.5. (Extension of each $f \in C(S^n, d^n)$ to $(\overline{S}^n, \overline{d}^n)$).** Let $n \geq 1$ be arbitrary. Then

$$C(S^n, d^n) \subset C(\overline{S}^n, \overline{d}^n)|S^n \subset C_{UB}(S^n, d^n).$$

**Proof.** 1. Let $h \in C(S^n, d^n)$ be arbitrary with a modulus of continuity $\delta_h$. Then there exists $r > 0$ with such that $K_r \equiv (d(x, \cdot) \leq r)$ is compact in $(S, d)$, and such that $K_r^n$ is a support of $h$. Let $s > 1$ be such that $K \equiv (d(K_r, \cdot) \leq s)$ is compact in $(S, d)$. Then $K_r, K$ are compact subsets of $C(\overline{S}, \overline{d})$, according to Proposition 3.3.3. By Definition 3.3.1 for each $\varepsilon > 0$, there exists $\delta_K(\varepsilon) \in (0, 1)$ such that, for each $x, y \in K$ with $\overline{d}(x, y) < \delta_K(\varepsilon)$, we have

$$d(x, y) < \varepsilon. \quad (3.3.7)$$

Now let $\varepsilon' \in (0, 1)$ be arbitrary. Write $\varepsilon \equiv 1 \wedge \delta_{h}(\varepsilon')$ and define $\overline{\delta}_K(\varepsilon') \equiv \delta_K(\varepsilon)$

Let $u \equiv (x_1, \ldots, x_n), v \equiv (y_1, \ldots, y_n) \in \overline{S}^n$ be arbitrary such that

$$\overline{d}^n(u, v) \equiv \sqrt[n]{d(x_i, y_i)} < \overline{\delta}_K(\varepsilon') \equiv \delta_K(\varepsilon) \equiv \delta_K(1 \wedge \delta_{h}(\varepsilon')). \quad (3.3.8)$$

We will prove that

$$|h(u) - h(v)| \leq \varepsilon'. \quad (3.3.9)$$

First note that, by inequality 3.3.8 we have

$$d(x_i, y_i) < \varepsilon \equiv 1 \wedge \delta_{h}(\varepsilon') \quad (3.3.9)$$

for each $i = 1, \ldots, n$. Suppose, for the sake of a contradiction, that

$$|h(u) - h(v)| > \varepsilon'. \quad (3.3.10)$$

Then $h(u) > 0$ or $h(v) > 0$. Then $(x_1, \ldots, x_n) \equiv u \in K^n_r$ since $K^n_r$ contains a support of $h$. Let $i = 1, \ldots, n$ be arbitrary. Then $x_i \in K_r$, whence, by inequality 3.3.9

$$y_i \in (d(\cdot, K_r) \leq 1) \subset (d(\cdot, K_r) \leq s) \equiv K.$$

Thus $x_i, y_i \in K$. At the same time, $\overline{d}(x_i, y_i) < \delta_K(\varepsilon)$ by inequality 3.3.8. Consequently, inequality 3.3.7 holds for $x_i, y_i$. Combining,

$$d^n(u, v) \equiv \sqrt[n]{d(x_i, y_i)} < \varepsilon \leq \delta_h(\varepsilon').$$

Yuen-Kwok Chan 42 Constructive Probability
Since $\delta_h$ is a modulus of continuity of $h \in C(S^n,d^n)$, it follows that
\[
|h(u) - h(v)| < \varepsilon',
\]
a contradiction to inequality $3.3.10$. Similarly, the assumption $h(v) > 0$ also leads to a contradiction. Summing up, the assumption of inequality $3.3.10$ leads to a contradiction. Hence
\[
|h(u) - h(v)| \leq \varepsilon',
\]
where $u, v \in S^n$ are arbitrary with $d'(u,v) < \delta_K(\varepsilon')$. In other words, $h$ is uniformly continuous on $(S^n,d')$, with modulus of continuity $\delta_K$.

2. Conversely, let $\bar{h} \in C(S^n,d'^n)$ be arbitrary. By Definition 3.3.1 of the compactification, the identity mapping $t : (S,d) \to (\bar{S},d')$ is uniformly continuous. Hence so is the identity mapping $t^n : (S^n,d^n) \to (S^n,d')$. Therefore $\bar{h}|S^n = \bar{h} \circ t^n$ is bounded and uniformly continuous on $(S^n,d')$.

3.3. ONE-POINT COMPACTIFICATION

Corollary 3.3.6. (Compactification of binary approximation). Use the same notations and assumptions as in Theorem 3.3.4. In particular, let $\xi \equiv (A_n)_{n=1,2,...}$ be a binary approximation of $(S,d)$ relative to the reference point $x_0$. For each $n \geq 1$, let $A_n = \{x_{1,n}, \ldots, x_{m(n)}\}$. Thus $\|\xi\| = (\|A_n\|)_{n=1,2,...} = (\|\kappa_n\|)_{n=1,2,...}.$

Let $p \geq 1$ be arbitrary. Write $m_p \equiv [(p+2) + \log_2 p]$. Define
\[
\bar{A}_p \equiv A_{m(p)} \cup \{\Delta\} \equiv \{x_{m(p),1}, \ldots, x_{m(p),\kappa(m(p))}, \Delta\}.
\]

Then $\xi \equiv (\bar{A}_p)_{p=1,2,...}$ is a binary approximation of $(\bar{S},d)$ relative to $x_0$, called the compactification of $\xi$. Thus the corresponding modulus of local compactness of $(\bar{S},d)$ is given by
\[
\|\xi\| = (\|\bar{A}_p\|)_{p=1,2,...} = (\kappa_{m(p)} + 1)_{p=1,2,...} = (\|A_{m(p)}\| + 1)_{p=1,2,...}
\]
and is therefore determined by $\|\xi\|$.

Proof. Let $p \geq 1$ be arbitrary. According to Step 6 of the proof of Theorem 3.3.4 the finite set $\bar{A}_p$ is a metrically discrete $2^{-p}$-approximation of $(\bar{S},d)$. Hence
\[
(\bar{d}(\cdot,x_0) \leq 2^p) \subset \bar{S} \subset \sum_{x \in \bar{A}_p} (\bar{d}(\cdot,x) \leq 2^{-p}).
\]

At the same time, Condition 1 of Definition 3.3.1 says that $\bar{d} \leq 1$. Hence
\[
\bigcup_{x \in \bar{A}_p} (\bar{d}(\cdot,x) \leq 2^{-p+1}) \subset \bar{S} \subset (\bar{d}(\cdot,x_0) \leq 1) \subset (\bar{d}(\cdot,x_0) \leq 2^{p+1}).
\]

Thus all the conditions in Definition 3.3.1 have been verified for $\bar{\xi} \equiv (\bar{A}_p)_{p=1,2,...}$ to be a binary approximation of $(\bar{S},d)$ relative to $x_0$. \[\square\]
Chapter 4

Integration and Measure

We introduce next the Riemann-Stieljes integral on \( \mathbb{R} \). Then we give a general treatment of integration- and measure theory in terms of Daniell integrals, adapted from [Bishop and Bridges 1985]. The standard graduate course in measure theory usually starts with a chapter of measurable sets, before defining a measure. In contrast, the Daniell integration theory starts with the integration and the integrable functions. Thus we discuss the computation of the integration early on. We remark that it is possible to adhere to the traditional approach of starting with measurable sets. (See [Bishop and Cheng 72]). However, Daniell integrals are more natural, and cleaner, in the present context.

4.1 The Riemann-Stieljes Integral

Definition 4.1.1. (Distribution function). A distribution function is a nondecreasing real-valued function \( F \) whose domain \((F)\) is dense in \( \mathbb{R} \).

Let \( F \) be a distribution function, and let \( X \in C(\mathbb{R}) \).

By a partition of \( \mathbb{R} \) we mean a finite and increasing sequence \((x_0, \cdots, x_n)\) in domain \((F)\). One partition is said to be a refinement of another if the former contains the latter as a subsequence. For any partition \((x_1, \cdots, x_n)\), define its mesh as \( \bigvee_{i=1}^n (x_i - x_{i-1}) \) and define the Riemann-Stieljes sum as

\[
S(x_0, \cdots, x_n) \equiv \sum_{i=1}^n X(x_i)(F(x_i) - F(x_{i-1}))
\]

Theorem 4.1.2. (Existence of Riemann-Stieljes integral). For any \( X \in C(\mathbb{R}) \), the Riemann-Stieljes sum converges as the mesh of the partition \((x_0, \cdots, x_n)\) approaches 0 with \( x_0 \to -\infty \) and \( x_n \to +\infty \). The limit will be called the Riemann-Stieljes integral of \( X \) with respect to the function \( F \), and will be denoted by \( \int_{-\infty}^{+\infty} X(x)dF(x) \), or more simply by \( \int X(x)dF(x) \).

Proof. Suppose \( X \) vanishes outside the compact interval \([a, b]\) where \( a, b \in \text{domain}(F) \).
Let \( \varepsilon > 0 \). Consider a partition \((x_0, \ldots, x_n)\) with (i) \( x_0 < a - 2 < b + 2 < x_n \) and (ii) it has mesh less than \( 1 \wedge \delta_X(\varepsilon) \) where \( \delta_X \) is a modulus of continuity for \( X \).

Let \( i \) be any index with \( 0 < i \leq n \). Suppose we insert \( m \) points between \((x_{i-1}, x_i)\) and make a refinement \((\ldots, x_{i-1}, y_1, \ldots, y_m, x_i, \ldots)\). Let \( y_0 \) and \( y_m \) denote \( x_{i-1} \) and \( x_i \) respectively. Then the difference in Riemann-Stieltjes sums for the new and old partitions is bounded by

\[
\left| X(x_i)(F(x_i) - F(x_{i-1})) - \sum_{j=1}^{m} X(y_j)(F(y_j) - F(y_{j-1})) \right|
\]

\[
= \left| \sum_{j=1}^{m} (X(x_i) - X(y_j))(F(y_j) - F(y_{j-1})) \right|
\]

\[
\leq \left| \sum_{j=1}^{m} \varepsilon(F(y_j) - F(y_{j-1})) \right| = \varepsilon(F(x_i) - F(x_{i-1})
\]

Moreover, the difference is 0 if \( x_i < a - 2 \) or \( x_{i-1} > b + 2 \). Since \( x_i - x_{i-1} < 1 \), the difference is 0 if \( x_{i-1} < a - 1 \) or \( x_i > b + 1 \).

Since any refinement of \((x_0, \ldots, x_n)\) can be obtained by inserting points between the pairs \((x_{i-1}, x_i)\), we see that the Riemann-Stieltjes sum of any refinement differs from that for \((x_0, \ldots, x_n)\) by at most \( \sum \varepsilon(F(x_i) - F(x_{i-1})) \) where the sum is over all \( i \) for which \( a < x_{i-1} \) and \( x_i < b \). The difference is therefore at most \( \varepsilon(F(b) - F(a)) \).

Consider a second partition \((u_0, \ldots, u_p)\) satisfying the conditions (i) and (ii). Because the domain of \( F \) is dense, we can find a third partition \((v_0, \ldots, v_q)\) satisfying the same conditions and the additional condition that \( |v_k - x_i| > 0 \) and \( |v_k - u_j| > 0 \) for all \( i, j, k \). Then \((v_0, \ldots, v_q)\) and \((x_0, \ldots, x_n)\) have a common refinement, namely the merged sequence rearranged in increasing order. So their Riemann-Stieltjes sums differ from each other by at most \( 2\varepsilon(F(b) - F(a)) \) by the first part of this proof. Similarly, the Riemann-Stieltjes sum for \((u_0, \ldots, u_p)\) differs from that of \((v_0, \ldots, v_q)\) by at most \( 2\varepsilon(F(b) - F(a)) \). Hence the Riemann-Stieltjes sums for \((u_0, \ldots, u_p)\) and \((x_0, \ldots, x_n)\) differ by at most \( 4\varepsilon(F(b) - F(a)) \).

Since \( \varepsilon \) is arbitrary, the asserted convergence is proved. \( \square \)

**Theorem 4.1.3. (Basic properties of the Riemann-Stieltjes integral).** The Riemann-Stieltjes integral is linear on \( C(R) \). It is also positive: if \( \int X(x)dF(x) > 0 \), then there exists \( x \in R \) such that \( X(x) > 0 \).

**Proof.** Linearity follows trivially from the defining formulas. Suppose \( a, b \in \text{domain}(F) \) are such that \( X \) vanishes outside \([a, b]\). If the integral is greater than some positive number \( c \), then the Riemann-Stieltjes sum \( S(x_0, \ldots, x_n) \) for some partition with \( x_1 = a \) and \( x_n = b \) is greater than \( c \). If it follows that \( X(x_i)(F(x_i) - F(x_{i-1})) \) is greater than or equal to \( c/n \) for some index \( i \). Hence \( X(x_i)(F(b) - F(a)) \geq X(x_i)(F(x_i) - F(x_{i-1})) \geq c/n \). This implies \( X(x_i) > c/(n(F(b) - F(a))) > 0 \). \( \square \)

In the special case where \( \text{domain}(F) = R \) and \( F(x) = x \) for each \( x \in R \), the Riemann-Stieltjes sums and Riemann-Stieltjes integral are called the Riemann sums and the Riemann integral respectively.
4.2 Integration on Locally Compact Metric Spaces

In this section, the Riemann-Stieljes integration is generalized to a locally compact metric space $(S,d)$.

Classically, integration is usually defined in terms of a measure, a function on a family of subsets which is closed relative to the operations of countable unions, countable intersections, and relative complements. In the case of a metric space, one such family can be generated via these three operations from the family of all open subsets. Members of the family thus generated are called Borel sets. In the special case of $R$, the open sets can in turn be generated from a countable subfamily of intervals in successive partitions of $R$, wherein ever smaller intervals cover any compact interval in $R$. The intervals in the countable family can thus serve as building blocks in the analysis of measures on $R$.

The Daniell integration theory is a more natural choice for the constructive development. Integrals of functions, rather than measures of sets, are the starting point. In the special case of a locally compact metric space $(S,d)$, the family $C(S)$ supplies the basic integrable functions. The family $C(S)$ can be generated, via linear operations and uniform convergence, from a countable subfamily obtained from successive partitions of the unit function 1 by non-negative members of $C(S)$, wherein members with ever smaller compact supports sum to 1 on any given compact subset in $S$. The functions in this countable subfamily can then serve as building blocks in the analysis of integrations on $S$.

**Definition 4.2.1. (Integration on a locally compact metric space).** An integration on a locally compact metric space $(S,d)$ is a real-valued linear function $I$ on the linear space $C(S)$ such that (i) $I(X) > 0$ for some $X \in C(S)$, and (ii) for each $X \in C(S)$ with $I(X) > 0$ there exists a point $x$ in $S$ for which $X(x) > 0$. □

The Riemann-Stieljes integration defined for a distribution function $F$ on $R$ is an integration on $(R,d)$ where $d$ is the Euclidean metric, and is denoted by $\int dF$, with $I(X)$ written as $\int X(x)dF(x)$ for each $X \in C(S)$. Riemann-Stieljes integrals provide an abundance of examples for integration on locally compact metric spaces.

It follows from the linearity of $I$ that if $X, Y \in C(S)$ are such that $I(X) > I(Y)$, then there exists a point $x$ in $S$ for which $X(x) > Y(x)$. The positivity condition (ii), extended in the next proposition, is a powerful tool in proving existence theorems. It translates a condition on integrals into the existence of a point in $S$ with certain properties. To prove the next proposition, we need the following lemma which will be used again in a later chapter. This lemma, from [Chan 1975] is a pleasant surprise because, in general, the convergence of a series of non-negative real numbers does not follow constructively from the boundlessness of partial sums.

**Lemma 4.2.2. (Positivity of a linear function on a linear space of functions).** Suppose $I$ is a linear function on a linear space $L$ of functions on a set $S$. Suppose $I$ satisfies the following condition: for each $X_0 \in L$ there exists a non-negative function $Z \in L$ such that, for each sequence $(X_i)_{i=1,2,\ldots}$ of non-negative functions in $L$ with $\sum_{i=1}^{\infty} I(X_i) < I(X_0)$, there exists $x \in S$ with (i) $Z(x) = 1$ and (ii) $\sum_{i=1}^{\infty} X_i(x) \leq X_0(x)$ for each $p > 0$. Then, for each $X_0 \in L$ and for each sequence $(X_i)_{i=1,2,\ldots}$ of non-negative
functions in \( L \) with \( \sum_{i=1}^{\infty} I(X_i) < I(X_0) \), there exists \( x \in S \) such that \( \sum_{i=1}^{\infty} X_i(x) \) converges and is less than \( X_0(x) \).

Proof. Classically, the convergence of \( \sum_{i=1}^{\infty} X_i(x) \) follows trivially from the boundlessness of the partial sums. Note that if the constant function 1 is a member of \( L \), then the lemma can be simplified with \( Z \equiv 1 \), or with \( Z \) altogether omitted.

Suppose \( X_0 \in L \) and \( (X_i)_{i=1,2,...} \) is a sequence of non-negative functions in \( L \) with \( \sum_{i=1}^{\infty} I(X_i) < I(X_0) \). Let \( Z \) be as given in the hypothesis. Choose a positive real number \( \alpha \) so small that

\[
\alpha I(Z) + \sum_{i=1}^{\infty} I(X_i) + \alpha < I(X_0)
\]

Choose an increasing sequence \( (n_k)_{k=1,2,...} \) of integers such that

\[
\sum_{i=n(k)}^{\infty} I(X_i) < 2^{-2k} \alpha
\]

for each \( k \geq 1 \).

Consider the sequence of functions

\[
(\alpha Z, X_1, 2 \sum_{i=n(1)}^{n(2)} X_i, X_2, 2^2 \sum_{i=n(2)}^{n(3)} X_i, X_3, \cdots)
\]

It can easily be verified that the series of the corresponding values for the function \( I \) then converges to a sum less than \( \alpha I(Z) + \sum_{i=1}^{\infty} I(X_i) + \alpha \), which is in turn less than \( I(X_0) \) by the choice of the number \( \alpha \).

By the hypothesis, there exists a point \( x \in S \) with \( Z(x) = 1 \) such that

\[
\alpha Z(x) + X_1(x) + \cdots + X_k(x) + 2^k \sum_{i=n(k)}^{n(k+1)} X_i(x) \leq X_0(x)
\]

for each \( k \geq 1 \). In particular \( \sum_{i=n(k)}^{n(k+1)} X_i(x) \leq 2^{-k} X_0(x) \) so \( \sum_{i=1}^{\infty} X_i(x) < \infty \). The last displayed inequality implies also that

\[
\alpha Z(x) + \sum_{i=1}^{\infty} X_i(x) \leq X_0(x)
\]

Because \( Z(x) = 1 \), we have

\[
\alpha + \sum_{i=1}^{\infty} X_i(x) \leq X_0(x)
\]

as desired. \( \square \)

**Proposition 4.2.3. (Positivity of an integration on a locally compact metric space).**

Let \( I \) be an integration on a locally compact metric space \( (S,d) \). Let \( (X_i)_{i=0,1,2,...} \) be a sequence in \( C(S) \) such that \( X_i \) is non-negative for \( i \geq 1 \), and such that \( \sum_{i=1}^{\infty} I(X_i) < I(X_0) \). Then there exists \( x \in S \) such that \( \sum_{i=1}^{\infty} X_i(x) < X_0(x) \).
4.2. INTEGRATION ON LOCALLY COMPACT METRIC SPACES

**Proof.** Let $K$ be a compact support of $X_0$. The set $B \equiv \{x \in S : d(x, K) \leq 1\}$ is bounded. Hence, since $S$ is locally compact, there exists a compact subset $K'$ such that $B \subset K'$. Define $Z \equiv (1 - d(\cdot, K'))^+.

Let $\varepsilon \in (0, 1)$ be arbitrary. By Lemma 3.1.2, there exists a metrically discrete and enumerated finite set $A \equiv \{y_1, \ldots, y_n\}$ which is an $\varepsilon$-approximation of $K$. Let \{\{Y_{y(1)}, \ldots, Y_{y(n)}\}\} be the $\varepsilon$-partition of unity determined by $A$, as in Definition 3.2.2. For short, abuse notations and write $Y_k \equiv Y_{y(k)}$ for each $k = 1, \cdots, n$. By Proposition 3.2.3, we have $\sum_{i=1}^{n} Y_k \leq 1$, with equality prevailing on $K \subset \bigcup_{x \in A} (d(\cdot, x) \leq \varepsilon)$. It follows that $\sum_{i=1}^{n} I(X_i Y_k) \leq I(X_i)$ for each $i \geq 0$, with equality in the case $i = 0$. Therefore

\[
\sum_{i=1}^{n} \sum_{j=1}^{\infty} I(X_i Y_k) \leq \sum_{i=1}^{\infty} I(X_i) < I(X_0) = \sum_{i=1}^{n} I(X_i Y_k)
\]

Hence there exists some $k = 1, \cdots, n$ for which

\[
\sum_{i=1}^{\infty} I(X_i Y_k) < I(X_0 Y_k)
\]

Again by Proposition 3.2.3, for each $x$ with $Y_k(x) > 0$, we have $d(x, y_k) < 2\varepsilon$. Hence

\[
(Y_k(x) > 0 \text{ and } Y_k(x') > 0) \Rightarrow (d(x, x') \leq 4\varepsilon \text{ and } x \in B \subset K')
\]

for $x, x' \in S$.

Define $Z_1 \equiv Y_k$. By repeating the above argument with $\varepsilon_m = \frac{1}{m}$ ($m = 1, 2, \cdots$), we can construct inductively a sequence of non-negative continuous functions $(Z_m)_{m=1, 2, \cdots}$ such that, for each $m \geq 1$ and for each $x, x' \in S$, we have

\[
(Z_m(x) > 0 \text{ and } Z_m(x') > 0) \Rightarrow (d(x, x') \leq \frac{1}{m} \text{ and } x, x' \in K')
\]

and such that

\[
\sum_{i=1}^{\infty} I(X_i Z_1 \cdots Z_m) < I(X_0 Z_1 \cdots Z_m)
\]

(4.2.2)

Since all terms in (4.2.2) are non-negative, the same inequality holds if the infinite sum is replaced by the partial sum of the first $m$ terms. By the positivity of $I$, this implies for each $m \geq 1$ the existence of a point $x_m$ such that

\[
\sum_{i=1}^{m} X_i Z_1 \cdots Z_m(x_m) < X_0 Z_1 \cdots Z_m(x_m)
\]

(4.2.3)

In particular $Z_p(x_m) > 0$ for each $p \leq m$. Therefore the inference (4.2.1) yields $x_p \in K'$ and $d(x_p, x_m) \leq \frac{1}{p}$ for each $p \leq m$. Hence $(x_m)_{m=1, 2, \cdots}$ is a Cauchy sequence in $K'$ and converges to some point $x \in K'$. By the definition of the function $Z$ at the beginning of this proof, we have $Z(x) = 1$.

Canceling positive common factors on both sides of inequality (4.2.3) we obtain $\sum_{i=1}^{p} X_i(x_m) < X_0(x_m)$ for each $p \leq m$. Letting $m \to \infty$ yields $\sum_{i=1}^{p} X_i(x) \leq X_0(x)$ for each $p \geq 1$.

The conditions in Lemma 4.2.2 have been established. The conclusion of the present proposition follows. \qed
4.3 Integration Space — the Daniell Integral

Integration on a locally compact space is a special case of Daniell integration, introduced next.

**Definition 4.3.1. (integration Space).** An integration space is a triple \((\Omega, L, I)\) where \(\Omega\) is a non-empty set, \(L\) is a set of real-valued functions on \(\Omega\), and \(I\) is a non-zero real-valued function with \(\text{domain}(I) = L\), satisfying the following conditions.

1. If \(X, Y \in L\) and \(a, b \in \mathbb{R}\), then \(aX + bY, |X|\), and \(X \land 1\) belong to \(L\), and \(I(aX + bY) = aI(X) + bI(Y)\). In particular, if \(X, Y \in L\), then there exists \(\omega \in \text{domain}(X) \cap \text{domain}(Y)\).

2. If a sequence \((X_i)_{i=0,1,2,...}^\infty\) of functions in \(L\) is such that \(X_i\) is non-negative for each \(i \geq 1\) and such that \(\sum_{i=1}^\infty I(X_i) < I(X_0)\), then there exists a point \(\omega \in \bigcap_{i=0}^\infty \text{domain}(X_i)\) such that \(\sum_{i=1}^\infty X_i(\omega) < X_0(\omega)\). This condition will be referred to as the positivity condition for \(I\).

3. For each \(X \in L\), we have \(I(X \land n) \to I(X)\) and \(I(|X| \land n^{-1}) \to 0\) as \(n \to \infty\).

\(I\) is then called an integration or integral on \((\Omega, L)\), and \(I(X)\) called the integral of \(X\). A function \(X \in L\) is said to be integrable relative to \(I\). □

Note that given \(X \in L\), the function \(X \land n = n((1X) \land 1)\) belongs to \(L\) by condition 1 of Definition 4.3.1. Similarly the function \(|X| \land n^{-1}\) belongs to \(L\). Hence \(I(X \land n)\) and \(I(|X| \land n^{-1})\) in Condition 3 are defined.

In the following, in order to minimize clutter, we will write \(IX\) for \(I(X)\), and \(IXY\) etc for \(I(XY)\) etc, when there is no risk of confusion.

Note that, in general, there is no assumption that two functions should have a point in the intersection of their domains. The positivity condition is an existence condition useful in many constructions.

One trivial example of an integration space is the triple \((\Omega, L, \delta_\omega)\) where \(\omega\) is a given point in a given set \(\Omega\), where is the set of all functions \(X\) on \(\Omega\) whose domains contain \(\omega\), and where \(\delta_\omega\) is defined on \(L\) by \(\delta_\omega(X) = X(\omega)\). The integration \(\delta_\omega\) is called the point mass at \(\omega\).

**Proposition 4.3.2. (An integration on a locally compact space entails an integration space).** Let \(I\) be an integration on the locally compact metric space \((S, d)\) as defined in Definition 4.2.1. Then \((S, C(S,d), I)\) is an integration space.

**Proof.** The positivity condition in Definition 4.3.1 has been proved for \((S, C(S,d), I)\) in Proposition 4.2.3. The other conditions are trivial. □

The next proposition collects some simple properties of integration spaces.

**Proposition 4.3.3. (Basic properties of an integration space).** Let \((\Omega, L, I)\) be an integration space. Then the following holds.

1. If \(X, Y \in L\), then \(X \lor Y, X \land Y \in L\). If in addition \(a > 0\), then \(X \land a \in L\) and \(I(X \land a)\) is continuous in \(a\).
2. If $X \in L$, then $X_+, X_- \in L$ and $IX = IX_+ + IX_-$. 

3. For any $X \in L$ with $IX > 0$, there exists $\omega$ such that $X(\omega) > 0$.

4. Suppose $X(\omega) \geq 0$ for each $\omega \in \text{domain}(X)$. Then we have $IX \geq 0$.

5. There exists a non-negative $X \in L$ such that $IX = 1$.

6. For any sequence $(X_i)_{i=1,2,...}$ in $L$, there exists a point $\omega \in \cap_{i=0}^{\infty} \text{domain}(X_i)$.

**Proof.** 1. The first part follows from $X \lor Y = (X + Y + |X - Y|)/2$ and $X \land Y = (X + Y - |X - Y|)/2$. The second part follows from $X \land a = a \land (X \land 1)$ and, in view of Condition 3 in Definition 4.3.1, from $I[X \land a - X \land b] \leq I([b - a] \land |X|)$ for $a, b > 0$.

2. The conclusion follows from $X_+ = X \lor 0X$, $X_- = X \land 0X$, and $X = X_+ + X_-$. 

3. Suppose $X \in L$ has integral $IX > 0$. The positivity condition in Definition 4.3.1, applied to the sequence $(X, 0X, 0X, \ldots)$, guarantees an $\omega$ such that $X(\omega) > 0$.

4. Suppose $IX < 0$. Then $I(-X) > 0$, and part 3 of this proposition would give an $\omega \in \text{domain}(X)$ with $X(\omega) < 0$, a contradiction. Hence $IX \geq 0$.

5. Since $I$ is nonzero and linear, there exists $X$ such that $I(X) > 0$. By part 4 of this proposition, and by the linearity of $I$, we see that $IX \leq I|X|$ and so $I|X| > 0$. Let $X_0$ denote the function $|X|/|X|$. Then $X_0$ is non-negative and $IX_0 = 1$.

6. Let a non-negative $X_0 \in L$ be such that $IX_0 = 1$. Suppose $(X_i)_{i=1,2,...}$ is a sequence of functions in $L$. Then the sequence $(X_0, 0X_1, 0X_2, \ldots)$ trivially satisfies the requirements in the positivity condition in Definition 4.3.1, which therefore guarantees a point in the intersection of the domains. 

**Definition 4.3.4. (Integration subspace).** Let $(\Omega, L, I)$ be an integration space. Let $L'$ be a subfamily of $L$ such that $(\Omega, L', I)$ is an integration space. We will then call $(\Omega, L', I)$ an integration subspace of $(\Omega, L, I)$. When confusion is unlikely, we will abuse terminology and simply call $L'$ an integration subspace of $L$, with $\Omega$ and $I$ understood.

**Proposition 4.3.5. (Linear subspace of integrable functions closed to absolute values and minimum with constants is an integrations subspace).** Let $(\Omega, L, I)$ be an integration space. Let $L'$ be a linear subspace of $L$ such that if $X, Y \in L'$ then $|X|, X \land 1 \in L'$. Then $(\Omega, L', I)$ is an integration subspace of $(\Omega, L, I)$.

**Proof.** By hypothesis, $L'$ is closed to linear operations, absolute values, and the operation of taking minimum with the constant 1. Condition 1 in Definition 4.3.1 for an integration space is thus satisfied by $L'$. Conditions 2 and 3 are inherited by $(\Omega, L', I)$ from $(\Omega, L, I)$.

**Proposition 4.3.6. (Integration induced by a surjection).** Let $(\Omega, L, I)$ be an integration space. Let $\pi : \hat{\Omega} \rightarrow \Omega$ be a function from some set $\hat{\Omega}$ onto $\Omega$. For each $f \in L$ write $f(\pi) \equiv f \circ \pi$. Define $\overline{\Omega} \equiv \{ f(\pi) : f \in L \}$ and define $\overline{I} : \overline{\Omega} \rightarrow R$ by $\overline{I}X \equiv I(f)$ for each $f \in L$ and $X = f(\pi) \in \overline{\Omega}$. Then $(\overline{\Omega}, \overline{L}, \overline{I})$ is an integration space.
CHAPTER 4. INTEGRATION AND MEASURE

Proof. Suppose \( X = f(\pi) = g(\pi) \) for some \( f, g \in L \). Let \( \omega \in \text{domain}(f) \) be arbitrary. Since \( \pi \) is an on-to function, there exists \( \sigma \in \bar{\Omega} \) such that \( \pi(\sigma) = \omega \in \text{domain}(f) \). It follows that \( \sigma \in \text{domain}(f(\pi)) = \text{domain}(g(\pi)) \) and so \( \omega = \pi(\sigma) \in \text{domain}(g) \).

Since \( \omega \in \text{domain}(f) \) is arbitrary, we see that \( \text{domain}(f) \subset \text{domain}(g) \) and, by symmetry, \( \text{domain}(f) = \text{domain}(g) \). Moreover \( f(\omega) = f(\pi(\sigma)) = g(\pi(\sigma)) = g(\omega) \). We conclude that \( f = g \).

Next let and \( a, b \in \mathbb{R} \) be arbitrary, where \( f, h \in L \). Then \( af + bh \in L \) and so \( aX + bY = (af + bh)(\pi) \in \mathcal{L} \). Furthermore \( I(af + bh) = af(l) + bh(l) = aI(f) + bI(h) \). Thus \( \mathcal{L} \) is a linear space and \( I \) is a linear function. Similarly, \( |X| = |f(\pi)| \in \mathcal{T} \) and \( a \land X = (a \land f)(\pi) \in \mathcal{L} \). Furthermore \( I(a \land f) = I(a \land f) \rightarrow I(f) \equiv I(X) \) as \( a \rightarrow \infty \), while \( I(a \land |X|) \equiv I(a \land |f|) \rightarrow 0 \) as \( a \rightarrow 0 \). Thus Conditions 1 and 3 in Definition [4.3.1] for an integration space are verified for the triple \( (\Omega, \mathcal{L}, I) \).

It remains to prove the positivity condition, Condition 2 in Definition [4.3.1]. To that end, let \( \{X_i\}_{i=0,1,2,\ldots} \) be a sequence in \( \mathcal{T} \) such that \( X_i \) is non-negative for each \( i \geq 1 \) and such that \( \sum_{i=1}^{\infty} I(X_i) < I(X_0) \). For each \( i \geq 0 \) let \( f_i \in L \) be such that \( X_i = f_i(\pi) \). Then, since \( \pi \) is an on-to function, \( f_i \geq 0 \) for each \( i \geq 1 \). Moreover \( \sum_{i=1}^{\infty} I(f_i) = \sum_{i=1}^{\infty} I(X_i) < I(X_0) \equiv I(f_0) \). Since \( I \) is an integration, there exists \( \omega \in \bigcap_{i=0}^{\infty} \text{domain}(f_i) \) such that \( \sum_{i=1}^{\infty} f_i(\omega) < f_0(\omega) \). Let \( \sigma \in \bar{\Omega} \) be such that \( \pi(\sigma) = \omega \). Then

\[
\sigma \in \bigcap_{i=0}^{\infty} \text{domain}(f_i(\pi)) = \bigcap_{i=0}^{\infty} \text{domain}(X_i).
\]

By hypothesis \( \sum_{i=1}^{\infty} X_i(\sigma) = \sum_{i=1}^{\infty} f_i(\omega) < f_0(\omega) = X_0(\sigma) \). All the conditions in Definition [4.3.1] have been established. Accordingly, \( (\bar{\Omega}, \mathcal{T}, I) \) is an integration space. \( \square \)

4.4 Complete Extension of Integrations

Because discontinuous real random variables will be of interest, integration spaces like \( (S, C(S,d), I) \) will need to be expanded. More generally, given an integration space \( (\Omega, \mathcal{L}, I) \), we can expand the set \( \mathcal{L} \) to a larger set \( L_1 \), and extend the integration \( I \) to \( L_1 \), by summing a series of small pieces in \( L \), small in the sense that the integrals of the absolute values of these pieces sum to a finite number. This is analogous to the usual extension of rational numbers to reals by representing a real number as the sum of an absolutely convergent series of rational numbers.

Definition 4.4.1. (Integrable functions, and Completion of an integration space).

Let \( (\Omega, \mathcal{L}, I) \) be an integration space. A function \( X \) on a subset of \( \Omega \) is called an integrable function if there exists a sequence \( \{X_n\}_{n=1,2,\ldots} \in L \) such that (i) \( \sum_{i=1}^{\infty} I|X_i| < \infty \), (ii) \( \text{domain}(X) \) contains the set

\[
D \equiv \{ \omega \in \bigcap_{i=1}^{\infty} \text{domain}(X_i) : \sum_{i=1}^{\infty} |X_i(\omega)| < \infty \},
\]

and (iii) \( X(\omega) = \sum_{i=1}^{\infty} X_i(\omega) \) for each \( \omega \in D \). The sequence \( \{X_n\}_{n=1,2,\ldots} \) is called a representation of \( X \) by elements of \( L \) relative to \( I \). The set of integrable functions will

Yuen-Kwok Chan 52 Constructive Probability
be denoted by $L_1$. Define the sum

$$I_1(X) \equiv \sum_{i=1}^{\infty} I X_i$$

and call it the integral of $X$. Then $I_1$ is called the complete extension of $I$. Likewise, $L_1$ and $(\Omega, L_1, I_1)$ are called the complete extensions, or simply completion, of $L$ and $(\Omega, L, I)$ respectively.

The next proposition and theorem prove that (i') $I$ is well defined on $L$, and (ii) $(\Omega, L_1, I_1)$ is indeed an integration space with $L \subseteq L_1$ and $I = I_1|L$. Henceforth we can use the same symbol $I$ to denote the given integration and its complete extension, and write $I$ also for $I_1$.

An integration space $(\Omega, L, I)$ is said to be complete if $(\Omega, L, I) = (\Omega, L_1, I_1)$. $\square$

Suppose $(X_n)_{n=1,2,\ldots}$ is a representation of $X$. If we define $X_0 \equiv \sum_{i=1}^{\infty} X_i$, then $(X_n)_{n=1,2,\ldots}$ is a representation also of $X_0$, with $\text{domain}(X_0) = D \subseteq \text{domain}(X)$ and $X = X_0$ on $\text{domain}(X_0)$.

The next proposition shows that $I_1 X$ is well-defined; in other words, it is independent of the representation.

**Proposition 4.4.2.** (Complete extension of integration is well defined). If $(X_n)_{n=1,2,\ldots}$ and $(Y_n)_{n=1,2,\ldots}$ are two representations of the integrable function $X$, then $\sum_{i=1}^{\infty} I X_i = \sum_{i=1}^{\infty} I Y_i$.

**Proof.** By the definition of a representation, the series $\sum_{i=1}^{\infty} I|X_i|$ and $\sum_{i=1}^{\infty} I|Y_i|$ converge. Suppose $\sum_{i=1}^{\infty} I X_i < \sum_{i=1}^{\infty} I Y_i$. Then for some large number $m$ we have

$$\sum_{i=m+1}^{\infty} I|X_i| + \sum_{i=m+1}^{\infty} I|Y_i| + \sum_{i=m+1}^{\infty} I|Y_i - X_i| < \sum_{i=1}^{m} I Y_i - \sum_{i=1}^{m} I X_i = m \sum_{i=1}^{m} (Y_i - X_i)$$

The conditions in Definition 4.3.1 of integration space then implies the existence of a point $\omega \in \cap_{i=1}^{\infty} (\text{domain}(X_i) \cap \text{domain}(Y_i))$ such that

$$\sum_{i=m+1}^{\infty} |X_i(\omega)| + \sum_{i=m+1}^{\infty} |Y_i(\omega)| + \sum_{i=m+1}^{\infty} |Y_i(\omega) - X_i(\omega)| < \sum_{i=1}^{m} Y_i(\omega) - \sum_{i=1}^{m} X_i(\omega)$$

Hence, applying the triangle inequality, we have

$$0 < \sum_{i=1}^{m} Y_i(\omega) - \sum_{i=1}^{m} X_i(\omega) - \sum_{i=m+1}^{\infty} |Y_i(\omega) - X_i(\omega)|$$

$$\leq |\sum_{i=1}^{m} Y_i(\omega) - \sum_{i=1}^{m} X_i(\omega)| - |\sum_{i=m+1}^{\infty} Y_i(\omega) - \sum_{i=m+1}^{\infty} X_i(\omega)|$$

$$\leq |\sum_{i=1}^{m} Y_i(\omega) - \sum_{i=1}^{m} X_i(\omega)| = |X(\omega) - X(\omega)| = 0$$
The next to last equality is because both \((Y_n)_{n=1,2,...}\) and \((X_n)_{n=1,2,...}\) are, by hypothesis, representations of \(X\). Thus the assumption \(\sum_{i=1}^{\infty} |X_i| < \sum_{i=1}^{\infty} |Y_i|\) leads to a contradiction. Therefore \(\sum_{i=1}^{\infty} |X_i| \geq \sum_{i=1}^{\infty} |Y_i|\). Similarly \(\sum_{i=1}^{\infty} |X_i| \leq \sum_{i=1}^{\infty} |Y_i|\), and the equality follows. 

**Theorem 4.4.3. (Complete extension of an integration space is an integration space).** Let \((\Omega, L, I)\) be an integration space. Then \((\Omega, L_1, I_1)\) is an integration space. Moreover, \(L \subset L_1\), and \(I_1 X = IX\) for each \(X \in L\).

**Proof.** Let \(X \in L\) be arbitrary. Then \((X, 0X, 0X, ...)\) is a representation of \(X\). Hence \(X \in L_1\) and \(I_1 X = IX\). It remains to verify, for the triple \((\Omega, L_1, I_1)\), the conditions in Definition 4.3.1 of integration spaces. Proposition 4.3.3 and Condition 2 in Definition 4.3.1 guarantees that \(\text{domain}(X)\) is non-empty for each \(X \in L_1\).

First let \(X, Y \in L_1\) be arbitrary, with representations \((X_n)_{n=1,2,...}\) and \((Y_n)_{n=1,2,...}\) respectively. Let \(a, b \in R\). Then clearly the sequence

\[
(aX_n + bY_n, X_n, -X_n, Y_n, -Y_n)_{n=1,2,...}
\]

is a representation of \(aX + bY\). The seemingly redundant terms \(X_n, -X_n, Y_n, -Y_n, \ldots\) are included to ensure that the absolute convergence of the resulting series at some \(\omega\) implies that \(\omega \in \text{domain}(aX + bY)\). Similar tricks will be used several times later without further comments. Thus we see that \(aX + bY \in L_1\) and \(I_1(aX + bY) = aI_1X + bI_1Y\). Similarly, let \(a > 0\) be arbitrary. Because

\[
I[a \wedge \sum_{i=1}^{n} X_i - a \sum_{i=1}^{n-1} X_i] \leq I[X_n]
\]

for each \(n \geq 1\), the sequence

\[
(a \wedge \sum_{i=1}^{n} X_i - a \wedge \sum_{i=1}^{n-1} X_i, X_n, -X_n)_{n=1,2,...}
\]

is a representation of \(X \wedge a\). Hence \(X \wedge a\) belongs to \(L_1\), and

\[
I_1(X \wedge a) = \lim_{n \to \infty} I(a \wedge \sum_{i=1}^{n} X_i) \leq \lim_{n \to \infty} I(\sum_{i=1}^{n} X_i) = I_1 X
\]

(4.4.1)

In particular \(1 \wedge X \in L_1\). Again, because

\[
I[|\sum_{i=1}^{n} X_i| - |\sum_{i=1}^{n-1} X_i|] \leq I[X_n]
\]

for each \(n \geq 1\), the sequence

\[
(|\sum_{i=1}^{n} X_i| - |\sum_{i=1}^{n-1} X_i, X_n, -X_n)_{n=1,2,...}
\]
is a representation of \(|X|\). Hence \(|X|\) belongs to to \(L_1\), with

\[
I_1|X| = \lim_{n \to \infty} I_1 \left| \sum_{i=1}^{n} X_i \right|
\]  

(4.4.2)

It follows that \(I_1\) is a nonnegative function on \(L_1\). In other words, if \(X, Y \in L_1\) are such that \(X \leq Y\) on \(\text{domain}(X) \cap \text{domain}(Y)\), then \(I_1 X \leq I_1 Y\).

We next verify the positivity condition in Definition 4.3.1. To that end, let \((X_i)_{i=0,1,2,\ldots}\) be a sequence of functions in \(L_1\) such that \(X_i\) is non-negative for \(i \geq 1\) and such that

\[
\sum_{i=1}^{\infty} I_1 X_i < I_1 X_0
\]

For each \(i \geq 0\), let \((X_{i,k})_{k=1,2,\ldots}\) be a representation of \(X_i\). Then \(\sum_{k=1}^{\infty} I|X_{i,k}| < \infty\) for each \(i \geq 0\). Since \(X_i\) is non-negative for \(i \geq 1\), we see from part 1 of this proof that

\[
\lim_{n \to \infty} I_1 \left| \sum_{k=1}^{\infty} X_{i,k} \right| = I_1|X_i| = I_1 X_i
\]

for \(i \geq 1\). Therefore there exists a sequence \((m_i)_{i=0,1,2,\ldots}\) of integers such that

\[
\sum_{i=1}^{\infty} L_i \left| \sum_{k=1}^{m(i)} X_{i,k} \right| < \sum_{i=1}^{\infty} \sum_{k=m(i)+1}^{m(i)} I|X_{i,k}| < \sum_{k=1}^{\infty} I|X_{0,k}|
\]

The positivity condition of 4.3.1 on \((\Omega, L, I)\) therefore guarantees the existence of \(\omega \in \bigcap_{i=0}^{\infty} \bigcap_{k=1}^{m(i)} \text{domain}(X_{i,k})\) such that

\[
\sum_{i=1}^{\infty} \sum_{k=1}^{m(i)} X_{i,k}(\omega) + \sum_{i=0}^{\infty} \sum_{k=m(i)+1}^{m(i)} |X_{i,k}(\omega)| < \sum_{k=1}^{\infty} X_{0,k}(\omega)
\]

(4.4.3)

It follows from the definition of a representation that \(X_i(\omega)\) is defined and \(\sum_{k=1}^{\infty} X_{i,k}(\omega) = X_i(\omega)\) for each \(i \geq 0\). Moreover

\[
\sum_{i=1}^{\infty} X_i(\omega) = \sum_{i=1}^{\infty} \sum_{k=1}^{m(i)} X_{i,k}(\omega) = \sum_{i=1}^{\infty} \sum_{k=1}^{m(i)} X_{i,k}(\omega)
\]

\[
\leq \sum_{i=1}^{\infty} \sum_{k=1}^{m(i)} |X_{i,k}(\omega)| + \sum_{i=0}^{\infty} \sum_{k=m(i)+1}^{m(i)} |X_{i,k}(\omega)| - \sum_{k=m(0)+1}^{\infty} |X_{0,k}(\omega)|
\]

\[
< \sum_{k=1}^{\infty} X_{0,k}(\omega) - \sum_{k=m(0)+1}^{\infty} |X_{0,k}(\omega)| \leq \sum_{k=1}^{\infty} X_{0,k}(\omega) = X_0(\omega)
\]

where the next to last inequality follows from inequality 4.4.1 above. This proves condition 2 of Definition 4.3.1 for \((\Omega, L_1, I_1)\).
Now let \( X \in L_1 \), with a representation \((X_i)_{i=1,2,\ldots} \) in \( L \). Then, for every \( m > 0 \), the sequence  
\[
(X_1,-X_1,X_2,-X_2,\ldots,X_m,-X_m,X_{m+1},X_{m+1},X_{m+2},X_{m+2},\ldots)
\]
is a representation of the function \( X - \sum_{i=1}^{m} X_i \in L_1 \). Therefore, applying equation 4.4.2 in above, we have  
\[
I_1|X - \sum_{i=1}^{m} X_i| = \lim_{n \to \infty} I_1|X| - \sum_{i=m+1}^{n} I_1|X_i| \to 0
\]  
Hence, for any given \( \varepsilon > 0 \), there exists \( m \) so large that \( I_1|X - \sum_{i=1}^{m} X_i| < \varepsilon \). Write \( Y = \sum_{i=1}^{m} X_i \). Then  
\[
I_1|X - Y| < \varepsilon
\]
and so  
\[
I_1|X \cap n - Y \cap n| \leq I_1|X - Y| < \varepsilon
\]
for each \( n \geq 1 \). In view of Condition 3 of Definition 4.3.1 for \((\Omega, L, I)\), there exists \( p \geq 1 \) so large that  
\[
|I_1(Y \cap n) - I_1Y| = |I(Y \cap n) - IY| < \varepsilon
\]
for each \( n \geq p \). Hence  
\[
I_1X \geq I_1(X \cap n) > I_1(Y \cap n) - \varepsilon > I_1Y - 2\varepsilon > I_1X - 3\varepsilon
\]
for each \( n \geq p \). Since \( \varepsilon \) is arbitrary, we have \( I_1(X \cap n) \to I_1X \) as \( n \to \infty \). Separately, again by Condition 3 of Definition 4.3.1 for \((\Omega, L, I)\), there exists \( p \geq 1 \) so large that \( I(|Y| \cap n^{-1}) < \varepsilon \) for each \( n \geq p \). Therefore  
\[
I_1(|X| \cap n^{-1}) \leq I_1(\{|Y| \cap n^{-1}\} + I_1|X - Y| < 2\varepsilon
\]
Hence \( I_1(|X| \cap n^{-1}) \to 0 \) as \( n \to \infty \). All three conditions in Definition 4.3.1 have been verified for \((\Omega, L, I)\) to be an integration space. \( \square \)

**Corollary 4.4.4. (L is dense in its complete extension).** If \( X \in L_1 \) has representation \((X_i)_{i=1,2,\ldots} \), then \( \lim_{n \to \infty} I|X - \sum_{i=1}^{n} X_i| = 0 \).

**Proof.** See expression 4.4.4 in the proof of 4.4.3. \( \square \)

Henceforth we will, write \( I \) also for \( I_1 \). In words, we will use the symbol for a given integration also for its complete extension.

**Proposition 4.4.5. (Complete extension of an integration space is a complete metric space).** Let \( X, Y \in L_1 \) be arbitrary. Define \( \rho_1(X,Y) = I|X - Y| \). Then \((L_1, \rho_1)\) is a complete metric space, and \( L \) is a dense subset of \( L_1 \).

**Proof.** The proof that \((L_1, \rho_1)\) is a metric space is trivial. Corollary 4.4.4 implies that \( L \) is a dense subset of \((L_1, \rho_1)\). It remains to prove that the latter is complete.

Let \((X_n)_{n=1,2,\ldots} \) be any Cauchy sequence in \((L_1, \rho_1)\). To prove completeness we need to find some \( Z \in L_1 \) such that \( \lim_{n \to \infty} I|X_n - Z| = 0 \). Let \((n_i)_{i=1,2,\ldots} \) be an increasing sequence such that \( I|X_{n_i} - Z_n| < 2^{-i} \) for each \( n > n_i \) and \( i \geq 1 \). Because \( L \) is dense
4.4. COMPLETE EXTENSION OF INTEGRATIONS

in $L_1$, there exists for each $i \geq 1$ some $Z_i \in L$ such that $|X_n(i) - Z_i| < 2^{-i}$. Then $|Z_i - Z_{i+1}| < 2^{-i+1} + 2^{-i-1}$ for each $i \geq 1$. Hence the sequence $(Z_1, Z_2 - Z_1, Z_3 - Z_2, \cdots)$ is the representation of some $Z \equiv Z_1 + \sum_{i=1}^{\infty} (Z_{i+1} - Z_i) \in L_1$. Corollary 4.4.4 therefore implies that $\lim_{i \to \infty} I[Z_i - Z] = 0$. At the same time, for each $n > n_i$ and $i \geq 1$ we have

$$|X_n - Z| \leq |X_n - X_n(i)| + |X_n(i) - Z| < 2^{-i} + |X_n(i) - Z|$$

Combining, we see that $\lim_{n \to \infty} I[X_n - Z] = 0$. \hfill \Box

Corollary 4.4.6. (Nothing is gained from further complete extension). Let $L_1$ be space of integrable functions on $(\Omega, L, I)$. Let $(L_1)_1$ be space of integrable functions on $(\Omega, L_1, I)$. Then $(L_1)_1 = L_1$.

Proof. Let $Z \in (L_1)_1$. By Proposition 4.4.5 for any $\varepsilon > 0$ there exists a function $Y \in L_1$ with $|Z - Y| < \varepsilon$, and there exists a function $X \in L$ with $|Y - X| < \varepsilon$, and so $|Z - X| < 2\varepsilon$. Thus we can construct a sequence in $L$ which converges to $Z$. Proposition 4.4.5 implies that $Z \in L_1$. \hfill \Box

Corollary 4.4.7. (Two integrations on the same space of integrable functions are equal if they agree on some dense subset). Let $(\Omega, L, I)$ and $(\Omega, L, I')$ be complete integration spaces. Suppose $I = I'$ on some subset $L_0$ of $L$ which is dense in $L$ relative to the metric defined by $p_I(X, Y) = |X - Y|$ for all $X, Y \in L$. Then $I = I'$ on $L$.

Proof. Let $X \in L$ be arbitrary. Let $(X_n)_{n=1,2,\cdots}$ be a sequence in $L_0$ which converges to $X$ relative to the metric $p_I$. As in the proof of Proposition 4.4.5, we can then construct a sequence $(Y_n)_{n=1,2,\cdots}$ in $L_0$ which is a representation of $X$ relative to $I$. Since $I = I'$ on $L_0$, it follows immediately that $(Y_n)_{n=1,2,\cdots}$ is also a representation of $X$ relative to $I'$, with

$$I'X = \sum_{i=1}^{\infty} I'Y_n = \sum_{i=1}^{\infty} IY_n = IX.$$ 

Since $X \in L$ is arbitrary, we conclude that $I = I'$. \hfill \Box

For monotone sequences, we have a very useful theorem for establishing convergence in $L_1$.

Theorem 4.4.8. (Monotone Convergence Theorem). Let $(\Omega, L_1, I)$ be a complete integration space. Suppose $(X_i)_{i=1,2,\cdots}$ is a sequence in $L_1$ such that $X_{i-1} \leq X_i$ on $\cap_{i=1}^{\infty} \text{domain}(X_i)$, and such that $\lim_{i \to \infty} I(X_i)$ exists. Then $X \equiv \lim_{i \to \infty} X_i \in L_1$. Moreover $\lim_{i \to \infty} I|X - X_i| = 0$. Similarly, suppose $(Y_i)_{i=1,2,\cdots}$ is a sequence in $L_1$ such that $Y_{i-1} \geq Y_i$ on $\cap_{i=1}^{\infty} \text{domain}(Y_i)$, and such that $\lim_{i \to \infty} I(Y_i)$ exists. Then $Y \equiv \lim_{i \to \infty} Y_i \in L_1$. Moreover $\lim_{i \to \infty} I|Y - Y_i| = 0$.

Proof. The sequence $(X_1, X_2 - X_1, X_3 - X_2, \cdots)$ is obviously a representation of $X$, with $IX = \lim_{i \to \infty} I(X_1 + (X_2 - X_1) + \cdots + (X_i - X_{i-1})) = \lim_{i \to \infty} IX_i$. Corollary 4.4.4 implies $\lim_{i \to \infty} I|X - X_i| = 0$. The second part of the theorem follows by applying the first part to the sequence $(-Y_i)_{i=1,2,\cdots}$.
4.5 Integrable Sets

To model an event in a chance experiment which may or may not have occurred after the outcome is observed, we can use a function with only two possible values, 1 or 0. Equivalently we can specify the subset of those outcomes that realize the event. We make these notions precise in the present section.

**Definition 4.5.1. (Indicators and mutually exclusive subsets).** Subsets $A_1, \cdots, A_n$ of a set $\Omega$ are said to be mutually exclusive if $A_iA_j = \emptyset$ for all $i, j$ with $i \neq j$. A function $X$ on a set $\Omega$ with only two possible values, 1 or 0, is called an indicator. Indicators $X_1, \cdots, X_n$ are said to be mutually exclusive if the sets $\{ \omega \in \text{domain}(X_i) : X_i(\omega) = 1 \}$ ($i = 1, \cdots, n$) are mutually exclusive. □

In the remainder of this section, let $(\Omega, L, I)$ be a complete integration space. Recall that an integrable function need not be defined everywhere. However, they are defined almost everywhere in the sense of the next definition.

**Definition 4.5.2. (Full set and almost everywhere properties).** A subset $D$ of $\Omega$ is called a full set if $D \supset \text{domain}(X)$ for some integrable function $X \in L$. Two functions $Y, Z$ on $\Omega$ are said to be equal almost everywhere, with abbreviation $Y = Z$ a.e., if $Y = Z$ on a full set $D$. In other words, $Y = Z$ a.e. if there exists a full set $D$ such that (i) $D \cap \text{domain}(Y) = D \cap \text{domain}(Z)$ and (ii) $Y(\omega) = Z(\omega)$ for each $\omega \in D \cap \text{domain}(Y)$. In general, a statement about a general element $\omega$ of $\Omega$ is said to hold almost everywhere, a.e. for short, if it holds for each $\omega$ in a full set. □

For example, since according to the terminology established in the Introduction of this book, the statement $Y \leq Z$ means that for each $\omega \in \Omega$ we have (i) $\omega \in \text{domain}(Y) \Leftrightarrow \omega \in \text{domain}(Z)$ and (ii) $Y(\omega) \leq Z(\omega)$ if $\omega \in \text{domain}(Y)$. So the statement $Y \leq Z$ a.e. means that there exists some full set $D$ such that for each $\omega \in D$ the conditions (i) and (ii) hold. Equivalently, $Y \leq Z$ a.e. iff (i') $\omega \in D \cap \text{domain}(Y) \Leftrightarrow \omega \in D \cap \text{domain}(Z)$ and (ii') $Y(\omega) \leq Z(\omega)$ for each $\omega \in D \cap \text{domain}(Y)$. Thus $Y \leq Z$ a.e. iff $Y \leq Z$ on some full set $D$.

Similarly, if $A, B$ are subsets of $\Omega$, then $A \subset B$ a.e. iff $AD \subset BD$ for some full set $D$.

Every integrable function is defined a.e. The last sentence, however, does not tell us anything until we explore the properties of full sets, in the next proposition.

**Proposition 4.5.3. (Properties of full sets).** Let $X, Y, Z \in L$ denote integrable functions.

1. A subset which contains a full set is a full set. The intersection of a sequence of full sets is again a full set.

2. Suppose $W$ is a function on $\Omega$ and $W = X$ a.e. Then $W$ is an integrable function with $IW = IX$.

3. If $D$ is a full set then $D = \text{domain}(X)$ for some $X \in L$.

4. $X = Y$ a.e. if and only if $|X - Y| = 0$.

5. If $X \leq Y$ a.e. then $IX \leq IY$. 

Yuen-Kwok Chan 58 Constructive Probability
6. If \( X \leq Y \ \text{a.e.} \) and \( Y \leq Z \ \text{a.e.} \) then \( X \leq Z \ \text{a.e.} \) Moreover, if \( X \leq Y \ \text{a.e.} \) and \( X \geq Y \ \text{a.e.} \) then \( X = Y \ \text{a.e.} \)

7. Almost everywhere equality is an equality relation in \( L \). In other words, for all \( X, Y, Z \in L \) we have (i) \( X = X \ \text{a.e.} \) (ii) if \( X = Y \ \text{a.e.} \) then \( Y = X \ \text{a.e.} \) and (iii) if \( X = Y \ \text{a.e.} \) and \( Y = Z \ \text{a.e.} \) then \( X = Z \ \text{a.e.} \)

Proof. 1. Suppose \( D_\infty \supset domain(X_n) \) where \( X_n \in L \) for \( n \geq 1 \). Define \( X \equiv \sum_{n=1}^\infty X_n \). Then \( X \in L \) since \( L \) is complete. Moreover

\[
\bigcap_{n=1}^\infty D_n \supset \bigcap_{n=1}^\infty domain(X_n) = \bigcap_{n=1}^\infty domain(0X_n) = domain(X)
\]

2. By the definition of a.e. equality, there exists a full set \( D \) such that \( D \cap domain(W) = D \cap domain(X) \) and \( W(\omega) = X(\omega) \) for each \( \omega \in D \cap domain(X) \). By the definition of a full set, \( D \supset domain(Z) \) for some \( Z \in L \). It is then easily verified that the sequence \( (X, 0Z, 0Z, \cdots) \) is a representation of the function \( W \). Therefore \( W \in L_1 = L \) with \( IW = IX \).

3. Suppose \( D \) is a full set. By definition \( D \supset domain(X) \) for some \( X \in L \). Define a function \( W \) by \( domain(W) \equiv D \) and \( W(\omega) \equiv 0 \) for each \( \omega \in D \). Then \( W = 0X \) on the full set \( domain(X) \). Hence by assertion 2 above, \( W \) is an integrable function, with \( D \equiv domain(W) \).

4. Suppose \( X = Y \ \text{a.e.} \). Then \( |X - Y| = 0(X - Y) \ \text{a.e.} \). Hence \( |X - Y| = 0 \) according to assertion 2. Suppose conversely that \( |X - Y| = 0 \). Then the function defined by \( Z \equiv \sum_{n=1}^\infty |X - Y| \) is integrable. By definition

\[
domain(Z) \equiv \{ \omega \in domain(X - Y) : \sum_{n=1}^\infty |X(\omega) - Y(\omega)| < \infty \}
\]

Thus we see that \( X = Y \) on the full set \( domain(Z) \).

5. Because \( Y - X = |Y - X| \ \text{a.e.} \), we have, by assertion 4, \( I(Y - X) = I|Y - X| \geq 0 \).

6. Suppose \( X \leq Y \ \text{a.e.} \) and \( Y \leq Z \ \text{a.e.} \). Then there exists a full set \( D \) such that \( D \cap domain(X) = D \cap domain(Y) \) and \( X(\omega) \leq Y(\omega) \) for each \( \omega \in D \cap domain(X) \). Similarly, there exists a full set \( D' \) such that \( D' \cap domain(Y) \equiv D' \cap domain(Z) \) and \( Y(\omega) \leq Z(\omega) \) for each \( \omega \in D' \cap domain(Y) \). By assertion 1, the set \( DD' \) is a full set. Furthermore, \( DD' \cap domain(X) = DD' \cap domain(Y) = DD' \cap domain(Z) \) and \( X(\omega) \leq Y(\omega) \leq Z(\omega) \) for each \( \omega \in DD' \cap domain(X) \). It follows that \( X \leq Z \ \text{a.e.} \). The remainder of the assertion is similarly proved.

\[ \square \]

\textbf{Definition 4.5.4.} (Integrable set, measure of integrable set, complement of integrable set, and null set). A subset \( A \) of \( \Omega \) is called an integrable set if there exists an indicator \( X \) which is an integrable function such that \( A = (X = 1) \). In this case call \( X \) an indicator of \( A \). We then define the measure of \( A \) to be \( \mu(A) \equiv IX \), and call the set \( (X = 0) \) a measure-theoretic complement of \( A \). We write \( 1_A \) for an indicator of \( A \), and write \( A^c \) for a measure-theoretic complement of \( A \). An integrable set with measure \( \mu(A) = 0 \) is called a null set. \[ \square \]
Two distinct integrable indicators \( X \) and \( Y \) can be indicators of the same integrable set \( A \); hence \( 1_A \) is not uniquely defined relative to the set-theoretic equality for functions. However, as shown in the next proposition, given an integrable set, its indicator, measure, and measure-theoretic complement are all uniquely defined relative to a.e. equality.

**Proposition 4.5.5. (Properties of integrable sets).** Let \( A \) and \( B \) be integrable sets. Let \( X, Y \) be integrable indicators of \( A, B \) respectively.

1. \( A = B \) a.e. if \( X = Y \) a.e. In particular, \( 1_A \) is well-defined relative to a.e. equality, and the measure \( \mu(A) \) is well-defined.

2. If \( A = B \) a.e., then \( (X = 0) = (Y = 0) \) a.e. In particular, \( A^c \) is well-defined relative to equality a.e.

3. The empty set \( \emptyset \) is a null set, and \( \Omega \) is a full set.

4. Any full set is a measure-theoretic complement of a null set.

5. Any measure-theoretic complement of a null set is a full set.

6. If \( C \) is a subset of \( \Omega \) such that \( C = A \) a.e., then \( C \) is integrable with \( \mu(A) = \mu(C) \).

**Proof.** By the definition of an indicator for an integrable set, we have \( A = (X = 1) \) and \( B = (Y = 1) \). Let \( D \) be an arbitrary full set. Then the intersection \( D' = D \cap \text{domain}(X) \cap \text{domain}(Y) \) is a full set. Since \( D' \subseteq D \), we have \( D\Delta A = D\Delta D(X = 1) \) and \( D\Delta B = D\Delta D(Y = 1) \).

1. Suppose \( A = B \) on the full set \( D \). Then \( DA = DB \). It follows from the previous paragraph that \( D'(X = 1) = D'\Delta D(X = 1) = D'\Delta D(Y = 1) = D'(Y = 1) \). By the remark following Definition 4.5.1, we see that for each \( \omega \in D' \), \( X(\omega) \) and \( Y(\omega) \) are defined and equal. Hence \( X = Y \) a.e. Moreover, it follows from Proposition 4.5.3 that \( \mu(A) \equiv IX = IY \equiv \mu(B) \). Conversely, suppose \( X = Y \) a.e. with \( D \cap \text{domain}(X) = D \cap \text{domain}(Y) \) and \( X(\omega) = Y(\omega) \) for each \( \omega \in D \cap \text{domain}(X) \). Then \( D'\Delta A = D'\Delta D(X = 1) = D'(Y = 1) = D'\Delta B \). Hence \( A = B \) a.e.

2. Suppose \( A = B \) a.e. In the above proof for assertion 1, we see that for each \( \omega \) in the full set \( D' \), we have \( X(\omega) = 0 \) iff \( Y(\omega) = 0 \).

3. Let \( X \) be any integrable function. Then \( 0X \) is an indicator for \( \phi \), with \( \mu(\phi) = I(0X) = 0 \). Hence \( \phi \) is a null set. Trivially \( \Omega \supseteq \text{domain}(X) \), and so \( \Omega \) is a full set.

4. Suppose \( D \) is a full set. By Proposition 4.5.3, we have \( D = \text{domain}(X) \) for some integrable function \( X \). Since \( \phi = (0X = 1) \) we see that \( 0X \) is an indicator for \( \phi \). Hence \( \phi^c \equiv (0X = 0) = \text{domain}(X) = D \) is a measure-theoretic complement of the null set \( \phi \).

5. Suppose \( A \) is a null set, with \( Z \in L \) as an indicator and \( A^c \equiv (Z = 0) \). Since \( IZ = 0 \), the function \( X \equiv \sum_{i=1}^{\infty} Z \) is integrable. Moreover,

\[
\text{domain}(X) = \{ \omega \in \text{domain}(Z) : \sum_{i=1}^{\infty} Z(\omega) = 0 \} = (Z = 0) = A^c
\]

Hence \( A^c \) is a full set.
6. Suppose \( C = A \) on the full set \( D \). Define a function \( W \) by \( \text{domain}(W) = C \cup (X = 0) \) and \( W(\omega) = 1 \) or 0 according as \( \omega \in C \) or \( (X = 0) \). Then \( W = X \) on the full set \( D \cap \text{domain}(X) \). By Proposition 4.5.5, the function \( W \) is integrable. Hence \( C = (W = 1) \) has an integrable indicator. Moreover \( \mu(C) = IW = IX = \mu(A) \). □

Suppose each of a sequence of statements is valid a.e. Then in view of Proposition 4.5.5 there exists a full set on which all of these statements are valid; in other words, a.e. we have the validity of all the statements. For example if \( (A_n)_{n=1,2,...} \) is a sequence of integrable sets with \( A_n \subset A_{n+1} \) a.e. for each \( n > 0 \), then \( A_1 \subset A_2 \subset \cdots \) a.e.

**Proposition 4.5.6. (Basics of measures of integrable sets).** Let \( A, B \) be integrable sets, with indicators \( 1_A, 1_B \) respectively, and with \( A^c \equiv (1_A = 0) \) and \( B^c \equiv (1_B = 0) \). Then the following holds.

1. \( A \cup A^c \) is a full set, and \( AA^c = \emptyset \).
2. \( A \cup B \) is an integrable set, with \( 1_{A \cup B} = 1_A \lor 1_B \) a.e.
3. \( AB \) is an integrable set, with \( 1_{AB} = 1_A \land 1_B \) a.e. Moreover \( AB^c \) is an integrable set, with \( 1_{AB^c} = 1_A - 1_A \land 1_B \) a.e. Furthermore \( \mu(AB^c) = AB \).
4. \( \mu(A \cup B) + \mu(AB) = \mu(A) + \mu(B) \).
5. If \( A \supset B \) a.e. then \( \mu(AB^c) = \mu(A) - \mu(B) \).

**Proof.**

1. We have \( A = (1_A = 1) \) and \( A^c = (1_A = 0) \). Hence \( AA^c = \emptyset \). Moreover \( A \cup A^c = \text{domain}(1_A) \), a full set.
2. Define the function \( X \) by \( \text{domain}(X) \equiv (A \cup B) \cup (A^c B^c) \) and \( X(\omega) \equiv 1 \) or 0 according as \( \omega \in A \lor B \) or \( \omega \in A^c B^c \). Then \( X = 1_A \lor 1_B \) on the full set \( \text{domain}(1_A \lor 1_B) \). Hence \( X \) is an integrable function according to 4.5.5. Since \( A \cup B = (X = 1) \), the function \( X \) is an indicator of \( A \cup B \). In other words \( 1_{A \cup B} = X = 1_A \lor 1_B \) a.e.
3. Obviously \( AB = (1_A \land 1_B = 1) \). Hence \( 1_{AB} = 1_A \land 1_B \). Next define the function \( X \) by \( \text{domain}(X) \equiv (AB^c) \cup (A^c B) \) and \( X(\omega) \equiv 1 \) or 0 according as \( \omega \in AB^c \) or \( \omega \in A^c B \). Then \( X = 1_A - 1_A \land 1_B \) on the full set \( \text{domain}(1_A \land 1_B) \). Hence \( X \) is an integrable function according to 4.5.5. Since \( AB^c = (X = 1) \), the function \( X \) is an indicator of \( AB^c \). In other words \( 1_{AB^c} = X = 1_A - 1_A \land 1_B \) a.e. Furthermore, \( A(AB^c) = A(X = 0) = A(1_A \land 1_B = 1) = AB \).
4. Since \( 1_A \lor 1_B + 1_A \land 1_B = 1_A + 1_B \), the conclusion follows from linearity of \( I \).
5. Suppose \( AD \supset BD \) for a full set \( D \). Write \( A' \equiv AD \) and \( B' \equiv BD \) and define \( B'^c \equiv B'D \). Then \( B'^c \) is a measure-theoretic complement of \( B' \). We have \( A' \supset B' \) and so \( B' = B'A' \). According to Proposition 4.5.5, the sets \( A' \) and \( B' \) are integrable, with \( \mu(A') = \mu(A) \) and \( \mu(B') = \mu(B) \). By the same token, since \( A'B'^c = AB^c \) on the full set \( D \), the set \( A'B'^c \) is integrable with \( \mu(A'B'^c) = (A'B)^c = (B'C') \). On the other hand, from assertion 4, we have

\[
\mu(B') + \mu(A'B'^c) = \mu(B'A') + \mu(B'^cA')
\]

\[
= \mu((B'A') \cup (B'^cA')) = \mu((B' \cup B'^c)A') = \mu(A')
\]

Yuen-Kwok Chan 61 Constructive Probability
where the next to last equality is because \((B^c \cup B')A' = A'\) on the full set \(B^c \cup B'\). The assertion is proved. \(\square\)

**Proposition 4.5.7. (Sequence of integrable sets).** For each \(n \geq 1\) let \(A_n\) be an integrable set with a measure-theoretic complement \(A_n^c\). Then the following holds.

1. If \(A_n \subset A_{n+1}\) a.e. for each \(n \geq 1\), and if \(\mu(A_n)\) converges, then \(\bigcup_{n=1}^\infty A_n\) is an integrable set with \(\mu(\bigcup_{n=1}^\infty A_n) = \lim_{n \to \infty} \mu(A_n)\) and \((\bigcup_{n=1}^\infty A_n)^c = \bigcap_{n=1}^\infty A_n^c\).

2. If \(A_n \supset A_{n+1}\) a.e. for each \(n \geq 1\), and if \(\mu(A_n)\) converges, then \(\bigcap_{n=1}^\infty A_n\) is an integrable set with \(\mu(\bigcap_{n=1}^\infty A_n) = \lim_{n \to \infty} \mu(A_n)\) and \((\bigcap_{n=1}^\infty A_n)^c = \bigcup_{n=1}^\infty A_n^c\).

3. If \(A_n A_m = \phi\) a.e. for each \(n > m \geq 1\), and if \(\sum_{n=1}^\infty \mu(A_n)\) converges, then \(\bigcup_{n=1}^\infty A_n\) is an integrable set with \(\mu(\bigcup_{n=1}^\infty A_n) = \sum_{n=1}^\infty \mu(A_n)\).

4. If \(\sum_{n=1}^\infty \mu(A_n)\) converges, then \(\bigcup_{n=1}^\infty A_n\) is an integrable set with \(\mu(\bigcup_{n=1}^\infty A_n) \leq \sum_{n=1}^\infty \mu(A_n)\).

**Proof.** For each \(n \geq 1\) let \(1_{A_n}\) be the integrable indicator of \(A_n\) such that \(A_n^c = (1_{A_n} = 0)\).

1. Define a function \(Y\) by

\[
\text{domain}(Y) \equiv \left( \bigcup_{n=1}^\infty A_n \right) \cup \left( \bigcap_{n=1}^\infty A_n^c \right)
\]

with \(Y(\omega) \equiv 1\) or 0 according as \(\omega \in \bigcup_{n=1}^\infty A_n\) or \(\omega \in \bigcap_{n=1}^\infty A_n^c\). Then \((Y = 1) = \bigcup_{n=1}^\infty A_n\) and \((Y = 0) = \bigcap_{n=1}^\infty A_n^c\). For each \(n \geq 1\), we have \(A_n \subset A_{n+1}\) a.e. and so \(1_{A_{n+1}} \geq 1_{A_n}\) a.e. By assumption we have the convergence of

\[
I(1_{A_1}) + I(1_{A_2} - 1_{A_1}) + \cdots + I(1_{A_n} - 1_{A_{n-1}}) = I1_{A_n} = \mu(A_n)
\]

as \(n \to \infty\). Hence \(X \equiv 1_{A_1} + (1_{A_2} - 1_{A_1}) + (1_{A_3} - 1_{A_2}) + \cdots\) is an integrable function. Consider an arbitrary \(\omega \in \text{domain}(X)\). The limit

\[
\lim_{n \to \infty} 1_{A_n}(\omega) = \lim_{n \to \infty} (1_{A_1}(\omega) + (1_{A_2} - 1_{A_1})(\omega) + \cdots + (1_{A_n} - 1_{A_{n-1}})(\omega)) = X(\omega)
\]

exists, and is either 0 or 1 since it is the limit of a sequence in \(\{0, 1\}\). Suppose \(X(\omega) = 1\). Then \(1_{A_n}(\omega) = 1\) for some \(n \geq 1\). Hence \(\omega \in \bigcup_{n=1}^\infty A_n\) and so \(Y(\omega) \equiv 1 = X(\omega)\). Suppose \(X(\omega) = 0\). Then \(1_{A_n}(\omega) = 0\) for each \(n \geq 1\). Hence \(\omega \in \bigcap_{n=1}^\infty A_n^c\) and so \(Y(\omega) \equiv 0 = X(\omega)\). Combining, we see that \(Y = X\) on the full set \(\text{domain}(X)\). According to Proposition 4.5.3, we therefore have \(Y \in L\). Thus \(\bigcup_{n=1}^\infty A_n = (Y = 1)\) is an integrable set with \(Y\) as its indicator, and has measure equal to

\[
\mu(\bigcup_{n=1}^\infty A_n) = \lim_{n \to \infty} \mu(A_n)
\]

Moreover \((\bigcup_{n=1}^\infty A_n)^c = (Y = 0) = \bigcap_{n=1}^\infty A_n^c\).

2. Similar.

3. Write \(B_n = \bigcup_{i=1}^n A_i\). Repeated application of Proposition 4.5.6 leads to \(\mu(B_n) = \sum_{i=1}^n \mu(A_i)\). From assertion 1 we see that \(\bigcup_{n=1}^\infty A_n = \bigcup_{n=1}^\infty B_n\) is an integrable set with \(\mu(\bigcup_{n=1}^\infty A_n) = \mu(\bigcup_{n=1}^\infty B_n) = \lim_{n \to \infty} \mu(B_n) = \sum_{i=1}^\infty \mu(A_i)\).

Yuen-Kwok Chan 62 Constructive Probability
4.6. ABUNDANCE OF INTEGRABLE SETS

4. Define \( B_1 = A_1 \) and \( B_n = (\bigcup_{k=1}^{n-1} A_k)^c \) for \( n > 1 \). Let \( D \) denote the full set \( \bigcap_{k=1}^{\infty} (A_k \cup A_k^c) \). Clearly \( B_nB_k = \emptyset \) on \( D \) for each positive integer \( k < n \). This implies \( \mu(B_nB_k) = 0 \) for each positive integer \( k < n \). Furthermore, for every \( \omega \in D \), we have \( \omega \in \bigcup_{k=1}^{\infty} A_k \) iff there is a smallest \( n > 0 \) such that \( \omega \in \bigcup_{k=1}^{n-1} A_k \). Since for every \( \omega \in D \) either \( \omega \in A_k \) or \( \omega \in A_k^c \), we have \( \omega \in \bigcup_{k=1}^{\infty} A_k \) iff there is an \( n > 0 \) such that \( \omega \in B_n \). In other words \( \bigcup_{k=1}^{n-1} A_k = \bigcup_{k=1}^{n} B_k \) a.e. Moreover \( \mu(B_n) = \mu(\bigcup_{k=1}^{n-1} A_k) = \mu(\bigcup_{k=1}^{n} A_k) \). Hence the sequence \( (B_n) \) of integrable sets satisfies the hypothesis in assertion 3. Therefore \( \bigcup_{k=1}^{\infty} B_k \) is an integrable set, with

\[
\mu(\bigcup_{k=1}^{\infty} A_k) = \mu(\bigcup_{k=1}^{\infty} B_k) = \lim_{n \to \infty} \sum_{k=1}^{n} \mu(B_k) \leq \lim_{n \to \infty} \sum_{k=1}^{n} \mu(A_k) = \sum_{n=1}^{\infty} \mu(A_n).
\]

\[\square\]

Proposition 4.5.8. (Convergence in \( L \) implies an a.e. convergent subsequence). Let \( X \in L \) and let \( (X_n)_{n=1,2,...} \) be a sequence in \( L \). If \( I|X_n - X| \to 0 \) then there exists a subsequence \( (Y_n)_{n=1,2,...} \) such that \( Y_n \to X \) a.e.

Proof. Let \( (Y_n)_{n=1,2,...} \) be a subsequence such that \( I|Y_n - X| < 2^{-n} \). Then the sequence \( (Z_n)_{n=1,2,...} \) defined as \( X, -X + Y_1, X - Y_1, -X + Y_2, X - Y_2, \cdots \) is a representation of \( X \). Define \( Z = \sum_{n=1}^{\infty} Z_n \in L \). On the full set \( \text{domain}(Z) \), then we have \( Y_n = (Z_1 + \cdots Z_{2n}) \to X \).

\[\square\]

We will use the next theorem many times to construct integrable functions.

Theorem 4.5.9. (A sufficient condition for a function to be integrable). Suppose \( X \) is a function defined a.e. on \( \Omega \). Suppose there exist two sequences \( (X_n)_{n=1,2,...} \) and \( (Z_n)_{n=1,2,...} \) in \( L \) such that \( |X - X_n| \leq Z_n \) a.e. for each \( n \geq 1 \) and such that \( IZ_n \to 0 \). Then \( X \in L \). Moreover \( I|X - Y| \to 0 \).

Proof. According to Proposition 4.5.8 by passing to a subsequence, we can assume that \( Z_n \to 0 \) a.e. Since, by assumption, \( |X - X_n| \leq Z_n \) a.e. for each \( n \geq 1 \), it follows that \( Y_n \to X \) a.e. On the other hand, we have \( |Y_n - Y_n| \leq |Y_n - X| + |X_n - X| \leq Z_n + Z_m \). Consequently \( |Y_n - Y_m| \leq IZ_n + IZ_m \to 0 \) as \( n, m \to \infty \). By the completeness of \( L \), there exists \( Y \in L \) such that \( I|Y_n - Y| \to 0 \). By passing again to a subsequence, we may assume that \( Y_n \to Y \) a.e. Combining, we see that \( X = Y \) a.e. According to Proposition 4.5.3 we therefore have \( X \in L \). Moreover, \( I|X - Y_n| \leq IZ_n \to 0 \).

\[\square\]

4.6 Abundance of Integrable Sets

In this section let \( (\Omega, L, I) \) be a complete integration space.

Let \( X \) be any function defined on a subset of \( \Omega \) and let \( t \) be a real number. Recall from the Notations and Conventions in the Introduction that we use the abbreviation \( \{ \omega \in \text{domain}(X) : t \leq X(\omega) \} \). Similar notations are used for \( \{ X < t \} \) and \( \{ X = t \} \), and \( \{ X < t \} \). We will also write \( \{ t < X \leq u \} \) etc for the intersection \( \{ t < X \} \{ X \leq u \} \) etc. If \( J \) is a subset of \( R \), let \( J^c \) denote the metric complement of \( J \) in \( R \).
We will show in this section that if $X$ is an integrable function, then $(t \leq X)$ and $(t < X)$ are integrable sets for each positive $t$ in the metric complement of some countable subset of $R$.

Define some functions which will serve as approximations for step functions on $R$. For any real numbers $0 < s < t$ define $g_{s,t}(x) = \frac{x - s}{t - s}$. Then the function $g_{s,t}(X) = \frac{X - X_s}{t - s}$ is integrable for all $s,t \in R$ with $0 < s < t$. Clearly $1 \geq g_{s,t} \geq g_{s,s'} \geq 0$ for all $t', t, s, s' \in R$ with $t' < t < s < s'$. If we can prove that $\lim_{t\uparrow} I_{g_{s,t}}(X)$ exists, then we can use the Monotone Convergence Theorem to show that $\lim_{t\uparrow} I_{g_{s,t}}(X)$ is integrable and is an indicator of $(t \leq X)$, proving that the latter set is integrable. Classically the existence of $\lim_{t\uparrow} I_{g_{s,t}}(X)$ is trivial since for fixed $t$ the integral $I_{g_{s,t}}(X)$ is nonincreasing in $s$ and bounded from below by 0. A constructive proof that the limit exists for all but countably many $t$'s is given below. The proof is in terms of a general theory of profiles which finds applications also outside measure or integration theory.

**Definition 4.6.1. (Profile).** Let $K$ be a non-empty open interval in $R$. Let $G$ be a family of continuous functions on $R$, such that $0 \leq g \leq 1$ for each $g \in G$. Let $t \in K$ and $g \in G$ be arbitrary. We say $t$ precedes $g$ and write $t \Diamond g$ if $g = 0$ on $(-\infty, t] \cap K$. We say $g$ precedes $t$ and write $g \circ t$ if $g = 1$ on $[t, \infty) \cap K$. We write $t \Diamond g \circ s$ and say $g$ separates $t$ and $s$ if both $t \Diamond g$ and $g \circ s$. We say $G$ separates points in $K$ if for all $t, s \in K$ with $t < s$ there exists $g \in G$ such that $t \Diamond g \circ s$. A function $\lambda$ on $G$ is said to be nondecreasing if for each $g, g'$ with $g \leq g'$ on $K$ we have $\lambda(g) \leq \lambda(g')$. We say $(G, \lambda)$ is a profile on the interval $K$ if $G$ separates points in $K$ and if $\lambda$ is a nondecreasing function on $G$. We say that a closed interval $[t, s] \subset K$ has a positive real number $\alpha$ as a profile bound, and write $[t, s] \ll \alpha$, if there exist $t', s' \in K$ and $f, g \in G$ such that (i) $f \circ t'$, $t' < t < s < s'$, $s' \Diamond g$, and (ii) $\lambda(f) - \lambda(g) < \alpha$. Suppose $a, b \in R$ and $a \leq b$. We say that the open interval $(a, b) \subset K$ has a positive real number $\alpha$ as a profile bound, and write $(a, b) \ll \alpha$ if $[t, s] \ll \alpha$ for each closed subinterval $[t, s]$ of $(a, b)$. Note that the open interval $(a, b)$, defined as the set $\{ x \in R : a < x < b \}$, can be empty. □

Note that $t \Diamond g$ is merely an abbreviation for $1_{[t, \infty)} \geq g$; and $g \circ t$ is an abbreviation for $g \geq 1_{[t, \infty)}$.

The motivating example of a profile is when $K \equiv (0, \infty), G \equiv \{ g_{s,t} : s, t \in K$ and $0 < s < t \}$, and the function $\lambda$ is defined on $G$ by $\lambda(g) \equiv Ig(X)$ for each $g \in G$. It can easily be verified that $(G, \lambda)$ is a profile on $K$.

In the following let $(G, \lambda)$ be a general profile on an open interval $K$ in $R$. The next lemma lists some basic properties.

**Lemma 4.6.2. (Basics of profiles).**

1. If $f \circ t, t \leq s$, and $s \Diamond g$ then $f \geq g$ and $\lambda(f) \geq \lambda(g)$.

2. If $t \leq s$ and $s \Diamond g$ then $t \Diamond g$.

3. If $g \circ t$ and $t \leq s$ then $g \circ s$.

4. In view of the transitivity in assertions 2 and 3 above, we can rewrite, without ambiguity, condition (i) in Definition 4.6.1 as $f \circ t' < t \leq s < s' \Diamond g$. 

Yuen-Kwok Chan 64 Constructive Probability
5. Suppose \([t, s] \ll \alpha\) and \(t_0 < t < s < s_0\). Let \(\varepsilon > 0\) be arbitrary. Then there exist \(t_1, s_1 \in K\) and \(f_1, g_1 \in G\) such that (i) \(t_0 \triangleleft f_1 \triangleleft t_1 < t \leq s < s_1 \triangleleft g_1 \triangleleft s_0\), (ii) \(\lambda(f_1) - \lambda(g_1) < \alpha\), and (iii) \(t - \varepsilon < t_1 < t\) and \(s < s_1 < s + \varepsilon\).

6. Every closed sub-interval of \(K\) has a finite profile bound.

Proof: We will prove assertions 5 and 6, the rest being trivial.

Suppose \([t, s] \ll \alpha\) and \(t_0 < t < s < s_0\). Let \(\varepsilon > 0\) be arbitrary. Then there exist \(t', s' \in K\) and \(f, g \in G\) such that (i) \(f \cap t' < t < s < g\), and (ii) \(\lambda(f) - \lambda(g) < \alpha\).

Pick real numbers \(t'', t_1\) such that \(t_0 \cap f \cap t' \cap (t - \varepsilon) < t'' < t_1 < t\). Since \(G\) separates points in \(K\), there exists \(f_1 \in G\) such that \(t_0 \cap f \cap f_1 \cap t_1 < t\). Since \(f \cap t' \cap t'' \cap f_1\), we have, in view of assertion 1, \(\lambda(f) \geq \lambda(f_1)\). Similarly, we obtain \(s''\), \(s_1 \in K\) and \(g_1 \in G\) such that \(s < s_1 < s'' < s_0 \cap s' \cap (s + \varepsilon)\) and \(s < s_1 \cap g_1 \cap s'' < s_0\) with \(\lambda(g_1) \geq \lambda(g)\). Hence \(\lambda(f_1) - \lambda(g_1) \leq \lambda(f) - \lambda(g) < \alpha\). Conditions (i) and (iii) are obviously also satisfied. Assertion 5 is proved.

Given any interval \([t, s] \subset K\), let \(t'', t', s'\) be members of \(K\) such that \(t'' < t' \leq t \leq s'' < s'\). Since \(G\) separates points in \(K\), there exist \(f, g \in G\) such that \(t'' \cap f \cap t' \cap t \cap s'' \cap g\). Hence \([t, s] \ll \alpha\) for any real number \(\alpha\) such that \(\lambda(f) - \lambda(g) < \alpha\). Assertion 6 is proved.

Lemma 4.6.3. (Bound for the number of intervals with significant profiles). Let \((G, \lambda)\) be a profile on a proper open interval \(K\) in \(R\). Let \([a, b]\) be a closed sub-interval of \(K\) with \([a, b] \ll \alpha\). Let \(\varepsilon > 0\) be arbitrary. Let \(q\) be any integer with \(q \geq \alpha / \varepsilon\). Then there exists a sequence \(s_0 = a \leq s_1 \leq \ldots \leq s_q = b\) of \((q + 1)\) points in \(K\) such that \((s_i, s_{i+1}) 

Proof. For abbreviation, write \(d_n \equiv 2^{-n}(-b - a)\) for each \(n \geq 1\). By hypothesis \([a, b] \ll \alpha\). Hence there exist \(a', b' \in K\) and \(f', f'' \in G\) such that (i) \(f' \cap a' < a \leq b < b' \cap f''\), and (ii) \(\lambda(f') - \lambda(f'') < \alpha \leq q\). Define \(F' \equiv \lambda(f')\) and \(F'' \equiv \lambda(f'')\). Then \(0 \leq F' - F'' < q\).

Let \(n \geq 1\) be arbitrary. For \(i = 0, \ldots, 2^n\), define \(t_{n,i} \equiv a + id_n\). Clearly \(t_{n,0} = a\) and \(t_{n,2^n} = b\). Define \(D_n \equiv \{t_{n,i} : 0 \leq i \leq 2^n\}\). The set \(D_n\) is a result of binary subdivisions of the interval \([a, b]\). Specifically, consider any \(n \geq 1\) and \(t = t_{n,i} \in D_n\). Then we have

\[
t_{n,i} \equiv c + id_n = c + 2id_{n+1} \equiv t_{n+1,2i} \in D_{n+1}
\]

Hence \(D_n \subset D_{n+1}\). For each \(1 \leq i \leq 2^n\), we have \(t_{n,i-1}, t_{n,i} \in [a, b] \subset K\) and there exists a function \(f_{n,i} \in G\) with \(t_{n,i-1} \cap f_{n,i} \cap t_{n,i}\). In addition, define \(f_{n,0} \equiv f'\) and \(f_{n,2^n+1} \equiv f''\). Then \(f_{n,0} \cap f_{n,0} \equiv d'\) and \(b \equiv t_{n+1,2i} \cap f_{n,2^n+1}\). Combining, we have

\[
f_{n,0} \cap f_{n,0} \cap f_{n,1} \cap f_{n,1} \cap \cdots \cap f_{n,2^n} \cap f_{n,2^n+1} \cap f_{n,2^n+1}
\]

Next, for each \(t = t_{n,i} \in D_n\) define \(F_n(t) \equiv F_n(t_{n,i}) \equiv \lambda(f_{n,i})\). By the relation 4.6.1 and Lemma 4.6.2, we see that \(F_n\) is a nonincreasing function on \(D_n\):

if \(s, t \in D_n\) are such that \(s \leq t\), then \(F_n(s) \geq F_n(t)\).

Next let \(t = t_{n,i} \in D_n\) and let \(s = t_{n+1,j} \in D_{n+1}\). Suppose \(s \leq t - d_n\). Then \(t > a\). Consequently \(i \geq 1\) and \(t_{n,i-1} = t - d_n \geq s\). Hence \(f_{n+1,j} \cap t_{n+1,j} = s \leq t_{n,i-1} \cap f_{n,i-1}\).

Yuen-Kwok Chan 65 Constructive Probability
Hence, by Lemma 4.6.2 we have \( F_{n+1}(s) \equiv \lambda(f_{n+1,j}) \geq \lambda(f_{n,i}) \equiv F_n(t) \). We have thus proved that

\[
\text{if } t \in D_n \text{ and } s \in D_{n+1} \text{ are such that } s \leq t - d_n, \text{ then } F_{n+1}(s) \geq F_n(t) \quad (4.6.2)
\]

Similarly we can prove that

\[
\text{if } t \in D_n \text{ and } s \in D_{n+1} \text{ are such that } t + d_{n+1} \leq s, \text{ then } F_n(t) \geq F_{n+1}(s) \quad (4.6.3)
\]

For each \( n \geq 1 \) and integer \( i \) with \( 0 \leq i \leq 2^n \) define \( S_{n,i} \equiv F_n(t_{n,0}) - F_n(t_{n,i}) = F' - F_n(t_{n,i}) \). Pick an \( \varepsilon' > 0 \) such that

\[
q\varepsilon > q\varepsilon' > F' - F'' \quad (4.6.4)
\]

and such that \(|\varepsilon' - S_{n,i}|/k| > 0 \) for each \( i \) with \( 0 \leq i \leq 2^n \), for each \( k = 1, \cdots, q \), and for each \( n \geq 1 \). Now let \( n \geq 1 \) be arbitrary. Define also \( S_{n,2^n+1} \equiv q\varepsilon' \). Then we have

\[
0 = S_{n,0} \leq S_{n,1} \leq \cdots \leq S_{n,2^n+1} = q\varepsilon' \quad (4.6.5)
\]

Consider each \( k = 1, \cdots, q \). From inequality 4.6.3 we see that \( S_{n,0} < k\varepsilon' \leq S_{n,2^n+1} \). Hence there exists an integer \( n_{i,k} \) with \( 0 \leq i_{n,k} \leq 2^n \) such that

\[
S_{n,i_{n,k}} < k\varepsilon' \leq S_{n,i_{n,k}+1} \quad (4.6.6)
\]

Define \( s_{n,k} \equiv t_{n,i_{n,k}} \in [a,b] \). Clearly \( s_{n,k} \leq s_{n,k+1} \) for \( k < q \). Moreover \( S_{n,2^n} < q\varepsilon' \equiv S_{n,2^n+1} \). Hence \( i_{n,q} = 2^n \) and

\[
s_{n,q} \equiv t_{n,i_{n,q}} = t_{n,2^n} = b \quad (4.6.7)
\]

Fix any \( k = 1, \cdots, q \). We will show that the sequence \((s_{n,k})_{n=1,2,...}\) converges. Consider the terms \( S_{n,k} \) and \( S_{n+1,k} \). For ease of notations, write \( i = i_{n,k} \) and \( j = i_{n+1,k} \).

Suppose \( s_{n,k} < s_{n+1,k} \). Then \( t_{n,j} = s_{n,k} < b \) and \( i \leq 2^n - 1 \). It follows that \( S_{n,j+1} = F' - F_n(t_{n,j+1}) \). By the definition for \( i_{n,k} \) and \( i_{n+1,k} \) we have

\[
F' - F_{n+1}(t_{n+1,j+1}) = S_{n+1,j+1} < k\varepsilon' \leq S_{n,i_{n,k}+1} = F' - F_n(t_{n,i_{n,k}+1})
\]

whence

\[
F_n(t_{n,i_{n,k}}) < F_{n+1}(t_{n+1,j+1})
\]

This implies, in view of inference 4.6.3 that \( t_{n,j+1} + d_{n+1} \geq t_{n+1,j} \). Hence

\[
s_{n+1,k} - s_{n,k} = t_{n+1,j} - t_{n,i_{n,k}+1} + d_{n+1} = t_{n,j} + d_n + d_{n+1} = s_{n,k} + d_n + d_{n+1}
\]

Therefore \( s_{n+1,k} - s_{n,k} \leq d_n + d_{n+1} \).

On the other hand, suppose \( s_{n,k} > s_{n+1,k} \). Then \( t_{n+1,j} = s_{n+1,k} < b \) and \( j \leq 2^{n+1} - 1 \). It follows that \( S_{n+1,j+1} = F' - F_{n+1}(t_{n+1,j+1}) \). By the definition for \( i_{n,k} \) and \( i_{n+1,k} \) we have

\[
F' - F_n(t_{n,j+1}) \equiv S_{n,j} < k\varepsilon' \leq S_{n+1,j+1} = F' - F_{n+1}(t_{n+1,j+1})
\]
whence  

\[ F_{n+1}(t_{n+1,j+1}) < F_n(t_n) \]

This implies, in view of inference 4.6.2, that \( t_{n+1,j+1} \geq t_n,j - d_n \). Hence  

\[
s_{n+1,k} = t_{n+1,j} = t_{n+1,j+1} - d_n \geq t_n,j - d_n - d_n = s_{n,k} - d_n - d_n \]

Therefore  

\[
s_{n,k} - s_{n,k+1} \leq d_n + d_n + 1. \]

Combining, we obtain  

\[
|s_{n,k} - s_{n,k+1}| \leq d_n + d_n + 1 = 3 \cdot 2^{-n-1} (b - a). \]

Thus we see that the sequence \( \{s_{n,k}\}_{n=1,2,\ldots} \) is Cauchy, and converges to some \( s_k \in [a,b] \). Furthermore, for \( k = 1, \ldots, q \),

\[
|s_{n,k} - s_k| = \lim_{p \to \infty} |(s_{n,k} - s_{n,k+1}) + (s_{n+1,k} - s_{n+2,k}) + \cdots + (s_{p-1,k} - s_{p,k})| 
\leq 3(2^{-n-1} + 2^{-n} + \cdots)(b - a) \leq 3 \cdot 2^{-n}(b - a) = 3d_n \quad (4.6.8)
\]

For ease of notations, we will also define \( s_{n,0} = s_0 = a \) and \( s_{n,q+1} = s_{q+1} = b \). Then  

\[ s_k \leq s_{k+1} \text{ for } 0 \leq k \leq q. \]

Now let \( k = 0, \ldots, q \) be arbitrary. Suppose \([t,s] \subset (s_k,s_{k+1})\) for some real numbers \( t \leq s \). We will show that \([t,s] \ll \epsilon\). To this end, let \( n \) be so large that \( s_k + 4d_n < t < s_{k+1} - 4d_n \). This implies, in view of inequality 4.6.8, that \( s_{n,k} + d_n < t < s_{n,k+1} - d_n \). For abbreviation write \( i \equiv i_{n,k} \) and \( j \equiv i_{n,k+1} \). According to the definition of \( i_{n,k} \) and \( i_{n,k+1} \) we then have \( k\epsilon' \leq s_{n,i+1} \) and \( s_{n,j} < (k + 1)\epsilon' \). Moreover \( t_{n,i} = s_{n,k} < s_{n,k+1} \leq b \). In view of equality 4.6.7 we have \( k < q \) and \( i < 2^n \). Hence \( t_{n,i+1} = t_{n,i} + d_n = s_{n,k} + d_n < t \). Similarly, we have \( S_{n,j} < (k + 1)\epsilon' \leq s_{n,j+1} \). Moreover \( t_{n,j} = s_{n,k+1} > s_{n,k} \geq a \). We therefore have \( j > 0 \). Hence  

\[
t_{n,j-1} - d_n = s_{n,k+1} - d_n > s. \]

Combining, we have \( f_{n,i+1} \cap t_{n,j+1} < t < s < t_{n,j-1} \cap f_{n,j} \). Furthermore, \( S_{n,j} - S_{n,i+1} < (k + 1)\epsilon' - k\epsilon' = \epsilon' \). Equivalently \( F_n(t_{n,j+1}) - F_n(t_{n,i+1}) < \epsilon' \), which is in turn equivalent to \( \lambda(f_{n,j+1}) - \lambda(f_{n,i+1}) < \epsilon' \). Therefore \([t,s] \ll \epsilon' \ll \epsilon\). Since \([t,s]\) is an arbitrary closed sub-interval of \((s_k,s_{k+1})\), we have proved that \((s_k,s_{k+1}) \ll \epsilon\).

\[ \Box \]

**Theorem 4.6.4. (All but countably many points have arbitrarily low profile).** Let \((G,\lambda)\) be a profile on a proper open interval \(K\). Then there exists a countable subset \(J\) of \(K\) such that for each \(t \in K \cap J\) we have \([t,t] \ll \epsilon\) for arbitrarily small \(\epsilon > 0\).

**Proof.** Let \([a,b] \subset [a_2,b_2] \subset \cdots\) be a sequence of subintervals of \(K\) such that \(K = \bigcup_{p=1}^{\infty} [a_p,b_p]\). According to Lemma 4.6.3 there exists for each \(p \geq 1\), a finite sequence \(s_0^{(p)} = a_p \leq s_1^{(p)} \leq \cdots \leq s_q^{(p)} = b_p\) such that \((s_{k-1}^{(p)},s_k^{(p)}) \ll \frac{1}{p}\) for \(k = 1, \ldots, q_p\). Define \(J \equiv \{s_k^{(p)} : 1 \leq k \leq q_p; p \geq 1\}\). Suppose \(t \in K \cap J\). Let \(\epsilon > 0\) be arbitrary. Let \(p \geq 1\) be so large that \(t \in [a_p,b_p]\) and that \(\frac{1}{p} < \epsilon\). By the definition of the metric complement \(J\), we have \(|t - s_k^{(p)}| > 0\) for each \(k = 1, \ldots, q_p\). Hence \(t \in (s_{k-1}^{(p)},s_k^{(p)})\) for some \(k = 1, \ldots, q_p\). But \((s_{k-1}^{(p)},s_k^{(p)}) \ll \frac{1}{p}\). We conclude that \([t,t] \ll \frac{1}{p} < \epsilon\). \[ \Box \]

An immediate application of the preceding Theorem 4.6.4 is to establish the abundance of integrable sets, in the next theorem.
CHAPTER 4. INTEGRATION AND MEASURE

Theorem 4.6.5. (Abundance of integrable sets). Given an integrable function $X$ on the complete integration space $(\Omega, L, I)$, there exists a countable subset $J$ of $(0, \infty)$ such that for each positive real number $t$ in the metric complement $J^c$ of $J$, the sets $(t < X)$ and $(t < X)$ are integrable, with $(t < X)^c = (X < t)$ and $(t < X)^c = (X \leq t)$. Furthermore, the measures $\mu(t \leq X)$ and $\mu(t < X)$ are equal and are continuous at each $t > 0$ with $t \in J$.

Proof. Recall the previously defined profile $(G, \lambda)$ on the interval $K \equiv (0, \infty)$, where $G = \{ g_{s,t} : s, t \in K \text{ and } 0 < s < t \}$, and $\lambda_g(X) \equiv \int g(X) \, d\mu$ for each $g \in G$. Here $g_{s,t}$ denotes the function defined on $R$ by $g_{s,t}(x) \equiv \frac{\lambda(x) - \lambda(s)}{t-s}$ for each $x \in R$. Let the countable subset $J$ of $K$ be constructed as in Theorem 4.6.4.

Suppose $p \in K \cap J$. We have $\lfloor t, t \rfloor < \frac{1}{p}$ for each $p \geq 1$. Recursively applying Lemma 4.6.2 we can construct two sequences $(u_p)_p=0,1,\ldots$ and $(v_p)_p=0,1,\ldots$ in $G$ such that for each $p \geq 1$ we have $u_p \downarrow f_p \downarrow v_p < t < v_p \downarrow g_p \downarrow v_p < t$. By symmetry we also have $\lambda(u_p) \geq \lambda(f_p) \geq \lambda(v_p) - \frac{1}{p}$. Combining, we see that $|\lambda(u_p) - \lambda(v_p)| < \frac{1}{p} + \frac{1}{p}$. Hence $(\lambda(u_p))_{p=0,1,\ldots}$ is a Cauchy sequence and converges. Similarly $(\lambda(g_p))_{p=0,1,\ldots}$ converges. In view of condition (ii), the two limits are equal.

By the definition of $\lambda$, we see that $\lim_{p \to \infty} I_{f_p}(X)$ exists. Since $f_{p-1} \geq f_p$ for each $p > 1$, the Monotone Convergence Theorem 4.4.8 implies that $Y \equiv \lim_{p \to \infty} I_{f_p}(X)$ is an integrable function, with $\lim_{p \to \infty} I_{f_p}(X) - Y = 0$. Likewise $Z \equiv \lim_{p \to \infty} g_p(X)$ is an integrable function, with $\lim_{p \to \infty} I_{g_p}(X) - Z = 0$. Furthermore

$$I[Y - Z] = \lim_{p \to \infty} I_{f_p}(X) - g_p(X) = \lim_{p \to \infty} (\lambda(f_p) - \lambda(g_p)) = 0$$

According to Proposition 4.5.3 we have $Y = Z$ a.e.

We next show that $Y$ is an indicator with $(Y = 1) = (t \leq X)$. Consider $\omega \in \text{domain}(Y)$. Suppose $Y(\omega) > 0$. Then $\omega \in \text{domain}(Y)$ and $f_p(X(\omega)) \geq Y(\omega) > 0$ for each $p \geq 1$. It follows, in view of condition (i) above, that $u_{p-1} \leq X(\omega)$ and so $f_{p-1}(X(\omega)) = 1$ for each $p > 1$. Passing to limit as $p \to \infty$, we conclude that $t \leq X(\omega)$ and so $Y(\omega) = 1$. In particular $Y$ can have only two possible values, 0 or 1. Thus $Y$ is an indicator. We have also seen that $(Y = 1) \subset (t \leq X)$. Conversely, suppose $t \leq X(\omega)$. Then, in view of $f_p \downarrow u_p < t$ in condition (i) above, we have $f_p(X(\omega)) = 1$ for each $p \geq 1$. It follows trivially that $\lim_{p \to \infty} f_p(X(\omega)) = 1$ and so $\omega \in \text{domain}(Y)$ and $Y(\omega) = 1$. Summing up, the set $\{X \geq t\}$ has $Y$ as an indicator.

We will now prove that $Y = 0 = (X < t)$. Let $\omega \in (Y = 0)$. Then the definition of $Y$ we have $\omega \in \text{domain}(X)$ and $0 \equiv \lim_{p \to \infty} f_p(X(\omega))$. Then there exists $p \geq 1$ such that $1 > f_p(X(\omega))$. This implies, in view of $f_p \downarrow u_p$ in condition (i) above, that $X(\omega) \leq u_p < t$. In other words $\omega \in (X < t)$. Conversely, suppose $\omega \in (X < t)$. Then $X(\omega) < t$. Since $u_p \uparrow t$ as $p \to \infty$ there exists $q$ so large that $X(\omega) < u_{p-1}$ for each $p > q$. In view of $u_{p-1} \downarrow f_p$ in condition (i) above, we have $f_p(X(\omega)) = 0$ for each $p \geq q$. It follows that $\lim_{p \to \infty} f_p(X(\omega)) = 0$ and so $\omega \in \text{domain}(Y)$ and $Y(\omega) = 0$. Summing up, we have $(Y = 0) = (X < t)$. Thus $(t \leq X)^c = (X < t)$.
4.6. ABUNDANCE OF INTEGRABLE SETS

Similarly we can prove that \( t < X \) has \( Z \) as an indicator, and that \( t < X \) is integrable at \( t \). It follows that \( \mu(t \leq X) = IY = IZ = \mu(t < X) \).

It remains to show that \( \mu(t \leq X) \) is continuous at \( t \). Let \( p > 1 \) be arbitrary. Recall that \( u_{p-1} \cap f_p \cap v_p < t < v_p \cap g_p \cap v_{p-1} \) where \( u_p \) and \( v_p \) are arbitrarily close to \( t \) if \( p \) is sufficiently large. From the previous paragraphs we see that \( |\lambda(f_p) - \mu(t \leq X)| = \lambda(f_p) - \lim_{q \to \infty} \lambda(f_q) \leq \frac{1}{p} \). Now consider any \( t' \in K \cap J_c \) such that \( t' \in (u_p, v_p) \). We can similarly construct an arbitrarily large \( q \), points \( t'_{q-1}, t'_q, s'_q \) and \( s'_{q-1} \) in \( K \) that are arbitrarily close to \( t' \in (t_p, s_p) \), and functions \( f'_q, g'_q \in G \) such that

\[
t_p < t'_{q-1} < t'_q < t < s'_q < s'_{q-1} < s_p
\]

and such that \( |\lambda(f'_q) - \mu(t' \leq X)| \leq \frac{1}{q} \). It follows that \( f_p \cap t_p < t'_{q-1} \cap f'_q \) and so \( \lambda(f_p) \geq \lambda(f'_q) \). Similarly \( \lambda(g'_q) \leq \lambda(g_p) \). Hence

\[
0 \leq \lambda(f_p) - \lambda(f'_q) < \lambda(g_p) + \frac{1}{p} - \lambda(g'_q) \leq \frac{1}{p}
\]

Using the triangle inequality twice, we obtain \( |\mu(t' \leq X) - \mu(t \leq X)| < \frac{1}{q} + \frac{2}{p} \). Since \( q \) is arbitrarily large, we see that \( |\mu(t' \leq X) - \mu(t \leq X)| \leq \frac{2}{p} \) for each \( t' \) in the neighborhood \((t_p, s_p)\) of \( t \). Continuity of \( \mu(t \leq X) \) at \( t \) has thus been established. \( \square \)

**Corollary 4.6.6. (Abundance of integrable sets).** Let \( X \) be an integrable function. There exists a countable subset \( J \) of \( R \) such that for each \( t \) in the metric complement \( J_c \) of \( J \) the following conditions hold.

1. If \( t > 0 \) then \( (t < X) \) and \( (t \leq X) \) are integrable, with equal measures that are continuous at \( t \).

2. If \( t < 0 \) then \( (X < t) \) and \( (X \leq t) \) are integrable, with equal measures that are continuous at \( t \).

**Proof.** Apply Theorem 4.6.5 to \( X \) and \( -X \) and let \( J \) be the union of the two corresponding countable exceptional sets. \( \square \)

**Definition 4.6.7. (Regular and continuity points of an integrable function relative to an integrable set).** Let \( X \) be an integrable function, let \( A \) be an integrable set, and let \( t \in R \). We say that \( t \) is a regular point of \( X \) relative to \( A \) if (i) there exists a sequence \((s_n)_{n=1,2,...} \) of real numbers decreasing to \( t \) such that \( (s_n < X)A \) is integrable for each \( n \geq 1 \) and such that \( \lim_{n \to \infty} \mu(s_n < X)A \) exists, and (ii) there exists a sequence \((r_n)_{n=1,2,...} \) of real numbers increasing to \( t \) such that \( (r_n < X)A \) is integrable for each \( n \geq 1 \) and such that \( \lim_{n \to \infty} \mu(r_n < X)A \) exists. If in addition the two limits in (i) and (ii) are equal, then we call \( t \) a continuity point of \( X \) relative to \( A \). We say that a positive real number \( t > 0 \) is a regular point of \( X \) if conditions (i) and (ii), with \( A \) omitted, are satisfied. We say that a negative real number \( t < 0 \) is a regular point of \( X \) if \( -t \) is a regular point of \( -X \). \( \square \)

**Corollary 4.6.8. (Simple properties of regular and continuity points).** Let \( X \) be an integrable function, let \( A \) be an integrable set, and let \( t \) be a regular point of \( X \) relative to \( A \). Then the following holds.
1. If \( u \) is a regular point of \( X \), then \( u \) is a regular point for \( X \) relative to any integrable set \( B \). If \( u \) is a continuity point of \( X \), then \( u \) is a continuity point for \( X \) relative to any integrable set \( B \).

2. All but countably many real numbers are continuity points of \( X \).

3. All but countably many real numbers are continuity points of \( X \) relative to \( A \). Hence all but countably many real numbers are regular points of \( X \) relative to \( A \).

4. The sets \( A(t < X), A(t \leq X), A(X < t), A(X \leq t) \), and \( A(X = t) \) are integrable sets.

5. \( (X \leq t)A = A((t < X)A)^c \) a.e. and \( (t < X)A = A((X \leq t)A)^c \) a.e.

6. \( (X < t)A = A((t \leq X)A)^c \) a.e. and \( (t \leq X)A = A((X < t)A)^c \) a.e.

7. For a.e. \( \omega \in A \), we have \( t < X(\omega), t = X(\omega) \), or \( t > X(\omega) \). Thus we have a limited, but very useful, version of the principle of excluded middle.

8. Let \( \varepsilon > 0 \) be arbitrary. There exists \( \delta > 0 \) such that if \( r \in (t - \delta, t] \) and \( A(X < r) \) is integrable, then \( \mu(A(X < t)) - \mu(A(X < r)) < \varepsilon \). There exists \( \delta > 0 \) such that if \( s \in [t, t + \delta] \) and \( A(X \leq s) \) is integrable, then \( \mu(A(X \leq s)) - \mu(A(X \leq t)) < \varepsilon \).

9. If \( t \) is a continuity point of \( X \) relative to \( A \), then \( \mu((t < X)A) = \mu((t \leq X)A) \).

Proof. 1. Suppose \( u > 0 \) and \( u \) is a regular point of \( X \). Then by Definition \([4.6.7] \) (i’) there exists a sequence \((s_n)_{n=1,2,...}\) of real numbers decreasing to \( u \) such that \((s_n < X)\) is integrable and \(\lim_{n \to \infty} \mu(s_n < X)\) exists, and (ii’) there exists a sequence \((r_n)_{n=1,2,...}\) of positive real numbers increasing to \( u \) such that \((r_n < X)\) is integrable and \(\lim_{n \to \infty} \mu(r_n < X)\) exists. Now let \( B \) be any integrable set. Then for all \( m > n \geq 1 \), we have

\[
0 \leq \mu((s_m < X)B) - \mu((s_n < X)B) = \mu(B(s_m < X)(s_n < X)^c)
\]

\[
\leq \mu((s_m < X)(s_n < X)^c) = \mu(s_m < X) - \mu(s_n < X) \downarrow 0
\]

Therefore \( (\mu((s_n < X)B))_{n=1,2,...} \) is a Cauchy sequence and converges, verifying condition (i) in Definition \([4.6.7] \). Condition (ii) is similarly verified. Hence \( u \) is a regular point of \( X \) relative to \( B \). Suppose in addition that \( u \) is a continuity point of \( X \). Then for each \( n \geq 1 \), we have

\[
0 \leq \mu((r_n < X)B) - \mu((s_n < X)B) = \mu(B(r_n < X)(s_n < X)^c)
\]

\[
\leq \mu((r_n < X)(s_n < X)^c) = \mu(r_n < X) - \mu(s_n < X) \downarrow 0
\]

Therefore the two sequences \( (\mu((r_n < X)B))_{n=1,2,...} \) and \( (\mu((s_n < X)B))_{n=1,2,...} \) have the same limit. Thus assertion 1 is proved for the case \( t > 0 \). The case \( t < 0 \) is similar.

2. Assertion 2 is an immediate consequence of Corollary \([4.6.6] \).

3. Assertion 3 is follows from assertions 1 and 2.

4. Let \( (s_n)_{n=1,2,...} \) and \( (r_n)_{n=1,2,...} \) be sequences of real numbers satisfying conditions (i) and (ii) in Definition \([4.6.7] \). Then \((s_n < X)A\) is an integrable set for \( n \geq 1 \), and
4.6. ABUNDANCE OF INTEGRABLE SETS

\[ \lim_{n \to \infty} \mu(s_n < X)A \text{ exists. Since } (s_n) \text{ decreases to } t, \text{ we have } (t < X)A = \bigcup_{n=1}^{\infty} (s_n < X)A \text{ a.e. This union is integrable, and } \mu(s_n < X)A \uparrow \mu((t < X)A), \text{ according to Proposition 4.5.7.} \]

Define \( B \equiv (X \leq t)A \) and \( C \equiv (t < X)A \). Because the set \( C \) has just been proved integrable, the set \( D \equiv C \cup C^c \) is a full set. Consider \( \omega \in AD \). Then either \( \omega \in C \) or \( \omega \in C^c \). Consider \( \omega \in B \). Then \( X(\omega) \leq t \). If \( \omega \in C \) then we would have \( t < X(\omega) \), a contradiction. Hence \( \omega \in C^c \). Conversely, consider \( \omega \in C^c \). If \( t < X(\omega) \) we would have \( \omega \in CC^c = \phi \), a contradiction. Hence \( X(\omega) \leq t \) and so \( \omega \in B \). Summing up, we have \( ADB = ADC^c \). In other words \( (X \leq t)A \equiv B = AB = AC^c = A((t < X)A)^c \text{ a.e.} \)

It follows from Proposition 4.5.6 that \( (X \leq t)A \equiv B \text{ is integrable.} \)

Similarly, since \((r_n)\) increases to \( t \), we have \( (X < t)A = \bigcup_{n=1}^{\infty} A((r_n < X)A)^c \text{ a.e.} \) This union is integrable, with \( \mu(A((r_n < X)A)^c) = \mu(A) - \mu((r_n < X)A) \uparrow \mu((X < t)A). \) Since we can show, in a proof similar to the one above, that \( (t \leq X)A = A((X < t)A)^c \text{ a.e.,} \) it follows from Proposition 4.5.6 that \( (X \leq t)A \text{ is integrable.} \)

Since \( A(X = t) = A(t \leq X)((t < X)A)^c \text{ a.e.} \) the set \( A(X = t) \) is integrable. Assertion 4 is proved.

5. We have seen in the proof of assertion 4 that \( B = AC^c \text{ a.e.} \) where \( B \equiv (X \leq t)A \) and \( C \equiv (t < X)A \). Using Proposition 4.5.6, we have \( AB^c = A(AC^c)^c = AC \text{ a.e.} \)

6. Similar.

7. With the notations in the above proof for assertion 4, we have \( B = ADC^c \text{ where } D \equiv C \cup C^c \) is a full set. Consider any \( \omega \in AD \). Then, we have either \( t < X(\omega) \) or \( \omega \in B \). Hence, we have either \( t < X(\omega) \) or \( \omega \in B \). Therefore \( t < X(\omega) \) or \( X(\omega) \leq t \).

In other words, for a.e. \( \omega \in A \), we have \( t < X(\omega) \) or \( X(\omega) \leq t \).

Similarly, for a.e. \( \omega \in A \), we have \( X(\omega) \leq t \) or \( t < X(\omega) \).

Combining, for a.e. \( \omega \in A \), we have \( t < X(\omega) \) or \( X(\omega) \leq t \) or \( t < X(\omega) \).

Assertion 7 is proved.

8. Use the notations in the above proof for assertion 4. Let \( \varepsilon > 0 \) be arbitrary. Let \( n \geq 1 \) be so large that \( \mu((r < X)A) = \mu(s_n < X)A < \varepsilon \).

Define \( \delta = s_n - t \). Suppose \( s \in [t, t + \delta] \) and \( A(X \leq s) \) is integrable. Then \( s < s_n \) and so

\[
\mu(A(X \leq s)) - \mu(A(X \leq t)) = (\mu(A) - \mu(s < X)A) - (\mu(A) - \mu(t < X)A)) = \mu((t < X)A) - \mu(s < X)A \leq \mu((t < X)A) - \mu(s_n < X)A < \varepsilon
\]

This proves the second half of assertion 8, the first half having a similar proof.

9. Suppose \( t \) is a continuity point of \( X \) relative to \( A \). Then the limits \( \lim_{n \to \infty} \mu(s_n < X)A \) and \( \lim_{n \to \infty} \mu(r_n < X)A \) are equal. The proof of assertion 4 therefore shows

\[
\mu((t < X)A) = \mu(A) - \mu((X < t)A) \text{ which is in turn equal to } \mu((t \leq X)A) \text{ in view of assertion 6.}
\]

\[ \square \]

**Definition 4.6.9.** (Convection of implicit assumption of regular points of integrable functions) Let \( X \) be an integrable function, and let \( A \) be an integrable set. Henceforth, if the integrability of the set \( (X < t)A \) or \( (X \leq t)A \), for some \( t \in R \), is required in a discussion, then it is understood that the real number \( t \) has been chosen from the regular points of the integrable function \( X \) relative to the integrable set \( A \).

Likewise, if the integrability of the set \( (t < X)A \) or \( (t \leq X) \), for some \( t > 0 \), is required in a discussion, then it is understood that the number \( t > 0 \) has been chosen from the regular points of the integrable function \( X \).

Separately, we will sometimes write \( (X < t; Y \leq s; \cdots) \) for \( (X < t)(Y \leq s; \cdots) \) for brevity.
Recall that $C_{ab}(R)$ is the space of bounded and uniformly continuous functions on $R$.

**Proposition 4.6.10.** (Product of bounded continuous function of an integrable function and an integrable indicator is integrable). Suppose $X \in L$, $A$ is an integrable set, and $f \in C_{ab}(R)$. Then $f(X)1_A \in L$. In particular, if $X \in L$ is bounded, then $X1_A$ is integrable.

**Proof.** Let $c > 0$ be so large that $|f| \leq c$ on $R$. Let $\varepsilon > 0$ be arbitrary. Since $X$ is integrable, there exists $a \geq 0$ so large that $I|X| - I|X| \land (a - 1) < \varepsilon$. Since $f$ is uniformly continuous, there exists a sequence $-a = t_0 < t_1 < \cdots < t_n = a$ whose mesh is so small that $|f(t_i) - f(x)| \leq \varepsilon$ for each $x \in (t_{i-1}, t_i]$, for each $i = 1, \ldots, n$. Then

$$Y = \sum_{i=1}^n f(t_i)1_{(i-1)<X\leq i}]A$$

is an integrable function. Moreover, since $1_{(|X|>a)A} \leq |X| - |X| \land (a - 1)$, we have

$$|f(X)1_A - Y| \leq \left| \sum_{i=1}^n (f(X) - f(t_i))1_{(i-1)<X\leq i}]A \right| + c1_{(|X|>a)}A$$

$$\leq \varepsilon 1_A + c(|X| - |X| \land (a - 1)) \quad a.e.,$$

where

$$I(\varepsilon 1_A + c(|X| - |X| \land (a - 1)))$$

$$= \varepsilon \mu(A) + c(I|X| - I|X| \land (a - 1)) < \varepsilon \mu(A) + c\varepsilon \to 0$$

as $\varepsilon \to 0$. Hence, by Theorem 4.5.9, $f(X)1_A \in L$.

Now suppose $X \in L$ is bounded. Let $b > 0$ be such that $|X| \leq b$. Define $f \in C_{ab}(R)$ by $f(r) \equiv b \land r \lor -b$. Then $X = f(X)$ and so, according to the first part of this proposition, $X1_A \in L$. \hfill $\square$

### 4.7 Uniform Integrability

In this section, let $(\Omega, L, I)$ be a complete integration space. We will give some useful propositions on bounds of integrals and measures.

**Proposition 4.7.1.** (Chebychev’s Inequality). Let $X \in L$ be arbitrary. Then he following holds.

1. (First and common version). If $t > 0$ is a regular point of $X$, then we have $\mu(|X| > t) \leq t^{-1}I|X|$. 

2. (Second version). If $|X| < b$ for some $b > 0$, then for each $s > 0$, we have $(|X| > s) \subset B$ for some integrable set $B$ with $\mu(B) < s^{-1}b$. This second version of Chebychev’s inequality is useful when a real number $s > 0$ is given without any assurance that the set $(|X| > s)$ is integrable.

**Proof.** 1. $1_{(|X|>t)} \leq t^{-1}|X|$.  

2. Take an arbitrary regular point $t$ of the integrable function $X$ in the open interval $(b^{-1}I|X|, s)$. Let $B \equiv (|X| > t)$. By Assertion 1, we then have $\mu(B) \leq t^{-1}I|X| < s^{-1}b$. Moreover, $(|X| > s) \subset (|X| > t) \equiv B$. \hfill $\square$
Proposition 4.7.2. (Bounds related to integrable functions). Let $X \in L$ be arbitrary. Let $A$ be an arbitrary integrable set. Then the following holds.

1. $X 1_A \in L$.
2. $I(|X| 1_A) \to 0$ as $\mu(A) \to 0$. Specifically, for each $\varepsilon > 0$ there exists $\delta = \delta(\varepsilon) > 0$ such that $I(|X| 1_A) \leq \varepsilon$ if $\mu(A) < \delta(\varepsilon)$.
3. $I(|X| 1_{|X| > a}) \to 0$ as $a \to \infty$. Specifically, suppose $|X| \leq b$ for some $b > 0$, and suppose the operation $\delta$ is as in assertion 2. For each $\varepsilon > 0$, if we define $\eta(\varepsilon) = b/\delta(\varepsilon)$, then $I(|X| 1_{|X| > a}) \leq \varepsilon$ for each $a > \eta(\varepsilon)$.
4. Suppose an operation $\eta > 0$ is such that $I(|X| 1_{|X| > a}) \leq \varepsilon$ for each $a > \eta(\varepsilon)$. Then the operation $\delta$ defined by $\delta(\varepsilon) = \frac{\varepsilon}{\eta(\varepsilon)}$ satisfies the conditions in assertion 2.

Proof. 1. Let $n > 0$ be arbitrary. Then $|X 1_A| \land n = |X| \land (n 1_A)$ is integrable. Moreover for $n > p$ we have $I(|X 1_A| \land n - |X 1_A| \land p) \leq I(|X| \land n - |X| \land p) \to 0$ as $p \to \infty$ since $|X| \in L$. Hence $\lim_{p \to \infty} I(|X 1_A| \land n)$ exists. By the Monotone Convergence Theorem, the limit $|X 1_A| = \lim_{n \to \infty} |X 1_A| \land n$ is integrable. Similarly, $|X + 1_A|$ is integrable and so also is $X 1_A = 2 |X 1_A| - |X 1_A|$.

2. Suppose $a > 0$. Since $|X 1_A| \leq (|X| - |X| \land a) 1_A + a 1_A$ we have $I(|X 1_A|) \leq I(|X| - I(|X| \land a) + a \mu(A)$. Given any $\varepsilon > 0$, since $X$ is integrable, there exists $a > 0$ so large that $I(|X| - I(|X| \land a) < \varepsilon$. Then for each $A$ with $\mu(A) < \varepsilon/a$ we have $I(|X 1_A|) \leq 2 \varepsilon$.

3. Suppose $a > \eta(\varepsilon) = b/\delta(\varepsilon)$ where $\delta$ is an operation as in assertion 2. Chebychev's inequality gives $\mu(|X| > a) \leq I(|X| / a) \leq b/a < \delta(\varepsilon)$. Hence $I(1_{|X| > a}) < \varepsilon$.

4. Suppose $\mu(A) < \varepsilon/\eta(\varepsilon)$. For each $a > \eta(\varepsilon)$ we have $I(|X| 1_A) \leq I(a 1_A(X \land a) + 1_{|X| > a}) \leq a \mu(A) + \varepsilon \leq a \varepsilon/\eta(\varepsilon) + \varepsilon$. By taking $a$ arbitrarily close to $\eta(\varepsilon)$ we see that $I(|X 1_A|) \leq \eta(\varepsilon) \varepsilon/\eta(\varepsilon) + \varepsilon = 2 \varepsilon$. Replace $\varepsilon$ by $\varepsilon/2$ and the assertion is proved.

Note that in the proof for assertion 4 of Proposition 4.7.2 we use a real number $a > \eta(\varepsilon)$ arbitrarily close to $\eta(\varepsilon)$ rather than simply $a = \eta(\varepsilon)$. This ensures that $a$ can be a regular point of $|X|$, as required in Convention 4.6.9.

Definition 4.7.3. (Uniform integrability and simple modulus of integrability). A family $G$ of integrable functions is said to be uniformly integrable if for each $\varepsilon > 0$, there exists $\eta(\varepsilon)$ such that $E(|X| 1_{|X| > a}) \leq \varepsilon$ for each $a > \eta(\varepsilon)$, for each $X \in G$. The operation $\eta$ is then called a simple modulus of integrability of $G$.

Proposition 4.7.2 ensures that each family $G$ consisting finitely many integrable functions is uniformly integrable.

Proposition 4.7.4. (Alternative definition of uniform integrability, and modulus of integrability). Suppose the integration space $(\Omega, L, I)$ is such that $1 \in L$ and $I1 = 1$. Then a family $G$ of integrable r.v.'s is uniformly integrable iff (i) there exists $b \geq 0$ such that $I|X| \leq b$ for each $X \in G$, and (ii) for each $\varepsilon > 0$, there exists $\delta(\varepsilon)$ such that $I|X| 1_A \leq \varepsilon$ for each integrable set $A$ with $\mu(A) < \delta(\varepsilon)$, and for each $X \in G$. The operation $\delta$ is then called a modulus of integrability of $G$. 

Yuen-Kwok Chan 73 Constructive Probability
**Proof.** First suppose the family $G$ is uniformly integrable. In other words, for each $\varepsilon > 0$, there exists $\eta(\varepsilon)$ such that

$$I(|X| \cdot 1_{\{|X| > \varepsilon\}}) \leq \varepsilon$$

for each $a > \eta(\varepsilon)$, and for each $X \in G$. Define $b = \eta(1) + 2$. Let $X \in G$ be arbitrary. Take any $a \in (\eta(1), \eta(1) + 1)$. Then

$$I[X] = I(1_{\{|X| > \varepsilon\}}|X|) + I(1_{\{|X| \leq \varepsilon\}}|X|) \leq 1 + aI1 = 1 + a < 1 + \eta(1) + 1 = b,$$

where the second equality follows from the hypothesis that $I1 = 1$. This verifies Condition (i) \[4.7.3\]. Now let $\varepsilon > 0$ be arbitrary. Define the operation $\delta$ by $\delta(\varepsilon) \equiv \frac{\eta(\varepsilon)}{\eta(\varepsilon)}$. Then Assertion 4 of Proposition 4.7.2 \[4.7.2\] implies that $I(|X| \cdot 1_{A}) \leq \varepsilon$ for each integrable set $A$ with $\mu(A) < \delta(\varepsilon)$, for each $X \in G$. This verifies Condition (ii).

Conversely, suppose the Conditions (i) and (ii) hold. For each $\varepsilon > 0$, define $\eta(\varepsilon) \equiv b/\delta(\varepsilon)$. Then, according to Assertion 3 of Proposition 4.7.2 \[4.7.2\], we have $I(|X| \cdot 1_{\{|X| > a\}}) \leq \varepsilon$ for each $a > \eta(\varepsilon)$. Thus $G$ is uniformly integrable according to Definition \[4.7.3\].

**Proposition 4.7.5.** (Dominated uniform integrability). If there is an integrable function $Y$ such that $|X| \leq Y$ for each $X$ in a family $G$ of integrable functions, then $G$ is uniformly integrable.

**Proof.** Note that $b \equiv |Y|$ satisfies Conditions (i) in Definition \[4.7.3\]. Let $\varepsilon > 0$ be arbitrary. Then Assertion 3 of Proposition 4.7.2 \[4.7.2\] guarantees an operation $\eta$ such that, for each $\varepsilon > 0$, we have $I(1_{\{|Y| > a\}}|Y|) \leq \varepsilon$ for each $a > \eta(\varepsilon)$. Hence, for each $X \in G$, and for each $a > \eta(\varepsilon)$, we have

$$I(1_{\{|X| > a\}}|X|) \leq I(1_{\{|Y| > a\}}Y) \leq \varepsilon.$$ 

Thus $\eta$ is a common simple modulus of integrability for members $X$ of $G$. The conditions in Definition \[4.7.3\] have been verified for the family $G$ to be uniformly integrable.

**Proposition 4.7.6.** (Each integrable function is the $L_1$ limit of some sequence of linear combinations of integrable indicators).

1. Suppose $X$ is an integrable function with $X \geq 0$ a.e. Then there exists a sequence $(Y_k)_{k=1,2,\ldots}$ such that for each $k \geq 1$ we have (i) $Y_k \equiv \sum_{j=1}^{n_k} t_{k,j} 1_{\{t_{k,j} < X \leq t_{k,j+1}\}} \in L$ for some sequence $0 < t_{k,1} < \cdots < t_{k,n_k}$, (ii) $|Y_k - X| \to 0$, and (iii) $Y_k \uparrow X$ on $D \equiv \bigcap_{k=1}^\infty \text{domain}(Y_k)$. Moreover, we can take $n_k \equiv 2^{2k}$ and $t_{k,i} \equiv 2^{-k}ia$ for $i = 1, \cdots, n_k$ where $a$ is some positive real number.

2. Suppose $X$ is an integrable function. Then there exists a sequence $(Z_k)_{k=1,2,\ldots}$ of linear combinations of mutually exclusive integrable indicators such that $|X - Z_k| \leq 2^{-k}$ and such that $Z_k \to X$ on $\bigcap_{k=1}^\infty \text{domain}(Z_k)$. Furthermore, there exists a sequence $(U_k)_{k=1,2,\ldots}$ of linear combinations of integrable indicators which is a representation of $X$ in $L$.

3. Suppose $X$ and $X'$ are bounded integrable functions. Then $XX'$ is integrable.
4.7. UNIFORM INTEGRABILITY

Proof. 1. Let $a > 0$ be such that $(a < i^{-1}2^k X)$ is integrable for all $k, i \geq 1$. For $k \geq 1$ define $Y_k \equiv \sum_{i=1}^{2^k-1} t_{k,i} 1_{(X < X_{k,i+1})} \in L$ where $n_k \equiv 2^k$ and $t_{k,i} \equiv 2^{-k}ia$ for $i = 1, \cdots, n_k$. For all $k, i \geq 1$, the set $(t_{k,i} < X) \equiv (2^{-k}ia < X) = (a < i^{-1}2^k X)$ is integrable. Hence $Y_k \in L$ for $k \geq 1$. By definition, $t_{k,n_k} \equiv 2^k a \to \infty$ and $t_{k,i} - t_{k,i-1} = 2^{-k}a \to 0$ for $i = 1, \cdots, n_k$. Let $h > k \geq 1$ be arbitrary. Consider any $\omega \in D$. Suppose $Y_k(\omega) > 0$. Then $Y_k(\omega) = t_{k,i}1_{(X < \omega \leq X_{k,i+1})} = t_{k,i}$ for some $i = 1, \cdots, n_k - 1$. Write $p = 2^{-h}i$ and $q = 2^{-h}(i+1) \leq 2^{-h}n_k \equiv 2^h < n_h$. Then

$$t_{h,p} = 2^{-h}pa \equiv 2^{-h}(2^h-i)a = t_{k,i} < X(\omega)$$

$$\leq t_{k,i+1} = 2^{-h}(2^{-h}(i+1))a = 2^{-h}qa \equiv t_{h,q}$$

Therefore there exists $j$ with $p \leq j < q$ such that $t_{h,j} < X(\omega) \leq t_{h,j+1}$. Consequently

$$Y_k(\omega) = t_{k,i} = t_{h,p} \leq t_{h,j} = Y_h(\omega) < X(\omega) \leq t_{h,j+1} = t_{h,q} = t_{k,i+1}$$

(4.7.1)

Thus we see that $0 \leq Y_k \leq Y_h \leq X$ on $D$ for $h > k \geq 1$. Next, let $\varepsilon > 0$ be arbitrary. Then either $X(\omega) > 0$ or $X(\omega) < \varepsilon$. In the first case, $Y_m(\omega) > 0$ for some $m \geq 1$, whence $Y_k(\omega) > 0$ for each $k \geq m$, and so, for each $k \geq k_0 \equiv m \lor \log_2(\varepsilon^{-1})$, we see from inequality (4.7.1) that

$$X(\omega) - Y_k(\omega) < t_{k,i+1} - t_{k,i} = 2^{-k}a < \varepsilon$$

In the second case, we have, trivially, $X(\omega) - Y_k(\omega) < \varepsilon$ for each $k \geq 1$. Combining, we have $Y_k \uparrow X$ on $D$. We will show next that $Y_k \uparrow IX$. By Proposition 4.7.2, there exists $k_1 \geq 1$ so large that $|I(1_{(2^{-k}a < X)})| \leq \varepsilon$ for each $k \geq k_1$. At the same time, since $X \geq 0$ is integrable, there exists $k_2 \geq 1$ so large that $|I(2^{-k}a \land X)| < \varepsilon$ for each $k \geq k_2$. Hence, for each $k \geq k_0 \lor k_1 \lor k_2$, we have

$$I(X - Y_k) = I(X - Y_k)1_{(X \leq 2^{-k}a)} + I(X - Y_k)1_{(2^{-k}a < X \leq 2^k a)} + I(X - Y_k)1_{(2^k a < X)}$$

$$\leq I(2^{-k}a \land X)1_{(X \leq 2^{-k}a)} + I(2^{-k}a \land X)1_{(2^{-k}a < X \leq 2^k a)} + IX 1_{(2^k a < X)}$$

$$\leq I(2^{-k}a \land X)1_{(X \leq 2^k a)} + \varepsilon$$

$$\leq I(2^{-k}a \land X) + \varepsilon < 2\varepsilon$$

Since $\varepsilon > 0$ is arbitrary, we conclude that $|I(Y_k - X) \to 0$.Assertion 1 is proved.

2. By assertion 1, we see that there exists a sequence $(Y_k^+)_{k=1,2,\cdots}$ of linear combinations of mutually exclusive indicators such that $I|X_+ - Y_k^+| < 2^{-k-1}$ for each $k \geq 1$ and such that $Y_k^+ \uparrow X_+$ on $D^+ \equiv \bigcap_{k=1}^\infty \text{domain}(Y_k^+)$. By the same token, there exists a sequence $(Y_k^-)_{k=1,2,\cdots}$ of linear combinations of mutually exclusive indicators such that $I|X_+ - Y_k^-| < 2^{-k-1}$ for each $k \geq 1$ and such that $Y_k^- \uparrow X_-$ on $D^- \equiv \bigcap_{k=1}^\infty \text{domain}(Y_k^-)$. For each $k \geq 1$ define $Z_k \equiv Y_k^+ - Y_k^-$ whence $|I|X - Z_k| \leq |I|X_+ - Y_k^+| + |I|X_+ - Y_k^-| < 2^{-k}$. Moreover, we see from the proof of assertion 1 that, for each $k \geq 1$, $Y_k^+$ can be taken to be a linear combination of indicators of subsets of $(X_+ > 0)$, and, by the same token, $Y_k^-$ can be taken to be a linear combination of indicators of subsets of $(X_- > 0)$. Since $(X_+ > 0)$ and $(X_- > 0)$ are disjoint, so $Z_k \equiv Y_k^+ - Y_k^-$ is a linear
combination of mutually exclusive indicators. Since \( Y^+_k \uparrow X_+ \) on \( D^+ \) and \( Y^-_k \uparrow X_- \) on \( D^- \), we have \( Z_k \to X = X_+ - X_- \) on \( \bigcap_{k=1}^{\infty} \text{domain}(Z_k) = D^+ \cap D^- \). Next, define \( Z_0 \equiv 0 \) and define \( U_k \equiv Z_k - Z_{k-1} \) for each \( k \geq 1 \). Then \( \sum_{k=1}^{\infty} I(U_k) < \infty \) and \( \sum_{k=1}^{\infty} U_k = X \) on \( \bigcap_{k=1}^{\infty} \text{domain}(U_k) \). Hence \((U_k)_{k=1,2,\ldots} \) is a representation of \( X \) in \( L \).

3. The assertion is trivial if \( X \) and \( X' \) are integrable indicators. Hence it is also valid if \( X \) and \( X' \) are linear combinations of integrable indicators. Now suppose \( X \) and \( X' \) are integrable functions bounded in absolute value by some \( a > 0 \). By assertion 2, there exists sequences \((Z_n)_{n=1,2,\ldots} \) and \((Z'_n)_{n=1,2,\ldots} \) of linear combinations of integrable indicators such that \( I[X - Z_n] \to 0 \) and \( I[X' - Z'_n] \to 0 \). Then, for each \( n \geq 1 \), \( Z_nZ'_n \) is integrable by the previous remarks, and \( |XX' - Z_nZ'_n| \leq a|X - Z_n| + a|X' - Z'_n| \). Therefore, by Theorem 4.5.9, \( XX' \) is integrable. \( \square \)

4.8 Measurable Functions and Measurable Sets

In this section, let \((\Omega, L, I)\) be a complete integration space, and let \((S, d)\) be a complete metric space with a fixed reference point \( x_0 \in S \). In the case where \( S = R \), it is understood that \( d \) is the Euclidean metric and that \( x_0 = 0 \).

We will write \( \mu A \equiv \mu(A) \) for the measure of an integrable set \( A \), and similarly write \( \mu AB \equiv \mu(AB) \) for integrable sets \( A \) and \( B \). Recall that \( C_{ab}(S) \) is the space of bounded and uniformly continuous real-valued functions on \( S \). Recall from the Notations and Conventions in the Introduction that if \( X \) is a real-valued function on \( \Omega \) and if \( t \in R \), then we use the abbreviation \((t \leq X)\) for the subset \( \{ \omega \in \text{domain}(X) : t \leq X(\omega) \} \). Similarly with \( "\leq" \) replaced by \( "\geq" \), \( "<" \), or \( "=" \). As usual we write \( a_b \) interchangeably with \( a(b) \) to lessen the burden on subscripts.

**Definition 4.8.1. (Measurable functions).** A function \( X \) from \((\Omega, L, I)\) to the complete metric space \((S, d)\) is called a measurable function if, for each integrable set \( A \) and each \( f \in C_{ab}(S) \), we have (i) \( f(X)1_A \in L \), and (ii) \( \mu(d(x, X) > a)A \to 0 \) as \( a \to \infty \). A subset \( B \) of \( \Omega \) is said to be a measurable set if \( B = \{X = 1\} \) for some real-valued measurable indicator function \( X \). The set \( \{X = 0\} \) is then called a measure-theoretic complement of \( B \). We write \( 1_B \) for a measurable indicator function of \( B \), and write \( B^c \) for a measure-theoretic complement of \( B \). If the constant function 1 is integrable, then Conditions (i) and (ii) reduce to (i') \( f(X) \in L \), and (ii') \( \mu(d(x, X) as \( a \to \infty \). \( \square \)

It is obvious that if condition (ii) holds for one point \( x_0 \in S \), then it holds for any point \( x' \in S \). The next lemma shows that, given condition (i), the measure in condition (ii) is well-defined for all but countably many \( a \in R \). Thus condition (ii) makes sense.

**Lemma 4.8.2. (Integrability of some basic sets).** Let \( X \) be a function from \( \Omega \) to \( S \). Suppose \( f(X)1_A \in L \) for each \( f \in C_{ab}(S) \) and for each integrable set \( A \). Let \( A \) be an arbitrary integrable set. Then the set \( \{d(x, X) > a\}A \) is integrable for all but countably many \( a \in R \). Thus \( \mu(d(x, X) > a)A \) is well-defined for all but countably many \( a \in R \).

**Proof.** Let \( n \geq 0 \) be arbitrary. Then \( h_n \equiv 1 \land (n + 1 - d(x, \cdot))_+ \in C_{ab}(S) \) and so \( h_n(X)1_A \in L \) by hypothesis. Hence all but countably many \( b \in (0, 1) \) are regular points of \( h_n(X)1_A \). Therefore the set \( \{d(x, X) > n + 1 - b\}A = (h_n(X)1_A < b)A \)
4.8. MEASURABLE FUNCTIONS AND MEASURABLE SETS

is integrable for all but countably many \( b \in (0, 1) \). Equivalently, \( d(x_0, X) > a \)\( A \) is integrable for all but countably many \( a \in (n, n + 1) \). Since \( n \geq 0 \) is arbitrary, we see that \( d(x_0, X) > a \)\( A \) is integrable for all but countably many points \( a > 0 \). For each \( a \leq 0 \), the set \( (d(x_0, X) > a)A = A \) is integrable by hypothesis.

The next proposition gives an obviously equivalent condition to (ii) in Definition 4.8.1.

**Proposition 4.8.3. (Alternative definition of measurable functions).** For each \( n \geq 0 \), define the function \( h_n \equiv 1 \wedge (n + 1 - d(x_0, \cdot))_+ \in C_{ab}(S) \). A function \( X \) from \( (\Omega, L, I) \) to the complete metric space \( (S, d) \) is a measurable function iff, for each integrable set \( A \) and each \( f \in C_{ab}(S) \), we have (i) \( f(X)1_A \in L \), and (ii) \( Ih_n(X)1_A \to \mu(A) \) as \( n \to \infty \).

**Proof.** Suppose Conditions (i) and (ii) hold. Let \( n \geq 0 \) be arbitrary. We need to verify that the function \( X \) is measurable. Then, since \( h_n \in C_{ab}(S) \), we have \( h_n(X)1_A \in L \) by Condition (i). Let \( A \) be an arbitrary integrable set. Then, for each \( n \geq 1 \) and \( a > n + 1 \),

\[
Ih_n(X)1_A \leq \mu(d(x_0, X) \leq a)A \leq \mu(A).
\]

Letting \( n \to \infty \), Condition (ii) and the last displayed inequality imply that \( \mu(d(x_0, X) \leq a)A \to \mu(A) \) as \( a \to \infty \). Equivalently \( \mu(d(x_0, X) > a)A \to 0 \) as \( a \to \infty \). The conditions in Definition 4.8.1 are satisfied for \( X \) to be measurable.

Conversely, suppose \( X \) is measurable. Then Definition 4.8.1 of measurability implies Condition (i) in the present lemma. It implies also that \( \mu(d(x_0, X) \leq a)A \to \mu(A) \) as \( a \to \infty \). At the same time, for each \( a > 0 \) and \( n > a \),

\[
\mu(d(x_0, X) \leq a)A \leq Ih_n(X)1_A \leq \mu(A).
\]

Letting \( a \to \infty \), we see that \( Ih_n(X)1_A \to \mu(A) \).

**Proposition 4.8.4. (Basic properties of measurable functions).**

1. The domain of each measurable function is a full set. In particular if \( A \) is a measurable set, then \( A \cup A^c \) is a full set.

2. Each function that is equal a.e. to a measurable function is itself measurable.

3. Each integrable function is a real-valued measurable function. Each integrable set is measurable.

**Proof.**

1. Suppose \( X \) is a measurable function. Let \( A \) be an integrable set. Let \( f \equiv 0 \) be the constant 0 function. Then \( f \in C_{ab}(S) \). Hence, by condition (i) in Definition 4.8.1 we have \( f(X)1_A \in L \). Consequently \( D \equiv dom(f(X)1_A) \) is a full set. Since \( dom(X) = dom(f(X)) \supseteq D \), we see that \( dom(X) \) is a full set. In other words, \( X \) is defined a.e. Now let \( A \) be an arbitrary measurable set. In other words, \( 1_A \) is measurable. Then \( A \cup A^c = dom(1_A) \) is a full set according to the previous argument.

2. Now suppose \( Y \) is a function on \( \Omega \), with values in \( S \), such that \( Y = X \) a.e. where \( X \) is a measurable function. Let \( A \) be any integrable set. Let \( f \in C_{ab}(S) \) be arbitrary. Then, by condition (i) in Definition 4.8.1 we have \( f(X)1_A \in L \). Moreover, because \( Y = X \) a.e., we have \( f(Y)1_A = f(X)1_A \) a.e. Consequently \( f(X)1_A \in L \). Again because \( Y = X \) a.e.,

\[
\mu(d(x_0, Y) > a)A = \mu(d(x_0, X) > a)A \to 0
\]
as \( a \to \infty \). Thus the conditions in Definition 4.8.1 are verified for \( Y \) to be measurable.

3. Next, let \( X \) be any integrable function. Let \( f \in C_{ub}(S) \) be arbitrary and let \( A \) be an arbitrary integrable set. By Proposition 4.6.10, we have \( f(X)_A \in L \), which establishes condition (i) of Definition 4.8.1. By Chebychev’s inequality, \( \mu(|X| > a)A \leq a^{-1}I|X| \to 0 \) as \( a \to \infty \). Condition (ii) of Definition 4.8.1 follows. Hence \( X \) is measurable. In particular, \( 1_A \) and \( A \) are measurable.

Suppose two real-valued measurable functions \( X \) and \( Y \) are indicators to the same measurable set \( A \). Then \( X = Y \) on \( D = \text{domain}(X) \cap \text{domain}(Y) \) and so \( X = Y \) a.e. Therefore the indicator \( 1_A \) is well-defined relative to a.e. equality. Moreover \( (X = 0)D = (Y = 0)D \) and so \( (X = 0) = (Y = 0) \) a.e. Hence the measure-theoretic complement is also well-defined relative to a.e. equality.

The next proposition will be used repeatedly to construct measurable functions from given ones.

**Proposition 4.8.5.** (Construction of a measurable function from pieces of given measurable functions on measurable sets in a disjoint union). Let \((S,d)\) be a complete metric space. Let \((X_i,A_i)_{i=1,2,...}\) be a sequence where, for each \( i, j \geq 1 \), \( X_i \) is a measurable function on \((\Omega,L,\mathcal{F})\) with values in \( S \), and (i) \( A_i \) is a measurable subset of \( \Omega \), (ii) if \( i \neq j \) then \( A_i \cap A_j \) is \( \emptyset \), (iii) \( \bigcup_{k=1}^{\infty}A_k \) is a full set, and (iv) \( \sum_{k=1}^{\infty}\mu(A_kA) = \mu(A) \) for each integrable set \( A \).

Define a function \( X \) on \( \text{domain}(X) \equiv \bigcup_{k=1}^{\infty}\text{domain}(X_k)A_k \) by \( X \equiv X_i \) on \( \text{domain}(X_k)A_i \), for each \( i \geq 1 \). Then \( X \) is a measurable function on \( \Omega \) with values in \( S \).

The same conclusion holds for a finite sequence \((X_i,A_i)_{i=1,...,n}\).

**Proof.** We will give the proof for the infinite case only. For each \( n \geq 1 \) define \( h_n = 1 \wedge (n+1-d(x,\cdot))_+ \in C_{ub}(S) \).

Let \( f \in C_{ub}(S) \) be arbitrary, with \( |f| \leq c \) on \( S \) for some \( c > 0 \). Let \( A \) be an arbitrary integrable set. Since

\[
\sum_{i=1}^{\infty}I_f(X_i)1_{A_i\mid A} \leq c \sum_{i=1}^{\infty}\mu A_i A < \infty,
\]

the function \( Y \equiv \sum_{i=1}^{\infty}f(X_i)1_{A_i\mid A} \) is integrable. At the same time \( f(X)1_A = Y \) on the full set

\[
(\bigcup_{i=1}^{\infty}A_i)(\bigcap_{i=1}^{\infty}\text{domain}(X_i)).
\]

Hence \( f(X)1_A \) is integrable. In particular \( h_n(X)1_A \) is integrable for each \( n \geq 1 \). Moreover

\[
I_{h_n}(X)1_A = \sum_{i=1}^{\infty}I_{h_n(X)}(1_{A_i\mid A}) + \sum_{i=1}^{\infty}\mu(A_iA) = \mu(A).
\]

Hence, by Lemma 4.8.3, \( X \) is a measurable function.

Next is a metric space lemma.

**Lemma 4.8.6.** (Sufficient condition for uniform continuity on a metric space). Let \((S,d)\) be an arbitrary metric space. Let \( A,B \) be subset of \( S \) and let \( a > 0 \) be such that, for each \( x \in S \) we have either (i) \( d(\cdot,x) < a \) \( \subset A \), or (ii) \( d(\cdot,x) < a \) \( \subset B \). Suppose
4.8. MEASURABLE FUNCTIONS AND MEASURABLE SETS

\( \lambda : S \to R \) is a function with domain(\( \lambda \)) = \( S \) such that \( \lambda \) is uniformly continuous on each of \( A \) and \( B \). Then \( \lambda \) is uniformly continuous on \( S \).

**Proof.** Let \( \varepsilon > 0 \) be arbitrary. Since \( \lambda \) is uniformly continuous on each of \( A \) and \( B \), there exists \( \delta_0 > 0 \) so small that \( |\lambda(x) - \lambda(y)| < \varepsilon \) for each \( x, y \) with \( d(x, y) < \delta_0 \), provided that either \( x, y \in A \) or \( x, y \in B \).

Let \( \delta \equiv a \land \delta_0 \). Consider each \( x, y \in S \) with \( d(x, y) < \delta \). By hypothesis, either condition (i) or condition (ii) holds. Assume that condition (i) holds. Then since \( d(x, x) = 0 < a \) and \( d(y, x) < \delta \leq a \) we have \( x, y \in A \). Hence, since \( d(y, x) < \delta \leq \delta_0 \), we have \( |\lambda(x) - \lambda(y)| < \varepsilon \). Similarly, if condition (ii) holds, then \( |\lambda(x) - \lambda(y)| < \varepsilon \).

Combining, we see that \( \lambda \) is uniformly continuous on \( S \).

**Proposition 4.8.7.** (A continuous function of a measurable function is measurable). Let \( (S, d) \) and \( (S', d') \) be complete metric spaces. Let \( X \) be a measurable function on \( (\Omega, L, I) \), with values in \( S \). Suppose a function \( f : (S, d) \to (S', d') \) with domain(\( f \)) = \( S \) is uniformly continuous on each bounded subset of \( S \), and bounded on each bounded subset of \( S \). Then the composite function \( f(X) \equiv f \circ X \) is measurable. In particular, \( d(x, X) \) is a real-valued measurable function for each \( x \in S \).

**Proof.** We need to prove that \( Y \equiv f(X) \) is measurable. To that end, let \( g \in C_{\text{ub}}(S') \) be arbitrary, with \( |g| \leq b \) for some \( b > 0 \). Consider arbitrary integrable \( A \) and \( \varepsilon > 0 \). Since \( X \) is measurable by hypothesis, there exists \( a > 0 \) so large that \( \mu(B) < \varepsilon \) where \( B \equiv \{ d(x_0, X) > a \} \). Define \( h \equiv 1 \land (a - d(x_0, \cdot))_+ \in \mathcal{C}(S) \).

The function \( f \) is, by hypothesis, uniformly continuous on the bounded set \( G \equiv \{ d(\cdot, x_0) < 2 + a \} \). By assumption, \( g \) is uniformly continuous. Therefore \( (g \circ f) \) and \( (g \circ f)h \) are uniformly continuous on \( G \). At the same time \( h \equiv 0 \) on \( H \equiv \{ d(\cdot, x_0) > a \} \).

Hence \( (g \circ f)h \equiv 0 \) on \( H \). Thus \( (g \circ f)h \equiv 0 \) is uniformly continuous on \( H \).

Now consider each \( x \in S \). Either (i) \( d(x, x_0) < a + \frac{3}{2} \), or (ii) \( d(x, x_0) > a + \frac{1}{2} \). In Case (i), we have \( \{ d(\cdot, x) < \frac{1}{2} \} \subset \{ d(\cdot, x_0) < 2 + a \} \equiv G \). In Case (ii), we have \( \{ d(\cdot, x) < \frac{1}{2} \} \subset \{ d(\cdot, x_0) > a \} \equiv H \). Combining, Lemma 4.8.6 implies that \( (g \circ f)h \) is uniformly continuous on \( S \). Moreover, since \( (g \circ f)h \) is bounded on \( G \) by hypothesis, and is equal to \( 0 \) on \( H \), it is bounded on \( S \). In short \( (g \circ f)h \in C_{\text{ub}}(S) \). Since \( X \) is measurable, the function \( g(Y)h(X)1_A = (g \circ f)(X)h(X)1_A \) is integrable. At the same time,

\[
|g(Y)1_A - g(Y)h(X)1_A| \leq b(1 - h(X))1_A
\]

where

\[
I(1 - h(X))1_A \leq \mu(d(x_0, X) > a)A = \mu(B) < \varepsilon.
\]

Since \( \varepsilon > 0 \) is arbitrary, Theorem 4.5.9 implies that the function \( g(Y)1_A \) is integrable.

Now let \( c > a \) be arbitrary. By hypothesis, there exists \( c' > 0 \) so large that \( |f| \leq c' \) on \( d(x_0, \cdot) < c \). Combining, we see that

\[
\mu(d(x_0, Y) > c')A \equiv \mu(d(x_0, f(X)) > c')A
\]

\[
\leq \mu(d(x_0, X) \geq c)A \leq \mu(d(x_0, X) > a)A < \varepsilon.
\]

Since \( \varepsilon > 0 \) is arbitrary, we conclude that \( \mu(d(x_0, Y) > c')A \to 0 \) as \( c' \to \infty \). Thus we have verified the conditions of Definition 4.8.1 for \( Y \) to be measurable. In other words, \( f(X) \) is measurable. 

Yuen-Kwok Chan 79 Constructive Probability
CHAPTER 4. INTEGRATION AND MEASURE

Corollary 4.8.8. *(Condition for measurability of identity function, and of continuous function of a measurable function).* Let $(S,d)$ be a complete metric space. Suppose $(S,C_{ub}(S),I)$ is an integration space, with completion $(S,L,I)$, such that $Ih_k1_A \uparrow \mu(A)$ for each integrable set $A$, where $h_k \equiv 1 \wedge (1 + k - d(\cdot,x_0))_+$ for each $k \geq 1$. Then the following holds.

1. The identity function $X : (S,L,I) \to (S,d)$, defined by $X(x) \equiv x$ for each $x \in S$, is a measurable function on $(S,L,I)$.
2. Let $(S',d')$ be a second complete metric space. Suppose a function $f : (S,d) \to (S',d')$ with domain $f = S$ is uniformly continuous and bounded on each bounded subset of $S$. Then the function $f : (S,L,I) \to (S',d')$ is measurable. In particular, $d(x,\cdot)$ is a real-valued measurable function for each $x \in S$.

Proof. 1. Let $f \in C_{ub}(S)$ be arbitrary, and let $A$ be an arbitrary integrable set. Then $f(X) \equiv f \in L$. Hence $f(X)1_A \in L$. Moreover, $Ih_k(X)1_A = Ih_k1_A \uparrow \mu(A)$ by hypothesis. Hence $X$ is measurable according to Lemma 4.8.3.

2. The conditions in the hypothesis of Proposition 4.8.7 are satisfied by the functions $X : (S,L,I) \to (S,d)$ and $f : (S,d) \to (S',d')$. Accordingly, the function $f \equiv f(X)$ is measurable.

The next proposition says that, in the case where $(S,d)$ is locally compact, the conditions for measurability in Definition 4.8.1 can be weakened somewhat, by replacing $C_{ub}(S)$ with the subset $C(S)$.

Proposition 4.8.9. *(Sufficient condition for measurability in case $S$ is locally compact).* Let $(S,d)$ be a locally compact metric space. Define $h_n \equiv 1 \wedge (n + 1 - d(x_0,\cdot))_+ \in C(S)$ for each $n \geq 1$. Let $X$ be a function from $(\Omega,L,I)$ to $(S,d)$ such that $f(X)1_A \in L$ for each integrable set $A$ and each $f \in C(S)$. Then the following holds.

1. If $Ih_n(X)1_A \uparrow \mu(A)$ for each integrable set $A$, then $X$ is measurable.
2. If $\mu(d(x_0,X) > a)A \to 0$ as $a \to \infty$, for each integrable set $A$, then $X$ is measurable.

Proof. Let $A$ be an arbitrary integrable set. Let $g \in C_{ub}(S)$ be arbitrary, with $|g| \leq c$ on $S$. For each $n \geq 1$, since $S$ is locally compact, we have $h_n,h_ng \in C(S)$. Hence, for each $n \geq 1$, we have $h_n(X)g(X)1_A \in L$, and, by hypothesis,

$$|g(X)1_A - h_n(X)g(X)1_A| \leq c(1-h_n(X))1_A.$$ (4.8.1)

1. By hypothesis, $I(1-h_n(X))1_A \to 0$. Hence, in view of inequality 4.8.1, Theorem 4.5.5 is applicable, to yield $g(X)1_A \in L$, where $g \in C_{ub}(S)$ is arbitrary. Thus the conditions in Proposition 4.8.3 are satisfied for $X$ to be measurable.

2. For each $a > 0$ and for each $n > a$,

$$0 \leq \mu(A) - Ih_n(X)1_A = I(1-h_n(X))1_A \leq \mu(d(x_0,X) > a)A,$$

which, by hypothesis, converges to 0 as $a \to \infty$. Hence, by Assertion 1, $X$ is measurable.

Yuen-Kwok Chan 80 Constructive Probability
4.8. MEASURABLE FUNCTIONS AND MEASURABLE SETS

Definition 4.8.10. (Regular- and Continuity points of a measurable function relative to each integrable set). Suppose $X$ is a real-valued measurable function on $(\Omega, L, I)$. We say that $t \in R$ is a regular point of $X$ relative to an integrable set $A$ if (i) there exists a sequence $(s_n)_{n=1,2,\ldots}$ of real numbers decreasing to $t$ such that $(s_n < X)A$ is integrable for each $n \geq 1$ and such that $\lim_{n \to \infty} \mu((s_n < X)A)$ exists, and (ii) there exists a sequence $(r_n)_{n=1,2,\ldots}$ of real numbers increasing to $t$ such that $(r_n < X)A$ is integrable for each $n \geq 1$ and such that $\lim_{n \to \infty} \mu((r_n < X)A)$ exists. If, in addition, the two limits in (i) and (ii) are equal, then we call $t$ a continuity point of $X$ relative to $A$.

If a real number $t$ is a regular point of $X$ relative to each integrable set $A$, then we call $t$ a regular point of $X$. If a real number $t$ is a continuity point of $X$ relative to each integrable set $A$, then we say $t$ is a continuity point of $X$. □

The next proposition shows that regular points and continuity points of a real-valued measurable function are abundant, and that they inherit the properties of regular points and continuity points of integrable functions.

Proposition 4.8.11. (All but countably many points are continuous points of a real measurable function, relative to each given integrable set $A$). Let $X$ be a real-valued measurable function on $(\Omega, L, I)$. Let $A$ be an integrable set and let $t$ be a regular point of $X$ relative to $A$.

1. All but countably many $u \in R$ are continuity points of $X$ relative to $A$. Hence all but countably many $u \in R$ are regular points of $X$ relative to $A$.

2. $A^c$ is a measurable set.

3. The sets $A(t < X), A(t \leq X), A(X < t), A(X = t)$ are integrable sets.

4. $(X \leq t)A = A((t < X)A)^c$ a.e., and $(t < X)A = A((X \leq t)A)^c$ a.e.

5. $(X < t)A = A((t \leq X)A)^c$ a.e., and $(t \leq X)A = A((X < t)A)^c$ a.e.

6. For a.e. $\omega \in A$, we have $t < X(\omega)$, $t = X(\omega)$, or $t > X(\omega)$. Thus we have a limited, but useful, version of the principle of excluded middle.

7. Let $\varepsilon > 0$ be arbitrary. There exists $\delta > 0$ such that if $r \in (t - \delta, t]$ and $A(X < r)$ is integrable, then $\mu(A(X < r)) - \mu(A(X < r)) < \varepsilon$. There exists $\delta > 0$ such that if $s \in [t, t + \delta)$ and $A(X \leq s)$ is integrable, then $\mu(A(X \leq s)) - \mu(A(X \leq t)) < \varepsilon$.

8. If $t$ is a continuity point of $X$ relative to $A$, then $\mu((t < X)A) = \mu((t \leq X)A)$.

Proof. In the special case where $X$ is an integrable function, the assertions have been proved in Corollary 4.6.8. In general, suppose $X$ is a real-valued measurable function. Let $n \geq 1$ be arbitrary. Then, by Definition 4.8.1, $((-n) \lor X \land n)I_A \in L$. Hence all but countably many $u \in (-n,n)$ are continuity points of the integrable function $((-n) \lor X \land n)I_A$ relative to $A$. On the other hand, for each $t \in (-n,n)$, we have $(X < t)A = (((-n) \lor X \land n)I_A < t)A$. Hence, a point $u \in (-n,n)$ is a continuity point of $(((-n) \lor X \land n)I_A$ relative to $A$ iff it is a continuity point of $X$ relative to $A$. Combining, we
see that all but countably many points in the interval \((-n, n)\) are continuity points of \(X\) relative to \(A\). Therefore all but countably many points in \(R\) are continuity points of \(X\) relative to \(A\). This proves assertion 1. The remaining assertions are proved by similarly reducing to assertions about the integrable functions \(((−n) \vee X \wedge n)1_A\).

Suppose \(X\) is a measurable function. Note that we defined the regular points and continuity points of \(X\) relative to a specific integrable set \(A\). In the case of a \(\sigma\)-finite integration space, to be defined next, all but countably many real numbers \(t\) are regular points of \(X\) relative to each integrable set \(A\).

**Definition 4.8.12.** \((\sigma\text{-finiteness and } I\text{-basis}).\) The complete integration space \((\Omega, L, I)\) is said to be finite if the constant function 1 is integrable, and \((\Omega, L, I)\) is said to be sigma finite, or \(\sigma\)-finite, if there exists a sequence \((A_k)_{k=1,2,\ldots}\) of integrable sets with positive measures such that (i) \(A_k \subset A_{k+1}\) for \(k = 1, 2, \ldots\), (ii) \(\bigcup_{k=1}^{\infty} A_k\) is a full set, and (iii) for any integrable set \(A\) we have \(\mu(A_k A) \to \mu(A)\). The sequence \((A_k)_{k=1,2,\ldots}\) is then called an \(I\)-basis for \((\Omega, L, I)\).

If \((\Omega, L, I)\) is finite, then it is \(\sigma\)-finite, with an \(I\)-basis given by \((A_k)_{k=1,2,\ldots}\) where \(A_k \equiv \Omega\) for each \(k \geq 1\). In particular, if \((S, C_{ab}(S), I)\) is an integration space, with completion \((S, L, I)\), then the constant function 1 is integrable, and so \((S, L, I)\) is finite.

**Lemma 4.8.13.** \((\text{Completion of an integration on a locally compact metric space results in a } \sigma\text{-finite integration space}).\) Suppose \((S, d)\) is locally compact. Let \((S, L, I)\) be the completion of some integration space \((S, C(S), I)\). Then \((\Omega, L, I) \equiv (S, L, I)\) is \(\sigma\)-finite. Specifically, there exists an increasing sequence \((a_k)_{k=1,2,\ldots}\) of positive real numbers with \(a_k \uparrow \infty\) such that \((A_k)_{k=1,2,\ldots}\) is an \(I\)-basis for \((S, L, I)\), where \(A_k \equiv (d(x, \cdot) \leq a_k)\) for each \(k \geq 1\).

**Proof.** Consider each \(k \geq 1\). Define \(X_k \equiv 1_{\{k + 1 - d(x, \cdot)\}} \in C(S) \subset L\). Let \(c \in (0, 1)\) be arbitrary and let \(a_k \equiv k + 1 - c\). Then the set \(A_k \equiv (d(x, \cdot) \leq a_k) = (X_k \geq c)\) is integrable. Conditions (i) and (ii) in Definition 4.8.12 are easily verified. For condition (iii), consider any integrable set \(A\). According to Assertion 2 of Corollary 4.8.8 the real-valued function \(d(x, \cdot)\) is measurable on \((\Omega, L, I) \equiv (S, L, I)\). Hence

\[
\mu A - \mu A_k A = \mu (d(x, \cdot) > a_k) A \to 0
\]

Thus condition (iii) in Definition 4.8.12 is also verified for \((A_k)_{k=1,2,\ldots}\) to be an \(I\)-basis.

**Proposition 4.8.14.** \((\text{In the case of a } \sigma\text{-finite integration space, all but countably many points are continuous points of a real measurable function}).\) Suppose \(X\) is a real-valued measurable function on a \(\sigma\)-finite integration space \((\Omega, L, I)\). Then all but countably many real numbers \(t\) are continuity points, hence regular points, of \(X\).

**Proof.** Let \((A_k)_{k=1,2,\ldots}\) be an \(I\)-basis for \((\Omega, L, I)\). According to Proposition 4.8.11 for each \(k\) there exists a countable subset \(J_k\) of \(R\) such that if \(t \in (J_k)_{c}\), where \((J_k)_{c}\) stands for the metric complement of \(J_k\) in \(R\), then \(t\) is a continuity point of \(X\) relative to \(A_k\). Define \(J \equiv \bigcup_{k=1}^{\infty} J_k\).
Consider each \( t \in J_c \). Let the integrable set \( A \) be arbitrary. According to condition (iii) in Definition 4.8.12, we can select a subsequence \( (A_k(n))_{n=1}^\infty \) of \( (A_k) \) such that \( \mu(A) - \mu(A_k(n)) < \frac{1}{n} \) for each \( n \geq 1 \). Let \( n \geq 1 \) be arbitrary. Write \( B_n \equiv A_k(n) \). Then \( t \in (J_k(n))_c \), and so \( t \) is a continuity point of \( X \) relative to \( B_n \). Consequently, according to Proposition 4.8.11, the sets \( (X < t)B_n \) and \( (X \leq t)B_n \) are integrable, with \( \mu(X < t)B_n = \mu(X \leq t)B_n \). Furthermore, according to the same proposition, there exists \( \delta_n > 0 \) such that (i) if \( r \in (t - \delta_n, t) \) and \( (X < r)B_n \) is integrable, then \( \mu(X < t)B_n - \mu(X < r)B_n < \frac{1}{n} \), and (ii) if \( s \in [t, t + \delta_n) \) and \( (X \leq s)B_n \) is integrable, then \( \mu(X \leq t)B_n - \mu(X \leq s)B_n < \frac{1}{n} \).

Let \( r_0 \equiv t - 1 \) and \( s_0 \equiv t + 1 \). Inductively we can select \( r_n \in (t - \delta_n, t) \cap (r_{n-1}, t) \cap (t - \frac{1}{n}, t) \) such that \( r_n \) is a regular point of \( X \) relative to both \( B_n \) and \( A \). Similarly we can select \( s_n \in (t, t + \delta_n) \cap (s_{n-1}, t) \) such that \( s_n \) is a regular point of \( X \) relative to both \( B_n \) and \( A \). Then, for each \( n \geq 1 \), we have

\[
\mu(r_n < X)A - \mu(s_n < X)A = \mu(A(r_n < X)(X \leq s_n))A \\
= \mu(X \leq s_n)B_n - \mu(X \leq r_n)B_n + \mu(A) - \mu(AB_n) \\
\leq (\mu(X \leq t)B_n + \frac{1}{n}) - (\mu(X < t)B_n - \frac{1}{n}) + (\mu(A) - \mu(AA_k(n))) \\
\leq \frac{1}{n} + \frac{1}{n} + \frac{1}{n} \quad (4.8.2)
\]

Since the sequence \( \mu(r_n < X)A \) is nonincreasing and the sequence \( \mu(s_n < X)A \) is nondecreasing, inequality 4.8.2 implies that both sequences converge, and to the same limit. By Definition 4.8.10, \( t \) is a continuity point of \( X \) relative to \( A \).

We now expand Convention 4.6.9 to cover also measurable functions.

**Definition 4.8.15. (Convention regarding regular points of measurable functions).** Let \( X \) be a real-valued measurable function, and let \( A \) be an integrable set. Henceforth, when the integrability of the set \( (X < t)A \) or \( (X \leq t)A \) is required in a discussion, for some \( t \in R \), then it is understood that the real number \( t \) has been chosen from the regular points of the measurable function \( X \) relative to the given integrable set \( A \).

Furthermore, if \( (\Omega, L, I) \) is a \( \sigma \)-finite integration space, when the measurability of the set \( (X < t) \) or \( (X \leq t) \) is required in a discussion, for some \( t \in R \), then it is understood that the real number \( t \) has been chosen from the regular points of the measurable functions \( X \).

**Corollary 4.8.16. (Properties of regular points).** Let \( X \) be a real-valued measurable function on a \( \sigma \)-finite integration space \( (\Omega, L, I) \), and let \( t \) be a regular point of \( X \). Then \( (X \leq t) = (t < X)^c \) and \( (X < t) = (X \leq t)^c \) are measurable sets. Similarly, \( (X < t) = (t \leq X)^c \) and \( (t \leq X) = (X < t)^c \) are measurable sets. The equalities here are understood to be a.e. equalities, and the measure theoretic complement of a measurable set is defined a.e.
CHAPTER 4. INTEGRATION AND MEASURE

Proof. We will prove only the first alleged equality, the rest being similar. Define an indicator function \( Y \), with domain \( Y = (X \leq t) \cup (t < X) \), by \( Y = 1 \) on \( (X \leq t) \) and \( Y = 0 \) on \( (t < X) \). It suffices to show that \( Y \) satisfies conditions (i) and (ii) of Definition 4.8.1 for a measurable function. To that end, consider an arbitrary \( f \in C_{ab}(R) \) and an arbitrary integrable subset \( A \). By hypothesis, and by Definition 4.8.15 \( t \) is a regular point of \( X \) relative to \( A \). Moreover

\[
 f(Y) \mathbb{1}_A = f(1) \mathbb{1}_{(X \leq t)\cap A} + f(0) \mathbb{1}_{(t < X)\cap A},
\]

which is integrable according to Proposition 4.8.11. Thus condition (i) of Definition 4.8.1 is verified. Moreover, since \( Y \) has only the possible values of 0 and 1, the set \( \{|Y| > a\} \) is empty for each \( a > 1 \). Hence, trivially, \( \mu(|Y| > a)A \to 0 \) as \( a \to \infty \), thereby establishing also condition (ii) of Definition 4.8.1. Consequently \( Y \) is a measurable indicator for \( (X \leq t) \), and \( (t < X) = (Y = 0) = (X \leq t)^c \).

Proposition 4.8.17. (A vector of measurable functions constitutes a measurable function). Let \( (\Omega, L, I) \) be a complete integration space.

1. Let \( (S', d'), (S'', d'') \) be complete metric spaces. Let \( (\tilde{S}, \tilde{d}) \equiv (S' \times S'', d' \otimes d'') \) be their product metric space. Let \( X' : \Omega \to S' \) and \( X'' : \Omega \to S'' \) be measurable functions. Define \( X : \Omega \to \tilde{S} \) by \( X(\omega) \equiv (X'(\omega), X''(\omega)) \) for each \( \omega \in \text{domain}(X) \equiv \text{domain}(X') \cap \text{domain}(X'') \). Then \( X \) is a measurable function.

2. Suppose \( (S, d) \) is a complete metric space and a function \( g : \tilde{S} \to S \) is (i) uniformly continuous on bounded subsets, and (ii) bounded on bounded subsets. Then \( g(X') \equiv g(X', X'') \) is a measurable function with values in \( S \).

The above assertions generalize trivially to any finite number of measurable functions \( X', X'', \ldots, X^{(n)} \).

3. As a special case of Assertion 2 above, suppose \( (S', d') = (S'', d'') \). Then for arbitrary measurable functions \( X', X'' : \Omega \to S' \), the function \( d'(X', X'') : \Omega \to R \) is measurable.

Proof. 1. Let \( x'_i, x''_i \) be arbitrary, but fixed, reference points of \( (S', d'), (S'', d'') \) respectively. Designate the point \( x_0 \equiv (x'_0, x''_0) \) as the reference point in the product \( (\tilde{S}, \tilde{d}) \). Consider each integrable set \( A \), and consider each \( f \in C_{ab}(\tilde{S}) \) with a bound \( b > 0 \) and with a modulus of continuity \( \delta_f \). Let \( \varepsilon > 0 \) be arbitrary. Since \( X' \) and \( X'' \) are, by hypothesis, measurable, there exists a continuity point \( a > 0 \) of the measurable functions \( d'(x'_i, X'), d''(x''_i, X'') \) so large that \( \mu(d'(x'_i, X') > a)A < \varepsilon \) and \( \mu(d''(x''_i, X'') > a)A < \varepsilon \).

Now take a sequence \( -a = a_0 < a_1 < \cdots < a_n \equiv a \) such that \( a_i - a_{i-1} < \delta_f(\varepsilon) \) for each \( i = 1, \ldots, n \). For each \( i, j = 1, \ldots, n \), define the integrable set

\[
 \Delta_{i,j} \equiv (a_{i-1} - d'(x'_i, X') \leq a_i)A \cup (a_{j-1} < d''(x''_i, X'') \leq a_j)A.
\]

Partition the set \( H \equiv \{(i, j) : 1 \leq i \leq n; 1 \leq j \leq n\} \) of double subscripts into two disjoint subsets \( H_1 \) and \( H_2 \) such that (i) \( \mu(\Delta_{i,j}) > 0 \) for each \( (i, j) \in H_1 \), and (ii) \( \mu(\Delta_{i,j}) < n^{-2}\varepsilon \) for each \( (i, j) \in H_2 \). Then, for each \( (i, j) \in H_1 \), there exists \( \omega_{i,j} \in \Delta_{i,j} \). Note that, for each \( (i, j) \in H_1 \), we have

\[
 \tilde{d}(X(\omega_{i,j}), X) \equiv d'(X'(\omega_{i,j}), X') \lor d''(X''(\omega_{i,j}), X'') \leq |a_i - a_{i-1}| + |a_j - a_{j-1}| < \delta_f(\varepsilon).
\]

Yuen-Kwok Chan 84  Constructive Probability
on $\Delta_{i,j}$, whence
$$|f(X(\omega_{i,j})) - f(X)| < \varepsilon$$
on $\Delta_{i,j}$. Moreover, the set $\Delta \equiv (\bigcup_{(i,j) \in H} \Delta_{i,j})^c$ is measurable, with
$$D \equiv \Delta \cup \bigcup_{(i,j) \in H} \Delta_{i,j}$$
equal to a full set. At the same time $\Delta_{i,j}\Delta = \emptyset$ for each $(i,j) \in H$. Consequently, for each integrable set $B$, we have
$$\mu DB + \bigcup_{(i,j) \in H} \mu \Delta_{i,j}B = \mu (\Delta \cup \bigcup_{(i,j) \in H} \Delta_{i,j})B = \mu B.$$Thus the finite family $\{\Delta_{i,j} : (i,j) \in H\} \cup \{\Delta\}$ of measurable sets satisfies Conditions (i-iv) in Proposition [4.8.5]. Accordingly, we can define two integrable functions $Y, Z : \Omega \to \mathbb{R}$ by $Y \equiv f(X(\omega_{i,j}))$ and $Z \equiv \varepsilon 1_A$ on $\Delta_{i,j}$, for each $(i,j) \in H_1$, (ii') $Y \equiv 0$ and $Z \equiv b1_A$ on $\Delta_{i,j}$, for each $(i,j) \in H_2$. and (iii') $Y \equiv 0$ and $Z \equiv b1_A$, on $\Delta$. Then, for each $(i,j) \in H_1$, we have
$$|Y - f(X)|1_A = |f(X(\omega_{i,j})) - f(X)|1_A < \varepsilon 1_A = Z$$
on $\Delta_{i,j}$. At the same time, for each $(i,j) \in H_2$, we have
$$|Y - f(X)|1_A = |0 - f(X)|1_A \leq b1_A = Z$$
on $\Delta_{i,j}$. Likewise,
$$|Y - f(X)|1_A \leq |0 - f(X)|1_A \leq b1_A = Z$$
on $\Delta$. Summing up, we obtain
$$|Y1_A - f(X)1_A| \leq Z$$
on the full set $D \equiv \Delta \cup \bigcup_{(i,j) \in H} \Delta_{i,j}$. Now estimate
$$IZ = \sum_{(i,j) \in H(1)} IZ1_{\Delta_{i,j}} + \sum_{(i,j) \in H(2)} IZ1_{\Delta_{i,j}} + IZ1_{\Delta}$$
$$= \sum_{(i,j) \in H(1)} \varepsilon 1_{A\Delta_{i,j}} + \sum_{(i,j) \in H(2)} b1_{A\Delta_{i,j}} + b1_{A\Delta}$$
$$= \varepsilon \sum_{(i,j) \in H(1)} \mu (A\Delta_{i,j}) + b \sum_{(i,j) \in H(2)} \mu (A\Delta_{i,j}) + b\mu (A\Delta)$$
$$\leq \varepsilon \mu \left( \bigcup_{(i,j) \in H(1)} A\Delta_{i,j} \right) + b \sum_{(i,j) \in H(2)} \mu (A\Delta_{i,j}) + b\mu ((d''(x'_n, X') > a)\cap (d''(x''_n, X''_n) > a)\cap \Delta)$$
$$\leq \varepsilon \mu (A) + bn^2n^{-2}\varepsilon + b(\varepsilon + \varepsilon) = \varepsilon \mu (A) + 3b\varepsilon,$
where \( \varepsilon > 0 \) is arbitrary. By repeating the above argument with a sequence \((\varepsilon_k)_{k=1,2,\ldots} \) with \( \varepsilon_k \downarrow 0 \), we can construct a two sequences of integrable functions \((Y_k1_A)_{k=1,2,\ldots} \) and \((Z_k)_{k=1,2,\ldots} \) such that
\[
|Y_k1_A - f(X)1_A| \leq Z_k \quad \text{a.s.}
\]
and such that
\[
IZ_k \leq \varepsilon_k \mu(A) + 3b\varepsilon_k \downarrow 0
\]
as \( k \to \infty \). The conditions in Theorem 4.5.9 are satisfied, to yield \( f(X)1_A \in L \), where \( f \in C_{ab}(\mathcal{S}) \) and the integrable set \( A \) are arbitrary. At the same time,
\[
(d(x_0,X) > a)A \equiv (d'(x_0',X') \lor d''(x_0'',X'') > a)A
\]
is integrable, with
\[
\mu(d(x_0,X) > a)A \leq \mu(d'(x_0',X') > a)A + \mu(d(x_0'',X'') > a)A < 2\varepsilon,
\]
where \( \varepsilon > 0 \) is arbitrarily small. All the conditions in Proposition 4.8.9 for \( X : \Omega \to \mathcal{S} \) to be measurable have thus been verified. Assertion 1 is proved.

2. Next, suppose \((S,d)\) is a complete metric space and a function \( g : \mathcal{S} \to \mathcal{S} \) is (i) uniformly continuous on bounded subsets, and (ii) bounded on bounded subsets. Then the composite function \( g(X) : \Omega \to \mathcal{S} \) is a measurable function according to Proposition 4.8.7. Assertion 2 is proved.

3. Now suppose \((S',d') = (S'',d'')\), and suppose \( S = R \). Then the distance function \( d' : \tilde{S} \equiv S^2 \to R \) is uniformly continuous, and is bounded on bounded subsets. Hence \( d'(X',X'') \) is measurable by Assertion 2.

**Corollary 4.8.18. (Operations preserving measurability).** Let \( X,Y \) be real-valued measurable functions. Then \( aX + bY, 1, X \lor Y, X \land Y, |X|, \) and \( X^\alpha \) are measurable functions for any real numbers \( a,b, \alpha \) with \( \alpha \geq 0 \). Let \( A,B \) be measurable sets. Then \( A \cup B \) and \( AB \) are measurable. Moreover \((A \cup B)^c = A^c \lor B^c \) and \((AB)^c = A^c \land B^c \).

**Proof.** \( aX + bY, 1, X \lor Y, X \land Y, |X|, \) and \( X^\alpha \) are uniformly continuous real-valued functions of \( X \) and \( Y \) which are bounded on bounded subsets of \( R \), and so are measurable by Assertion 2 of Proposition 4.8.7. Let \( A,B \) be measurable sets with indicators \( U,V \) respectively. Then \( U \lor V \) is a measurable indicator, with
\[
(U \lor V = 1) = (U = 1) \lor (V = 1) = A \cup B.
\]
Hence \( A \cup B \) is a measurable set, with \( U \lor V \) as indicator. Moreover, \((A \cup B)^c = (U \lor V = 0) = (U = 0) \lor (V = 0) = A^c \lor B^c \). Similarly \( AB \) is measurable, with \((AB)^c = A^c \land B^c \).

**Proposition 4.8.19. (Measurable function dominated by integrable function is integrable).** If \( X \) is a real-valued measurable function such that \( |X| \leq Y \) a.e. for some non-negative integrable function \( Y \), then \( X \) is integrable. In particular, if \( A \) is a measurable set and \( Z \) is an integrable function, then \( Z1_A \) is integrable.
4.9. CONVERGENCE OF MEASURABLE FUNCTIONS

Proof. Let \((a_n)_{n=1,2,\ldots}\) be an increasing sequence of positive real numbers with \(a_n \to \infty\). Let \((b_n)_{n=1,2,\ldots}\) be a decreasing sequence of positive real numbers with \(b_n \to 0\). Let \(n \geq 1\) be arbitrary. Then the function \(X_n \equiv (-(a_n) \land X \lor a_n) \mathbb{1}_{(b_n < Y)}\) is integrable. Moreover, \(X = X_n\) on \((b_n < Y)\). Hence

\[
|X - X_n| \leq |X - X_n|(1_{(Y \leq b(n))} + 1_{(|X| > a(n))})
\]

\[
\leq 2Y(1_{(Y \leq b(n))} + 1_{(|X| > a(n))}) \leq 2Y \land b_n + 2Y1_{(Y > a(n))}
\]

(4.8.3)

By Proposition 4.7.2 we have \(I(Y'(Y > a(n))) \to 0\). At the same time \(I(Y \land a(n)) \to 0\) since \(Y\) is integrable. Therefore \(I(2Y \land b_n + 2Y1_{(Y > a(n))}) \to 0\). Hence, by Theorem 4.5.9, inequality 4.8.3 implies that \(X\) is integrable. 

4.9 Convergence of Measurable Functions

In this section, let \((\Omega, L, I)\) be a complete integration space, and let \((S, d)\) be a complete metric space, with a fixed reference point \(x_0 \in S\). In the case where \(S = R\), it is understood that \(d\) is the Euclidean metric and that \(x_0 = 0\). We will introduce several notions of convergence of measurable functions on \((\Omega, L, I)\) with values in \((S, d)\).

First recall some notations and definitions. We will write \((a_i)_{i=1,2,\ldots}\) for short for a given sequence \((a_i)_{i=1,2,\ldots}\). If \((Y_i)_{i=1,2,\ldots}\) is a sequence of functions from a set \(\Omega'\) to the metric space \(S\), and if

\[
D \equiv \{ \omega \in \cup_{n=1}^{\infty} \cap_{i=n}^{\infty} \text{domain}(Y_i) : \lim_{i \to \infty} Y_i(\omega) \text{ exists in } S \}
\]

is non-empty, then the function \(\lim_{i \to \infty} Y_i\) is defined by \(\text{domain}(\lim_{i \to \infty} Y_i) \equiv D\) and by \(\lim_{i \to \infty} Y_i(\omega)\) for each \(\omega \in D\). We write \(\mu A \equiv \mu (A) \equiv I1_A\) for the measure of an integrable set \(A\), and similarly write \(\mu AB \equiv \mu (A;B) \equiv \mu (AB)\) for integrable sets \(A\) and \(B\). If \(Z\) is a real-valued function on \(\Omega\) and if \(a \in R\) then

\[
(Z \leq a) \equiv \{ \omega \in \text{domain}(Z) : Z(\omega) \leq a \} \subset \text{domain}(Z).
\]

Similarly when \(\leq\) is replaced by \(<,\geq,>\), or =.

Definition 4.9.1. (Convergence in measure, a.u., a.e., and in \(L_1\)). For each \(n \geq 1\), let \(X, X_n\) be functions on the complete integration space \((\Omega, L, I)\), with values in the complete metric space \((S, d)\).

1. The sequence \((X_n)\) is said to converge to \(X\) uniformly on a subset \(A\) of \(\Omega\) if, for each \(\varepsilon > 0\), there exists \(p \geq 1\) so large that \(A \subset \cap_{n=p}^{\infty} (d(X_n, X) \leq \varepsilon)\).

2. The sequence \((X_n)\) is said to converge to \(X\) almost uniformly (a.u.) if, for each integrable set \(A\) and real number \(\varepsilon > 0\), there exists an integrable set \(B\) with \(\mu (B) < \varepsilon\) such that \(X_n\) converges to \(X\) uniformly on \(AB^c\).

3. The sequence \((X_n)\) is said to converge to \(X\) in measure if, for each integrable set \(A\) and each \(\varepsilon > 0\), there exists \(p \geq 1\) so large that, for each \(n \geq p\), there exists an integrable set \(B_n\) with \(\mu (B_n) < \varepsilon\) and \(AB_n^c \subset (d(X_n, X) \leq \varepsilon)\).
4. The sequence \((X_n)\) is said to be \textit{Cauchy in measure} if for each integrable set \(A\) and each \(\varepsilon > 0\), there exists \(p \geq 1\) so large that for each \(m, n \geq p\), there exists an integrable set \(B_{m,n}\) with \(\mu(B_{m,n}) < \varepsilon\) and \(AB_{m,n}^c \subset (d(X_n, X_m) \leq \varepsilon)\).

5. Suppose \(S = \mathbb{R}\) and \(X, X_n \in L\) for \(n \geq 1\). The sequence \((X_n)\) is said to \textit{converge to} \(X\) \textit{in} \(L_1\) if \(\|X_n - X\| \to 0\).

6. The sequence \((X_n)\) is said to converge to \(X\) on a subset \(A\) if \(A \subset \text{domain}(\lim_{n \to \infty} X_n)\) and if \(X = \lim_{n \to \infty} X_n\) on \(A\). The sequence \((X_n)\) is said to converge to \(X\) \textit{almost everywhere} (a.e.) if \((X_n)\) converges to \(X\) on some full subset \(DA\) of each integrable set \(A\). \(\square\)

We will use the abbreviation \(X_n \to X\) to stand for “\((X_n)\) converges to \(X\)”, in whichever sense specified.

**Proposition 4.9.2.** (a.u. Convergence implies convergence in measure, etc). For each \(n \geq 1\), let \(X, X_n\) be functions on the complete integration space \((\Omega, L, I)\), with values in the complete metric space \((S, d)\). Then the following holds.

1. If \(X_n \to X\) a.u. then (i) \(X\) is defined a.e. on each integrable set \(A\), (ii) \(X_n \to X\) in measure, and (iii) \(X_n \to X\) a.e.

2. If (i) \(X_n\) is measurable for each \(n \geq 1\), and (ii) \(X_n \to X\) in measure, then \(X\) is measurable.

3. If (i) \(X_n\) is measurable for each \(n \geq 1\), and (ii) \(X_n \to X\) a.u., then \(X\) is measurable.

**Proof.** 1. Suppose \(X_n \to X\) a.u. Let the integrable set \(A\) and \(n \geq 1\) be arbitrary. Then, by Definition 4.9.1, there exists an integrable set \(B_n\) with \(\mu(B_n) < 2^{-n}\) such that \(X_n \to X\) uniformly on \(AB_n^c\). Hence there exists \(p \equiv p_n \geq 1\) so large that

\[
AB_n^c \subset \bigcap_{h=p(n)}^{\infty} (d(X_k, X) \leq 2^{-h}). \tag{4.9.1}
\]

In particular, \(AB_n^c \subset \text{domain}(X)\). Define the integrable set \(B \equiv \bigcap_{k=1}^{\infty} \bigcup_{n=k}^{\infty} B_n\). Then

\[
\mu(B) \leq \sum_{n=k}^{\infty} \mu(B_n) \leq \sum_{n=k}^{\infty} 2^{-n} = 2^{-k+1}
\]

for each \(k \geq 1\). Hence \(B\) is a null set, and \(D \equiv B^c\) is a full set. Moreover,

\[
AD \equiv AB^c = \bigcup_{k=1}^{\infty} \bigcap_{n=k}^{\infty} AB_n^c \subset \bigcup_{k=1}^{\infty} \bigcap_{n=k}^{\infty} \text{domain}(X) \subset \text{domain}(X).
\]

In other words, \(X\) is defined a.e. on the integrable set \(A\). Part (i) of Assertion 1 is proved.

Now let \(\varepsilon > 0\) be arbitrary. Let \(m \geq 1\) be so large that \(2^{-p(m)} < \varepsilon\). Then, for each \(n \geq p_m\), we have \(\mu(B_{n,m}) < 2^{-n} < \varepsilon\). Moreover,

\[
AB_n^c \subset (d(X_n, X) \leq 2^{-n}) \subset (d(X_n, X) < 2^{-p(m)}) \subset (d(X_n, X) < \varepsilon).
\]
Thus the condition in Definition 4.9.1 is verified for $X_n \rightarrow X$ in measure. Part (ii) of Assertion 1 is proved. Furthermore, since $X_n \rightarrow X$ uniformly on $X_n \rightarrow X$ uniformly on $AB_n^c$, it follows that $X_n \rightarrow X$ at each point in $AD = \bigcup_{k=1}^{\infty} \bigcap_{n=k}^{\infty} AB_n^c$, where $D$ is a full set. Thus $X_n \rightarrow X$ a.e. on $A$, where $A$ is an arbitrary integrable set. In other words, $X_n \rightarrow X$ a.e. Part (iii) of Assertion 1 is also proved.

2. Suppose $X_n$ is measurable for each $n \geq 1$, and suppose $X_n \rightarrow X$ in measure. We need to prove that $X$ is measurable. To that end, let $f \in C_{ad}(S)$ be arbitrary. Then $|f| \leq c$ on $S$ for some $c > 0$, and $f$ has a modulus of continuity $\delta_f$. Let the integrable set $A$ and $m \geq 1$ be arbitrary. Take any $\alpha_m > 0$ with $\alpha_m < 2^{-m} \wedge \delta_f(2^{-m})$. By hypothesis, $X_n \rightarrow X$ in measure. Hence, there exists $p_m \geq 1$ such that, for each $n \geq p_m$, there exists an integrable set $B_n$ with $\mu(B_n) < \alpha_m$ and with

$$AB_n^c \subset (d(X_n, X) \leq \alpha_m).$$

In particular, $AB_n^c \subset \text{domain}(X)$. Define the integrable set $B = \bigcap_{k=1}^{\infty} \bigcup_{n=k}^{\infty} B_n$. Then $B$ is a null set, and $D = B^c$ is a full set. Moreover,

$$AD = AB^c = \bigcup_{k=1}^{\infty} \bigcap_{n=k}^{\infty} AB_n^c \subset \text{domain}(X).$$

In other words, $X$ is defined a.e. on the integrable set $A$. Define a function $Y : \Omega \rightarrow S$ by $\text{domain}(Y) = AD \cup A^c D$, and by $Y = X$ and $Y = x_0$ on $AD$ and $A^c D$ respectively. Then $f(Y)$ is defined a.e., and $f(Y)_1 = f(X)$ on $AD$. We will show that $Y$ is a measurable function.

To that end, let $m \geq 1$ be arbitrary, and consider each $n \geq p_m$. Then, since $\alpha_m < \delta_f(2^{-m})$, we have

$$AB_n^c \subset A(d(X_n, X) \leq \alpha_m) \subset A(|f(X_n) - f(X)| \leq 2^{-m}) = A(|f(X_n) - f(Y)| \leq 2^{-m}).$$

Hence

$$|f(Y)_1 A - f(X_n)_1 A| \leq |f(Y) - f(X_n)| (1_{AB_n^c} + 1_{B_n}) \leq 2^{-m} 1_A + 2c 1_{B_n}. \quad (4.9.2)$$

Write $Z_n = |f(Y)_1 A - f(X_n)_1 A|$. Then

$$I(Z_n) \leq c \mu(A) + 2c \mu(B_n) < 2^{-m} \mu(A) + 2c \alpha_m < 2^{-m} \mu(A) + 2c 2^{-m}, \quad (4.9.3)$$

Furthermore, $X_n$ is measurable for each $n \geq 1$, by hypothesis. Hence $f(X_n)_1 A \in L$ for each $n \geq 1$. Therefore Theorem 4.5.9 implies that $f(X)_1 A \in L$. Condition (i) in Definition 4.8.1 has been proved for $X$. Hence, by Lemma 4.8.2, the set $(d(X, x_0) > a)A$ is integrable for all but countably many $a \in R$.

It remains to verify Condition (ii) in Definition 4.8.1 for $X$ to be measurable. For that purpose, consider each $m \geq 1$ and $n \geq p_m$. Since $X_n$ is a measurable function, there exists $a > 0$ so large that

$$\mu(d(X_n, x_0) > a) A < 2^{-m}.$$ 

Take any $b > a + 1 > a + \alpha_m > a + 2^{-m}$. Then

$$(d(X_n, x_0) > b) A \subset (d(X_n, x_0) > a) A \cup (d(X, X) > \alpha_m) A \subset (d(X_n, x_0) > a) A \cup AB_n.$$
Hence

\[ \mu((d(X,x_0) > b)A) \leq \mu((d(X_n,x_0) > a)A) + \mu(AB_n) < 2^{-m} + 2^{-m} = 2^{-m+1}, \]

where \( 2^{-m} > 0 \) is arbitrarily small. We conclude that \( \mu((d(X,x_0) > b)A) \rightarrow 0 \) as \( b \rightarrow \infty. \)

Thus Condition (ii) in Definition 4.8.1 is also verified. Accordingly, the function \( X \) is measurable.

3. Suppose \( (i) \ X_n \ \text{is measurable for each} \ n \geq 1, \) and \( (ii) \ X_n \rightarrow X \) a.u. Then, by Assertion 1, we have \( X_n \rightarrow X \) in measure. Hence, by Assertion 2, the function \( X \) is measurable. Assertion 3 and the proposition is proved. \( \square \)

**Proposition 4.9.3.** (In case of \( \sigma \)-finite \( \Omega \), each sequence Cauchy in measure converges in measure, and contains an a.u. convergent subsequence) Suppose \( (\Omega,L,I) \) is \( \sigma \)-finite. For each \( n,m \geq 1 \), let \( X_n \) be a function on \( (\Omega,L,I) \), with values in the complete metric space \( (S,d) \), such that \( d(X_n,X_m) \) is measurable. Suppose \( (X_n)_{n=1,2,...} \) is Cauchy in measure. Then there exists a subsequence \( (X_n(k))_{k=1,2,...} \) such that \( X \equiv \lim_{k \rightarrow \infty} X_n(k) \) is a measurable function, with \( X_n(k) \rightarrow X \) a.u. and \( X_n(k) \rightarrow X \) a.e. Moreover, \( X_n \rightarrow X \) in measure.

**Proof.** Let \( (A_k)_{k=1,2,...} \) be a sequence of integrable sets that is an \( I \)-basis of \( (\Omega,L,I) \). Thus (i) \( A_k \subset A_{k+1} \) for each \( k \geq 1 \), and (ii) \( \bigcup_{k=1}^{\infty} A_k \) is a full set, and (iii) for any integrable set \( A \) we have \( \mu(A_1A) = \mu(A) \).

By hypothesis, \( (X_n) \) is Cauchy in measure. By Definition 4.9.1, for each \( k \geq 1 \) there exists \( n_k \geq 1 \) such that, for each \( m,n \geq n_k \), there exists an integrable set \( B_{m,n,k} \) with

\[ \mu(B_{m,n,k}) < 2^{-k} \]  \hspace{1cm} (4.9.4)

and with

\[ A_k B_{m,n,k} \subset (d(X_n,X_m) \leq 2^{-k}). \]  \hspace{1cm} (4.9.5)

By inductively replacing \( n_k \) with \( n_1 \vee \cdots \vee n_k \) we may assume that \( n_{k+1} \geq n_k \) for each \( k \geq 1 \). Define

\[ B_k \equiv B_{n(k+1),n(k),k} \]

for each \( k \geq 1 \). Then \( \mu(B_k) < 2^{-k} \) and

\[ A_k B_k^c \subset (d(X_{n(k+1)},X_{n(k)}) \leq 2^{-k}). \]  \hspace{1cm} (4.9.6)

For each \( i \geq 1 \) let

\[ C_i \equiv \bigcup_{k=i}^{\infty} B_k. \]  \hspace{1cm} (4.9.7)

Then

\[ \mu(A_i^c C_i) \leq \mu(C_i) \leq \sum_{k=i}^{\infty} 2^{-k} = 2^{-i+1} \]  \hspace{1cm} (4.9.8)

for each \( i \geq 1 \), whence \( \bigcap_{i=1}^{\infty} A_i^c C_i \) is a null set. Hence \( D \equiv \bigcup_{i=1}^{\infty} A_i C_i^c \) is a full set.

Let \( i \geq 1 \) be arbitrary. Then

\[ A_i C_i^c \subset \bigcap_{k=i}^{\infty} A_k B_k^c \subset \bigcap_{k=i}^{\infty} A_k B_k^c \subset \bigcap_{k=i}^{\infty} (d(X_{n(k+1)},X_{n(k)}) \leq 2^{-k}), \]  \hspace{1cm} (4.9.9)
in view of relation $4.9.6$. Note that the second inclusion is because $A_j \subset A_k$ for each $k \geq i$. Therefore, since $(S, d)$ is complete, $(X_{n(k)})_{k=1, \ldots}$ converges uniformly on $A_i C^c_i$.

In other words, $X_{n(k)} \to X$ uniformly on $A_i C^c_i$, where $X \equiv \lim_{k \to \infty} X_{n(k)}$.

Next let $A$ be an arbitrary integrable set. Let $\varepsilon > 0$ be arbitrary. In view of in view of Condition (iii) above, there exists $i \geq 1$ so large that $2^{-i+1} < \varepsilon$ and $\mu(A_i C^c_i) < \varepsilon$. Such an $i$ exists. Let $B \equiv A_i C^c_i$. Then $\mu(B) < 2\varepsilon$. Moreover, $AB^c = AA_i C^c_i \subset A_i C^c_i$, whence $X_{n(k)} \to X$ uniformly on $AB^c$. Since $\varepsilon > 0$ is arbitrary, we conclude that $X_{n(k)} \to X$ a.e., It then follows from Proposition $4.9.2$ that $X_{n(k)} \to X$ in measure, $X_{n(k)} \to X$ a.e., and $X$ is measurable. Now define, for each $m \geq n_i$,

$$\bar{B}_m \equiv AA_i \cup B_{m,n(i)} \cup C_i.$$ 

Then, in view of expressions $4.9.4$ and $4.9.8$ we have, for each $m \geq n_i$,

$$\mu(\bar{B}_m) = \mu(AA_i \cup B_{m,n(i)} \cup C_i) < \varepsilon + 2^{-i} + 2^{-i+1} < 3\varepsilon.$$ 

(4.9.10)

Moreover,

$$AB^c_\varepsilon = A(A^c \cup A_1) B^c_{m,n(i)} \subset C_i$$

$$= AA_i B^c_{m,n(i)} \subset C_i = (A_i B^c_{m,n(i)}) (A C^c_i)$$

$$\subset (d(X_m, X_{n(i)}) \leq 2^{-i})(d(X, X_{n(i)}) \leq 2^{-i+1})$$

$$\subset (d(X, X_m) \leq 2^{-i} + 2^{-i+1})$$

$$\subset (d(X, X_{n(i)}) < 2\varepsilon)$$

(4.9.11)

for each $m \geq n(i)$, where the first inclusion is because of expressions $4.9.5$ and $4.9.8$.

Since $\varepsilon > 0$ is arbitrary, we have verified the condition in Definition $4.9.1$ for $X_m \to X$ in measure.

**Proposition 4.9.4. (Convergence in measure in terms of convergence of integrals).**

For each $n \geq 1$, let $X, X_n$ be functions on $(\Omega, L, I)$, with values in the complete metric space $(S, d)$, such that $d(X_n, X_m)$ and $d(X_n, X)$ are measurable, for each $n, m \geq 1$. Then the following holds.

1. If $I(1 \wedge d(X_n, X))1_A \to 0$ for each integrable set $A$, then $X_n \to X$ in measure.

2. Conversely, if $X_n \to X$ in measure, then $I(1 \wedge d(X_n, X))1_A \to 0$ for each integrable set $A$.

3. The sequence $(X_n)$ is Cauchy in measure iff $I(1 \wedge d(X_n, X))1_A \to 0$ as $n, m \to \infty$ for each integrable set $A$.

**Proof.** Let the integrable set $A$ and the positive real number $\varepsilon \in (0, 1)$ be arbitrary.

1. Suppose $I(1 \wedge d(X_n, X))1_A \to 0$. Let $\varepsilon > 0$ be arbitrary. Then, by Chebychev’s inequality,

$$\mu(d(X_n, X) > \varepsilon)A \leq \mu(1 \wedge d(X_n, X))1_A > \varepsilon) \leq \varepsilon^{-1}I(1 \wedge d(X_n, X))1_A \to 0$$

as $n \to \infty$. In particular, there exists $p \geq 1$ so large that $\mu(1 \wedge d(X_n, X) > \varepsilon)A < \varepsilon$ for each $n \geq p$. Now consider each $n \geq p$. Define the integrable set $B_n \equiv (1 \wedge d(X_n, X) > \varepsilon)A$. Then $\mu(B_n) < \varepsilon$ and $AB^c_n \subset (d(X_n, X) \leq \varepsilon)$. Thus $X_n \to X$ in measure.

Yuen-Kwok Chan

91 Constructive Probability
CHAPTER 4. INTEGRATION AND MEASURE

2. Conversely, suppose \( X_n \to X \) in measure. Let \( \varepsilon > 0 \) be arbitrary. Then there exists \( p \geq 1 \) so large that, for each \( n \geq p \), there exists an integrable set \( B_n \) with \( \mu(B_n) < \varepsilon \) and \( AB_n \subset (d(X_n,X) \leq \varepsilon) \). Hence

\[
I(1 \land d(X_n,X))1_A = I(1 \land d(X_n,X))1_{AB(n)} + I(1 \land d(X_n,X))1_{AB(n)^c} \\
\leq I1_{B(n)} + \varepsilon 1_A < \varepsilon + \varepsilon \mu(A),
\]

where \( \varepsilon > 0 \). Thus \( I(1 \land d(X_n,X))1_A \to 0 \).

3. The proof of Assertion 4 is similar to that of Assertions 1 and 2. \( \square \)

The next Proposition will be convenient for establishing a.u. convergence.

Proposition 4.9.5. (Sufficient condition for a.u. convergence). Suppose \( (\Omega, L, I) \) is \( \sigma \)-finite, with an \( I \)-basis \( (A_i)_{i=1,2,...} \). For each \( n, m \geq 1 \), let \( X_n \) be a function on \( (\Omega, L, I) \), with values in the complete metric space \( (S,d) \), such that \( d(X_n,X_m) \) is measurable. Suppose that, for each \( i \geq 1 \), there exists a sequence \( (\varepsilon_n)_{n=1,2,...} \) of positive real numbers such that \( \sum_{n=1}^{\infty} \varepsilon_n < \infty \) and such that \( I(1 \land d(X_n,X_{n+1}))1_{A(i)} < \varepsilon_n^2 \) for each \( n \geq 1 \). Then \( X \equiv \lim_{n \to \infty} X_n \) exists on a full set, and \( X_n \to X \) a.u. If, in addition, \( X_n \) is measurable for each \( n \geq 1 \), then the limit \( X \) is measurable.

Proof. For abbreviation write \( Z_n \equiv 1 \land d(X_{n+1},X_n) \) for each \( n \geq 1 \). Let \( A \) be an arbitrary integrable set and let \( \varepsilon > 0 \). Let \( i \geq 1 \) be so large that \( \mu(A_A(i)) < \varepsilon \). By hypothesis, there exists a sequence \( (\varepsilon_n)_{n=1,2,...} \) of positive real numbers such that \( \sum_{n=1}^{\infty} \varepsilon_n < \infty \) and such that \( \mu(Z_n1_{A(i)}) < \varepsilon_n^2 \) for each \( n \geq 1 \). Chebychev’s inequality then implies that

\[
\mu(Z_n > \varepsilon_n)A_i \leq I(\varepsilon_n^{-1}Z_n1_{A(i)}) < \varepsilon_n
\]

for each \( n \geq 1 \). Let \( p \geq 1 \) be so large that \( \sum_{n=p}^{\infty} \varepsilon_n < 1 \land \varepsilon \). Let \( C \equiv \bigcup_{n=p}^{\infty} (Z_n > \varepsilon_n)A_i \) and let \( B \equiv AA_i \cup C \). Then \( \mu(B) < \varepsilon \). Moreover,

\[
AB' \subset AA_iC' = AA_i \bigcap_{n=p}^{\infty} (Z_n \leq \varepsilon_n) \subset \bigcap_{n=p}^{\infty} (Z_n \leq \varepsilon_n)
\]

\[
\subset \bigcap_{n=p}^{\infty} (d(X_{n+1},X_n) \leq \varepsilon_n).
\]

Since \( \sum_{n=p}^{\infty} \varepsilon_n < \infty \), it follows that \( X_n \to X \) uniformly on \( AB' \), where \( X \equiv \lim_{n \to \infty} X_n \). Since \( A \) and \( \varepsilon > 0 \) are arbitrary, we see that \( X_n \to X \) a.u.

If, in addition, \( X_n \) is measurable for each \( n \geq 1 \), then \( X \) is measurable by Proposition 4.9.2. \( \square \)

Proposition 4.9.6. (A continuous function preserves convergence in measure). Let \( (\Omega, L, I) \) be a complete integration space. Let \( (S',d'),(S'',d'') \) be locally compact metric spaces and let \( (S,d) \equiv (S',d') \odot (S'',d'') \) denote the product metrics space. Let \( X'_1,X'_2,\cdots \) be a sequence of measurable functions with values in \( S' \) such that \( X'_n \to X' \) in measure. Similarly, let \( X''_1,X''_2,\cdots \) be a sequence of measurable functions with values in \( S'' \) such that \( X''_n \to X'' \) in measure.

Yuen-Kwok Chan 92 Constructive Probability
Let \( f : (\tilde{S}, \tilde{d}) \to S \) be a continuous function with values in a complete metric space \((S, d)\) which is (i) uniformly continuous on bounded subsets, and (ii) bounded on bounded subsets. Then \( f(X'_n, X''_n) \to f(X', X'') \) in measure as \( n \to \infty \).

Generalization to \( m \geq 2 \) sequences of measurable functions is similar.

**Proof.** Let \( x'_1 \) and \( x''_1 \) be fixed reference points in \( S', S'' \) respectively. Write \( x_n \equiv (x'_n, x''_n) \).

For each \( x, y \in \tilde{S} \), write \( x \equiv (x', x'') \) and \( y \equiv (y', y'') \). Likewise, write \( X \equiv (X', X'') \) and \( X_n \equiv (X'_n, X''_n) \) for each \( n \geq 1 \). Note that, for each \( n \geq 1 \), the functions \( f(X), f(X_n) \) are measurable functions with values in \( S \), thanks to Assertion 2 of Proposition 4.8.1.

Let \( A \) be an arbitrary integrable set. Let \( \varepsilon > 0 \) be arbitrary. By condition (ii) in Definition 4.8.1, there exists \( a > 0 \) so large that \( \mu(B') < \varepsilon \) and \( \mu(B'') < \varepsilon \), where \( B' \equiv (\tilde{d}(x'_1, X') > a)A \) and \( B'' \equiv (\tilde{d}(x''_1, X'') > a)A \). Since \((\tilde{S}, \tilde{d})\) is locally compact, the bounded subset \((\tilde{d}(x'_1, \cdot) \leq a) \times (\tilde{d}(x''_1, \cdot) \leq a)\) is contained in some compact subset.

On the other hand, by hypothesis, the function \( f : \tilde{S} \to S \) is uniformly continuous on each compact subset of \( \tilde{S} \). Hence there exists \( \delta_1 > 0 \) so small that, for each

\[
x, y \in (d'(x'_1, \cdot) \leq a) \times (d''(x''_1, \cdot) \leq a) \subset S
\]

with \( \tilde{d}(x, y) < \delta_1 \), we have \( d(f(x), f(y)) < \varepsilon \). Take any \( \delta \in (0, \frac{1}{2} \delta_1) \). For each \( n \geq 1 \), define \( C'_n \equiv (d'(X'_n, X') \geq \delta)A \) and \( C''_n \equiv (d''(X''_n, X'') \geq \delta)A \). By hypothesis, \( X'_n \to X' \) and \( X''_n \to X'' \) in measure as \( n \to \infty \). Hence there exists \( p \geq 1 \) so large that \( \mu(C'_n) < \varepsilon \) and \( \mu(C''_n) < \varepsilon \) for each \( n \geq p \). Consider any \( n \geq p \). We have

\[
\mu(B' \cup B'' \cup C'_n \cup C''_n) < 4\varepsilon.
\]

Moreover,

\[
A(B' \cup B'' \cup C'_n \cup C''_n) = AB' \cup B'' \cup C'_n \cup C''_n
\]

\[
= A(d'(x'_1, X') \leq a; d''(x''_1, X'') \leq a; d'(X'_n, X') < \delta; d''(X''_n, X'') < \delta)
\]

\[
\subset A((d'(x'_1, X') \leq a) \times (d''(x''_1, X'') \leq a)) \tilde{d}(X_n, X) < \delta_1)
\]

\[
\subset (d(f(X), f(X_n)) < \varepsilon).
\]

Since \( \varepsilon > 0 \) and \( A \) are arbitrary, the condition in Definition 4.9.1 is verified for \( f(X_n) \to f(X) \) in measure.

**Theorem 4.9.7. (Dominated Convergence Theorem).** Let \((X_n)_{n=1,2,...}\) be a sequence of real-valued measurable functions on the complete integration space \((\Omega, L, I)\), and let \( X \) be a real-valued function defined a.e. on \( \Omega \), with \( X_n \to X \) in measure. Suppose there exists an integrable function \( Y \) such that \( |X| \leq Y \) a.e. and \( |X_n| \leq Y \) a.e. for each \( n \geq 1 \). Then \( X, X_n \) are integrable for each \( n \geq 1 \), and \( I|X_n - X| \to 0 \).

**Proof.** By Proposition 4.8.19, \( X_n \) is integrable for each \( n \geq 1 \). Let \( \varepsilon > 0 \) be arbitrary. Since \( Y \) is integrable and is non-negative a.e., there exists \( a > 0 \) so small that \( I(Y \wedge a) < \varepsilon \). Define \( A \equiv (Y > a) \). Then \( |X_n - X| \leq 2Y = 2(Y \wedge a) \) a.e. on \( A^c \) for each \( n \geq 1 \). By Proposition 4.7.2, there exists \( \delta \in (0, \varepsilon/(1 + \mu(A))) \) so small that \( IY_{1_B} < \varepsilon \) for each integrable set \( B \) with \( \mu(B) < \delta \). On the other hand, by hypothesis, \( X_n \to X \) in measure. Hence there exists \( m > 0 \) so large that, for each \( n \geq m \),

Yuen-Kwok Chan

93

Constructive Probability
we have \( AB_n^c \subset (|X_n - X| \leq \delta) \) for some integrable set \( B_n \) with \( \mu(B_n) < \delta \). Combining, for each \( n \geq m \), we have

\[
|X - X_n| \leq |X - X_n|1_{AB(n)} + |X - X_n|1_{AB(n)^c} + |X - X_n|1_{A^c} \\
\leq 2Y1_{B(n)} + \delta1_A + 2(Y \wedge a) \quad a.e.,
\]

(4.9.12)

where

\[
I(2Y1_{B(n)} + \delta1_A + 2(Y \wedge a)) \leq 2\epsilon + \delta\mu(A) + 2\epsilon \leq 2\epsilon + \epsilon + 2\epsilon.
\]

(4.9.13)

Since \( \epsilon > 0 \) is arbitrary, inequalities 4.9.12 and 4.9.13 together with Theorem 4.5.9 imply that \( X \) is integrable and that \( I|X_n - X| \to 0 \).

The next definition introduces Newton’s notation for the Riemann-Stieljes integration relative to a distribution function.

**Definition 4.9.8. (Newton’s notation).** Suppose \( F \) is a distribution function on \( R \). Let \( I \) be the Riemann-Stieljes integration with respect to \( F \), and let \( (R,L,I) \) be the completion of \( (R,C(R),I) \). We will use the notation \( \int \cdot dF \) for \( I \). For each \( X \in L \), we write \( \int X \cdot dF \) or \( \int X(x)dF(x) \) for \( IX \). An integrable function in \( L \) is then to be integrable relative to \( F \), and a measurable function on \( (R,L,I) \) said to be measurable relative to \( F \).

Suppose \( X \) is a measurable function relative to \( F \), and suppose \( s,t \in R \) such that the functions \( 1_{(s,t)}X \) and \( 1_{(s,t)}X \) are integrable relative to \( F \). Then we write

\[
\int_s^t XdF \equiv \int_s^t X(x)dF(x) \equiv \int X1_{(s,t)}dF - \int X1_{(s,t)}dF.
\]

Thus

\[
\int_s^t XdF = -\int_t^s XdF.
\]

If \( A \) is a measurable set relative to \( F \) such that \( X1_A \) is integrable, then we write

\[
\int_A XdF \equiv \int_{x \in A} X(x)dF(x) \equiv \int X1_AdF.
\]

In the special case where \( F(x) \equiv x \) for \( x \in R \), we write \( \int \cdot dx \) for \( \int \cdot dF \). Let \( s < t \) in \( R \) be arbitrary. The integration spaces \( (R,L,\int \cdot dx) \) and \( ([s,t],L_{[s,t]},\int_{[s,t]} \cdot dx) \) are called the Lebesgue integration spaces on \( R \) and \( [s,t] \) respectively, and \( \int \cdot dx \) and \( \int_{[s,t]} \cdot dx \) are called the Lebesgue integration. Then an integrable function in \( L \) or \( L_{[s,t]} \) is said to be Lebesgue integrable; and a measurable function is said to be Lebesgue measurable.

Since the identity function \( Z \), defined by \( Z(x) \equiv x \) for each \( x \in R \), is continuous and is therefore a measurable function on \( (R,L,\int \cdot dF) \), all but countably many \( t \in R \) are regular points of \( Z \). Hence \( (s,t) = (s < Z \leq t) \) is a measurable set in \( (R,L,\int \cdot dF) \) for all but countably many \( s,t \in R \). In other words \( 1_{(s,t)} \) is measurable relative to \( F \) for all but countably many \( s,t \in R \). Therefore the definition of \( \int_s^t X(x)dF(x) \) is not vacuous.
4.9. CONVERGENCE OF MEASURABLE FUNCTIONS

Proposition 4.9.9. (Intervals are Lebesgue integrable). Let \( s, t \in \mathbb{R} \) be arbitrary with \( s \leq t \). Then each of the intervals \([s, t] \), \((s, t)\), \([s, t)\), and \((s, t] \) is Lebesgue integrable, with Lebesgue measure equal to \( t - s \), and with measure-theoretic complements \((-\infty, s) \cup (t, \infty), (-\infty, s) \cup [t, \infty), (\infty, s) \cup (t, \infty), (\infty, s) \cup [t, \infty), \) respectively. Each of the intervals \((-\infty, s)\), \((s, \infty)\), and \([s, \infty) \) is Lebesgue measurable.

Proof. Consider the Lebesgue integration \( \int f \cdot dx \) and the Lebesgue measure \( \mu \).

Let \( a, b \in \mathbb{R} \) be such that \( a < s \leq t < b \). Define \( f \equiv f_{a,s,t,b} \in C(\mathbb{R}) \) such that \( f \equiv 1 \) on \([s, t]\), \( f \equiv 0 \) on \((-\infty, a] \cup [b, \infty)\), and \( f \) is linear on \([a, s]\) and on \([t, b]\). Let \( t_0 < \cdots < t_n \) be any partition in the definition of a Riemann-Stieltjes sum \( S = \sum_{i=1}^{n} f(t_i)(t_i - t_{i-1}) \) such that \( a = t_j \) and \( b = t_k \) for some \( j, k = 1, \cdots , n \) with \( j \leq k \). Then \( S = \sum_{i=j+1}^{k} f(t_i)(t_i - t_{i-1}) \) since \( f \) has \([a, b]\) as support. Hence \( 0 \leq S \leq \sum_{i=j+1}^{k} (t_i - t_{i-1}) = t_k - t_j = b - a \). Now let \( n \to \infty, t_0 \to -\infty, t_n \to \infty, \) and let the mesh of the partition approach 0. It follows from the last inequality that \( \int f(x)dx \leq b - a \). Similarly \( t - s \leq \int f(x)dx \). Now, with \( s, t \) fixed, let \((a_k)_{k=1,2,\cdots}\) and \((b_k)_{k=1,2,\cdots}\) be sequences in \( R \) such that \( a_k \uparrow s \) and \( b_k \downarrow t \), and let \( g_k \equiv f_{a_k,s,t,b_k} \). Then, by the previous argument, we have \( t - s \leq \int g_k(x)dx \leq b_k - a_k \downarrow t - s \). Hence, by the Monotone Convergence Theorem, the limit \( g = \lim_{k \to \infty} g_k \) is integrable, with integral \( t - s \). It is obvious that \( g = 1 \) or \( 0 \) on domain \( g \). In other words, \( g \) is an indicator function. Moreover, \([s, t] = (g = 1) \). Hence \([s, t] \) is an integrable set, with \( 1_{[s, t]} = g \), with measure \( \mu([s, t]) = \int g(x)dx = t - s \), and with measure-theoretic complement \([s, t]^c = (-\infty, s) \cup (t, \infty) \).

Next consider the half open interval \((s, t]\). Since \((s, t] = \bigcup_{k=1}^{\infty} [s + \frac{1}{k}, t]\) where \([s + \frac{1}{k}, t]\) is integrable for each \( k \geq 1 \), and where \( \mu([s + \frac{1}{k}, t]) = t - s - \frac{1}{k} \uparrow t - s \) as \( k \to \infty \), we have the integrability of \((s, t]\), and \( \mu((s, t]) = \lim_{k \to \infty} \mu([s + \frac{1}{k}, t]) = t - s \). Moreover
\[
(s, t]^c = \bigcap_{k=1}^{\infty} [s + \frac{1}{k}, t]^c
\]

\[
= \bigcap_{k=1}^{\infty} ((-\infty, s + \frac{1}{k}) \cup (t, \infty)) = (-\infty, s] \cup (t, \infty).
\]

The proofs for the intervals \((s, t)\) and \([s, t)\) are similar.

Now consider the interval \((-\infty, s)\). Define the function \( X \) on the full set \( D \) by \( X(x) = 1 \) or 0 according as \( x \in (-\infty, s) \) or \( x \in [s, \infty) \). Let \( A \) be any integrable subset of \( \mathbb{R} \). Then, for each \( n \geq 1 \) with \( n > -s \), we have \( |X_1A - 1_{[-n,0)}|A| \leq 1_{[-\infty,-n)} \) on the full set \( D(A \cup A^c)(\{-n, s\} \cup [-n, s]^c) \). At the same time, \( \int 1_{[\infty, \infty]}(x) 1_A(x)dx \to 0 \). Therefore, by Theorem 4.5.9. The function \( X_1A \) is integrable. It follows that, for any \( f \in C(\mathbb{R}) \), the function \( f(X)_1A = f(1)X_1A + f(0)(1_A - X_1A) \) is integrable. We have thus verified condition (i) in Definition 4.8.1 for \( X \) to be measurable. At the same time, since \( |X| \leq 1 \), we have trivially \( \mu(|X| > a) = 0 \) for each \( a > 1 \). Thus condition (ii) in Definition 4.8.1 is also verified. We conclude that \((-\infty, s)\) is measurable. Similarly we can prove that each of \((-\infty, s]\), \((s, \infty)\), and \([s, \infty) \) is measurable. \( \square \)

Yuen-Kwok Chan 95 Constructive Probability
4.10 Product Integrals and Fubini’s Theorem

In the next definition and the following lemma, let $\Omega'$ and $\Omega''$ be two sets, and let $L'$ and $L''$ be linear spaces of real-valued functions on $\Omega'$ and $\Omega''$ respectively, such that if $X', Y'$ are indicators in $L'$ then $X'Y' \in L'$, and such that if $X'', Y''$ are indicators in $L''$ then $X''Y'' \in L''$. It follows that if $X', Y'$ are indicators in $L'$ then $Y'(1 - X') = Y' - Y'X' \in L'$.

Similarly for $L''$.

**Definition 4.10.1. (Direct product of functions)**. Let $X' \in L'$ and $X'' \in L''$ be arbitrary. Define a function $X' \otimes X'' : \Omega' \times \Omega'' \to R$ by $\text{domain}(X' \otimes X'') \equiv \text{domain}(X') \times \text{domain}(X'')$ and by $(X' \otimes X'')(\omega', \omega'') \equiv X'(\omega')X''(\omega'')$. The function $X' \otimes X''$ is then called the direct product of the functions $X'$ and $X''$. When the risk of confusion is low, we will write $X' \otimes X''$ and $X'X''$ interchangeably. Generalization to direct products $X'_1 \otimes \cdots \otimes X'^n$ with $n \geq 2$ factors is similar. Further generalization to direct products $\otimes_{i=1}^\infty X^{(i)}$ of countably many factors is similar, provided that we restrict its domain by

$$\text{domain}(\otimes_{i=1}^\infty X^{(i)}) \equiv \{(\omega', \omega'', \cdots) \in \prod_{i=1}^\infty \text{domain}(X^{(i)}) : \ X^{(i)}(\omega^{(i)}) \to 1 \text{ and } \prod_{i=1}^\infty X^{(i)}(\omega^{(i)}) \text{ converges}\}.$$

**Definition 4.10.2. (Simple functions)**. A real valued function $X$ on $\Omega' \times \Omega''$ is called a **simple function relative to** $L', L''$ if $X = \sum_{i=0}^n \sum_{j=0}^m c_{i,j} X'^i X''^j$ where (i) $n, m \geq 1$, (ii) $X'^i, \cdots, X'^n \in L'$ are mutually exclusive indicators, (iii) $X''^j, \cdots, X''^m \in L''$ are mutually exclusive indicators, (iv) $X'^0 = 1 - \sum_{i=1}^n X'^i$, (v) $X''^0 = 1 - \sum_{j=1}^m X''^j$, (vi) $c_{i,j} \in R$ with $c_{i,j} = 0$ or $|c_{i,j}| > 0$ for each $i = 0, \cdots, n$ and $j = 0, \cdots, m$, and (vii) $c_{i,0} = 0 = c_{0,j}$ for each $i = 0, \cdots, n$ and $j = 0, \cdots, m$. Let $L_0$ denote the set of simple functions on $\Omega' \times \Omega''$. Two simple functions are said to be equal if they have the same domain and the same values on the common domain. In other words, equality in $L_0$ is the set-theoretic equality. Note that, in the above notations, $X'^0, \cdots, X'^n$ are mutually exclusive indicators on $\Omega'$ that sum to 1 on the intersection of their domains. Similarly $X''^0, \cdots, X''^m$ are mutually exclusive indicators on $\Omega''$ that sum to 1 on the intersection of their domains.

The definition can be extended in a straightforward manner to **simple functions relative to linear spaces** $L^{(1)}, \cdots, L^{(k)}$ of functions on any $k \geq 1$ sets $\Omega^{(1)}, \cdots, \Omega^{(k)}$ respectively.

If $1 \in L'$ and $1 \in L''$ then $X'^0 \in L'$ and $X''^0 \in L''$, and the definition can be simplified. To be precise, if $1 \in L'$ and $1 \in L''$, then $X$ is a simple function relative to $L', L''$ iff $X = \sum_{i=0}^n \sum_{j=0}^m c_{i,j} X'^i X''^j$ where (i') $n, m \geq 1$, (ii') $X'^0, \cdots, X'^n \in L'$ are mutually exclusive indicators, (iii') $X''^0, \cdots, X''^m \in L''$ are mutually exclusive indicators, (iv') $\sum_{i=0}^n X'^i = 1$, (v') $\sum_{j=0}^m X''^j = 1$, and (vi') $c_{i,j} \in R$ with $c_{i,j} = 0$ or $|c_{i,j}| > 0$ for each $i = 0, \cdots, n$ and $j = 0, \cdots, m$.

In the notations of Definition 4.10.2 if $Y'$ is an indicator with $Y' \in L'$, then we have $Y'X'^0 = Y'(1 - \sum_{i=1}^n X'^i) \in L'$ by the remark preceding the definition, whence $Y'X'^i \in L'$ for each $i = 0, \cdots, n$. Similarly for $L''$.

**Lemma 4.10.3. (Simple functions constitute a linear space)**. Let $L_0$ be the set of simple functions on $\Omega' \times \Omega''$ relative to $L', L''$. Then the following holds.
1. If $X \in L_0$ then $|X|, a \wedge X \in L_0$ for each $a > 0$. Specifically, let $X$ be a simple function with $X = \sum_{i=0}^{n} \sum_{j=0}^{m} c_{i,j} X'_i X''_j$ as in Definition 4.10.2 Then (i) $|X| = \sum_{i=0}^{n} \sum_{j=0}^{m} |c_{i,j}| X'_i X''_j \in L_0$ and (ii) $a \wedge X = \sum_{i=0}^{n} \sum_{j=0}^{m} (a \wedge c_{i,j}) X'_i X''_j \in L_0$ for each $a > 0$.

2. $L_0$ is a linear space.

3. Assertions 1 and 2 generalize to the case of simple functions relative to linear spaces $L(1), \ldots, L(k)$ of functions on sets $\Omega(1), \ldots, \Omega(k)$ respectively, for any $k \geq 1$.

Proof. 1. Consider any $(\omega', \omega'') \in \text{domain}(X)$. Either $X'_i(\omega') X''_j(\omega'') = 0$ for each $i = 1, \ldots, n$ and $j = 1, \ldots, m$, or $X'_i(\omega') X''_j(\omega'') = 1$ for exactly one pair of $k, h$ with $k = 1, \ldots, n$ and $h = 1, \ldots, m$. In the first case,

$$|X(\omega', \omega'')| = 0 = \sum_{i=1}^{n} \sum_{j=1}^{m} |c_{i,j}| X'_i(\omega') X''_j(\omega'').$$

In the second case,

$$|X(\omega', \omega'')| = |c_{k,h}| = \sum_{i=1}^{n} \sum_{j=1}^{m} |c_{i,j}| X'_i(\omega') X''_j(\omega'').$$

Condition (i) is thus established. Condition (ii) is similarly proved.

2. Obviously $L_0$ is closed under scalar multiplication. To show that $L_0$ is closed also under addition, let

$$X = \sum_{i=0}^{n} \sum_{j=0}^{m} c_{i,j} X'_i X''_j$$

and

$$Y = \sum_{k=0}^{p} \sum_{h=0}^{q} b_{k,h} Y'_k Y''_h$$

be simple functions, as in Definition 4.10.2 Then

$$\sum_{i=0}^{n} \sum_{j=0}^{m} X'_i X''_j = (\sum_{i=0}^{n} X'_i)(\sum_{j=0}^{m} X''_j) = 1$$

on $\text{domain}(X)$ and similarly $\sum_{k=0}^{p} \sum_{h=0}^{q} Y'_k Y''_h = 1$ on $\text{domain}(Y)$. Hence

$$X + Y = \sum_{i=0}^{n} \sum_{j=0}^{m} c_{i,j} X'_i X''_j + \sum_{k=0}^{p} \sum_{h=0}^{q} b_{k,h} Y'_k Y''_h$$

$$= \sum_{i=0}^{n} \sum_{j=0}^{m} c_{i,j} X'_i X''_j (\sum_{k=0}^{p} \sum_{h=0}^{q} Y'_k Y''_h)$$

$$+ \sum_{k=0}^{p} \sum_{h=0}^{q} b_{k,h} Y'_k Y''_h (\sum_{i=0}^{n} \sum_{j=0}^{m} X'_i X''_j)$$
For each \( i = 0, \ldots, n \) and \( k = 0, \ldots, p \), the function \( X'_i Y'_k \) is an indicator, and, by the remark preceding this lemma, belongs to \( L' \) if \( (i, k) \neq (0, 0) \). Moreover

\[
\sum_{i=0}^{n} \sum_{k=0}^{p} X'_i Y'_k = (\sum_{i=0}^{n} X'_i)(\sum_{k=0}^{p} Y'_k) = 1.
\]

Suppose, \((i_1, k_1) \neq (i_2, k_2)\). Then either \( i_1 \neq i_2 \) or \( k_1 \neq k_2 \). In the first case, we have \( X'_{i_1} X'_{i_2} = 0 \) and so \((X'_{i_1} Y'_{k_1})(X'_{i_2} Y'_{k_2}) = 0\). Similarly \((X'_{i_1} Y'_{k_1})(X'_{i_2} Y'_{k_2}) = 0\) in the second case. Summing up, we see that the sequence

\[
(X'_0 Y'_0, X'_1 Y'_0, X'_0 Y'_1, X'_1 Y'_1, \ldots, X'_p Y'_p)
\]

satisfies conditions (ii-iv) in Definition 4.10.2. Similarly, the sequence

\[
(X''_0 Y''_0, X''_1 Y''_0, X''_0 Y''_1, X''_1 Y''_1, \ldots, X''_m Y''_m)
\]

satisfies conditions (v-vii) in Definition 4.10.2. Moreover, \( c_{i,0} + b_{k,0} = 0 + 0 = 0 \) for each \( i = 0, \ldots, n \) and \( k = 0, \ldots, p \). Similarly \( c_{0,j} + b_{0,h} = 0 + 0 = 0 \) for each \( j = 0, \ldots, m \) and \( h = 0, \ldots, q \). The right-hand side of equality 4.10.1 is thus seen to be a simple function. Therefore \( X + Y \) is a simple function, proving that \( L_0 \) is closed relative to addition and that it is a linear space.

3. The proof for the general case is similar to the above proof for \( k = 2 \), and is omitted.

In the remainder of this section, let \((\Omega', L', I')\) and \((\Omega'', L'', I'')\) be complete integration spaces. If \( X', Y' \in L' \) are indicators, then \( X' Y' \in L' \). Similarly for \( L'' \). Let \( \Omega \equiv \Omega' \times \Omega'' \) and let \( L_0 \) denote the linear space of simple functions on \( \Omega \). If \( X = \sum_{i=0}^{n} \sum_{j=0}^{m} c_{i,j} X'_i X''_j \in L_0 \) as in Definition 4.10.2 define

\[
I(X) = \sum_{i=0}^{n} \sum_{j=0}^{m} c_{i,j} I'(X'_i) I''(X''_j)
\]  

Lemma 4.10.4. (Product integral of simple functions is well defined). The function \( I \) defined by equality 4.10.2 is well defined, and is a linear function on \( L_0 \).

Proof. It is obvious that \( I(aX) = aI(X) \) for each \( X \in L_0 \) and \( a \in R \). Suppose \( X, Y \in L_0 \). Using the notations in equality 4.10.1 we have

\[
I(X + Y) = \sum_{i=0}^{n} \sum_{k=0}^{p} \sum_{j=0}^{m} c_{i,j} I'(X'_i Y'_k) I''(X''_j Y''_k)
\]

\[
= \sum_{i=0}^{n} \sum_{j=0}^{m} c_{i,j} I'(X'_i \sum_{k=0}^{p} Y'_k) I''(X''_j \sum_{h=0}^{q} Y''_h)
\]
4.10. PRODUCT INTEGRALS AND FUBINI’S THEOREM

\[ + \sum_{k=0}^{p} \sum_{h=0}^{q} b_{k,h} I'(\sum_{i=0}^{n} X'_i Y'_i) I''(\sum_{j=0}^{m} X''_j Y''_j) \]

\[ = \sum_{i=0}^{n} \sum_{j=0}^{m} c_{i,j} I'(X'_i) I''(X''_j) + \sum_{k=0}^{p} \sum_{h=0}^{q} b_{k,h} I'(Y'_k) I''(Y''_h) \]

\[ = I(X) + I(Y). \]

Thus \( I \) is a linear operation. Next, suppose a simple function

\[ X = \sum_{i=0}^{n} \sum_{j=0}^{m} c_{i,j} X'_i X''_j \]

is such that \( X = 0 \). Then \( c_{i,j} X'_i X''_j = 0 \) for each \( i = 0, \ldots, n \) and \( j = 0, \ldots, m \). It follows that the right-hand side of equality 4.10.2 vanishes, whence \( I(X) = 0 \). Now suppose simple functions \( X \) and \( Y \) are such that \( X = Y \). Then \( X - Y \) is a simple function and \( X - Y = 0 \). Hence \( I(X) - I(Y) = I(X - Y) = 0 \), or \( I(X) = I(Y) \). Thus \( I \) is a well-defined function.

**Theorem 4.10.5. (Integration on space of simple functions).** Let \( I \) be defined as in equality 4.10.2. Then the triple \((\Omega, L_0, I)\) is an integration space.

**Proof.** We need to verify the three conditions in Definition 4.3.1. The linearity of \( L_0 \) has been proved in Lemma 4.10.3. The linearity of the function \( I \) has been proved in Lemma 4.10.4.

Next consider any \( X \in L_0 \), with \( X = \sum_{i=0}^{n} \sum_{j=0}^{m} c_{i,j} X'_i X''_j \) in the notations of Definition 4.10.2. By Lemma 4.10.3

\[ |X| = \sum_{i=0}^{n} \sum_{j=0}^{m} |c_{i,j}| X'_i X''_j \in L_0 \]

and

\[ a \wedge X = \sum_{i=0}^{n} \sum_{j=0}^{m} (a \wedge c_{i,j}) X'_i X''_j \in L_0 \]

for each \( a > 0 \). Hence

\[ I(X \wedge a) = \sum_{i=0}^{n} \sum_{j=0}^{m} (a \wedge c_{i,j}) I'(X'_i) I''(X''_j) \]

\[ \rightarrow \sum_{i=0}^{n} \sum_{j=0}^{m} c_{i,j} I'(X'_i) I''(X''_j) \equiv I(X) \]

as \( a \rightarrow \infty \). Likewise

\[ I(|X| \wedge a) = \sum_{i=0}^{n} \sum_{j=0}^{m} (a \wedge |c_{i,j}|) I'(X'_i) I''(X''_j) \rightarrow 0 \]

as \( a \rightarrow 0 \). Conditions 1 and 3 in Definition 4.3.1 are thus satisfied.

Yuen-Kwok Chan 99 Constructive Probability
It remains to prove condition 2 in Definition 4.3.1, the positivity condition. To that end, suppose \( (X_k)_{k=0,1,2,...} \) is a sequence of functions in \( L_0 \) such that \( X_k \geq 0 \) for \( k \geq 1 \) and such that \( \sum_{k=1}^{\infty} I(X_k) \leq I(X_0) \). For \( k \geq 0 \), we have \( X_k = \sum_{i=0}^{n_k} \sum_{j=0}^{m_k} c_{k,i,j} X_{k,i,j}^n \) as in Definition 4.10.2. It follows that

\[
\sum_{k=1}^{\infty} \sum_{i=0}^{n_k} \sum_{j=0}^{m_k} c_{k,i,j} I'(X_{k,i,j}) I''(X_{k,i,j}^n) = \sum_{k=1}^{\infty} I(X_k)
\]

In view of the positivity condition of the integration \( I' \), there exists \( \omega' \subseteq \Omega' \) such that

\[
\sum_{k=1}^{\infty} \sum_{i=0}^{n_k} \sum_{j=0}^{m_k} c_{k,i,j} X_{k,i,j}(\omega') I''(X_{k,i,j}^n) < \sum_{k=1}^{\infty} \sum_{i=0}^{n_k} \sum_{j=0}^{m_k} c_{0,i,j} X_{0,i,j}(\omega') I''(X_{0,i,j}^n).
\]

In view of the positivity condition of the integration \( I'' \), the last inequality in turn yields some \( \omega'' \subseteq \Omega'' \) such that

\[
\sum_{k=1}^{\infty} \sum_{i=0}^{n_k} \sum_{j=0}^{m_k} c_{k,i,j} X_{k,i,j}(\omega') X_{k,i,j}(\omega'') < \sum_{k=1}^{\infty} \sum_{i=0}^{n_k} \sum_{j=0}^{m_k} c_{0,i,j} X_{0,i,j}(\omega') X_{0,i,j}(\omega'').
\]

Equivalently \( \sum_{k=1}^{\infty} X_k(\omega', \omega'') \leq X_0(\omega', \omega'') \). The positivity condition for \( I \) has thus also been verified. We conclude that \( (\Omega, L_0, I) \) is an integration space. \( \square \)

**Definition 4.10.6. (Product of two integration spaces).** The completion of the integration space \( (\Omega, L_0, I) \) is denoted by,

\[
(\Omega, L, I) = (\Omega' \times \Omega'', L' \otimes L'', I' \otimes I''),
\]

and is called the product integration space of \((\Omega', L', I')\) and \((\Omega'', L'', I'')\). The integration \( I \) is called the product integration. \( \square \)

**Proposition 4.10.7. (Product of integrable functions is integrable relative to the product integration).** Let \((\Omega, L, I)\) denote the product integration space of \((\Omega', L', I')\) and \((\Omega'', L'', I'')\).

1. Suppose \( X' \in L' \) and \( X'' \in L'' \). Then \( X' \otimes X'' \in L \) and \( I(X' \otimes X'') = (I'')(X'') \).

2. Moreover, if \( D' \) and \( D'' \) are full subsets of \( \Omega' \) and \( \Omega'' \) respectively, then \( D' \times D'' \) is a full subset of \( \Omega \).

**Proof.** First suppose \( X' = \sum_{i=1}^{n} a_i' X_i' \) and \( X'' = \sum_{i=1}^{m} a_i'' X_i'' \) where (i) \( X_1', \ldots, X_n' \) are mutually exclusive integrable indicator in \((\Omega', L', I')\), (ii) \( X_1'', \ldots, X_m'' \) are mutually exclusive integrable indicator in \((\Omega'', L'', I'')\), and (iii) \( a_1', \ldots, a_n', a_1'', \ldots, a_m'' \in R \). Define \( X_0' = 1 - \sum_{i=1}^{n} X_i' \), define \( X_0'' = 1 - \sum_{i=1}^{m} X_i'' \), and define \( a_0' = 0 \equiv a_0'' \). Then \( X'X'' = \sum_{i=0}^{n} \sum_{j=0}^{m} a_i' a_j'' I'(X_i') I''(X_j'') \in L_0 \subseteq L \). Moreover

\[
I(X'X'') = \sum_{i=0}^{n} \sum_{j=0}^{m} a_i' a_j'' I'(X_i') I''(X_j'').
\]
Next let $D'$ be a full subset of $\Omega'$ and define the measurable function $Y'$ on $\Omega'$ by $\text{domain}(Y') \equiv D'$ and $Y' \equiv 1$ on $D'$. Thus $Y'$ is an indicator of $D'$, and $X' = 1 - Y' = 0Y'$ is an integrable indicator. Define $Y'' \equiv 1$ and $X'' \equiv 0$ on $\Omega''$. Then $X''$ is an integrable indicator on $\Omega''$. Hence $X = 0(Y'Y'' + Y'X'' + X'Y'') + X'X''$ is a simple function, with $IX = (I'X')(I''X'') = 0$. On the other hand $\text{domain}(X) = \text{domain}(Y') \times \text{domain}(Y'') \equiv D' \times \Omega''$. Therefore $D' \times \Omega''$ is a full subset of $\Omega$. Suppose, $D''$ is a full subset of $\Omega''$. Then similarly $\Omega' \times D''$ is also a full subset of $\Omega$. It follows that $D' \times D'' = (D' \times \Omega'') \cap (\Omega' \times D'')$ is a full subset of $\Omega$, proving the last assertion of the proposition.

Now consider arbitrary $X' \in L'$ and $X'' \in L''$. We need to show that $X'X'' \in L$. By linearity, there is no loss of generality in assuming that $X' \geq 0$ and $X'' \geq 0$. By Proposition 4.10.3, there exist sequences $(X'_i)_{k=1,2,\ldots}$ and $(X''_i)_{k=1,2,\ldots}$ where (i) for each $n \geq 1$, the functions $X'_i$ and $X''_i$ are linear combinations of mutually exclusive integrable indicators in $(\Omega', L', I')$ and $(\Omega'', L'', I'')$ respectively, (ii) $0 \leq X'_i \uparrow X'$ and $0 \leq X''_i \uparrow X''$ on $D' \equiv \bigcap_{k=1}^n \text{domain}(X'_i)$ and $D'' \equiv \bigcap_{k=1}^n \text{domain}(X''_i)$ respectively, and (iii) $I'X'_i \uparrow IX'$ and $I''X''_i \uparrow IX''$. Let $k \geq 1$ be arbitrary. By the first paragraph of this proof, we have $I(X(X'_i)) = I'(X'_i)I''(X''_i) \uparrow I'(X')I''(X'')$. Therefore, by the Monotone Convergence Theorem, $X'(X'_i) \uparrow X$ a.e. relative to $I$ for some $X \in L$, and $IX = (I'X')(I''X'')$. On the other hand $X'_iX''_i \uparrow X'X''$ on the set $D' \times D''$, which is a full set as seen in the previous paragraph. Thus $X'X'' = X$ a.e. Hence $X'X'' \in L$ and $I(X'X'') = IX = (I'X')(I''X')$.

Next is Fubini’s Theorem which enables the calculation of the product integral as iterated integrals.

**Theorem 4.10.8. (Fubini’s Theorem for product of two integration spaces)** Let $(\Omega, L, I) \equiv (\Omega, L' \otimes L'', I' \otimes I'')$ be the product integration space of $(\Omega', L', I')$ and $(\Omega'', L'', I'')$. Let $X \in L' \otimes L''$ be arbitrary.

Then there exists a full subset $D'$ of $\Omega'$ such that (i) for each $\omega' \in D'$, the function $X(\omega', -)$ is a member of $L''$, (ii) the function $I'X$ defined by $\text{domain}(I'X) \equiv D'$ and $(I'X)(\omega) = I''(X(\omega', -))$ for each $\omega' \in D'$ is a member of $L'$, and (iii) $IX = I'(I'X)$.

Similarly, there exists a full subset $D''$ of $\Omega''$ such that (i) for each $\omega'' \in D''$, the function $X(-, \omega'')$ is a member of $L'$, (ii) the function $I''X$ defined by $\text{domain}(I''X) \equiv D''$ and $(I''X)(\omega'') = I'(X(-, \omega''))$ for each $\omega'' \in D''$ is a member of $L''$, and (iii) $IX = I''(I''X)$.

**Proof.** First consider a simple function $X = \sum_{i=0}^{n-1} \sum_{j=0}^{m-1} c_{i,j} X'_i X''_j$, in the notations of Definition 4.10.2. Define $D' \equiv \bigcap_{i=1}^n \text{domain}(X'_i)$. Then $D'$ is a full subset of $\Omega'$. Let $\omega' \in D'$ be arbitrary. Then $X(\omega', -) = \sum_{i=0}^{n-1} \sum_{j=0}^{m-1} c_{i,j} X'_i(\omega') X''_j \in L''$, verifying condition (i'). Define the function $I''X$ as in condition (ii'). Then

\[(I''X)(\omega') \equiv I''(X(\omega', -)) = \sum_{i=0}^{n-1} \sum_{j=0}^{m-1} c_{i,j} X'_i(\omega') I''X''_j\]
for each \( \omega' \in D' \). Thus \( l''X = \sum_{i=0}^{n} \sum_{j=0}^{m} (c_{i,j}l''X''_i)X'_i \in L' \), which verifies condition \((ii')\). It follows from the last equality that

\[
l'(l''X) = \sum_{i=0}^{n} \sum_{j=0}^{m} (c_{i,j}l''X''_i)(l'X'_i) = IX,
\]

proving also condition \((iii')\). Thus conditions \((i'\text{-}iii')\) are proved in the case of a simple function \( X \).

Next let \( X \in L' \otimes L'' \) be arbitrary. Then there exists a sequence \((X_k)_{k=1,2,\ldots}\) of simple functions which is a representation of \( X \) relative to the integration \( I \). Let \( k \geq 1 \) be arbitrary. We have

\[
X_k = \sum_{i=0}^{n} \sum_{j=0}^{m} c_{k,i,j}X'_iX''_{k,j},
\]

in the notations of Definition 4.10.2. By Lemma 4.10.3 we have

\[
|X_k| = \sum_{i=0}^{n} \sum_{j=0}^{m} |c_{k,i,j}|X'_iX''_{k,j}.
\]

For each \( k \geq 1 \) we have \( IX_k = l'(l''X_k) \) and \( |X_k| = l'(l''|X_k|) \) by the first part of this proof. Therefore

\[
\sum_{k=1}^{\infty} l'(l''X_k) \leq \sum_{k=1}^{\infty} l'(l''|X_k|) = \sum_{k=1}^{\infty} |X_k| < \infty.
\]

Hence the functions \( Y = \sum_{k=1}^{\infty} l''X_k \) and \( Z = \sum_{k=1}^{\infty} l''|X_k| \) are in \( L' \), with

\[
l'Y = \sum_{k=1}^{\infty} l'(l''X_k) = \sum_{k=1}^{\infty} IX_k = IX.
\]

Consider any \( \omega' \in D' \equiv \text{domain}(Z) \). Then \( \sum_{k=1}^{\infty} l''X_k(\omega',\cdot) \) is a representation of \( X(\omega',\cdot) \) in \( L'' \), with

\[
X(\omega',\cdot)(\omega'') = \sum_{k=1}^{\infty} X_k(\omega',\omega'') = \sum_{k=1}^{\infty} X_k(\omega',\cdot)(\omega'')
\]

In other words, for each \( \omega' \in D' \), the sequence \((X_k(\omega',\cdot))_{k=1,2,\ldots}\) is a representation of \( X(\omega',\cdot) \) in \( L'' \), and so \( X(\omega',\cdot) \in L'' \) with

\[
(l''X)(\omega') = l'X(\omega',\cdot) = \sum_{k=1}^{\infty} l''X_k(\omega',\cdot) = Y(\omega')
\]

Thus we see that \( l''X = Y \) on the full set \( D' \). Since \( Y \in L' \), so also \( l''X \in L' \). Moreover, \( l'(l''X) = l'(Y') = IX \). Conditions \((i'\text{-}iii')\) have thus been verified for an arbitrary \( X \in L \).

Conditions \((i''\text{-}iii'')\), where the roles of \( l' \) and \( l'' \) are reversed, is proved similarly. \( \square \)
Following is the straightforward generalization of Fubini’s theorem to product integration to many factors.

**Definition 4.10.9. (Product of several integration spaces).** Let $n \geq 1$ be arbitrary. Let $(\Omega^{(1)}, L^{(1)}, I^{(1)}), \ldots, (\Omega^{(n)}, L^{(n)}, I^{(n)})$ be complete integration spaces. If $n = 1$, let

$$
\prod_{i=1}^{n} \Omega^{(i)}, \bigotimes_{i=1}^{n} L^{(i)}, \bigotimes_{i=1}^{n} I^{(i)} \equiv (\Omega^{(1)}, L^{(1)}, I^{(1)}).
$$

Inductively for $n \geq 2$, define

$$
\prod_{i=1}^{n} \Omega^{(i)}, \bigotimes_{i=1}^{n} L^{(i)}, \bigotimes_{i=1}^{n} I^{(i)} \equiv \left( \prod_{i=1}^{n-1} \Omega^{(i)}, \bigotimes_{i=1}^{n-1} L^{(i)}, \bigotimes_{i=1}^{n-1} I^{(i)} \right) \bigotimes \left( \Omega^{(n)}, L^{(n)}, I^{(n)} \right)
$$

where the product of the two integration spaces $\left( \prod_{i=1}^{n-1} \Omega^{(i)}, \bigotimes_{i=1}^{n-1} L^{(i)}, \bigotimes_{i=1}^{n-1} I^{(i)} \right)$ and $(\Omega^{(n)}, L^{(n)}, I^{(n)})$ on the right-hand side is as in Definition 4.10.6. Then,

$$
\prod_{i=1}^{n} \Omega^{(i)}, \bigotimes_{i=1}^{n} L^{(i)}, \bigotimes_{i=1}^{n} I^{(i)}
$$

is called the **product integration space** of the given integration spaces.

In the special case where $(\Omega^{(1)}, L^{(1)}, I^{(1)}) = \ldots = (\Omega^{(n)}, L^{(n)}, I^{(n)})$ are all equal to the same integration space $(\Omega_0, L_0, I_0)$ we write

$$
\Omega_0^{(n)}, L_0^{(\otimes n)}, I_0^{(n)} \equiv \left( \prod_{i=1}^{n} \Omega^{(i)}, \bigotimes_{i=1}^{n} L^{(i)}, \bigotimes_{i=1}^{n} I^{(i)} \right)
$$

and call it the **$n$-th power of the integration space** $(\Omega_0, L_0, I_0)$.

**Theorem 4.10.10. (Fubini’s Theorem for product of several integration spaces).** Let $n \geq 1$ be arbitrary. Let $(\Omega^{(1)}, L^{(1)}, I^{(1)}), \ldots, (\Omega^{(n)}, L^{(n)}, I^{(n)})$ be complete integration spaces. Let $(\Omega, L, I) \equiv (\prod_{i=1}^{n} \Omega^{(i)}, \bigotimes_{i=1}^{n} L^{(i)}, \bigotimes_{i=1}^{n} I^{(i)})$ be their product space. Let $X \in \bigotimes_{i=1}^{n} L^{(i)}$ be arbitrary. Let $k \in \{1, \ldots, n\}$ be arbitrary. Then there exists a full subset $D^{(k)}$ of $\prod_{i=1, i \neq k}^{n} \Omega^{(i)}$ such that (i) for each $\omega_k \equiv (\omega_1, \ldots, \omega_{k-1}, \omega_{k+1}, \ldots, \omega_n) \in D^{(k)}$,

the function $X_{\omega(k)} : \Omega^{(k)} \to R$, defined by

$$
X_{\omega(k)}(\omega_k) \equiv X(\omega_1, \ldots, \omega_{k-1}, \omega_k, \omega_{k+1}, \ldots, \omega_n),
$$

is a member of $L^{(k)}$, (ii) the function $\tilde{X}_k : \prod_{i=1, i \neq k}^{n} \Omega^{(i)} \to R$, defined by domain($\tilde{X}_k$) $\equiv D^{(k)}$ and by $\tilde{X}_k(\omega_k) \equiv I^{(k)}(X_{\omega(k)})$ for each $\omega_k \in D^{(k)}$, is a member of $\bigotimes_{i=1, i \neq k}^{n} I^{(i)}$, and

(iii) ($\bigotimes_{i=1, i \neq k}^{n} I^{(i)}$)$X = (\bigotimes_{i=1, i \neq k}^{n} I^{(i)})\tilde{X}_k$.

A special example of is where $Y_k \in L^{(k)}$ is given for each $k = 1, \ldots, n$, and where we define the function $X : \Omega \to R$ by

$$
X(\omega_1, \ldots, \omega_n) \equiv Y_1(\omega_1) \cdot \ldots \cdot Y_n(\omega_n)
$$

for each $(\omega_1, \ldots, \omega_n) \in \Omega$ such that $\omega_k \in \text{domain}(Y_k)$ for each $k = 1, \ldots, n$. Then $X \in \bigotimes_{i=1}^{n} L^{(i)}$ and

$$
IX = I_1(Y_1) \cdots I_n(Y_n).
$$
CHAPTER 4. INTEGRATION AND MEASURE

Proof. The case where \( n = 1 \) is trivial. The case where \( n = 2 \) is proved in Theorem 4.10.8 and Proposition 4.10.11. The proof of the general case is by induction on \( n \), and is straightforward and omitted. \( \square \)

Theorem 4.10.11. (A measurable function on one factor of a product integration space can be regarded as measurable on the product).

1. Let \((\Omega, L, I)\) be the product integration space of \((\Omega', L', I')\) and \((\Omega'', L'', I'')\). Let \(X'\) be an arbitrary measurable function on \((\Omega', L', I')\) with values in some complete metric space \((S, d)\). Define \(X : \Omega \to S\) by \(X(\omega) \equiv X'(\omega')\) for each \((\omega', \omega'') \in \Omega\) such that \(\omega' \in \text{domain}(X')\). Then \(X\) is measurable on \((\Omega, L, I)\) with values in \((S, d)\). Moreover \(I f(X)_A \equiv X' \circ I f(X)\) for each \(f \in C_{ub}(S)\) and each integrable subset \(A'\) of \(\Omega'\).

2. Similarly, with an arbitrary measurable function \(X''\) on \((\Omega', L', I')\) and with \(X : \Omega \to S\) by \(X(\omega) \equiv X''(\omega'')\) for each \((\omega', \omega'') \in \Omega\) such that \(\omega'' \in \text{domain}(X'')\), the function \(X\) is measurable on \((\Omega, L, I)\) with values in \((S, d)\). Moreover \(I f(X)_A \equiv X'' \circ I f(X)\) for each \(f \in C_{ub}(S)\) and each integrable subset \(A'\) of \(\Omega''\).

3. More generally, let \(n \geq 1\) be arbitrary. Let \((\Omega^{(1)}, L^{(1)}, I^{(1)}), \ldots, (\Omega^{(n)}, L^{(n)}, I^{(n)})\) be complete integration spaces. Let \((\Omega, L, I) = (\prod_{i=1}^{n} \Omega^{(i)}, \bigotimes_{i=1}^{n} L^{(i)}, \bigotimes_{i=1}^{n} I^{(i)})\) be their product space. Let \(i = 1, \ldots, n\) be arbitrary, and suppose \(X^{(i)}\) is a measurable function on \((\Omega^{(i)}, L^{(i)}, I^{(i)})\) with values in some complete metric space \((S, d)\). Define the function \(X : \Omega \to S\) by \(X(\omega) \equiv X^{(i)}(\omega)\) for each \((\omega_1, \ldots, \omega_n) \in \Omega\) such that \(\omega_i \in \text{domain}(X^{(i)})\). Then \(X\) is a measurable function on \((\Omega, L, I)\) with values in \((S, d)\). Moreover \(I f(X)_A = I f(X^{(i)})_A\) for each \(f \in C_{ub}(S)\) and each integrable subsets \(A_i\) of \(\Omega^{(i)}\), where \(A = \prod_{i=1}^{n} A_i\), where \(A_k \equiv \Omega^{(k)}\) for each \(k = 1, \ldots, n\) with \(k \neq i\).

4. Suppose, in addition, \(\Omega^{(k)}\) is an integrable set with \(I^{(k)}(\Omega^{(k)}) = 1\), for each \(k = 1, \ldots, n\). Then \(X\) is a measurable function with values in \((S, d)\), such that \(I f(X) = I f(X^{(i)}) f(X^{(i)})\) for each \(f \in C_{ub}(S)\). Anticipating a definition later, we say that the measurable function \(X\) has the same distribution as \(X^{(i)}\).

Proof. Let \(x_0 \in S\) be an arbitrary, but fixed, reference point. For each \(n \geq 0\), define \(h_n \equiv 1 \wedge (n + 1 - d(x_0, \cdot))_+ \in C_{ub}(S)\).

Let \(f \in C_{ub}(S)\) and \(g \in L\) be arbitrary. Then \(|f| \leq b\) for some \(b > 0\). First assume that \(g \equiv 1_{A' \times A''}\) where \(A', A''\) are integrable subsets of \(\Omega', \Omega''\) respectively. Then \(f(X)g = (f(X')1_{A'})1_{A''n}1_{A''n}\) is integrable according to 4.10.7. Moreover,

\[
I h_n(X)_A \equiv X' \circ I h_n(X) \equiv (I f(X')_A)(I f(X')_A) \equiv (I f(X')_A)(I f(X')_A) \equiv I f(X')_A
\]

as \(n \to \infty\). Hence, by linearity, if \(g\) is a simple function \(\Omega\) relative to \(L', L''\), then we have (i) \(f(X)g \in L\), and (ii) \(I h_n(X)g \to I g\). Now let \((g_k)_{k=1,2,\ldots}\) be a sequence of simple functions which is a representation of \(g \in L\). Then

\[
\sum_{k=1}^{\infty} I f(X)g_k \leq b \sum_{k=1}^{\infty} |g_k| < \infty \quad (4.10.3)
\]

where \(b > 0\) is any bound for \(f \in C_{ub}(S)\). Hence

\[
f(X)g = \sum_{k=1}^{\infty} f(X)g_k \in L.
\]

Yuen-Kwok Chan 104 Constructive Probability
Similarly, $h_n(X)g \in L$ and

$$Ih_n(X)g = \sum_{k=1}^{\infty} Ih_n(X)g_k$$

for each $n \geq 0$. Now $|Ih_n(X)g_k| \leq |g_k|$, and, by Condition (ii) above, $Ih_n(X)g_k \rightarrow Ig_k$ as $n \rightarrow \infty$, for each $k \geq 1$. Hence $Ih_n(X)g \rightarrow \sum_{k=1}^{\infty} Ig_k = Ig$ as $n \rightarrow \infty$. In particular, if $A$ is an arbitrary integrable subset of $\Omega$, then $Ih_n(X)1_A \uparrow 1_A \equiv \mu(A)$, where $\mu$ is the measure relative to $I$. We have verified the conditions in Proposition 4.8.3 for $X$ to be measurable. Assertion 1 is proved. Assertion 2 is proved similarly. Assertion 3 follows from Assertion 1 and 2, by induction. Assertion 4 is a special case of Assertion 3, where $A_k \equiv \Omega^{(k)}$ for each $k = 1, \cdots, n$.

For products of integrations based on locally compact spaces, the following proposition will be convenient.

**Proposition 4.10.12. (Product of integration spaces based on locally compact metric spaces).** For each $i = 1, \cdots, n$, let $(S_i, d_i)$ be a locally compact metric space, and let $(S_i, C(S_i), I^{(i)})$ be an integration space, with completion $(S_i, L^{(i)}, I^{(i)})$. Let $(S, d)$ be their product metric space, and let

$$(S, L, I) \equiv \left( \prod_{i=1}^{n} S_i, \bigotimes_{i=1}^{n} L^{(i)}, \bigotimes_{i=1}^{n} I^{(i)} \right)$$

be the product integration space. Then $C(S) \subset L$, and $(S, C(S), I)$ is an integration space with $(S, L, I)$ as completion.

**Proof.** Consider only the case $n = 2$, the general case being similar. For arbitrary real valued functions $V_1, V_2$ on $S_1, S_2$ respectively, we will abuse notations and write $V_1V_2$ for the function whose value at $x \equiv (x_1, x_2)$ is $V_1(x_1)V_2(x_2)$ for each $x \equiv (x_1, x_2) \in S$. By Definition 4.10.6, the product integration space $(S, L, I)$ is the completion of the subspace $(S, L_0, I)$ of simple functions.

Let $X \in C(S)$ be arbitrary. Since $X$ has compact support, there exists $V_i \in C(S_i)$ for $i = 1, 2$ such that (i) $0 \leq V_i \leq 1$ for $i = 1, 2$, (ii) if $x \equiv (x_1, x_2) \in S$ is such that $|X(x)| > 0$ then $V_1(x_1) = 1 = V_2(x_2)$, and (iii) $I^{(1)}V_1 > 0$ and $I^{(2)}V_2 > 0$. Let $\varepsilon > 0$ be arbitrary. By Proposition 3.2.6, there exist $U_{i,1}, \cdots, U_{i,m} \in C(S_i)$ for $i = 1, 2$ such that

$$|X - \sum_{k=1}^{m} U_{1,k}U_{2,k}| < \varepsilon.$$

Multiplication by $V_1V_2$ yields, in view of Condition (ii),

$$|X - \sum_{k=1}^{m} (V_1U_{1,k})(V_2U_{2,k})| < \varepsilon V_1V_2. \quad (4.10.4)$$

Since $C(S) \subset L^{(i)}$ for each $i = 1, 2$, we have $V_1V_2 \in L$ and $(V_1U_{1,k})(V_2U_{2,k}) \subset L$ for each $k = 1, \cdots, m$, according to Proposition 4.10.7. Since $I(\varepsilon V_1V_2) > 0$ is arbitrarily small, inequality (4.10.4) implies that $X \in L$, thanks to Theorem 4.5.9. Since $X \in C(S)$ is arbitrary, we conclude that $C(S) \subset L$. 

Yuen-Kwok Chan 105 Constructive Probability
CHAPTER 4. INTEGRATION AND MEASURE

Since $I$ is a linear function on $L$, and since $C(S)$ is a linear subspace of $L$, it is a linear function on $C(S)$. Since $I(V_1V_2) = (f^{(1)}V_1)(f^{(2)}V_2) > 0$, the triple $(S, C(S), I)$ satisfies condition (i) of Definition 4.2.1. Condition (ii) of Definition 4.2.1, the positivity condition, follows trivially from the positivity condition of $(S, L, I)$. Hence $(S, C(S), I)$ is an integration space. Since $C(S) \subset L$ and since $(S, L, I)$ is complete, the completion $\bar{\mathcal{T}}$ of $C(S)$ relative to $I$ is such that $\bar{\mathcal{T}} \subset L$.

We will show that, conversely, $L \subset \bar{\mathcal{T}}$. To that end, consider any $Y_1 \in L^{(1)}$ and $Y_2 \in L^{(2)}$. Let $\varepsilon > 0$ be arbitrary. Then there exists $U_i \in C(S_i)$ such that $I^{(i)}|U_i - Y_i| < \varepsilon$ for each $i = 1, 2$. Consequently

$$I|Y_1Y_2-U_iU_2| \leq I|Y_1(Y_2-U_2)| + I|(Y_1-U_i)U_2|$$

$$= I^{(1)}|Y_1|I^{(2)}|Y_2-U_2| + I^{(1)}|Y_1-U_1||I^{(2)}|U_2|$$

$$\leq I^{(1)}|Y_1|\varepsilon + \varepsilon I^{(2)}|Y_2| + \varepsilon.$$ 

Since $\varepsilon > 0$ is arbitrary while $U_1U_2 \in C(S)$, we see that $Y_1Y_2 \in \bar{\mathcal{T}}$. Since every simple function on $S$, as in Definition 4.10.2 is a linear combination of functions of the form $Y_1Y_2$ where $Y_1 \in L^{(1)}$ and $Y_2 \in L^{(2)}$, we see that $L_0 \subset \bar{\mathcal{T}}$. On the other hand $\bar{\mathcal{T}}$ is complete relative to $I$. Hence the completion $L$ of $L_0$ is contained in $\bar{\mathcal{T}}$.

Summing up, we have $\bar{\mathcal{T}} = L$. In other words, the completion of $(S, C(S), I)$ is $(S, L, I)$. \qed

**Proposition 4.10.13. (Product of $\sigma$-finite integration spaces is $\sigma$-finite).** Let $(\Omega', L', I')$ and $(\Omega'', L'', I'')$ be arbitrary integration spaces which are $\sigma$-finite, with $I$-bases $(A_k)_{k=1,2,\ldots}$ and $(A'_k)_{k=1,2,\ldots}$ respectively. Then the product integration space

$$(\Omega, L, I) \equiv (\Omega' \times \Omega'', L' \otimes L'', I' \otimes I'')$$

is $\sigma$-finite, with an $I$-basis $(A_k)_{k=1,2,\ldots} \equiv (A_k \times A'_k)_{k=1,2,\ldots}$.

**Proof.** By the definition of an $I$-basis, we have $A'_k \subset A_{k+1}'$ and $A''_k \subset A''_{k+1}$ for each $k \geq 1$. Hence, $A_k \equiv A_k' \times A_k'' \subset A_{k+1}' \times A_{k+1}''$ for each $k \geq 1$. Consequently,

$$\bigcup_{k=1}^{\infty} (A_k' \times A_k'') = \left( \bigcup_{k=1}^{\infty} A_k' \right) \times \left( \bigcup_{k=1}^{\infty} A_k'' \right).$$

Again by the definition of an $I$-basis, the two unions on the right-hand side are full subsets in $\Omega', \Omega''$ respectively. Hence the union on the left-hand side is, according to Proposition 4.10.7 a full set in $\Omega$.

Now let $f \equiv 1_{B'}1_{B''}$ where let $B', B''$ are arbitrary integrable subsets in $\Omega', \Omega''$ respectively. Then

$$I(1_{A(k)}f) = I'(1_{A'(k)}1_{B'})I''(1_{A''(k)}1_{B''}) \rightarrow I'(1_{B'})I''(1_{B''}) = If.$$ 

By linearity, it follows that

$$I(1_{A(k)}g) \rightarrow Ig$$

for each simple function $g$ on $\Omega' \times \Omega''$ relative to $L', L''$. Consider each $h \in L$. Let $\varepsilon > 0$ be arbitrary. Since $(\Omega, L, I)$ is the completion of $(\Omega, L_0, I)$, where $L_0$ is the space
of simple functions on $\Omega' \times \Omega''$ relative to $L', L''$, it follows that $I|h - g| < \varepsilon$ for some $g \in L_0$. Hence
\[
|I_{1_{A(k)}}f - If| \leq |I_{1_{A(k)}}f - I_{1_{A(k)}}g| + |I_{1_{A(k)}}g - Ig| + |Ig - If| < \varepsilon
\]

\[
\leq |f - g| + |I_{1_{A(k)}}g - Ig| + |Ig - If| < 3\varepsilon
\]
for sufficiently large $k \geq 1$. Since $\varepsilon > 0$ is arbitrary, we conclude that $I(1_{A(k)})h \to Ih$. In particular, if $A$ is an arbitrary integrable subset of $\Omega$, we have $I(1_{A(k)})1_A \to I1_A$. In other words, $\mu(1_A A) \to \mu(A)$ for each integrable set $A \subset \Omega$. We have verified the conditions in Definition 1.8.12 for $(\Omega, L, I)$ to be $\sigma$-finite, with $(A_k)_{k=1,2,\ldots} \equiv (A_k' \times A_k'')_{k=1,2,\ldots}$ as an $I$-basis.

The next definition establishes some familiar notations for the special cases of the Lebesgue integration space on $\mathbb{R}^n$.

**Definition 4.10.14. (Lebesgue integration on $\mathbb{R}^n$).** The product integration space
\[
(\mathbb{R}^n, \mathcal{L}, \int \cdots \int dx_1 \cdots dx_n) \equiv \prod_{i=1}^{n} R_i \bigotimes_{i=1}^{n} L \bigotimes_{i=1}^{n} \int dx
\]
is called the Lebesgue integration space of dimension $n$. Similarly when $\mathbb{R}^n$ is replaced by an interval $\prod_{i=1}^{n} [s_i, t_i] \subset \mathbb{R}^n$. When confusion is unlikely we will also abbreviate $\int \cdots \int dx_1 \cdots dx_n$ to $\int dx$, with the understanding that the dummy variable $x$ is now a member of $\mathbb{R}^n$. An integrable function relative to $\int \cdots \int dx_1 \cdots dx_n$ will be called Lebesgue integrable.

**Corollary 4.10.15. (Power of Lebesgue integration space based on $\mathbb{R}^n$ is equal to the completion of Lebesgue integration on the locally compact metric space $\mathbb{R}^n$).** Let $n \geq 1$ be arbitrary. Then, in the notations of Definition 4.10.14, we have $C(\mathbb{R}^n) \subset \mathcal{L}$. Moreover, $(\mathbb{R}^n, C(\mathbb{R}^n), \int \cdots \int dx_1 \cdots dx_n)$ is an integration space, and its completion is equal to the Lebesgue integration space $(\mathbb{R}^n, \mathcal{L}, \int \cdots \int dx_1 \cdots dx_n)$.

**Proof.** Let $S_i \equiv R$ for each $i = 1, \ldots, n$. Let $S \equiv \mathbb{R}^n$. Proposition 4.4.12 then applies and yields the desired conclusions. □

**Definition 4.10.16. (Product of countably many complete integration spaces).** For each $n \geq 1$, let $(\Omega^{(i)}, L^{(i)}, I^{(i)})$ be a complete integration space. Consider the Cartesian product $\Omega' \equiv \prod_{i=1}^{n} \Omega^{(i)}$. Let $n \geq 1$ be arbitrary. Let $(\prod_{i=1}^{n} \Omega^{(i)}, \bigotimes_{i=1}^{n} L^{(i)}, \bigotimes_{i=1}^{n} I^{(i)})$ be the product of the first $n$ complete integration spaces. For each $g \in \bigotimes_{i=1}^{n} L^{(i)}$, define a function $\bar{f}$ on $\Omega'$ by $\text{doamin}(\bar{f}) \equiv \text{doamin}(g) \times \prod_{i=n+1}^{n} \Omega^{(i)}$, and by $\bar{f}(\omega_1, \omega_2, \ldots) \equiv g(\omega_1, \omega_2, \ldots)$ for each $(\omega_1, \omega_2, \ldots) \in \text{doamin}(\bar{f})$. Let
\[
G_n \equiv \{ \bar{f} : g \in \bigotimes_{i=1}^{n} L^{(i)} \}.
\]

Then $G_n \subset G_{n+1}$. Let $\mathcal{L} \equiv \bigcup_{n=1}^{\infty} G_n$ and define a function $\bar{T}: \mathcal{L} \to R$ by $\bar{T}(\bar{f}) \equiv (\bigotimes_{i=1}^{n} I^{(i)})(g)$ if $\bar{f} \in G_n$, for each $\bar{f} \in \mathcal{L}$. The next theorem says that $\mathcal{L}$ is a linear space, that $\bar{T}$ is a well defined linear function, and that $(\Omega', \mathcal{L}, \bar{T})$ is an integration space.
CHAPTER 4. INTEGRATION AND MEASURE

Let \((\prod_{i=1}^{\infty} \Omega^{(i)}, \otimes_{i=1}^{\infty} L^{(i)}, \otimes_{i=1}^{\infty} I^{(i)})\) denote the completion of \((\Omega, \mathcal{F}, \mathcal{F})\), and call it the product of the given sequence of complete integration spaces.

In the special case where \((\Omega^{(1)}, L^{(1)}, I^{(1)}) = (\Omega^{(2)}, L^{(2)}, I^{(2)}) = \cdots\) are all equal to the same integration space \((\Omega_0, L_0, I_0)\), then we write

\[
(\Omega_0^\infty, L_0^\infty, I_0^\infty) \equiv \left( \prod_{i=1}^{\infty} \Omega^{(i)}, \otimes_{i=1}^{\infty} L^{(i)}, \otimes_{i=1}^{\infty} I^{(i)} \right)
\]

and call it the countable power of the integration space \((\Omega_0, L_0, I_0)\).

\[\Box\]

**Theorem 4.10.17.** (Countable product of complete integration spaces is well-defined). Assume the same terms and notations in Definition 4.10.16. Then the following holds.

1. The set \(\mathcal{T}\) of functions is a linear space. Moreover, \(\mathcal{T}\) is a well-defined linear function, and \((\Omega, \mathcal{F}, \mathcal{F})\) is an integration space.

2. Let \(N \geq 1\) be arbitrary. Let \(Z^{(N)}\) be a measurable function on \((\Omega^{(N)}, L^{(N)}, I^{(N)})\) with values in some complete metric space \((S, d)\). Define the function \(Z^{(N)}(\omega) \equiv Z^{(N)}(\omega_j)\) for each \(\omega \equiv (\omega_1, \omega_2, \cdots) \in \Omega\) such that \(\omega_N \in \text{domain}(Z^{(N)})\). Let \(M \geq 1\) be arbitrary. Let \(f_j \in C_{\text{ub}}(S, d)\) be arbitrary for each \(j \leq M\). Then

\[
\mathcal{T}(\prod_{j=1}^{M} f_j(Z^{(j)}) = \prod_{j=1}^{M} f_j(\mathcal{T}(Z^{(j)}))
\]

3. For each \(N \geq 1\), the function \(Z^{(N)}\) is measurable on the countable product space \((\prod_{i=1}^{\infty} \Omega^{(i)}, \otimes_{i=1}^{\infty} L^{(i)}, \mathcal{T})\).

**Proof.** 1. Obviously \(G_n\) and \(\mathcal{T}\) are linear spaces. Suppose \(\overline{\mathcal{F}} = \overline{\mathcal{H}}\) for some \(\overline{\mathcal{F}} \in G_n\) and \(\overline{\mathcal{H}} \in G_m\) with \(n \leq m\). Then

\[
h(\omega_1, \cdots, \omega_m) \equiv \overline{h}(\omega_1, \omega_2, \cdots) = \overline{\mathcal{F}}(\omega_1, \omega_2, \cdots) = g(\omega_1, \cdots, \omega_m)
\]

where \(A = \prod_{i=n+1}^{\infty} \Omega^{(i)}\). Hence

\[
\mathcal{T}(\overline{\mathcal{F}}) \equiv \left( \bigotimes_{i=1}^{m} I^{(i)}(h) = \left( \bigotimes_{i=1}^{m} I^{(i)}(g \otimes 1_A) = \left( \bigotimes_{i=1}^{n} I^{(i)} \otimes \bigotimes_{i=n+1}^{m} I^{(i)}(g \otimes 1_A)
\right)
\right)
\]

Thus the function \(\mathcal{T}\) is well defined. Linearity of \(\mathcal{T}\) is obvious. The verification of the other conditions in Definition 4.3.1 is straightforward. Accordingly, \((\Omega, \mathcal{F}, \mathcal{F})\) is an integration space.

2. In view of Fubini’s Theorem 4.10.8 the proof of Assertions 2 and 3 are straightforward and omitted. \[\Box\]

Yuen-Kwok Chan 108 Constructive Probability
Following are two results which will be convenient for future reference.

**Proposition 4.10.18. (Region below graph of measurable function is measurable in product space).** Let \((Q,L,\lambda)\) be a complete integration space which is \(\sigma\)-finite. Let \((\Theta,\lambda,\int d\lambda)\) be the Lebesgue integration space based on \(\Theta \equiv R\) or \(\Theta \equiv [0,1]\). Let \(\lambda : Q \rightarrow R\) be an arbitrary measurable function on \((Q,L,\lambda)\). Then the sets

\[
A_{\lambda} \equiv \{(t,\theta) \in Q \times \Theta : \theta \leq \lambda(t)\}
\]

and

\[
A_{\lambda}' \equiv \{(t,\theta) \in Q \times \Theta : \theta < \lambda(t)\}
\]

are measurable on \((Q,L,\lambda) \otimes (\Theta,\lambda,\lambda_0)\). Suppose, in addition, that \(\lambda\) is a non-negative integrable function. Then the sets

\[
B_{\lambda} \equiv \{(t,\theta) \in Q \times \Theta : 0 \leq \theta \leq \lambda(t)\}
\]

and

\[
B_{\lambda}' \equiv \{(t,\theta) \in Q \times \Theta : 0 \leq \theta < \lambda(t)\}
\]

are integrable, with

\[
(I \otimes I_0)B_{\lambda} = I_0 = (I \otimes I_0)B_{\lambda}'.
\]

**Proof.** Let \(g\) be the identity function on \(\Theta\), with \(g(\theta) \equiv \theta\) for each \(\theta \in \Theta\). By Proposition [4.10.1], \(g\) and \(\lambda\) can be regarded as measurable functions on \(Q \times \Theta\). Define the function \(f : Q \times \Theta \rightarrow R\) by \(f(t,\theta) \equiv g(\theta) - \lambda(t) \equiv \theta - \lambda(t)\) for each \((t,\theta) \in Q \times \Theta\). Then \(f\) is the difference of two real valued measurable functions on \(Q \times \Theta\). Hence \(f\) is measurable. Therefore there exists a sequence \((a_n)_{n=1,2,\ldots}\) in \((0,\infty)\) with \(a_n \downarrow 0\) such that \((f \leq a_n)\) is measurable for each \(n \geq 1\). We will write \(a_n\) and \(a(n)\) interchangeably.

Let \(A \subset Q\) and \(B \subset \Theta\) be arbitrary integrable subsets of \(Q\) and \(\Theta\) respectively. Let \(h : \Theta \rightarrow \Theta\) be the identity function, with \(h(\theta) \equiv \theta\) for each \(\theta \in \Theta\). Let \(m \geq n\) be arbitrary. Then

\[
I \otimes I_0(1_{\{f \leq a(n)\}(A \times B)} - 1_{\{f \leq a(m)\}(A \times B)})
\]

\[
= I \otimes I_0(1_{\{a(m) \leq f < a(n)\}(A \times B)})
\]

\[
= I \otimes I_0(1_{\{\lambda - a(n) \leq h < \lambda - a(m)\}(A \times B)})
\]

\[
= I(1_A(\int_{[\lambda - a(n),\lambda - a(m)]} 1_B(\theta)d\theta)).
\]

Since, for each \(t \in Q\), the Lebesgue measure

\[
I_0[\lambda(t) - a_n, \lambda(t) - a_m] = (a_n - a_m) \downarrow 0
\]

as \(n \rightarrow \infty\), and since \(1_B\) is integrable, Proposition [3.7.2] implies that

\[
\int_{[\lambda - a(n),\lambda - a(m)]} 1_B(\theta)d\theta \downarrow 0
\]

uniformly on \(Q\). Since \(1_A\) is integrable, the Dominated Convergence Theorem implies that the right-hand side of equality [4.10.6] converges to 0 as \(n \rightarrow \infty\). Consequently,
CHAPTER 4. INTEGRATION AND MEASURE

$I \otimes I_0(1_{f \leq a(n)})(A \times B)$ converges as $n \to \infty$. Therefore, by the Monotone Convergence Theorem, the limit $1_{f \leq 0}(A \times B)$ is integrable on $Q \times \Theta$.

Now let $C$ be an arbitrary integrable subset of $Q \times \Theta$. Let $(A_i)_{i=1,2,\ldots}$ and $(B_i)_{i=1,2,\ldots}$ be $I$-bases of the $\sigma$-finite integration spaces $(Q,L,I)$ and $(\Theta,\Lambda,I_0)$ respectively. Then, by Proposition 4.10.13, $Q \times \Theta$ is $\sigma$-finite with an $I$-basis $(A_i \times B_i)_{i=1,2,\ldots}$. By the previous paragraph, $1_{f \leq 0}(A(e) \times B(e))C = 1_{f \leq 0}(A(e) \times B(e))1_C$ is integrable on $Q \times \Theta$, for each $i \geq 1$. Moreover, as $i, j \to \infty$ with $j \geq i$, we have

$$0 \leq I_{1_{f \leq 0}(A(e) \times B(e))C} - I_{1_{f \leq 0}(A(e) \times B(e))} \leq I_{1_{C(A(e) \times B(e))} - I_{1_{C(A(e) \times B(e))}}} \to 0$$

Hence, by the Monotone Convergence Theorem, $1_{f \leq 0}(A(e) \times B(e))$ is integrable, where $D \equiv \bigcup_{i=1}^{\infty} (A_i \times B_i)$ is a full set. Consequently, $1_{f \leq 0}C$ is integrable. In other words, $1_{f \leq 0}1_C$ is integrable. Since the integrable subset $C$ of $Q \times \Theta$ is arbitrary, we conclude that $1_{f \leq 0}$ is measurable. Equivalently, $(f \leq 0)$ is measurable. Recalling the definition of $f$ at the beginning of this proof, we obtain

$$A_\lambda = \{(t, \theta) \in Q \times \Theta : \theta - \lambda(t) \leq 0\} = \{(t, \theta) \in Q \times \Theta : 0 \leq f(t, \theta)\} \equiv (f \leq 0),$$

whence $A_\lambda$ is measurable. Similarly $A'_\lambda$ is measurable.

Suppose, in addition, that $\lambda$ is a non-negative integrable function. Then, for each $t \in Q$, we have

$$\int 1_{B(\lambda)}(t, \theta) d\theta = \int (1_{A(\lambda)}(t, \theta) - 1_{A(0)}(t, \theta)) d\theta = \int_{(0,\lambda(t))} d\theta = \lambda(t).$$

Fubini’s Theorem therefore yields $(I \otimes I_0)B_\lambda = I\lambda$, the first half of equality 4.10.3. The second half is similarly proved.

\[ \square \]

**Proposition 4.10.19. (Regions between graphs of integrable functions).** Let $(Q,L,I)$ be a complete integration space which is $\sigma$-finite. Suppose $\lambda_0 \equiv 0 \leq \lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_n$ are integrable functions with $\lambda_n \leq 1$. Define $\lambda_{n+1} \equiv 1$. For each $k = 1, \cdots, n + 1$, define

$$\Delta_k \equiv \{(t, \theta) \in Q \times R : \theta \in (\lambda_{k-1}(t), \lambda_k(t))\}.$$

Then $\Delta_1, \cdots, \Delta_{n+1}$ are mutually exclusive measurable subsets in $(Q,L,I) \otimes (R,M,J)$ whose union is a full set. Moreover, $\Delta_1, \cdots, \Delta_n$ are integrable in $(Q,L,I) \otimes (R,M,J)$, with integrals equal to $I\lambda_1, I\lambda_2 - I\lambda_1, \cdots, I\lambda_n - I\lambda_{n-1}$ respectively.

**Proof.** Use Proposition 4.10.18 above. \[ \square \]

### 4.11 Supplements and Exercises

**Exercise 4.11.1.** Let $X$ be a function defined a.e. on a complete integration space $(\Omega, L, I)$. Show that $X$ is measurable iff it satisfies the condition (*) that for each integrable set $A$ and $\varepsilon > 0$ there exist an integrable set $B$ and an integrable function $Y$
such that $B \subset A$, $\mu(AB^c) < \varepsilon$, and $|X - Y| < \varepsilon$ on $B$. Said condition (*) is used as the definition of a measurable function in [Bishop and Bridges 1985]. Thus our definition of a measurable function, which we find more convenient, is equivalent to the one in [Bishop and Bridges 1985].

**Hint.** Suppose $X$ is measurable. Let $A$ be any integrable set, and let $\varepsilon > 0$ be arbitrary. By condition (ii) in Definition 4.8.1, there exists $a > 0$ so large that $\mu(|X| \geq a)A < \varepsilon$. Define $B \equiv (|X| < a)A$. Then $B$ is integrable set, and $\mu(AB^c) < \varepsilon$. Define $Y \equiv (-a) \vee X \wedge a$. Then $Y$ is integrable by condition (i) in Definition 4.8.1. Moreover, $Y - X = 0$ on $B$. This verifies condition (*).

Conversely, suppose condition (*) holds. Let $\varepsilon > 0$ be arbitrary. Let the integrable set $B$ and the integrable function $Y$ satisfy condition (*) for $\varepsilon$. Let $a > 0$ be arbitrary. Write $X_a \equiv (-a) \vee X \wedge a$ and $Y_a \equiv (-a) \vee Y \wedge a$. Then

$$|X_a1_A - Y_a1_A|$$

$$\leq |X_a1_A - X_a1_B| + |X_a1_B - Y_a1_B| + |Y_a1_B - Y_a1_A|$$

$$\leq a1_{AB^c} + \varepsilon 1_B + a1_{AB^c}$$

where

$$I(a1_{AB^c} + \varepsilon 1_B + a1_{AB^c}) \leq a\varepsilon + \varepsilon \mu(A) + a\varepsilon \to 0$$

as $\varepsilon \to 0$ with $a$ fixed. Hence $(-a) \vee X1_A \wedge a = X_a1_A \in L$ by Theorem 4.5.9. This verifies condition (ii) in Definition 4.8.1. Moreover, $X_a \wedge a \in L$ by Chebychev’s inequality, we have $\mu(|Y| > a) \leq I|Y|/a < \varepsilon$. Hence

$$\mu(|X| > a + 1)A \leq \mu(|X| > a + 1)B + \mu(AB^c)$$

$$\leq \mu(|Y| > a)B + \mu(AB^c) < I|Y|/a + \varepsilon < 2\varepsilon$$

Since $\varepsilon > 0$ is arbitrary, we have $\mu(|X| > a)A \to 0$ as $a \to \infty$, verifying condition (ii) in Definition 4.8.1. Hence $X$ is a measurable function. □

**Exercise 4.11.2.** Let $A \subset B$ be integrable sets in a complete integration space $(\Omega, L, I)$ such that $\mu A = \mu B$. Then $A \cup B^c$ is a full set.

*Hint* $\mu(BA^c) = \mu B - \mu A = 0$. Hence $BA^c$ is a null set, and its complement $A \cup B^c$ is a full set. □
Chapter 5

Probability Space

In this chapter, we specialize the study of complete integration spaces to the case where the constant function 1 is integrable and has integral equal to 1. An integrable function can then be interpreted as an observable in a probabilistic experiment which, on repeated observations, has an expected value given by its integral. Likewise, an integrable set can be interpreted as an event, and its measure as the probability for said event to occur. We will transition from terms used in measure theory to commonly used terms in probability theory. Then we will introduce and study more concepts and tools common in probability theory.

In this chapter, unless otherwise specified, $(S, d)$ will denote a complete metric space, not necessarily locally compact. Let $x_0 \in S$ be an arbitrary, but fixed, reference point. Recall that $C_{ub}(S) \equiv C_{ub}(S, d)$ stands for the space of bounded and uniformly continuous functions on $S$, and that $C(S) \equiv C(S, d)$ stands for the space of continuous functions on $S$ with compact support.

Let $n \geq 1$ be arbitrary. Define the auxiliary function $h_n \equiv 1 \wedge (1 + n - d(\cdot, x_0))_+$ $\in C_{ub}(S)$. Note that the function $h_n$ has bounded support. Hence $h_n \in C(S)$ if $(S, d)$ is locally compact.

Separately, for each integration space $(\Omega, L, J)$, we will let $(\Omega, T, J)$ denote its complete extension.

5.1 Random Variables

Definition 5.1.1. (Probability Space and r.v.’s) Henceforth, unless otherwise specified, $(\Omega, L, E)$ will denote a complete integration space in which the constant function 1 is integrable, with $E1 = 1$. Then $(\Omega, L, E)$ is called a probability space. The integration $E$ is called an expectation, and the integral $EX$ of each $X \in L$ is called the expected value of $X$.

A measurable function $X$ on $(\Omega, L, E)$ with values in a complete metric space $(S, d)$ is called a random variable, or r.v. for abbreviation. Two r.v.’s are considered equal if they have equal values on a full subset of $\Omega$. A real-valued measurable function $X$ on $(\Omega, L, E)$ is then called a real random variable, or r.r.v. for abbreviation. An
integrable function $X$ is called an \textit{integrable real random variable}, its integral $EX$ called its \textit{expected value}.

A measurable set is sometimes called an \textit{event}. It is then integrable because $1_A \leq 1$, and its measure $\mu(A)$ is called its \textit{probability} and denoted by $P(A)$ or $PA$. The function $P$ on the set of measurable sets is called the \textit{probability function} corresponding to the expectation $E$. Sometimes we will write $E(A)$ for $P(A)$. The set $\Omega$ is called the \textit{sample space}, a point $\omega \in \Omega$ called a \textit{sample} or an \textit{outcome}. If an outcome $\omega$ belongs to an event $A$, the event $A$ is said to \textit{occur} for $\omega$, and $\omega$ is said to \textit{realize} $A$.

The phrases “\textit{almost surely}”, “\textit{almost sure}”, and the abbreviation “a.s.” will stand for “almost everywhere” or its abbreviation “a.e.”. Henceforth, unless otherwise specified, equality of r.v.’s and equality of events will mean a.s. equality, and the term “complement” for events will stand for “measure-theoretic complement”. If $X$ is an integrable r.r.v. and $A, B, \cdots$ are events, we will sometimes write $E(X; A, B, \cdots)$ for $EX1_{AB\cdots}$.

Let $X \in L$ be arbitrary. We will sometimes use the more suggestive notation
$$\int E(d\omega)X(\omega) \equiv EX,$$
where $\omega$ is a dummy variable. For example, if $Y \in L \otimes L \otimes L$, we can define a function $Z \in L \otimes L$ by the formula
$$Z(\omega_1, \omega_3) \equiv \int E(d\omega_2)Y(\omega_1, \omega_2, \omega_3) \equiv EY(\omega_1, \cdot, \omega_3)$$
for each $(\omega_1, \omega_3) \in \Omega^2$ for which the right-hand side is defined.

In [Billingsley 1968], a r.v. is called a random element, and a r.r.v. is called a random variable. Our usage of the two terms follows [Neveu 1965], for the benefit of both acronyms.

Being a measurable function, a r.v. inherits all the definitions and properties for measurable functions developed in preceding chapters. In particular, since the constant function 1 is integrable, $\Omega$ is an integrable set, with 1 as probability, a probability space is trivially $\sigma$-finite. Therefore r.v.’s inherit the theorems on measurable functions which require a $\sigma$-finite integration space.

First we restate Definition 4.8.10 of regular points in a simpler form, in the context of a probability space. The reader can verify that, in the present context, the restated definition below is equivalent to the

\textbf{Definition 5.1.2. (Regular and continuity points of a r.r.v.).} Let $(\Omega, L, E)$ be an arbitrary probability space. Let $X$ be a r.r.v. on $(\Omega, L, E)$. Then a point $t \in R$ is a regular point of $X$ if (i) there exists a sequence $(s_n)_{n=1,2,\cdots}$ of real numbers decreasing to $t$ such that $(X \leq s_n)$ is a measurable set for each $n \geq 1$ and such that $\lim_{n \to \infty} P(X \leq s_n)$ exists, and (ii) there exists a sequence $(r_n)_{n=1,2,\cdots}$ of real numbers increasing to $t$ such that $(X \leq r_n)$ is measurable for each $n \geq 1$ and such that $\lim_{n \to \infty} P(X \leq r_n)$ exists. If in addition the two limits in (i) and (ii) are equal, then we call $t$ a continuity point of the r.r.v. $X$. 

Yuen-Kwok Chan 114 Constructive Probability
Note that Condition (i) implies that, if \( t \in \mathbb{R} \) is a regular point of a r.r.v. \( X \), then \((X \leq t)\) is measurable, with
\[
P(X \leq s_n) \downarrow P(X \leq t)
\]
for each sequence \((s_n)_{n=1,2,\ldots}\) satisfying Condition (i), thanks to the Monotone Convergence Theorem. Similarly, in that case \((X < t)\) is measurable, with
\[
P(X \leq r_n) \uparrow P(X < t)
\]
for each sequence \((r_n)_{n=1,2,\ldots}\) satisfying Condition (ii). Consequently, \((X = t)\) is measurable, and \(P(X = t) = 0\) if \( t \) is a continuity point. □

We re-iterate Convention 4.8.15 regarding regular points, now in the context of a probability space and r.r.v.’s.

**Definition 5.1.3. (Convention regarding regular points of r.r.v.’s).** Let \( X \) be an arbitrary r.r.v. When the measurability of the set \((X < t)\) or \((X \leq t)\) is required in a discussion for some \( t \in \mathbb{R} \), it is understood that the real number \( t \) has been chosen from the regular points of the r.r.v. \( X \).

For example, a sequence of statements like “Let \( t \in \mathbb{R} \) be arbitrary. \( \ldots \) Then \( P(X_i > t) < a \) for each \( i \geq 1 \)” means “Let \( t \in \mathbb{R} \) be arbitrary, such that \( t \) is a regular point for \( X_i \) for each \( i \geq 1 \). \( \ldots \) Then \( P(X_i > t) < a \) for each \( i = 1,2,\ldots \)”. The purpose of this convention is to obviate unnecessary distraction from the main arguments.

If, for another example, the measurability of the set \((X \leq 0)\) is required in a discussion, we would need to first supply a proof that 0 is a regular point of \( X \), or, instead of \((X \leq 0)\), use \((X \leq a)\) as a substitute, where \( a \) is some regular point near 0. Unless the exact value 0 is essential to the discussion, the latter, usually effortless, alternative will be used. The implicit assumption of regularity of the point \( a \) is clearly possible, for example, when we have the freedom to pick the number \( a \) from some open interval, thanks to Proposition 4.8.11 which says that all but countably many real numbers are regular points of \( X \).

Classically, all \( t \in \mathbb{R} \) are regular points for each r.r.v. \( X \), and so this convention would be redundant classically. □

In the case of a measurable indicator \( X \), it is easily seen that 0 and 1 are regular points. We recall that the indicator \( 1_A \) and the complement \( A^c \) of an event are uniquely defined relative to a.s. equality.

**Proposition 5.1.4. (Basic Properties of r.v.’s).** Let \((\Omega, L, E)\) be a probability space.

1. Suppose \( A \) is an event. Then \( A^c \) is an event. Moreover \((A^c)^c = A\) and \( P(A^c) = 1 - P(A)\).

2. A subset \( A \) of \( \Omega \) is a full set iff it is an event with probability 1.

3. Let \((S,d)\) be a complete metric space. A function \( X : \Omega \to S \) is a r.v. with values in \((S,d)\) iff (i) \( f(X) \in L \) for each \( f \in C_{\text{ub}}(S,d) \), and (ii) \( P(d(X,x_c) \geq a) \to 0 \) as \( a \to \infty \). Note that if \( d \) is bounded, then Condition (ii) is automatically satisfied.
CHAPTER 5. PROBABILITY SPACE

4. Let $(S,d)$ be a complete metric space, with a reference point $x_0$. For each $n \geq 1$, define $h_n \equiv 1 \wedge (1 + n - d(\cdot,x_0))_+ \in C_{ab}(S)$. Then a function $X : \Omega \to S$ is a r.v. iff (i) $f(X) \in L$ for each $f \in C_{ab}(S)$ and (iii) $Eh_n(X) \uparrow 1$ as $n \to \infty$. In that case, we have $E[f(X) - f(X)h_n(X)] \to 0$, where $fh_n \in C(S)$.

5. Let $(S,d)$ be a locally compact metric space, with a reference point $x_0$. For each $n \geq 1$, define the function $h_n$ as above. Then $h_n \in C(S)$. A function $X : \Omega \to S$ is a r.v. iff (iv) $f(X) \in L$ for each $f \in C(S)$ and (iii) $Eh_n(X) \uparrow 1$ as $n \to \infty$. In that case, for each $f \in C_{ab}(S)$, there exists a sequence $(g_n)_{n=1,2,...}$ in $C(S)$ such that $E[f(X) - g_n(X)] \to 0$.

6. If $X$ is an integrable r.v. and $A$ is an event, then $EX = E(X;A) + E(X;A^c)$.

7. A point $t \in R$ is a regular point of a r.v. $X$ iff it is a regular point relative to $\Omega$.

8. If $X$ is a r.v. such that $(t - \varepsilon < X < t) \cup (t < X < t + \varepsilon)$ is a null set for some $t \in R$ and $\varepsilon > 0$, then the point $t \in R$ is a regular point of $X$.

Proof. 1. Suppose $A$ is an event with indicator $1_A$ and complement $A^c = (1_A = 0)$. Because $1$ is integrable, so is $1 - 1_A$. At the same time $A^c = (1_A = 0) = (1 - 1_A = 1)$. Hence $A^c$ is an event with indicator $1 - 1_A$. Moreover $P(A^c) = E(1 - 1_A) = 1 - P(A)$. Repeating the argument with the event $A^c$, we see that

$$\text{(A')^c = (1 - (1 - 1_A) = 1) = (1_A = 1) = A}$$

2. Suppose $A$ is a full set. Since any two full sets are equal a.s., we have $A = \Omega$ a.s. Hence $P(A) = P(\Omega) = 1$. Conversely, if $A$ is an event with $P(A) = 1$ then, according to Assertion 1, $A^c$ is a null set with $A = (A^c)^c$. Hence by Proposition 5.5, $A$ is a full set.

3. Suppose $X$ is a r.v. Since $\Omega$ is an integrable set, Conditions (i) and (ii) hold as special cases of Conditions (i) and (ii) in Definition 4.8.1 when we take $A = \Omega$.

Conversely, suppose conditions (i) and (ii) hold. Let $f \in C_{ab}(S)$ be arbitrary and let $A$ be an arbitrary integrable set. Then $f(X) \in L$ by condition (i), and so $f(X)1_A \in L$. Moreover $P(\{x_0 : \varepsilon \geq a\}) \leq P(\{x_0 : X \geq a\}) \to 0$ as $a \to \infty$. Thus conditions (i) and (ii) in Definition 4.8.1 are established for $X$ to be a measurable function. In other words, $X$ is a r.v. Consequently, Assertion 3 is proved.

4. Given Condition (i), the Conditions (ii) and (iii) are equivalent to each other, thanks to 4.8.3. Thus Assertion 4 follows from Assertion 3.

5. Suppose $(S,d)$ is locally compact. Assume that Condition (iii) holds. In view of Assertion 4, we need only verify that Conditions (i) and (iv) are then equivalent. Trivially Condition (i) implies Condition (iv). Conversely, suppose Condition (iv) holds. Let $f \in C_{ab}(S)$ be arbitrary. We need to prove that $f(X) \in L$. There is no loss of generality in assuming that $0 \leq f \leq b$ for some $b > 0$. Then

$$E(f(X)h_m(X) - f(X)h_n(X)) \leq bE(h_m(X) - h_n(X)) \to 0$$

as $m \geq n \to \infty$, thanks to Condition (iii). Thus $E(f(X)h_n(X)$ converges as $n \to \infty$. Hence the Monotone Convergence Theorem implies that $\lim_{n \to \infty} f(X)h_n(X)$ is integrable. Since $\lim_{n \to \infty} h_n = f$ on $S$, so $f(X) = \lim_{n \to \infty} f(X)h_n(X) \in L$. Thus Condition (i) holds. Summing up, given Condition (iii), the Conditions (i) and (iv) are
equivalent to each other, as alleged. The Monotone Convergence Theorem implies also that \( E(f(X)h_n(X) - f(X)) \to 0 \), where \( f \) is integrable, define \( \| f \|_p = (E|f|^p)^{1/p} \). Define \( L_p \) to be the family of all r.r.v. \( X \) such that \( X^p \) is integrable. We will refer to \( \| X \|_p \) as the \( L_p \)-norm of \( X \). Let \( n \geq 1 \) be an integer. If \( X \in L_n \), then \( E|X|^n \) is called the \( n \)th absolute moment, and \( EX^n \) the \( n \)th moment, of \( X \). If \( X \in L_1 \), then \( E|X| \) is also called the mean of \( X \).

If \( X, Y \in L_2 \), then, according to Proposition 5.1.7 below, \( X, Y \), and \( (X - EX)(Y - EY) \) are integrable. Then \( E(X - EX)^2 \) and \( E(X - EX)(Y - EY) \) are respectively called the variance of \( X \) and the covariance of \( X \) and \( Y \). The square root of the variance of \( X \) is called the standard deviation of \( X \).

Next are several basic inequalities for \( L_p \).

**Proposition 5.1.7. (Basic inequalities in \( L_p \)).** Let \( p, q \in [1, \infty) \) be arbitrary.

1. **(Hölder’s inequality)** Suppose \( p, q > 1 \) and \( \frac{1}{p} + \frac{1}{q} = 1 \). If \( X \in L_p \) and \( Y \in L_q \), then \( XY \in L_1 \) and \( E|XY| \leq \| X \|_p \| Y \|_q \). The special case where \( p = q = 2 \) is referred to as the Cauchy-Schwarz inequality.

2. **(Minkowski’s inequality)** If \( X, Y \in L_p \), then \( X + Y \in L_p \) and \( \| X + Y \|_p \leq \| X \|_p + \| Y \|_p \).
CHAPTER 5. PROBABILITY SPACE

3. (Lyapunov’s inequality) If $p \leq q$ and $X \in L_q$, then $X \in L_p$ and $\|X\|_p \leq \|X\|_q$

Proof. 1. Write $\alpha, \beta$ for $\frac{1}{p}, \frac{1}{q}$ respectively. Then $x^\alpha y^\beta \leq \alpha x + \beta y$ for non-negative $x, y$. This can be seen by noting that, with $y$ fixed, the function $f$ defined by $f(x) \equiv \alpha x + \beta y - x^\alpha y^\beta$ is equal to 0 at $x = y$, is decreasing for $x < y$, and is increasing for $x > y$. Let $a, b \in R$ be arbitrary with $a > \|X\|_p$ and $b > \|Y\|_q$. Replacing $x, y$ by $|X/a|^p, |Y/b|^q$ respectively, we see that

$$|XY| \leq (\alpha|X/a|^p + \beta|Y/b|^q)ab$$

It follows that $|XY|$ is integrable, with integral bounded by

$$E|XY| \leq (\alpha \|X\|_p^p/a^p + \beta \|Y\|_q^q/b^q)ab$$

As $a \to \|X\|_p$ and $b \to \|Y\|_q$, the last bound approaches $\|X\|_p \|Y\|_q$.

2. Suppose first that $p > 1$. Let $q = \frac{p}{p-1}$. Then $\frac{1}{p} + \frac{1}{q} = 1$. Because $\|X + Y\|^p \leq (2(|X| \lor |Y|))^p \leq 2^p(|X|^p + |Y|^p)$, we have $X + Y \in L_p$. It follows trivially that $|X + Y|^p \leq \|X\|_p \|Y\|_q$. Applying Hölder’s inequality, we estimate

$$E|X + Y|^p \leq E|X|^{p-1}|Y| + E|X + Y|^{p-1}|Y|$$

$$\leq (E|X + Y|^{(p-1)/q})^{1/q}(\|X\|_p + \|Y\|_p)$$

$$= (E|X + Y|^p)^{1/q}(\|X\|_p + \|Y\|_p)$$

(5.1.1)

Suppose $\|X + Y\|_p > \|X\|_p + \|Y\|_p$. Then inequality 5.1.1, when divided by $(E|X + Y|^p)^{1/q}$, would imply $\|X + Y\|_p = (E|X + Y|^p)^{1-1/q} \leq \|X\|_p + \|Y\|_p$, a contradiction. This proves Minkowski’s inequality for $p > 1$. Suppose now $p \geq 1$. Then $|X|^r, |Y|^r \in L_{pq}$ for any $r < 1$. The preceding proof of the special case of Minkowski’s inequality for the exponent $\frac{p}{r} > 1$ therefore implies

$$(E(|X|^r + |Y|^r)^{p/r})^{r/p} \leq (E(|X|^p)^{r/p} + (E(|Y|^p)^{r/p})^{r/p}$$

(5.1.2)

Since

$$\left(\|X\| + \|Y\|\right)^{p/r} \leq 2^{p/r}(\|X\| \lor \|Y\|)^{p/r}$$

$$= 2^{p/r}(\|X\| \lor \|Y\|)^{p/r} \leq 2^{p/r}(\|X\| + \|Y\|) \in L$$

we can let $r \to 1$ and apply the Dominated Convergence Theorem to the left-hand side of inequality 5.1.2. Thus we conclude that $(\|X\| + \|Y\|)^{p/r} \in L$, and that $(E(|X| + |Y|)^{p/r})^{1/p} \leq (E(|X|^p)^{1/p} + (E(|Y|^p)^{1/p})^{1/r}$. Minkowski’s inequality is proved.

3. Since $|X|^p \leq 1 \lor |X|^q \in L$, we have $X \in L_p$. Suppose $E|X|^p > (E|X|^q)^{p/q}$. Let $r \in (0, p)$ be arbitrary. Clearly $|X|^r \in L_{pq}$. Applying Hölder’s inequality to $|X|^r$ and 1, we obtain

$$E|X|^r \leq (E|X|^q)^{r/q}$$

At the same time $|X|^r \leq 1 \lor |X|^q \in L$. As $r \to p$ the Dominated Convergence Theorem yields $E|X|^p \leq (E|X|^q)^{p/q}$, establishing Lyapunov’s inequality. \qed

Yuen-Kwok Chan 118 Constructive Probability
Next we restate and simplify some definitions and theorems of convergence of measurable functions, in terms of r.v.'s

**Definition 5.1.8. (Convergence in probability, a.u., a.s., and in $L_i$).** For each $n \geq 1$, let $X_n, X$ be a functions on the probability space $(\Omega, L, E)$, with values in the complete metric space $(S, d)$.

1. The sequence $(X_n)$ is said to converge to $X$ almost uniformly (a.u.) on the probability space $(\Omega, L, E)$ if $X_n \to X$ a.u. on the integration space $(\Omega, L, E)$. In that case we write $X = \text{a.u. lim}_{n \to \infty} X_n$. Since $(\Omega, L, E)$ is a probability space, $\Omega$ is a full set. It can therefore be easily verified that $X_n \to X$ a.u. iff for each $\varepsilon > 0$, there exists a measurable set $B$ with $P(B) < \varepsilon$ such that $X_n$ converges to $X$ uniformly on $B$.

2. The sequence $(X_n)$ is said to converge to $X$ in probability on the probability space $(\Omega, L, E)$ if $X_n \to X$ in measure. Then we write $X_n \to X$ in probability. It can easily be verified that $X_n \to X$ in probability iff for each $\varepsilon > 0$, there exists $p \geq 1$ so large that, for each $n \geq p$, there exists a measurable set $B_n$ with $P(B_n) < \varepsilon$ such that $B_n \subset (d(X_n, X) \leq \varepsilon)$.

3. The sequence $(X_n)$ is said to be Cauchy in probability if it is Cauchy in measure. It can easily be verified that $(X_n)$ is Cauchy in probability iff for each $\varepsilon > 0$, there exists $p \geq 1$ so large that for each $m, n \geq p$, there exists a measurable set $B_{m,n}$ with $P(B_{m,n}) < \varepsilon$ such that $B_{m,n} \subset (d(X_n, X_m) \leq \varepsilon)$.

4. The sequence $(X_n)$ is said to converge to $X$ almost surely (a.s.) if $X_n \to X$ a.e.

**Proposition 5.1.9. (a.u. Convergence implies convergence in probability, etc).** For each $n \geq 1$, let $X, X_n$ be functions on the probability space $(\Omega, L, E)$, with values in the complete metric space $(S, d)$. Then the following holds.

1. If $X_n \to X$ a.u. then (i) $X$ is defined a.e., (ii) $X_n \to X$ in probability, and (iii) $X_n \to X$ a.s.

2. If (i) $X_n$ is a r.v. for each $n \geq 1$, and (ii) $X_n \to X$ in probability, then $X$ is a r.v.

3. If (i) $X_n$ is a r.v. for each $n \geq 1$, and (ii) $X_n \to X$ a.u., then $X$ is a r.v.

4. If (i) $X_n$ is a r.v. for each $n \geq 1$, and (ii) $(X_n)_{n=1,2,\ldots}$ is Cauchy in probability, then there exists a subsequence $(X_{n(k)})_{k=1,2,\ldots}$ such that $X = \lim_{k \to \infty} X_{n(k)}$ is a r.v., with $X_{n(k)} \to X$ a.u. and $X_{n(k)} \to X$ a.s. Moreover, $X_n \to X$ in probability.

5. Suppose (i) $X_n, X$ are r.r.v.'s for each $n \geq 1$, (ii) $X_n \uparrow X$ in probability, and (iii) $a \in \mathbb{R}$ is a regular point of $X_n, X$ for each $n \geq 0$. Then $P((X_n > a)B \uparrow P((X > a)B)$ for each measurable set $B$.

**Proof.** Assertions 1-3 are trivial consequences of the corresponding assertions in Proposition 4.9.2. Assertion 4 is a trivial consequence of Proposition 4.9.3. It remains to prove Assertion 5. To that end, let $\varepsilon > 0$ be arbitrary. Then, because $a$ is a regular point of the r.r.v. $X$, there exists $a' > a$ such that $P(a' \geq X > a) < \varepsilon$. Since, by hypothesis, $X_n \uparrow X$ in probability, there exists $m \geq 1$ so large that $P(X - X_n > a' - a) < \varepsilon$ for each $n \geq m$. Now let $n \geq m$ be arbitrary. Let $A \equiv (a' \geq X > a) \cup (X - X_n > a' - a)$. Then $P(A) < 2\varepsilon$. Moreover,

$$P((X > a)B) - P((X_n > a)B) \leq P(X > a; X_n \leq a)$$
= P((X > a; X_n ≤ a)A^c) + P(A)
< P((X > a) ∩ (X_n ≤ a) ∩ ((a' < X) ∪ (X ≤ a))) ∩ (X - X_n ≤ a' - a)) + 2ε
= P((X_n ≤ a) ∩ ((a' < X) ∩ (X - X_n ≤ a' - a)) + 2ε
= 0 + 2ε = 2ε.

Since P(A) < 2ε is arbitrarily small, we see that P((X_n > a)B) ↑ P((X > a)B), as alleged in Assertion 5.

The next definition and proposition shows that convergence in probability can be metrized.

**Definition 5.1.10. (Probability metric on the space of r.v.’s).** Let (Ω, L, E) be a probability space. Let (S, d) be a complete metric space. We will let M(Ω, S) denote the space of r.v.’s on (Ω, L, E) with values in (S, d), where two r.v.’s are considered equal if they are equal a.s. Define the metric

ρ_{Prob}(X, Y) \equiv E(1 ∧ d(X, Y))

(5.1.3)

for each X, Y ∈ M(Ω, S). The next proposition proves that ρ_{Prob} is indeed a metric. We will call ρ_{Prob} the probability metric on the space M(Ω, S) of r.v.’s.

**Proposition 5.1.11. (Basics of the probability metric ρ_{Prob} on the space M(Ω, S) of r.v.’s).** Let (Ω, L, E) be a probability space. Let X, X_1, X_2, · · · be r.v.’s with values in the complete metric space (S, d). Then the following holds.

1. The pair (M(Ω, S), ρ_{Prob}) is a metric space. Note that ρ_{Prob} ≤ 1.

2. X_n → X in probability iff, for each ε > 0, there exists p ≥ 1 so large that P(d(X_n, X) > ε) < ε for each n ≥ p.

3. Sequential convergence relative to ρ_{Prob} is equivalent to convergence in probability.

4. The metric space (M(Ω, S), ρ_{Prob}) is complete.

5. Suppose there exists a sequence (ε_n)_{n=1,2,...} of positive real numbers such that

\[ \sum_{n=1}^{\infty} ε_n < \infty \]

and such that ρ_{Prob}(X_n, X_{n+1}) ≡ E(1 ∧ d(X_n, X_{n+1})) < ε_n^2 for each n ≥ 1. Then Y ≡ lim_{n→∞} X_n is a r.v., and X_n → Y a.u.

**Proof.** 1. Let X, Y ∈ M(Ω, S) be arbitrary. Then d(X, Y) is a r.v according to Proposition 4.8.17. Hence 1 ∧ d(X, Y) is an integrable function, and ρ_{Prob} is well defined in equality 5.1.3. Symmetry and triangle inequality for the function ρ_{Prob} are obvious from its definition. Suppose ρ_{Prob}(X, Y) ≡ E(1 ∧ d(X, Y)) = 0. Let (ε_n)_{n=1,2,...} be a sequence in (0, 1) with ε_n ↓ 0. The Chebychev’s inequality implies

\[ P(d(X, Y) > ε_n) = P(1 ∧ d(X, Y) > ε_n) ≤ ε_n^{-1} E(1 ∧ d(X, Y)) = 0 \]

for each n ≥ 1. Hence A ≡ \bigcup_{n=1}^{\infty} \{d(X, Y) > ε_n\} is a null set. On the full set A^c, we have d(X, Y) ≤ ε_n for each n ≥ 1. Therefore d(X, Y) = 0 on the full set A^c. Thus X = Y in M(Ω, S). Summing up, ρ_{Prob} is a metric.
2. Suppose \( X_n \to X \) in probability. Let \( \varepsilon > 0 \) be arbitrary. Then, according to Definition 5.1.8 there exists \( p \geq 1 \) so large that, for each \( n \geq p \), there exists an integrable set \( B_n \) with \( P(B_n) < \varepsilon \) and \( B_n^c \subset (d(X_n, X) \leq \varepsilon) \). Now consider each \( n \geq p \). Then \( P(d(X_n, X) > \varepsilon) \leq P(B_n) < \varepsilon \) for each \( n \geq p \). Conversely, suppose, for each \( \varepsilon > 0 \), there exists \( p \geq 1 \) so large that \( P(d(X_n, X) > \varepsilon) < \varepsilon \) for each \( n \geq p \). Let \( \varepsilon > 0 \) be arbitrary and define the integrable set \( B_n \equiv (d(X_n, X) > \varepsilon) \) for each \( n \geq 1 \). Then \( P(B_n) < \varepsilon \) and \( B_n^c \subset (d(X_n, X) \leq \varepsilon) \). Hence \( X_n \to X \) in probability according to Definition 5.1.8.

3. Suppose \( \rho_{\text{prob}}(X_n, X) \equiv E(1 \wedge d(X_n, X)) \to 0 \). Let \( \varepsilon > 0 \) be arbitrary. Take \( p \geq 1 \) so large that \( E(1 \wedge d(X_n, X)) < \varepsilon(1 \wedge \varepsilon) \) for each \( n \geq p \). Then Chebychev’s inequality implies that

\[
P(d(X_n, X) > \varepsilon) \leq P(1 \wedge d(X_n, X) \geq 1 \wedge \varepsilon) \leq (1 \wedge \varepsilon)^{-1}E(1 \wedge d(X_n, X)) < \varepsilon
\]

for each \( n \geq p \). Thus \( X_n \to X \) in probability, by Assertion 2. Conversely, suppose \( X_n \to X \) in probability. Then, by Assertion 2, there exists \( p \geq 1 \) so large that \( P(d(X_n, X) > \varepsilon) < \varepsilon \) for each \( n \geq p \). Hence

\[
E(1 \wedge d(X_n, X)) = E(1 \wedge d(X_n, X))1_{(d(X_n, X) > \varepsilon)} + E(1 \wedge d(X_n, X))1_{(d(X_n, X) \leq \varepsilon)} \\
\leq E1_{(d(X_n, X) > \varepsilon)} + \varepsilon = P(d(X_n, X) > \varepsilon) + \varepsilon < 2\varepsilon
\]

for each \( n \geq p \). Thus \( \rho_{\text{prob}}(X_n, X) \equiv E(1 \wedge d(X_n, X)) \to 0 \). Assertion 3 is proved.

4. Suppose \( \rho_{\text{prob}}(X_n, X) \equiv E(1 \wedge d(X_n, X)) \to 0 \) as \( n, m \to \infty \). Let \( \varepsilon > 0 \) be arbitrary. Take \( p \geq 1 \) so large that \( E(1 \wedge d(X_n, X)) < \varepsilon(1 \wedge \varepsilon) \) for each \( n, m \geq p \). Then Chebychev’s inequality implies that

\[
P(d(X_n, X) > \varepsilon) \leq P(1 \wedge d(X_n, X) \geq 1 \wedge \varepsilon) \leq (1 \wedge \varepsilon)^{-1}E(1 \wedge d(X_n, X)) < \varepsilon
\]

for each \( n, m \geq p \). Thus the sequence \( (X_n)_{n=1,2,\ldots} \) of functions is Cauchy in probability. Hence Proposition 4.9.3 implies that \( X \equiv \lim_{k \to \infty} X_{n(k)} \) is a r.v. for some subsequence \( (X_{n(k)})_{k=1,2,\ldots} \) of \( (X_n)_{n=1,2,\ldots} \), and that \( X_n \to X \) in probability. By Assertion 3, it then follows that \( \rho_{\text{prob}}(X_n, X) \to 0 \). Thus The metric space \( (M(\Omega, S), \rho_{\text{prob}}) \) is complete, and Assertion 4 is proved.

5. Assertion 5 is a trivial special case of Proposition 4.9.5.

Corollary 5.1.12. (Reciprocal of an a.s. positive r.r.v.) Let \( X \) be a nonnegative r.r.v. such that \( P(X < a) \to 0 \) as \( a \to 0 \). Define the function \( X^{-1} \) by domain \((X^{-1}) \equiv D \equiv (X > 0) \) and \( X^{-1}(\omega) \equiv (X(\omega))^{-1} \) for each \( \omega \in D \). Then \( X^{-1} \) is a r.r.v.

Proof. Let \( a_1 > a_2 > \cdots > 0 \) be a sequence such that \( PD_k \to 0 \) where \( D_k \equiv P(X \geq a_k) \) for each \( k \geq 1 \). Then \( D = \bigcup_{k=1}^{\infty} D_k \), whence \( D \) is a full set. Let \( j \geq k \geq 1 \) be arbitrary. Define the r.r.v. \( Y_k \equiv (X \vee a_k)^{-1}1_{D(k)} \). Then \( X^{-1}1_{D(k)} = Y_k \). Moreover \( Y_j \geq Y_k \), and

\[
(Y_j - Y_k > 0) \subset (1_{D(j)} - 1_{D(k)} > 0) = D_j D_k^c \subset D_k^c.
\]

Consequently, since \( PD_k \to 0 \) as \( k \to \infty \), the sequence \((Y_k)_{k=1,2,\ldots} \) converges a.u. Hence, according to Proposition 5.1.9 \( Y \equiv \lim_{k \to \infty} Y_k \) is a r.r.v. Since \( X^{-1} = Y \) on the full set \( D \), so \( X^{-1} \) is a r.r.v.
We see in Proposition 5.1.11 that convergence in $L_1$ of r.r.v.’s implies convergence in probability. The next proposition gives the converse in the case of uniform integrability.

Proposition 5.1.13. (Uniform integrability of sequence of r.r.v.’s and convergence in probability implies convergence in $L_1$). Suppose $(X_n)_{n=1,2,\ldots}$ is a uniformly integrable sequence of r.r.v.’s. If $(X_n)$ converges in probability to some r.r.v. $X$, then $X$ is integrable and $X_n \to X$ in $L_1$.

Proof. Let $\varepsilon > 0$. By Proposition 4.7.4 there exists $\delta > 0$ so small that $E(|X_n|; A) < \varepsilon$ for each $n \geq 1$ and for each event $A$ with $PA < \delta$. By hypothesis $X_n \to X$ in probability. Hence there exists an integer $p \geq 1$ so large that $PA_n < \delta \wedge \varepsilon$ where $A_n \equiv \{|X_n - X| > \varepsilon\}$ for each $n \geq p$. Therefore

$$
E|X_n - X_m| \leq E(|X_n - X_m|; |X_n - X_m| > 2\varepsilon) + 2\varepsilon
$$

$$
\leq E(|X_n| + |X_m|; A_n \cup A_m) + 2\varepsilon
$$

$$
\leq E(|X_n|; A_n) + E(|X_n|; A_m) + E(|X_m|; A_n) + E(|X_m|; A_m) + 2\varepsilon \leq 6\varepsilon
$$

for all $m,n \geq p$. Since $\varepsilon > 0$ is arbitrary, we have $E|X_n - X_m| \to 0$ as $n,m \to \infty$. Hence $E|X_n - Y| \to 0$ for some integrable r.r.v. $Y$, thanks to the completeness of $(\Omega, L, E)$. Moreover, $P(|Y - X_n| > \varepsilon) \to 0$ by Chebychev’s inequality. It follows that

$$
P(|Y - X| > 2\varepsilon) \leq P(|Y - X_n| > \varepsilon) + P(|X_n - X| > \varepsilon) \to 0.
$$

Since $\varepsilon > 0$ is arbitrary, we see that $X = Y$ a.s. Since $Y$ is integrable, so is $X$, with

$$
\lim_{n \to \infty} E|X_n - X| = \lim_{n \to \infty} E|X_n - Y| = 0.
$$

Proposition 5.1.14. (Necessary and sufficient condition for a.u. convergence). For $n \geq 1$, let $X, X_n$ be r.r.v.’s with values in the locally compact metric space $(S, d)$. Then the following two conditions are equivalent: (i) for each $\varepsilon > 0$, there exist an integrable set $B$ with $P(B) < \varepsilon$ and an integer $m \geq 1$ such that for each $n \geq m$ we have $d(X, X_n) \leq \varepsilon$ on $B^c$, and (ii) $X_n \to X$ a.u.

Proof. Suppose Condition (i) holds. Let $(\varepsilon_k)_{k=1,2,\ldots}$ be a sequence of positive real numbers with $\sum_{k=1}^{\infty} \varepsilon_k < \infty$. By hypothesis, for each $k \geq 1$ there exist an integrable set $B_k$ with $P(B_k) < \varepsilon_k$ and an integer $m_k \geq 1$ such that for each $n \geq m_k$ we have $d(X, X_n) \leq \varepsilon_k$ on $D_n \cap B_k^c$ for some full set $D_n$. Let $\varepsilon > 0$ be arbitrary. Let $p \geq 1$ be so large that $\sum_{k=p}^{\infty} \varepsilon_k < \varepsilon$ and define $A \equiv \bigcup_{k=p}^{\infty} (B_k \cup \bigcup_{m=m_k}^{\infty} D_n)$. Then $P(A) \leq \sum_{k=p}^{\infty} \varepsilon_k < \varepsilon$. Moreover, on $A^c = \bigcap_{k=p}^{\infty} (\bigcup_{m=m_k}^{\infty} D_n \cap B_k)$ we have $d(X, X_n) \leq \varepsilon_k$ for each $n \geq m_k$ and each $k \geq p$. Therefore $X_n \to X$ uniformly on $A^c$. Since $P(A)$ is arbitrarily small, $X_n \to X$ a.u. Thus Condition (ii) is verified.

Conversely, suppose Condition (ii) holds. Let $\varepsilon > 0$ be arbitrary. Then, by 4.9.1 there exists a measurable set $B$ with $P(B) < \varepsilon$ such that $X_n$ converges to $X$ uniformly on $B^c$. Hence there exists $m \geq 1$ so large that $\bigcup_{n=m}^{\infty} (d(X_n, X) > \varepsilon) \subset B$. In particular, for each $n \geq m$, we have $(d(X_n, X) > \varepsilon) \subset B$, whence $d(X, X_n) \leq \varepsilon$ on $B^c$. Condition (i) is established.
5.1. RANDOM VARIABLES

Definition 5.1.15. (Probability subspace). Let $(\Omega, L, E)$ be a probability space and let $L'$ be a subset of $L$. If $(\Omega, L', E)$ is a probability space, then we call $(\Omega, L', E)$ a probability subspace of $(\Omega, L, E)$. When confusion is unlikely, we will abuse terminology and simply call $L'$ a probability subspace of $L$, with $\Omega$ and $E$ understood.

Let $G$ be a non-empty family of r.v.'s with values in a complete metric space $(S,d)$. Define

$$L_{C(ab)}(G) \equiv \{ f(X_1, \cdots, X_n) : n \geq 1; f \in C_{ab}(S^n); X_1, \cdots, X_n \in G \}.$$  

Then $(\Omega, L_{C(ab)}(G), E)$ is an integration subspace of $(\Omega, L, E)$. Its completion

$$L(G) \equiv L(X : X \in G) \equiv \overline{L_{C(ab)}(G)}$$

will be called the probability subspace of $L$ generated by the family $G$.

If $G$ is a finite or countably infinite set $\{X_1, X_2, \cdots\}$, we will write $L(X_1, X_2, \cdots)$ for $L(G)$. □

Note that $L_{C(ab)}(G)$ is a linear subspace of $L$ containing constants and is closed to the operation of maximum and absolute values. Hence $(\Omega, L_{C(ab)}(G), E)$ is indeed an integration space, according to Proposition 4.3.5. Since $1 \in L_{C(ab)}(G)$ with $E1 = 1$, the completion $(\Omega, L(G), E)$ is a probability space. Any r.v. in $L(G)$ has its value determined once all the values of the r.v.'s in the generating family $G$ have been observed. Intuitively, $L(G)$ contains all the information obtainable by observing the values of all $X \in G$.

Proposition 5.1.16. Let $(\Omega, L, E)$ be a probability space. Let $G$ be a non-empty family of r.v.'s with values in a locally compact metric space $(S,d)$. Let

$$L_{C}(G) \equiv \{ f(X_1, \cdots, X_n) : n \geq 1; f \in C(S^n); X_1, \cdots, X_n \in G \}.$$  

Then $(\Omega, L_{C}(G), E)$ is an integration subspace of $(\Omega, L, E)$. Moreover its completion $L_{C}(G)$ is equal to $L(G)$.

Proof. Note first that $L_{C}(G) \subset L_{C(ab)}(G)$, and $L_{C}(G)$ is a linear subspace of $\overline{L_{C(ab)}(G)}$ such that if $U, V \in L_{C}(G)$ then $|U|, |U \wedge 1 \in L_{C}(G)$. Hence $L_{C}(G)$ is an integration subspace of $(\Omega, L_{C(ab)}(G), E)$ according to Proposition 4.3.5. Consequently $L_{C}(G) \subset \overline{L_{C(ab)}(G)}$.

Conversely, let $U \in L_{C(ab)}(G)$ be arbitrary. Then $U = f(X_1, \cdots, X_n)$ for some $f \in C_{ab}(S^n)$ and some $X_1, \cdots, X_n \in G$. Then, by Proposition 5.1.4, there exists a sequence $(g_k)_{k=1,2,\cdots} \in C(S)$ such that $E|f(X) - g_k(X)| \to 0$, where we write $X \equiv (X_1, \cdots, X_n)$. Since $g_k(X) \in L_{C}(G) \subset \overline{L_{C}(G)}$ for each $k \geq 1$, and since $L_{C}(G)$ is complete, we see that $U = f(X) \in \overline{L_{C}(G)}$. Since $U \in L_{C(ab)}(G)$ is arbitrary, we obtain $L_{C(ab)}(G) \subset \overline{L_{C}(G)}$.

Consequently $L_{C(ab)}(G) \subset L_{C}(G)$.

Summing up, $L_{C}(G) = \overline{L_{C(ab)}(G)} \equiv L(G)$, as alleged. □

The next lemma sometimes comes in handy.
Lemma 5.1.17. (Intersection of probability subspaces is a probability subspace). Let \((Ω,L,E)\) be a probability space. Let \(L\) be a nonempty family of probability subspaces \(L'\) of \(L\). Then \(L'' = \bigcap_{L' \in L} L'\) is a probability subspace of \(L\).

Proof. Clearly the intersection \(L''\) is a linear subspace of \(L\), contains the constant function \(1\) with \(E1 = 1\), and is such that if \(X,Y \in L''\) then \(|X|,X \wedge Y \in L''\). Hence it is an integration subspace of \(L\), according to Proposition 4.3.5. At the same time, since the sets \(L'\) in the family \(L\) are closed in the space \(L\) relative to the norm \(E\cdot\cdot\cdot\), so is their intersection \(L''\). Since \(L\) is complete relative to \(E\), so is the closed subspace \(L''\). Summing up, \((Ω,L'',I)\) is a probability subspace of \((Ω,L,I)\). \(\Box\)

5.2 Probability Distributions on a Metric Space

Definition 5.2.1. (Distribution on a complete metric space). Suppose \((S,d)\) is a complete metric space. Let \(n \geq 1\) be arbitrary. Recall the function \(h_n \equiv 1 + (1 + n - d(x,y))_+ \in C_{ub}(S,d)\), where \(x,y \in S\) is an arbitrary, but fixed, reference point. Note that the function \(h_n\) has bounded support. Hence \(h_n \in C(S)\) if \((S,d)\) is locally compact. Let \(J\) be an integration on \((S,C_{ub}(S,d))\), in the sense of Definition 3.3.1. Suppose \(Jh_n \uparrow 1\) as \(n \to \infty\). Then the integration \(J\) is called a probability distribution, or simply a distribution, on \((S,d)\). We will let \(\hat{J}(S,d)\) denote the set of distributions on the complete metric space \((S,d)\). \(\Box\)

Lemma 5.2.2. (Distribution basics). Suppose \((S,d)\) is a complete metric space. Then the following holds.

1. Let \(J\) be an arbitrary distribution on \((S,d)\). Then \(J 1 = 1\), where \((S,L,J) \equiv (S,C_{ub}(S),J)\). Thus \((S,L,J)\) is a probability space.

2. Suppose the metric space \((S,d)\) is bounded. Let \(J\) be an integration on \((S,C_{ub}(S))\) such that \(J1 = 1\). Then the integration \(J\) is a distribution on \((S,d)\).

3. Suppose \((S,d)\) is locally compact. Let \(J\) be an integration on \((S,C(S))\) in the sense of Definition 3.2.7. Suppose \(Jh_n \uparrow 1\) as \(n \to \infty\). Then \(J\) is a distribution on \((S,d)\).

Proof. 1. By Definition 5.2.1 \(Jh_n \uparrow 1\) as \(n \to \infty\). At the same time \(h_n \uparrow 1\) on \(S\). The Monotone Convergence Theorem therefore implies that \(1 \in L\) and \(J1 = 1\).

2. Suppose \((S,d)\) is bounded. Then \(h_n = 1\) for sufficiently large \(n \geq 1\). Hence, trivially \(Jh_n \uparrow J1 = 1\), where the equality is by assumption. Therefore the integration \(J\) ion \((S,C_{ub}(S))\) satisfies the conditions in Definition 5.2.1 to be a distribution.

3. Since \((S,d)\) is locally compact. Then \(h_n \in C(S)\) for each \(n \geq 1\). Moreover \(Jh_n \uparrow 1\) by hypothesis. Let \((S,L,J)\) denote the completion of \((S,C(S),J)\). Let \(f \in C_{ub}(S)\) be arbitrary, with some bound \(b \geq 0\) for \(|f|\). Then

\[J|f|_{m,n} - h_n|f| \leq bJ|h_m - h_n| = bJ(h_m - h_n) \to 0\]

as \(m \geq n \to \infty\). Hence the sequence \((h_n|f|)_{n=1,2,\ldots}\) is Cauchy in the complete integration space \(L\) relative to \(J\). Therefore \(g \in L\) and \(Jg = \lim_{n \to \infty}Jh_n|f|\), where \(g \equiv \lim_{n \to \infty}(h_n|f|)\). At the same time, \(\lim_{n \to \infty}(h_n|f|) = f\) on \(S\). Hence \(f = g \in L\), with \(Jf = Jg = \lim_{n \to \infty}Jh_n|f|\). Since \(f \in C_{ub}(S)\) is arbitrary, we conclude that \(C_{ub}(S) \subset L\). Consequently \((S,C_{ub}(S),J)\) is an integration subspace of \((S,L,J)\). Moreover, in the
5.2. PROBABILITY DISTRIBUTIONS ON A METRIC SPACE

special case \( f \equiv 1 \), we obtain \( 1 \in L \) with \( J_1 = \lim_{n \to \infty} J_{h_n} = 1 \). Thus the integration \( J \) on \( C_{\text{ub}}(S) \) satisfies the conditions in Definition 5.2.1 to be a distribution. \( \square \)

Definition 5.2.3. (Distribution induced by a r.v.) Let \( X \) be a r.v. on a probability space \((\Omega, L, E)\) with values in the complete metric space \((S, d)\). For each \( f \in C_{\text{ub}}(S) \), define \( E_X f \equiv E f(X) \). Lemma 5.2.4 below proves that \( E_X \) is a distribution on \((S, d)\). We will call \( E_X \) the distribution on \( S \) induced by the r.v. \( X \). The completion \((S, L_X, E_X) \equiv (S, C_{\text{ub}}(S), E_X)\) of \((S, C_{\text{ub}}(S), E_X)\) is a probability space, called the probability space induced on the complete metric space \((S, d)\) by the r.v. \( X \). \( \square \)

Lemma 5.2.4. (Distribution induced by a r.v. is indeed a distribution). Let \( X \) be an arbitrary r.v. on a probability space \((\Omega, L, E)\) with values in the complete metric space \((S, d)\). Then the function \( E_X \) introduced in Definition 5.2.3 is indeed a distribution.

Proof. Let \( f \in C_{\text{ub}}(S) \) be arbitrary. By Proposition 5.1.4 we have \( f(X) \in L \). Hence \( E_X f \equiv E f(X) \) is well-defined. The space \( C_{\text{ub}}(S) \) is linear, contains constants, and is closed to absolute values and taking minimums. The remaining conditions in Definition 5.2.1 for \( E_X \) to be an integration on \((S, C_{\text{ub}}(S))\) follow from the corresponding conditions for \( E \). Moreover, \( E_X h_n \equiv E h_n(X) \uparrow 1 \) as \( n \to \infty \), where the convergence is by by Assertion 4 in Proposition 5.1.4. All the conditions in Definition 5.2.1 have been verified for \( E_X \) to be a distribution. \( \square \)

Proposition 5.2.5. (Each Distribution is induced by some r.v.) Suppose \( J \) is a distribution on a complete metric space \((S, d)\). Let \((S, L, J)\) denote the completion of the integration space \((S, C_{\text{ub}}(S), J)\). Then the following holds.

1. The identity function \( X : (S, L, J) \to (S, d) \), defined by \( X(x) = x \) for each \( x \in S \), is a r.v.
2. The function \( d(\cdot, x_0) \) is a r.v. on \((S, L, J)\).
3. \( J = E_X \). Thus each distribution is induced by some r.v.

Proof. By Lemma 5.2.2 \((S, L, J)\) is a probability space, and \( J_{h_n} \uparrow 1 \) as \( n \to \infty \). Hence the hypothesis in Corollary 4.3.8 is satisfied. Accordingly, \( X \) is a r.v. on \((\Omega, L, E) \equiv (S, L, J)\), and \( d(\cdot, x_0) \) is a r.v. Moreover, for each \( f \in C_{\text{ub}}(S) \), we have \( J f \equiv E f \equiv E f(X) \equiv E_X f \). Hence \( J = E_X \) on \( C_{\text{ub}}(S) \). Therefore the completion of \((S, C_{\text{ub}}(S), J)\) and that of \((S, C_{\text{ub}}(S), E_X)\) are the same. In other words, \((S, L, J) \equiv (S, L_X, E_X)\). \( \square \)

Proposition 5.2.6. (Relation between probability spaces generated and induced by a r.v.) Suppose \( X \) is a r.v. on the probability space \((\Omega, L, E)\) with values in a complete metric space \((S, d)\). Let \((\Omega, L(X), E)\) be the probability subspace generated by \( \{X\} \). Let \((S, L_X, E_X)\) be the probability space induced on \((S, d)\) by \( X \). Let \( f : S \to R \) be an arbitrary function. Then the following holds.

1. \( f \in L_X \) iff \( f(X) \in L(X) \), in which case \( E_X f = E f(X) \).
2. \( f \) is a r.v. on \((S, L_X, E_X)\) iff \( f(X) \) is a r.v. on \((\Omega, L(X), E)\).

Proof. 1. Suppose \( f \in L_X \). Then there exists sequence \((f_n)_{n=1,2,...} \in C_{\text{ub}}(S)\) such that \( E_X |f_n - f| \to 0 \) and \( f = \lim_{n \to \infty} f_n \). Consequently \( E_X |f_n(X) - f_m(X)| \equiv E_X |f_n - f_m| \to 0 \).

Yuen-Kwok Chan 125 Constructive Probability
Thus \((f_n(X))_{n=1,2,\ldots}\) is a Cauchy sequence in \(L(X)\) relative to the expectation \(E\). Since \(L(X)\) is complete, we have \(Y \equiv \lim_{n \to \infty} f_n(X) \in L(X)\) with \[E|f_n(X) - Y| \to 0,\]
whence
\[EY = \lim_{n \to \infty} E f_n(X) = \lim_{n \to \infty} E_X f_n = E_X f.\]
Since \(f(X) = \lim_{n \to \infty} f_n(X) = Y\) on the full set \(\text{domain}(Y)\), it follows that \(f(X) \in L(X)\), with \(E f(X) = EY = E_X f\).

Conversely, suppose \(Z \in L(X)\). We will show that \(Z = f(X)\) for some integrable function \(f\) relative to \(E_X\). Since \(L(X)\) is, by definition, the completion of \(L_{C_{ub}}(X) \equiv \{f(X) : f \in C_{ub}(S)\}\), the latter is dense in the former, relative to the norm \(E|\cdot|\). Hence there exists a sequence \((f_n)_{n=1,2,\ldots}\) in \(C_{ub}(S)\) such that
\[E|Z - f_n(X)| \to 0.\]  (5.2.1)
Consequently
\[E_X|f_n - f_m| = E|f_n(X) - f_m(X)| \to 0.\]
Hence \(E_X|f_n - f| \to 0\) where \(f \equiv \lim_{n \to \infty} f_n \in C_{ub}(S) \equiv L_X\). By the first part of this proof in the previous paragraph, we have
\[E|f_n(X) - Y| \to 0,\]  (5.2.2)
where
\[Y = f(X)\quad \text{a.s.} \]  (5.2.3)
Convergence expressions \(5.2.1\) and \(5.2.2\) together implies that \(Z = Y\) a.s., which, together with equality \(5.2.3\) in turn yields \(Z = f(X)\), where \(f \in L_X\). Assertion 1 is proved.

2. For each \(n \geq 1\), define \(g_n \equiv 1 \wedge (1 + n - |\cdot|)_+ \in C_{ub}(R)\). Suppose the function \(f\) is a r.v. on \((S,L_X,E_X)\). Then, by Proposition 5.1.4, we have (i) \(g \circ f \in L_X\) for each \(g \in C_{ub}(R)\), and (ii) \(E_X g_n \circ f \uparrow 1\) as \(n \to \infty\).

In view of Condition (i), we have \(g(f(X)) \equiv g \circ f(X) \in L(X)\) for each \(g \in C_{ub}(R)\) by Assertion 1. Moreover, \(E_X g_n(f(X)) = E_X g_n \circ f \uparrow 1\) as \(n \to \infty\). Combining, we can apply Assertion 4 of Proposition 5.1.4 to the function \(f(X) : \Omega \to R\) in the place of \(X : \Omega \to S\), and conclude that \(f(X)\) is a r.v. on \((\Omega,L(X),E)\).

Conversely, suppose \(f(X)\) is a r.v. on \((\Omega,L(X),E)\). Then, again by Assertion 4 of Proposition 5.1.4 we have (i') \(g(f(X)) \in L(X)\) for each \(g \in C_{ub}(R)\), and (ii') \(E(g_n(f(X))) \uparrow 1\) as \(n \to \infty\). In view of Condition (i'), we have \(g \circ f \in L_X\) for each \(g \in C_{ub}(R)\) by Assertion 1 of the present proposition. Moreover, \(E_X g_n \circ f = E g_n(f(X)) \uparrow 1\) as \(n \to \infty\). Combining, we see that \(f\) is a r.v. on \((S,L_X,E_X)\), again by Assertion 4 of Proposition 5.1.4.

Proposition 5.2.7. (Regular points of a r.v. \(f\) relative to induced distribution by a r.v. \(X\) are same as regular points of \(f(X)\)). Suppose \(X\) is a r.v. on the probability space \((\Omega,L,E)\) with values in a complete metric space \((S,d)\). Suppose \(f\) is a r.v. on \((S,L_X,E_X)\). Then \(t \in R\) is a regular point of \(f\) iff it is a regular point of \(f(X)\). Similarly, \(t \in R\) is a continuity point of \(f\) iff it is a continuity point of \(f(X)\).
5.3. WEAK CONVERGENCE OF DISTRIBUTIONS

Proof. Suppose $f$ is a r.v. on $(S, \mathcal{L}_X, E_X)$. By Definition 4.8.10, $t$ is a regular point of $f$ iff (i) there exists a sequence $(s_n)_{n=1,\ldots}$ of real numbers decreasing to $t$ such that $(s_n < f)$ is integrable relative to $E_X$ for each $n \geq 1$, and $\lim_{n \to \infty} P_X(s_n < f)$ exists, and (ii) there exists a sequence $(r_n)_{n=1,\ldots}$ of real numbers increasing to $t$ such that $(r_n < f)$ is integrable relative to $E_X$ for each $n \geq 1$, and $\lim_{n \to \infty} P_X(r_n < f)$ exists. In view of Proposition 5.2.6, conditions (i) and (ii) are equivalent to: (i') there exists a sequence $(s_n)_{n=1,\ldots}$ of real numbers decreasing to $t$ such that $(s_n < f(X))$ is integrable relative to $E$ for each $n \geq 1$, and $\lim_{n \to \infty} P(s_n < f(X))$ exists, and (ii') there exists a sequence $(r_n)_{n=1,\ldots}$ of real numbers increasing to $t$ such that $(r_n < f(X))$ is integrable relative to $E$ for each $n \geq 1$, and $\lim_{n \to \infty} P(r_n < f(X))$ exists. In other words, $t$ is a regular point of $f$ iff $t$ is a regular point of $f(X)$.

Moreover, a regular point $t$ of $f$ is a continuity point of $f$ iff the two limits in conditions (i) and (ii) exist and are equal. Equivalently, $t$ is a continuity point of $f$ iff the two limits in conditions (i') and (ii') exist and are equal. Combining, we conclude that $t$ is a continuity point of $f$ iff it is a continuity point of $f(X)$. □

5.3 Weak Convergence of Distributions

Recall that, if $X$ is a r.v. on a probability space $(\Omega, \mathcal{L}, E)$ with values in $S$, then $E_X$ denotes the distribution induced on $S$ by $X$.

Definition 5.3.1. (Weak convergence of distributions on a complete metric space).

Recall that $J(S, d)$ denotes the set of distributions on the complete metric space $(S, d)$. A sequence $(J_n)_{n=1,\ldots}$ in $J(S, d)$ is said to converge weakly to $J \in J(S, d)$ if $J_n f \to J f$ for each $f \in \mathcal{C}_{ab}(S)$. We then write $J_n \Rightarrow J$. Suppose $X, X_1, X_2, \ldots$ are r.v.'s with values in $S$, not necessarily on the same probability space. The sequence $(X_n)_{n=1,\ldots}$ is said to converge weakly, or to converge in distribution, to $X$ if $E_X(n) \Rightarrow E_X$. We then write $X_n \Rightarrow X$. □

Proposition 5.3.2. (Convergence in probability implies weak convergence). Let $(X_n)_{n=0,1,\ldots}$ be a sequence of r.v.'s on the same probability space $(\Omega, \mathcal{L}, E)$, with values in a complete metric space $(S, d)$. If $X_n \to X_0$ in probability, then $X_n \Rightarrow X_0$.

Proof. Suppose $X_n \to X_0$ in probability. Let $f \in \mathcal{C}_{ab}(S)$ be arbitrary, with $|f| \leq c$ for some $c > 0$, and with a modulus of continuity $\delta_f$. Let $\varepsilon > 0$ be arbitrary. By Definition 5.1.3 of convergence in probability, there exists $p \geq 1$ so large that, for each $n \geq p$, there exists an integrable set $B_n$ with $P(B_n) < \varepsilon$ and

$$B_n^c \subset (d(X_n, X_0) < \delta_f(\varepsilon)) \subset (|f(X_n) - f(X_0)| < \varepsilon).$$

Consider each $n \geq p$. Then

$$|E f(X_n) - E f(X_0)| = E |f(X_n) - f(X_0)| 1_{B_n} + E |f(X_n) - f(X_0)| 1_{B_n^c} \leq 2c P(B_n) + \varepsilon < 2c \varepsilon + \varepsilon.$$

Since $\varepsilon > 0$ is arbitrarily small, we conclude that $E f(X_n) \to E f(X_0)$. Equivalently, $J_{X(n)} f \to J_{X(0)} f$. Since $f \in \mathcal{C}_{ab}(S)$ is arbitrary, we have $J_{X(n)} \Rightarrow J_{X(0)}$. In other words, $X_n \Rightarrow X_0$. □
CHAPTER 5. PROBABILITY SPACE

Lemma 5.3.3. (Weak convergence of distributions on a locally compact metric space). Suppose $(S,d)$ is locally compact. Suppose $J,J',J_p \in \hat{J}(S,d)$ for each $p \geq 1$. Then $J_p \Rightarrow J$ iff $J_p f \rightarrow J f$ for each $f \in C(S)$. Moreover, $J = J'$ if $J f = J' f$ for each $f \in C(S)$. Consequently, a distribution on a locally compact metric space is uniquely determined by the expectation of continuous functions with compact supports.

Proof. Since $C(S) \subseteq C_{ab}(S)$, it suffices to prove the “if” part. To that end, suppose $J_p f \rightarrow J f$ for each $f \in C(S)$. Let $g \in C_{ab}(S)$ be arbitrary. We need to prove that $J_p g \rightarrow J g$. Let $\varepsilon > 0$ be arbitrary. We assume, without loss of generality, that $0 \leq g \leq 1$. Since $J$ is a distribution, there exists $n \geq 1$ so large that $J(1 - h_n) < \varepsilon$, where $h_n \in C_{ab}(S)$ is defined at the beginning of this chapter. Since $h_n, gh_n \in C(S)$, we have, by hypothesis, $J_m h_n \rightarrow J h_n$ and $J_m gh_n \rightarrow J g h_n$ as $m \rightarrow \infty$. Hence

\[ |J_m g - J g| \leq |J_m g - J_m g h_n| + |J_m g h_n - J g h_n| + |J g h_n - J g| \]

\[ \leq |1 - J_m h_n| + |J_m g h_n - J g h_n| + |J h_n - 1| < \varepsilon + \varepsilon + \varepsilon \]

for sufficiently large $m \geq 1$. Since $\varepsilon > 0$ is arbitrary, we conclude that $J_m g \rightarrow J g$, where $g \in C_{ab}(S)$ is arbitrary. Thus $J_p \Rightarrow J$.

Now suppose $J f = J' f$ for each $f \in C(S)$. Define $J_p \equiv J'$ for each $p \geq 1$. Then $J_p f \equiv J' f = J f$ for each $f \in C(S)$. Hence by the previous paragraphs, $J' g \equiv J_p g \rightarrow J g$ for each $g \in C_{ab}(S)$. Thus $J' g = J g$ for each $g \in C_{ab}(S)$. In other words, $J = J'$ on $C_{ab}(S)$. We conclude that $J = J'$ as distributions.

Definition 5.3.4. (Distribution metric for distributions on a locally compact metric space). Suppose the metric space $(S,d)$ is locally compact, with the reference point $x_0 \in S$. Let $\xi \equiv (A_n)_{n=1,2,\ldots}$ be a binary approximation of $(S,d)$ relative to $x_0$. Let

\[ \pi \equiv \{(g_{n,x} : x \in A_n)\}_{n=1,2,\ldots} \]

be the partition of unity of $(S,d)$ determined by $\xi$, as in Definition 3.2.4.

Let $\hat{J}(S,d)$ denote the set of distributions on the locally compact metric space $(S,d)$. Let $J, J' \in \hat{J}(S,d)$ be arbitrary. Define

\[ \rho_{\text{Dist},\xi}(J,J') \equiv \sum_{n=1}^{\infty} 2^{-n} |A_n|^{-1} \sum_{x \in A(n)} |g_{n,x} - J' g_{n,x}| \] (5.3.1)

and call $\rho_{\text{Dist},\xi}$ the distribution metric on $\hat{J}(S,d)$ relative to the binary approximation $\xi$. The next proposition shows that $\rho_{\text{Dist},\xi}$ is indeed a metric, and that sequential convergence relative to $\rho_{\text{Dist},\xi}$ is equivalent to weak convergence. Note that $\rho_{\text{Dist},\xi} \leq 1$.

Proposition 5.3.5. (Sequential metrical convergence implies weak convergence, on a locally compact metric space). Suppose the metric space $(S,d)$ is locally compact, with the reference point $x_0 \in S$. Let $\xi \equiv (A_n)_{n=1,2,\ldots}$ be a binary approximation of $(S,d)$ relative to $x_0$, with a corresponding modulus of local compactness $\|\xi\| \equiv (|A_n|)_{n=1,2,\ldots}$ of $(S,d)$. Let $\rho_{\text{Dist},\xi}$ be the function introduced in Definition 5.3.4.

Let $J_p \in \hat{J}(S,d)$ for $p \geq 1$. Let $f \in C(S)$ be arbitrary, with a modulus of continuity $\delta_f$, with $|f| \leq 1$, and with $(d(\cdot,x_0) \leq b)$ as support for some $b > 0$. Then the following holds.
1. Let $\varepsilon > 0$ be arbitrary. Then there exists $\delta_j(\varepsilon) \equiv \delta_j(\varepsilon, \delta_f, b, ||\xi||) > 0$ such that, for each $J, J' \in \mathcal{J}(S, d)$ with $\rho_{\text{Dist}, \xi}(J, J') < \delta_j(\varepsilon)$ we have $|Jf - J'f| < \varepsilon$.

2. Let

$$\pi \equiv (\{g_{n,x} : x \in A_n\})_{n=1,2,...}$$

be the partition of unity of $(S, d)$ determined by $\xi$. Suppose $J_p g_{n,x} \to J g_{n,x}$ as $p \to \infty$, for each $x \in A_n$ for each $n \geq 1$. Then $\rho_{\text{Dist}, \xi}(J_p, J) \to 0$.

3. $J_p f \to J f$ for each $f \in C(S)$ iff $\rho_{\text{Dist}, \xi}(J_p, J) \to 0$. Thus $J_p \Rightarrow J$ iff $\rho_{\text{Dist}, \xi}(J_p, J) \to 0$.

4. $\rho_{\text{Dist}, \xi}$ is a metric.

Proof. 1. Let $\varepsilon > 0$ be arbitrary. Let $n \equiv [0 \vee (1 - \log_2 \delta_j(\varepsilon)) \vee \log_2 b]$. We will show that

$$\delta_j(\varepsilon) \equiv \delta_j(\varepsilon, \delta_f, b, ||\xi||) \equiv \frac{1}{3}2^{-n}|A_n|^{-1}\varepsilon$$

has the desired property. To that end, suppose $J, J' \in \mathcal{J}(S, d)$ are such that $\rho_{\text{Dist}, \xi}(J, J') < \delta_j(\varepsilon)$. By Definition 3.2.4 of $\pi$, the sequence $\{g_{n,x} : x \in A_n\}$ is a $2^{-n}$-partition of unity determined by $A_n$. Separately, by hypothesis, the function $f$ has support

$$(d(\cdot, x_0) \leq b) \subset (d(\cdot, x_0) \leq 2^n) \subset \bigcup_{x \in A(n)} (d(\cdot, x) \leq 2^{-n}),$$

where the first inclusion is because $b < 2^n$, and the second inclusion is by Definition 5.1.1. Since $2^{-n} < \frac{1}{4}\delta_j(\frac{1}{4}\varepsilon)$, Proposition 3.2.6 then implies that

$$\|f - g\| \leq \frac{\varepsilon}{3} \quad (5.3.2)$$

where

$$g \equiv \sum_{x \in A(n)} f(x)g_{n,x}.$$

By the definition of $\rho_{\text{Dist}, \xi}$, we have

$$2^{-n}|A_n|^{-1}\sum_{x \in A(n)} |J g_{n,x} - J' g_{n,x}| \leq \rho_{\text{Dist}, \xi}(J, J') < \delta_j(\varepsilon).$$

Therefore

$$|Jg - J'g| \equiv \left| \sum_{x \in A(n)} f(x)(J g_{n,x} - J' g_{n,x}) \right|$$

$$\leq \sum_{x \in A(n)} |J g_{n,x} - J' g_{n,x}| < 2^n|A_n|\delta_j(\varepsilon) \equiv \frac{1}{3}\varepsilon.$$ 

Combining with inequality 5.3.2, we obtain

$$|Jf - J'f| \leq |Jg - J'g| + \frac{2}{3}\varepsilon < \frac{1}{3}\varepsilon + \frac{2}{3}\varepsilon = \varepsilon.$$
CHAPTER 5. PROBABILITY SPACE

Assertion 1 is proved.

2. Suppose \( J_p g_{n,x} \to J_{g,n,x} \) as \( p \to \infty \), for each \( x \in A_n \), for each \( n \geq 1 \). Let \( \varepsilon > 0 \) be arbitrary. Note that

\[
\rho_{\text{Dist}, \xi}(J, J_p) \equiv \sum_{n=1}^{\infty} 2^{-n}|A_n|^{-1} \sum_{x \in A(n)} |J_{g,n,x} - J_p g_{n,x}| \\
\leq \sum_{n=1}^{m} 2^{-n} \sum_{x \in A(n)} |J_{g,n,x} - J_p g_{n,x}| + 2^{-m}.
\]

We can first fix \( m \geq 1 \) so large that \( 2^{-m} < \frac{\varepsilon}{4} \). Then, for sufficiently large \( p \geq 1 \), the last sum is also less than \( \frac{\varepsilon}{4} \), whence \( \rho_{\text{Dist}, \xi}(J, J_p) < \varepsilon \). Since \( \varepsilon > 0 \) is arbitrary, we have \( \rho_{\text{Dist}, \xi}(J, J_p) \to 0 \).

3. Suppose \( \rho_{\text{Dist}, \xi}(J_p, J) \to 0 \). Then Assertion 1 implies that \( J_p f \to J f \) for each \( f \in C(S) \). Hence \( J_p \Rightarrow J \), thanks to Lemma 5.3.3. Conversely, suppose \( J_p f \to J f \) for each \( f \in C(S) \). Then, in particular, \( J_p g_{n,x} \to J_{g,n,x} \) as \( p \to \infty \), for each \( x \in A_n \), for each \( n \geq 1 \). Hence \( \rho_{\text{Dist}, \xi}(J_p, J) \to 0 \) by Assertion 2. Applying to the special case where \( J_p = J' \) for each \( p \geq 1 \), we obtain \( \rho_{\text{Dist}, \xi}(J', J) = 0 \) iff \( J = J' \).

4. Symmetry and the triangle inequality required for a metric follow trivially from the defining equality 5.3.1 Hence \( \rho_{\text{Dist}, \xi} \) is a metric. \( \square \)

From the defining equality 5.3.1 we have \( \rho_{\text{Dist}, \xi}(J, J') \leq 1 \) for each \( J, J' \in \mathcal{J}(S, d) \). Hence the metric space \( (\mathcal{J}(S, d), \rho_{\text{Dist}, \xi}) \) is bounded. It is not necessarily complete. An easy counterexample is by taking \( S \equiv \mathbb{R} \) with the Euclidean metric, and taking \( J_p \) to be the point mass at \( p \) for each \( p \geq 0 \). In other words \( J_p f \equiv f(p) \) for each \( f \in C(R) \). Then \( \rho_{\text{Dist}, \xi}(J_p, J_q) \to 0 \) as \( p, q \to \infty \). On the other hand \( J_p f \to 0 \) for each \( f \in C(R) \). Hence if \( \rho_{\text{Dist}, \xi}(J_p, J) \to 0 \) for some \( J \in \mathcal{J}(S, d) \), then \( J f = 0 \) for each \( f \in C(R) \), and so \( J = 0 \), contradicting the condition for \( J \) to be a distribution and an integration. The obvious problem here is that the mass of the distributions \( J_p \) escapes to infinity as \( p \to \infty \). The notion of tightness, defined next for a subfamily of \( \mathcal{J}(S, d) \), is to prevent this from happening.

**Definition 5.3.6. (Tightness).** Suppose the metric space \( (S, d) \) is locally compact. Let \( \beta : (0, \infty) \to [0, \infty) \) be an operation. Let \( \mathcal{J} \) be a subfamily of \( \mathcal{J}(S, d) \), such that, for each \( \varepsilon > 0 \) and for each \( J \in \mathcal{J} \), we have \( P_{\nu}(d(\cdot, x_0) > a) < \varepsilon \) for each \( a > \beta(\varepsilon) \), where \( P_{\nu} \) is the probability function of the distribution \( J \). Then we say the subfamily \( \mathcal{J} \) is **tight**, with \( \beta \) as a **modulus of tightness** relative to the reference point \( x_0 \). We say that a distribution \( J \) has modulus of tightness \( \beta \) if the singleton family \( \{J\} \) has modulus of tightness \( \beta \).

A family \( M \) of r.v.’s with values in the locally compact metric space \( (S, d) \), not necessarily on the same probability space, is said to be **tight**, with modulus of tightness \( \beta \), if the family \( \{E_X : X \in M\} \) is tight with modulus of tightness \( \beta \). We will say that a r.v. \( X \) has modulus of tightness \( \beta \) if the singleton \( \{X\} \) family has modulus of tightness \( \beta \). \( \square \)

We emphasize that we have defined tightness of a subfamily \( \mathcal{J} \) of \( \mathcal{J}(S, d) \) only when the metric space \( (S, d) \) is locally compact, even as weak convergence in \( \mathcal{J}(S, d) \) is defined for the more general case of any complete metric space \( (S, d) \).
5.3. WEAK CONVERGENCE OF DISTRIBUTIONS

Note that, according to Proposition 5.2.3, \( d(\cdot, x_0) \) is a r.r.v. relative to each distribution \( J \). Hence, given each \( J \in \mathcal{J} \), the set \( (d(\cdot, x_0) > a) \) is integrable relative to \( J \) for all but countably many \( a > 0 \). Therefore the probability \( P_J(d(\cdot, x_0) > a) \) makes sense for all but countably many \( a > 0 \). However, the countable exceptional set of values of \( a \) depends on \( J \).

A modulus of tightness for a family \( M \) of r.r.v.'s gives the uniform rate of convergence \( P(d(x_0, X) > a) \to 0 \) as \( a \to \infty \), independent of \( X \in M \), where the probability function \( P \) and the corresponding expectation \( E \) are specific to \( X \). This is analogous to a modulus of uniform integrability for a family \( G \) of integrable r.r.v.'s, which gives the rate of convergence \( E(|X|; |X| > a) \to 0 \) as \( a \to \infty \), independent of \( X \in G \).

The next lemma will be convenient.

**Lemma 5.3.7. (A family of r.r.v.'s bounded in \( L_p \) is tight).** Let \( p > 0 \) be arbitrary. Let \( M \) be a family of r.r.v.'s such that \( E|X|^p \leq b \) for each \( X \in M \), for some \( b \geq 0 \). Then the family \( M \) is tight, with a modulus of tightness \( \beta \) relative to \( 0 \in \mathbb{R} \) defined by \( \beta(\varepsilon) \equiv b\varepsilon^{-p} \), for each \( \varepsilon > 0 \).

**Proof.** Let \( X \in M \) be arbitrary. Let \( \varepsilon > 0 \) be arbitrary. Then, for each \( a > \beta(\varepsilon) \equiv b\varepsilon^{-p} \), we have

\[
P(|X| > a) = P(|X|^p > a^p) \leq a^{-p}E|X|^p \leq a^{-p}b < \varepsilon,
\]

where the first inequality is Chebychev’s, and the second is by the definition of the constant \( b \) in the hypothesis. Thus \( X \) has the operation \( \beta \) as a modulus of tightness relative to \( 0 \in \mathbb{R} \).

If a family \( \mathcal{J} \) of distributions is tight relative to a reference point \( x_0 \), then it is tight relative to any other reference point \( x_0' \), thanks to the triangle inequality. Intuitively, tightness limits the escape of mass to infinity as we go through distributions in \( \mathcal{J} \). Therefore a tight family of distributions remains so after a finite-distance shift of the reference point.

**Proposition 5.3.8. (Tightness and convergence of a sequence of distributions at each member of \( C(S) \) implies weak convergence to some distribution).** Suppose the metric space \( (S, d) \) is locally compact. Let \( \{J_n : n \geq 1\} \) be a tight family of distributions, with a modulus of tightness \( \beta \) relative to the reference point \( x_0 \).

Suppose \( J(f) \equiv \lim_{n \to \infty} J_n(f) \) exists for each \( f \in C(S) \). Then \( J \) is a distribution, and \( J_n \to J \). Moreover, \( J \) has the modulus of tightness \( \beta + 2 \).

**Proof.** Clearly \( J \) is a linear function on \( C(S) \). Suppose \( f \in C(S) \) is such that \( Jf > 0 \). Then, in view of the convergence in the hypothesis, there exists \( n \geq 1 \) such that \( J_n f > 0 \). Since \( J_n \) is an integration, there exists \( x \in S \) such that \( f(x) > 0 \). We have thus verified condition (ii) in Definition [5.2.1] for \( J \).

Next let \( \varepsilon \in (0, 1) \) be arbitrary, and take any \( a > \beta(\varepsilon) \). Then \( P_n(d(\cdot, x_0) > a) < \varepsilon \) for each \( n \geq 1 \), where \( P_n \equiv P_{J_n}(\cdot) \) is the probability function for \( J_n \). Define \( h_k \equiv 1 \wedge (1 + k - d(\cdot, x_0))_+ \in C(S) \) for each \( k \geq 1 \). Take any \( m \equiv m(\varepsilon, \beta) \in (a, a + 2) \). Then \( h_m \geq 1_{(d(\cdot, x_0) \leq a)} \), whence

\[
J_n h_m \geq P_n(d(\cdot, x_0) \leq a) > 1 - \varepsilon
\]

(5.3.3)
for each each \( n \geq 1 \). By hypothesis, \( J_n h_m \to J h_m \) as \( n \to \infty \). Inequality 5.3.4 therefore yields

\[
J h_m \geq 1 - \varepsilon > 0.
\] (5.3.4)

We have thus verified also condition (i) in Definition 4.2.1 for \( J \) to be an integration on \((S, d)\). Therefore, by Proposition 5.3.2 \((S, C(S), J)\) is an integration space. At the same time, inequality 5.3.4 implies that \( J h_m \uparrow 1 \). We conclude that \( J \) is a distribution. Since \( J_n f \to J f \) for each \( f \in C(S) \) by hypothesis, Lemma 5.3.3 implies that \( J_n \Rightarrow J \).

Now note that inequality 5.3.4 implies that

\[
P_J(d(\cdot, x_0) \leq a + 2) = J 1(d(\cdot, x_0) \leq a + 2) \geq J h_m \geq 1 - \varepsilon > 0,
\] (5.3.5)

where \( a > \beta(\epsilon) \) is arbitrary. Thus \( J \) is tight with the modulus of tightness \( \beta + 2 \). \( \square \)

**Corollary 5.3.9.** (A tight \( \rho_{\text{Dist,} \xi} \)-Cauchy sequence of distributions converges). Let \( \xi \) be a binary approximation of a locally compact metric space \((S, d)\) relative to a reference point \( x_0 \in S \). Let \( \rho_{\text{Dist,} \xi} \) be the distribution metric on the space \( J(S,d) \) of distributions, determined by \( \xi \). Suppose the subfamily \( \{J_n : n \geq 1\} \subset J(S,d) \) of distributions is tight, with a modulus of tightness \( \beta \) relative to \( x_0 \).

If \( \rho_{\text{Dist,} \xi}(J_n, J_m) \to 0 \) as \( n, m \to \infty \). Then \( J_n \Rightarrow J \) and \( \rho_{\text{Dist,} \xi}(J_n, J) \to 0 \), for some \( J \in J(S,d) \) with the modulus of tightness \( \beta + 2 \).

**Proof.** Suppose \( \rho_{\text{Dist,} \xi}(J_n, J_m) \to 0 \) as \( n, m \to \infty \). Let \( f \in C(S) \) be arbitrary. We will prove that \( J(f) = \lim_{n \to \infty} J_n(f) \) exists. Let \( \varepsilon > 0 \) be arbitrary. Then there exists \( a > \beta(\varepsilon) \) such that \( P_n(d(\cdot, x_0) > a) < \varepsilon \) for each \( n \geq 1 \), where \( P_n = P_{f(a)} \) is the probability function for \( J_n \). Let \( k \geq 1 \) be so large that \( k \geq a \), and recall that

\[
h_k \equiv 1 \wedge (1 + k - d(\cdot, x_0))_+.
\]

Then

\[
J_n h_k \geq P_n(d(\cdot, x_0) \leq a) > 1 - \varepsilon
\]

for each \( n \geq 1 \). At the same time \( f h_k \in C(S) \). Hence, since \( \rho_{\text{Dist,} \xi}(J_n, J_m) \to 0 \), implies that \( (J_n f h_k)_{n=1,2,\ldots} \) is a Cauchy sequence of real numbers, according to Assertion 1 of Proposition 5.3.8. Hence \( J f h_k = \lim_{n \to \infty} J_n(f h_k) \) exists. Consequently,

\[
|J_n f - J_m f| \leq |J_n f - J_n f h_k| + |J_n f h_k - J_m f h_k| + |J_m f h_k - J_m f|
\]

\[
\leq |1 - J_n h_k| + |J_n f h_k - J_m f h_k| + |J_m f h_k - J_m h_k| - 1
\]

\[
\leq \varepsilon + J_n f h_k - J_m f h_k + \varepsilon < \varepsilon + \varepsilon + \varepsilon
\]

for sufficiently large \( n, m \geq 1 \). Since \( \varepsilon > 0 \) is arbitrary, we conclude that \( J(f) = \lim_{n \to \infty} J_n f \) exists for each \( f \in C(S) \). By Proposition 5.3.8 \( J \) is a distribution with the modulus of tightness \( \beta + 2 \), and \( J_n \Rightarrow J \). Proposition 5.3.5 then implies that \( \rho_{\text{Dist,} \xi}(J_n, J) \to 0 \). \( \square \)

**Proposition 5.3.10.** (A weakly convergent sequence of distributions on a locally compact metric space is tight). Suppose the metric space \((S, d)\) is locally compact. Let \( J_n \) be distributions for each \( n \geq 1 \). Suppose \( J_n \Rightarrow J \). Then the family \( \{J, J_1, J_2, \ldots\} \) is tight. In particular, any finite family of distributions on \( S \) is tight, and any finite family of r.v.’s with values in \( S \) is tight.
5.3. WEAK CONVERGENCE OF DISTRIBUTIONS

Proof. For each \( n \geq 1 \) write \( P \) and \( P_n \) for \( P_J \) and \( P_{J(n)} \) respectively. Since \( J \) is a distribution, we have \( P(d(\cdot, x_0) > a) \to 0 \) as \( a \to \infty \). Thus any family consisting of a single distribution \( J \) is tight. Let \( \beta_0 \) be a modulus of tightness of \( \{ J \} \) with reference to \( x_0 \), and, for each \( k \geq 1 \), let \( \beta_k \) be a modulus of tightness of \( \{ J_k \} \) with reference to \( x_0 \). Let \( \epsilon > 0 \) be arbitrary. Let \( m \beta_0(\xi) \) and define \( f \equiv 1 \wedge (a + 1 - d(\cdot, x_0))_+ \). Then \( f \in C(S) \) with

\[
1_{d(\cdot, x_0) > a + 1} \leq 1 - f \leq 1_{d(\cdot, x_0) > a}.
\]

Hence \( 1 - Jf \leq P(d(\cdot, x_0) > a) < \frac{\epsilon}{2} \). By hypothesis, we have \( J_n \Rightarrow J \). Hence there exists \( m \geq 1 \) so large that \( |J_n f - J f| < \frac{\epsilon}{2} \) for each \( n > m \). Consequently

\[
P_n(d(\cdot, x_0) > a + 1) \leq 1 - J_n f < 1 - J f + \frac{\epsilon}{2} < \epsilon
\]

for each \( n > m \). Define \( \beta(\epsilon) \equiv (a + 1) \vee \beta_1(\epsilon) \vee \cdots \vee \beta_m(\epsilon) \). Then, for each \( a' > \beta(\epsilon) \) we have

(i) \( P(d(\cdot, x_0) > a') \leq P(d(\cdot, x_0) > a) < \frac{\epsilon}{2} \).
(ii) \( P_n(d(\cdot, x_0) > a') \leq P_n(d(\cdot, x_0) > a + 1) < \epsilon \) for each \( n > m \), and
(iii) \( a' > \beta_n(\epsilon) \) and so \( P_n(d(\cdot, x_0) > a') \leq \epsilon \) for each \( n = 1, \cdots, m \).

Since \( \epsilon > 0 \) is arbitrary, the family \( \{ J, J_1, J_2, \cdots \} \) is tight.

The next proposition provides some alternative characterization of weak convergence in the case of locally compact \((S, d)\).

Proposition 5.3.11. (Modulus of continuity of the function \( J \to J f \) for functions \( f \) with fixed Lipschitz constant). Suppose \((S, d)\) is locally compact, with a reference point \( x_0 \). Let \( \xi \equiv (A_n)_{n=1,2,\ldots} \) be a binary approximation of \((S, d)\) relative to \( x_0 \), with a corresponding modulus of local compactness \( \| \xi \| \equiv (|A_n|)_{n=1,2,\ldots} \) of \((S, d)\). Let \( p_{\text{Dist}^{\xi}} \) be the distribution metric on the space \( \hat{J}(S, d) \) of distributions on \((S, d)\), determined by \( \xi \), as introduced in Definition 5.3.2.

Let \( J, J', J_p \) be distributions on \((S, d)\), for each \( p \geq 1 \). Let \( \beta \) be a modulus of tightness of \( \{ J, J' \} \) relative to \( x_0 \). Then the following holds.

1. Let \( f \in C(S, d) \) be arbitrary with \( \| f \| \leq 1 \) and with modulus of continuity \( \delta_f \). Then, for each \( \epsilon > 0 \), there exists \( \Delta(\epsilon, \delta_f, \beta, \| \xi \|) > 0 \) such that if \( p_{\text{Dist}^{\xi}}(J, J') < \Delta(\epsilon, \delta_f, \beta, \| \xi \|) \) then \( |Jf - J'f| < \epsilon \).

2. The following three conditions are equivalent: (i) \( J_p f \to Jf \) for each Lipschitz continuous \( f \in C(S) \), (ii) \( J_p \Rightarrow J \), and (iii) \( J_p f \to Jf \) for each Lipschitz continuous \( f \) which is bounded.

Proof. By Definition 5.1.1 we have

\[
(d(\cdot, x_0) \leq 2^n) \subset \bigcup_{x \in A(n)} (d(\cdot, x) \leq 2^{-n})
\]

and

\[
\bigcup_{x \in A(n)} (d(\cdot, x) \leq 2^{-n+1}) \subset (d(\cdot, x_0) \leq 2^{n+1})
\]
for each \( n \geq 1 \).

1. Let
\[
b \equiv |1 + \beta(\varepsilon)|_1.
\]
Write \( h \equiv 1 \wedge \left( b - d(\cdot, x_0) \right)_+ \in C(S) \). Then \( h \) and \( fh \) have support \((d(\cdot, x_0) \leq b)\), and \( h = 1 \) on \((d(\cdot, x_0) \leq b - 1)\).

Moreover, since \( h \) has Lipschitz constants \( 1 \), the function \( fh \) has a modulus of continuity \( \delta_{fh} \) defined by \( \delta_{fh}(\alpha) \equiv \frac{\alpha}{2} \wedge \delta_f(\frac{\alpha}{2}) \). Hence, by Proposition 5.3.5 there exists \( \delta_f(\varepsilon) \equiv \delta_f(\varepsilon, \delta_{fh}, b, ||\xi||) > 0 \) such that if \( \rho_{\text{Dist}, \xi}(J, J') < \delta_f(\varepsilon) \) then
\[
|Jfh - J'fh| < \frac{\varepsilon}{2}. \tag{5.3.8}
\]

More precisely, according to said proposition, we can let
\[
n \equiv \left[ 0 \vee (1 - \log_2 \delta_{fh}(\varepsilon)) \wedge \log_2 b \right]_1
\]
\[
\equiv \left[ 0 \vee \log_2 \left( \frac{\varepsilon}{6} \wedge \delta_f(\frac{\varepsilon}{6}) \right) \wedge \log_2 b \right]_1
\]
and
\[
\delta_f(\varepsilon, \delta_{fh}, b, ||\xi||) \equiv \frac{1}{6} 2^{-n} |A_n|^{-1} \varepsilon.
\]

Now define
\[
\tilde{\Delta}(\varepsilon) \equiv \Delta(\varepsilon, \delta_f, \beta, ||\xi||) \equiv \delta_f(\varepsilon, \delta_{fh}, b, ||\xi||) \equiv \frac{1}{6} 2^{-n} |A_n|^{-1} \varepsilon.
\]

Suppose \( \rho_{\text{Dist},\xi}(J, J') < \tilde{\Delta}(\varepsilon) \). We need to prove that \( |Jf - J'f| < \varepsilon \). To that end, note that, since \( J, J' \) have tightness modulus \( \beta \), and since \( 1 - h = 0 \) on \((d(\cdot, x_0) \leq b - 1)\) where \( b - 1 > \beta(\frac{\varepsilon}{2}) \), we have \( J(1 - h) \leq \frac{\varepsilon}{4} \) and \( J'(1 - h) \leq \frac{\varepsilon}{4} \). Consequently,
\[
|Jf - Jfh| = |Jf(1 - h)| \leq J(1 - h) \leq \frac{\varepsilon}{4}. \tag{5.3.9}
\]

Similarly,
\[
|J'f - J'fh| \leq \frac{\varepsilon}{4}. \tag{5.3.10}
\]
Combining inequalities \( 5.3.8, 5.3.9 \) and \( 5.3.10 \) we obtain
\[
|Jf - J'f| < \frac{\varepsilon}{4} + \frac{\varepsilon}{2} + \frac{\varepsilon}{4} = \varepsilon.
\]

Assertion 1 is thus proved.

2. We need to prove that Conditions (i-iii) are equivalent. To that end, first suppose (i) \( J_p f \to Jf \) for each Lipschitz continuous \( f \in C(S) \). Let
\[
\pi \equiv \{ \{ g_{n,x} : x \in A_n \} \}_{n=1,2, \ldots}
\]
be the partition of unity of \((S,d)\) determined by \( \xi \). Then, for each \( n \geq 1 \) and each \( x \in A_n \), we have \( J_p g_{n,x} \to Jg_{n,x} \) as \( p \to \infty \), because \( g_{n,x} \in C(S) \) is Lipschitz continuous.
by Proposition 5.2.5. Hence $\rho_{\text{Dist}, \xi}(J_f, J) \to 0$ and $J_f \Rightarrow J$ by Proposition 5.3.5. Thus we have proved that Condition (i) implies Condition (ii).

Suppose next that $J_f \Rightarrow J$. Then $J_f \Rightarrow Jf$ for each $f \in C(S)$. Hence, since $(S, d)$ is locally compact, we have $\rho_{\text{Dist}, \xi}(J_f, J) \to 0$ by Proposition 5.3.5. Separately, in view of Proposition 5.3.10, the family $\{J, J_1, J_2, \cdots\}$ is tight, with some modulus of tightness $\beta$. Let $f \in C(S)$ be Lipschitz continuous. We need to prove that $I_p f \Rightarrow Jf$. By linearity, we may assume that $|f| \leq 1$, whence $I_p f \Rightarrow Jf$ by Assertion 1. Thus Condition (ii) implies Condition (iii).

Finally, Condition (iii) trivially implies Condition (i). Assertion 2 is proved. □

5.4 Probability Density Functions and Distribution Functions

Useful distributions can be obtained by using integrable functions as density functions. The Riemann-Stieltjes integration gives rise to other examples of distributions on $R$. This section makes these terms precise for later reference.

**Definition 5.4.1. (probability density function).** Let $I$ be an integration on a locally compact metric space $(S, d)$, and let $(S, \Lambda, I)$ denote the completion of the integration space $(S, C(S), I)$. Let $g \in \Lambda$ be arbitrary, with $p \geq 0$ and $Ig = 1$. Then $g$ will be called a probability density function, or p.d.f. for short, on the integration space $(S, \Lambda, I)$. Define $I_g h \equiv Ig h$ for each $h \in C(S)$. Then $(S, C(S), I_g)$ is an integration space, with a completion $(\Omega, \Lambda_g, I_g)$ which is a probability space.

Suppose $X$ is a r.v. with values in $S$ such that $X$ induces the distribution $I_g$. In other words, Suppose $E_X = I_g$. Then $X$ is said to have the p.d.f. $g$. □

Frequently used p.d.f.'s are defined on $(S, \Lambda, I) \equiv (R^n, \Lambda, \int dx)$, the $n$-dimensional Euclidean space equipped with the Lebesgue integral, and on $(S, \Lambda, I) \equiv (\{1, 2, \cdots\}, \Lambda, I)$ with the counting measure $I$ defined by $I_g \equiv \sum_{\{1, 2, \cdots\}} g(n)$ for each $g \in C(S)$.

**Proposition 5.4.2. (Integrable functions relative to a p.d.f.)** Use the notations of Definition 5.4.1. Let $g$ be a p.d.f. on $(S, \Lambda, I)$. Let $f, h$ be an arbitrary measurable function on $(S, \Lambda, I)$ such that $hg \in \Lambda$. Then (i) $h \in \Lambda_g$ and $I_g h = Ih g$, and (ii) $f$ is measurable on $(S, \Lambda_g, I_g)$.

**Proof.** 1. First suppose that $h \in \Lambda$ and $|h| \leq a$ for some $a > 0$. Let $k \geq 1$ be arbitrary. Then there exists $h_k \in C(S)$ such that $|I|h_k - h| < \frac{1}{k}$. By replacing $h_k$ with $-a \vee h_k \wedge a$, we may assume that $|h_k| \leq a$. It follows that $\tilde{h} \equiv \lim_{k \to \infty} h_k \in \Lambda$, that $h = \tilde{h}$ on the full subset $D \equiv \text{domain}(\tilde{h})$ of $(S, \Lambda, I)$. Hence $I_g|h_k - h_j| \equiv I|h_k - h_j|g \to 0$ as $k, j \to \infty$ by the Dominated Convergence Theorem. Since $h_k \in C(S) \subset \Lambda_g$ for each $k \geq 0$, we conclude that $\tilde{h} \in \Lambda_g$ and that

$$I_g \tilde{h} = \lim_{k \to \infty} I_g h_k = \lim_{k \to \infty} Ih_k g = I\tilde{h}g.$$

Hence $D \equiv \text{domain}(\tilde{h})$ is a full set also of $(S, \Lambda_g, I_g)$. Since $h = \tilde{h}$ on $D$, we conclude that $h \in \Lambda_g$ and $I_g h = I_g \tilde{h} = I\tilde{h}g$.

Yuen-Kwok Chan 135 Constructive Probability
2. Next, suppose \( h \geq 0 \). Let \( x_0 \in S \) be an arbitrary, but fixed, reference point. Let \( m \geq 1 \) be arbitrary. Then \((m \wedge h) f_m \in \Lambda\) where \( f_m \equiv 1 \wedge (m - d(\cdot, x_0))_+ \in C(S)\). Hence, by Step 1 of this proof, we have \((m \wedge h) f_m \in \Lambda_g\) and

\[
I_g (m \wedge h) f_m \equiv I(m \wedge h) f_m g.
\]

Since \((m \wedge h) f_m \uparrow h\), the Dominated Convergence Theorem implies that \(I(m \wedge h) f_m g \uparrow Ihg\). In turn, the Monotone Convergence Theorem then implies that \(h \in \Lambda_g\) with \(Igh = Ihg\).

3. Finally, let \( h \) be an arbitrary nonnegative measurable function on \((S, \Lambda, I)\) such that \(hg \in \Lambda\). Step 2 above implies \(h_+, |h| \in \Lambda_g\). Hence, since \(h = 2h_+ - |h|\), we have \(h \in \Lambda_g\) by linearity, with

\[
Igh = 2Igh_+ - Igh|h| = I(2h_+ - |h|)g = Ihg.
\]

Assertion (i) is proved.

4. By Assertion 1, we have \(f_k \equiv -k \vee f \wedge k \in \Lambda_g\) and \(1 \wedge |f_k - f| \in \Lambda_g\) for each \(k \geq 1\). Moreover, \(Ig1_{(1 \wedge |f_k - f|)} = I1_{(1 \wedge |f_k - f|)}g \to 0\) by the Monotone Convergence Theorem. Hence \(f_k \to f\) in probability on \((S, \Lambda_g, Ig)\), whence \(f\) is measurable on \((S, \Lambda_g, Ig)\). \(\square\)

**Proposition 5.4.3. (p.d.f. of a r.v. \(X\) is a.s. positive at \(X\)).** Let \(X : (\Omega, L, E) \to (S,d)\) be a r.v. with the p.d.f. \(g\) on \((S, \Lambda, I)\). In other words, \((S, \Lambda, EX) = (S, \Lambda_g, Ig)\). Then \(P_g(g \leq \varepsilon) = Ig1_{(g \leq \varepsilon)} \to 0\) as \(\varepsilon \to 0\). Moreover, \(P(g(X) \leq \varepsilon) \to 0\) as \(\varepsilon \to 0\).

Consequently, \(g(X) > 0\) a.s. on \((\Omega, L, E)\), and \(g > 0\) a.s. on \((S, \Lambda_g, Ig)\).

**Proof.** By Proposition 5.4.2, \(g(X)\) is measurable on \(\Omega\) and \(g\) is measurable on \((S, \Lambda_g, Ig)\). Then

\[
P_g(g \leq \varepsilon) = Ig1_{(g \leq \varepsilon)} = Ig \vee \varepsilon \to 0
\]

as \(\varepsilon \to 0\), because \(g \in \Lambda\). Consequently,

\[
P(g(X) \leq \varepsilon) = E1_{(g(X) \leq \varepsilon)} = E1_{(g \leq \varepsilon)}(X) = Ig1_{(g \leq \varepsilon) \to 0}
\]

as \(\varepsilon \to 0\), where the last inequality is because \((S, \Lambda_g, EX) = (S, \Lambda_g, Ig)\) by hypothesis. \(\square\)

Distributions on \(R\) can be studied in terms of their corresponding distribution functions, as introduced earlier in Definition 4.1.1 and specialized to probability distribution functions.

Recall the convention that if \(F\) is a function, then we write \(F(t)\) only with the implicit assumption that \(t \in \text{domain}(F)\).

**Definition 5.4.4. (Probability Distribution Functions).** Suppose \(F\) is a distribution function on \(R\) satisfying the following conditions: (i) \(F(t) \to 0\) as \(t \to -\infty\), and \(F(t) \to 1\) as \(t \to \infty\), (ii) for each \(t \in \text{domain}(F)\), the left limit \(\lim_{t \downarrow r} F(s)\) exists, (iii) for each \(t \in \text{domain}(F)\), the right limit \(\lim_{t \uparrow s} F(s)\) exists and is equal to \(F(t)\), (iv) \(\text{domain}(F)\) contains the metric complement \(\Lambda^c\) of some countable subset \(A\) of \(R\), and (v) if \(t \in R\) is such that both the above-defined left- and right limits exist, then
### 5.4. Probability Density Functions and Distribution Functions

Let $t \in \text{domain}(F)$. Then $F$ is called a probability distribution function, or a P.D.F. for abbreviation. A point $t \in \text{domain}(F)$ is called a regular point of $F$. A point $t \in \text{domain}(F)$ at which the above-defined left- and right limits are equal is called a continuity point of $F$.

Suppose $X$ is a r.r.v. on a probability space $(\Omega, L, E)$. Let $F_X$ be the function defined by (i) $\text{domain}(F_X) \equiv \{ t \in R : t$ is a regular point of $X \}$, and (ii) $F_X(t) \equiv P(X \leq t)$ for each $t \in \text{domain}(F_X)$. Then $F_X$ is called the P.D.F. of $X$. \( \square \)

Recall in the following that $\int dF$ denotes the Riemann-Stieljes integration relative to a distribution function $F$ on $R$.

**Proposition 5.4.5.** (F is indeed a P.D.F.) Let $X$ be a r.r.v. on a probability space $(\Omega, L, E)$ with $F_X$ as in Definition 5.4.4. Let $E_X$ denote the distribution induced on $R$ by $X$. Then the following holds.

1. $F_X$ is a P.D.F.
2. $\int dF_X = E_X$.

**Proof.** For abbreviation, write $J \equiv E_X$ and $F \equiv F_X$, and write $P$ for the probability function associated to $E$.

1. We are to verify conditions (i) through (v) in Definition 5.4.4 for $F$. Condition (i) holds because $P(X \leq t) \to 0$ as $t \to -\infty$ and $P(X \leq t) = 1 - P(X > t) \to 1$ as $t \to \infty$, by the definition of a measurable function. Next consider any $t \in \text{domain}(F)$. Then $t$ is a regular point of $X$, by the definition of $F_X$. Hence there exists a sequence $(s_n)_{n=1, 2, \ldots}$ of real numbers decreasing to $t$ such that $(X \leq s_n)$ is integrable for each $n \geq 1$ and such that $\lim_{n \to \infty} P(X \leq s_n)$ exists. Since $P(X \leq s_{n+1}) \leq F(s) \leq P(X \leq s_n)$ for each $s \in (s_{n+1}, s_n)$ and for each $n \geq 1$, we see that $\lim_{n \to \infty} F(s)$ exists. Similarly $\lim_{n \to \infty} F(s)$ exists. Moreover, by Proposition 4.5.7 we have $\lim_{n \to \infty} F(s) = \lim_{n \to \infty} P(X \leq s_n) = P(X \leq t) \equiv F(t)$. Conditions (ii) and (iii) in Definition 5.4.4 have thus been verified. Condition (iv) in Definition 5.4.4 follows from Assertion 1 of Proposition 4.8.11. Condition (v) remains. Suppose $t \in R$ is such that both $\lim_{\epsilon \to 0} F(t)$ and $\lim_{\epsilon \to 0} F(s)$ exist. Then there exists a sequence $(s_n)_{n=1, 2, \ldots}$ in $\text{domain}(F)$ decreasing to $t$ such that $F(s_n)$ converges. This implies that $(X \leq s_n)$ is an integrable set, and that $P(X \leq s_n)$ converges. Hence $(X > s_n)$ is an integrable set, and $P(X > s_n)$ converges. Similarly, there exists a sequence $(r_n)_{n=1, 2, \ldots}$ increasing to $t$ such that $P(X > r_n)$ is an integrable set and $P(X > r_n)$ converges. We have thus verified the conditions in Definition 4.8.10 for $t$ to be a regular point of $X$. In other words, $t \in \text{domain}(F)$. Condition (v) in Definition 5.4.4 have thus also been verified. Summing up, $F \equiv F_X$ is a P.D.F.

2. Note that both $\int dF_X$ and $E_X$ are complete extensions of integrations defined on $(R, C(R))$. Hence it suffices to prove that they are equal on $C(R)$. Let $f \in C(R)$ be arbitrary. We need to show that $\int f(x) dF_X(x) = E_X f$. Let $\epsilon > 0$ be arbitrary, and let $\delta_\epsilon$ be a modulus of continuity for $f$. The Riemann-Stieltjes integral $\int f(t) dF_X(t)$ is, by definition, the limit of Riemann-Stieltjes sums $S(t_1, \cdots, t_n) = \sum_{i=1}^{n} f(t_i)(F_X(t_i) - F_X(t_{i-1}))$ as $t_1 \to -\infty$ and $t_n \to \infty$ with the mesh of the partition $t_1 < \cdots < t_n$ approaching 0. Consider such a Riemann-Stieltjes sum where the mesh is smaller than $\delta_\epsilon(\epsilon)$, and where
CHAPTER 5. PROBABILITY SPACE

$[t_1, t_n]$ contains a support of $f$. Then

$$|S(t_1, \ldots, t_n) - Ef(X)| = |E \sum_{i=1}^n (f(t_i) - f(X))1_{(t_{i-1} < X \leq t_i)}| \leq \varepsilon$$

Passing to the limit, we have $\int f(t) dF_X(t) = Ef(X) \equiv E_X f$. \hfill \Box

Proposition 5.4.5 says that $F_X$ is a P.D.F. for each r.v. $X$. The next proposition gives the converse.

**Proposition 5.4.6. (Basics of P.D.F.)** The following holds.

1. Let $J$ be any distribution on $R$, and let $(R, L, J)$ denote the completion of $(R, C_{ab}(R), J)$. Then $J = \int \cdot dF_X$ where $F_X$ is the P.D.F. of the r.v. $X$ on $(R, L, J)$ defined by $X(x) \equiv x$ for $x \in R$.

2. Let $F$ be a P.D.F. For each $t \in \text{domain}(F)$, the interval $(-\infty, t]$ is integrable relative to $\int \cdot dF$, and $\int 1_{(-\infty, t]} dF = F(t)$.

3. If two P.D.F.'s $F$ and $F'$ equal on some dense subset $D$ of $\text{domain}(F) \cap \text{domain}(F')$, then $F = F'$.

4. If two P.D.F.'s $F$ and $F'$ are such that $\int dF = \int dF'$, then $F = F'$.

5. Let $F$ be any P.D.F. Then $F = F_X$ for some r.v. $X$.

6. Let $F$ be any P.D.F. Then all but countably many $t \in R$ are continuity points of $F$.

7. Let $J$ be any distribution on $R$. Then there exists a unique P.D.F. $F$ such that $J = \int \cdot dF$. Thus there is a bijection between distributions on $R$ and P.D.F.'s. For that reason, we will often abuse terminology and refer to $F$ as a distribution, and write $F$ for $J$.

**Proof.** 1. According to Proposition 5.2.3 $X$ is a r.v. on $(R, L, J)$. Moreover, for each $f \in C_{ab}(R)$, we have $f(X) = f \in C_{ab}(R)$. Hence, in view of Proposition 5.4.5 we have $Jf = Jf(X) \equiv E_X f = \int f(x) dF_X(x)$. Assertion 1 is validated.

2. Define $J = \int \cdot dF$. Consider any $t, s \in \text{domain}(F)$ with $t < s$, and any $f \in C(R)$ with $0 \leq f \leq 1$ such that $[t, s]$ is a support of $f$. Then $Jf \equiv \int f(x) dF(x)$ is the limit of Riemann-Stieljes sums $\sum_{i=1}^n f(t_i)(F(t_i) - F(t_{i-1}))$, where the sequence $t_0 < \cdots < t_n$ includes the points $t, s$.

Consider any such Riemann-Stieljes sum. If $i = 0, \cdots, n$ is such that $t_i < t$ or $t_i > s$, then $f(t_i) = 0$. We can, by excluding such indices $i$, assume that $t_0 = t$ and $t_n = s$. It follows that the Riemann-Stieljes sums in question are bounded by $\sum_{i=1}^n (F(t_i) - F(t_{i-1})) = F(s) - F(t)$. Passing to the limit, we see that $Jf \leq F(s) - F(t)$ for each $f \in C(R)$ with $0 \leq f \leq 1$ such that $[t, s]$ is a support of $f$. A similar argument shows that $Jf \geq F(s) - F(t)$ for each $f \in C(R)$ with $0 \leq f \leq 1$ such that $f = 1$ on $[t, s]$.

By condition (i) in Definition 5.4.4 there exists a decreasing sequence $(r_k)_{k=1,2,\cdots}$ in $\text{domain}(F)$ such that $r_1 < t$, $r_k \to -\infty$, and $F(r_k) \to 0$. By condition (iii) in Definition 5.4.4 we have $F(s_n) \to F(t)$ for some sequence $(s_n)_{n=1,2,\cdots}$ such that $s_n \downarrow t$.
5.4. PROBABILITY DENSITY FUNCTIONS AND DISTRIBUTION FUNCTIONS

For each $k,n \geq 1$, let $f_{k,n} \in C(R)$ be defined by $f_{k,n} = 1$ on $[r_k, s_{n+1}]$, $f_{k,n} = 0$ on $(-\infty, r_k) \cup [s_n, \infty)$, and $f_{k,n}$ is linear on $[r_k, r_{k+1}]$ and on $[s_{n+1}, s_n]$. Consider any $n \geq 1$ and $j > k \geq 1$. Then $0 \leq f_{k,n} \leq f_{j,n} \leq 1$, and $f_{j,n} - f_{k,n}$ has $[r_{j+1}, r_j]$ as support. Therefore, as seen earlier, $J f_{j,n} - J f_{k,n} \leq F(r_k) - F(r_{j+1})$ which implies that

$$\lim_{j \to \infty} J f_{j,n}$$

is integrable, with $J f_n = \lim_{k \to \infty} J f_{k,n}$. Moreover, $f_n = 1$ on $(-\infty, s_{n+1}]$, $f_n = 0$ on $[s_n, \infty)$, and $f_n$ is linear on $[s_{n+1}, s_n]$.

Now consider any $m \geq n \geq 1$. Then $0 \leq f_m \leq f_n \leq 1$, and $f_n - f_m$ has $[t, s_n]$ as support. Therefore, as seen earlier, $J f_n - J f_m \leq F(s_n) - F(t) \to 0$ as $m \geq n \to \infty$. Hence, the Monotone Convergence Theorem implies that $g \equiv \lim_{n \to \infty} f_n$ is integrable, with

$$J g = \lim_{n \to \infty} J f_n.$$  

It is evident that $(\infty, t)$ we have $f_n = 1$ for each $n \geq 1$. Hence $g$ is defined and equal to 1 on $(\infty, t]$. Similarly, $g$ is defined and equal to 0 on $(t, \infty)$.

Consider any $x \in \text{domain}(g)$. Then either $g(x) > 0$ or $g(x) < 1$. Suppose $g(x) > 0$. Then the assumption $x > t$ would imply $g(x) = 0$, a contradiction. Hence $x \in (-\infty, t]$ and so $g(x) = 1$. On the other hand, suppose $g(x) < 1$. Then $f_n(x) < 1$ for some $n \geq 1$, whence $x \geq s_{n+1}$ for some $n \geq 1$. Hence $x \in (t, \infty)$ and so $g(x) = 0$. Combining, we see that 1 and 0 are the only possible values of $g$. In other words, $g$ is an integrable indicator. Moreover ($g = 1$) = $(\infty, t]$ and $g = 0$ = $(t, \infty)$. Thus the interval $(-\infty, t]$ is an integrable set with 1 on $(-\infty, t] = g$.

Finally, for any $k, n \geq 1$, we have $F(s_{n+1}) - F(r_k) \leq J f_{k,n} \leq F(s_n) - F(r_{j+1})$. Letting $k \to \infty$, we obtain $F(s_{n+1}) - J f\n \leq F(s_n)$ for $n \geq 1$. Letting $n \to \infty$, we obtain in turn $J F = F(t)$. In other words $J 1_{(-\infty, t]} = F(t)$. Assertion 2 is proved.

3. Consider any $t \in \text{domain}(F)$. Let $(s_n)_{n=1,2,\ldots}$ be a decreasing sequence in $D$ converging to $t$. By hypothesis, $F'(t) = F(s_n)$ for each $n \geq 1$. At the same time $F'(s_n) \to F(t)$ since $t \in \text{domain}(F)$. Therefore $F'(s_n) \to F(t)$. By the monotonicity of $F'$, it follows that $\lim_{s \to t} F'(s) = F(t)$. Similarly, $\lim_{r \to t} F'(r)$ exists. Therefore, according to Definition 5.4.4 we have $t \in \text{domain}(F')$, and $F'(t) = \lim_{r \to t} F'(r) = F(t)$. We have thus proved that $\text{domain}(F) \subset \text{domain}(F')$ and $F' = F$ on $\text{domain}(F)$. By symmetry $\text{domain}(F) = \text{domain}(F')$.

4. Write $J \int J dF' = \int dF'$. Consider any $t \in D \equiv \text{domain}(F) \cap \text{domain}(F')$. By assertion 2, the interval $(-\infty, t]$ is integrable relative to $J$, with $F(t) = J 1_{(-\infty, t]} = F'(t)$. Since $D$ is a dense subset of $R$, we have $F' = F$ by Assertion 3. This proves Assertion 4.

5. Let $F$ be any P.D.F. By assertion 1, we have $\int dF = \int dF_X$ for some r.r.v. $X$. Therefore $F = F_X$ according to assertion 4. Assertion 5 is proved.

6. Let $F$ be any P.D.F. By assertion 5, $F = F_X$ for some r.r.v. $X$. Hence $F(t) = F_X(t) = P(X \leq t)$ for each regular point $t$ of $X$. Consider any continuity point $t$ of $X$. Then, by Definition 4.8.10, we have $\lim_{t \to t^-} P(X \leq t_n) = \lim_{t \to t^-} P(X \leq n)$ for some increasing sequence $t_n$ with $t_n \to t$ and some decreasing sequence $t_n$ with $t_n \to t$ and some increasing sequence $r_n$ with $r_n \to t$. Since $P(X \leq r_n) \leq P(X \leq t_n) \leq P(X \leq s_n)$ for all $x \in (r_n, s_n)$, it follows that $\lim_{x \to t} F(X) = \lim_{r \to t} F(r)$. Summing up, every continuity point of $X$ is a continuity point of $F$. By Proposition 4.8.11 all but countably many $t \in R$ are continuity points of $X$. Hence all but countably many $t \in R$ are continuity points of $F$. This validates Assertion 6.

7. Let $J$ be arbitrary. By Assertion 1, there exists a P.D.F. $F$ such that $J = \int dF$. Uniqueness of $F$ follows from Assertion 4. The proposition is proved. □
5.5 The Skorokhod Representation

In this section, let \((S, d)\) be a locally compact metric space with an arbitrary, but fixed, reference point \(x_0 \in S\). Let

\[
(\Theta_0, L_0, I) \equiv ([0, 1], L_0, \int d) \nonumber
\]

denote the Lebesgue integration space based on the unit interval \([0, 1]\), and let \(\mu\) the corresponding Lebesgue measure.

Given two distributions \(E\) and \(E'\) on the locally compact metric space \((S, d)\), we saw in Proposition 5.2.3 that they are equal to the distributions induced by \(X\) and \(X'\) respectively, where \(X\) and \(X'\) are some r.v.'s with values in \(S\). The underlying probability spaces on which \(X\) and \(X'\) are respectively defined are in general different. Therefore functions of both \(X\) and \(X'\), e.g. \(d(X, X')\), and their associated probabilities need not make sense. Additional conditions on joint probabilities are needed to construct one probability space on which both \(X\) and \(X'\) are defined.

One such condition is independence, to be made precise in a later section, where knowledge on the value of \(\pi\) of unity \(X\) makes sense. Additional conditions on joint probabilities are needed to construct one such distribution.

In this section, let \(\hat{J}(S, d)\) be a binary approximation of the locally compact metric space \((S, d)\), relative to the reference point \(x_0 \in S\). Let \(\hat{J}(S, d)\) be the set of distributions on \((S, d)\). Recall that \(M(\Theta_0, S)\) stands for the space of r.v.'s on the probability space \((\Theta_0, L_0, I)\) with values in \((S, d)\).

Then there exists a function

\[
\Phi_{Sk, \xi} : \hat{J}(S, d) \to M(\Theta_0, S) \nonumber
\]

where \(\xi\) is the Skorokhod representation which, to each distribution that it is continuous relative to weak convergence of \(E\) fields, Theorem 3.1.1 of [Skorokhod 1956] introduced said representation and proves Skorokhod’s representation is uniformly continuous relative to the distribution metric \(\rho\).

In some other situations, it is desirable to have models where \(X = X'\) if \(E = E'\), and more generally where \(d(X, X')\) is small when \(E\) is close to \(E'\). In this section, we construct the Skorokhod representation which, to each distribution \(E\) on \(S\), assigns a unique r.v. \(X : [0, 1] \to S\) which induces \(E\). In the context of applications to random fields, Theorem 3.1.1 of [Skorokhod 1956] introduced said representation and proves that it is continuous relative to weak convergence of \(E\) and a.u. convergence of \(X\). We will prove this result, for applications in the next chapter.

In addition, we will prove that, when restricted to a tight subset of distributions, Skorokhod’s representation is uniformly continuous relative to the distribution metric \(\rho_{Dist, \xi}\), and the metric \(\rho_{Prob}\) on r.v.'s. The metrics \(\rho_{Dist, \xi}\) and \(\rho_{Prob}\) were introduced in Definition 5.3.4 and in Proposition 5.1.11 respectively.

The Skorokhod representation is a generalization of the quantile mapping which, to each P.D.F. \(F\), assigns the r.v. \(X \equiv F^{-1} : [0, 1] \to \mathbb{R}\) on the probability space \([0, 1]\) relative to the uniform distribution, where \(X\) can easily shown to induce the P.D.F. \(F\).

Skorokhod’s proof, in terms of Borel sets, is recast here in terms of a given partition of unity \(\pi\). The use of a partition of unity facilitates the proof of the aforementioned metrical continuity.

Recall that \(\lfloor x \rfloor \) is an operation which assigns to each \(x \in (0, \infty)\) an integer \(\lfloor x \rfloor \in (r, r + 2)\).

**Theorem 5.5.1. (Construction of the Skorokhod Representation)** Let \(\xi \equiv (A_n)_{n=1,2,...}\) be a binary approximation of the locally compact metric space \((S, d)\), relative to the reference point \(x_0 \in S\). Let \(\hat{J}(S, d)\) be the set of distributions on \((S, d)\). Recall that \(M(\Theta_0, S)\) stands for the space of r.v.'s on the probability space \((\Theta_0, L_0, I)\) with values in \((S, d)\).

Then there exists a function

\[
\Phi_{Sk, \xi} : \hat{J}(S, d) \to M(\Theta_0, S) \nonumber
\]
such that, for each $E \in \hat{\mathcal{J}}(S,d)$, the r.v. $X \equiv \Phi_{\text{Sk},\xi}(E) : \Theta_0 \to S$ induces the distribution $E$, or $I_X = E$ in symbols.

The function $\Phi_{\text{Sk},\xi}$ is called the Skorokhod representation of distributions on $(S,d)$ determined by $\xi$.

Proof. Let $E \in \hat{\mathcal{J}}(S,d)$ be arbitrary. Let

$$\pi \equiv \{\{g_{n,x} : x \in A_n\}_n=1,2,\ldots\}$$

be the partition of unity of $(S,d)$ determined by $\xi$, as in Definition 3.2.4.

1. Let $n \geq 1$ be arbitrary. By Definition of 3.1.1, the enumerated finite set $A_n \equiv \{x_{n,1}, \ldots, x_{n,K(n)}\}$ is a $2^{-n}$-approximation of $(d(\cdot,x_0) \leq 2^n)$. In other words,

$$A_n \subset (d(\cdot,x_0) \leq 2^n)$$

and

$$(d(\cdot,x_0) \leq 2^n) \subset \bigcup_{x \in A(n)} (d(\cdot,x) \leq 2^{-n}).$$

Recall from Proposition 3.2.5 that $0 \leq g_{n,x} \leq \sum_{x \in A(n)} g_{n,x} \leq 1$,

$$(g_{n,x} > 0) \subset (d(\cdot,x) \leq 2^{-n+1}),$$

for each $x \in A_n$, and that

$$\bigcup_{x \in A(n)} (d(\cdot,x) \leq 2^{-n}) \subset (\sum_{x \in A(n)} g_{n,x} = 1).$$

Define $K_n \equiv K_n + 1$, and define the sequence

$$(f_{n,1}, \ldots, f_{n,K(n)})$$

$$\equiv (g_{n,x(n,1)}, \ldots, g_{n,x(n,K(n))}, (1 - \sum_{x \in A(n)} g_{n,x}))$$

of nonnegative continuous functions on $S$. Then

$$\sum_{k=1}^{K(n)} f_{n,k} = 1$$

on $S$.

2. For the purpose of this proof, an open interval is defined by the pair of its endpoints $a,b$, where $0 \leq a \leq b \leq 1$. Two open intervals $(a,b),(a',b')$ are considered equal if $a = a'$ and $b = b'$. For arbitrary open intervals $(a,b),(a',b') \subset [0,1]$ we will write $(a,b) < (a',b')$ if $b \leq a'$.

3. Let $n \geq 1$ be arbitrary. Define the product set

$$B_n \equiv \{1, \ldots, K_1\} \times \cdots \times \{1, \ldots, K_n\}.$$
CHAPTER 5. PROBABILITY SPACE

Let $\mu$ denote the Lebesgue measure on $[0, 1]$. Define the open interval $\Theta \equiv (0, 1)$. Then, since

$$
\sum_{k=1}^{K(1)} E f_{n,k} = E \sum_{k=1}^{K(1)} f_{n,k} = E 1 = 1,
$$

we can subdivide the open interval $\Theta$ into mutually exclusive open subintervals $\Theta_1, \cdots, \Theta_{K(1)}$ such that

$$
\mu \Theta_k = E f_{n,k}
$$

for each $k = 1, \cdots, K_1$, and such that $\Theta_k < \Theta_j$ for each $k = 1, \cdots, K_1$ with $k < j$.

4. We will construct, for each $n \geq 1$, a family of mutually exclusive open subintervals

$$
\{ \Theta_{k(1), \cdots, k(n)} : (k_1, \cdots, k_n) \in B_n \}
$$

of $(0, 1)$ such that, for each $(k_1, \cdots, k_n) \in B_n$, we have

(i) $\mu \Theta_{k(1), \cdots, k(n)} = E f_{1,k(1)} \cdots f_{n,k(n)}$,

(ii) $\Theta_{k(1), \cdots, k(n)} \subset \Theta_{k(1), \cdots, k(n-1)}$ if $n \geq 2$,

(iii) $\Theta_{k(1), \cdots, k(n-1), k(n)} < \Theta_{k(1), \cdots, k(n-1), j}$ for each $k, j = 1, \cdots, K_n$ with $k < j$.

5. Proceed inductively. Step 3 above gave the construction for $n = 1$. Now suppose the construction has been carried out for some $n \geq 1$ such that Conditions (i-iii) are satisfied. Consider each $(k_1, \cdots, k_n) \in B_n$. Then

$$
\sum_{k=1}^{K(n+1)} E f_{1,k(1)} \cdots f_{n,k(n)} f_{n+1,k} = E f_{1,k(1)} \cdots f_{n,k(n)} \sum_{k=1}^{K(n+1)} f_{n+1,k} = E f_{1,k(1)} \cdot \cdots \cdot f_{n,k(n)} = \mu \Theta_{k(1), \cdots, k(n)}
$$

where the last equality is because of Condition (i) in the induction hypothesis. Hence we can subdivide $\Theta_{k(1), \cdots, k(n)}$ into $K_{n+1}$ mutually exclusive open subintervals

$$
\Theta_{k(1), \cdots, k(n), 1}, \cdots, \Theta_{k(1), \cdots, k(n), K(n+1)}
$$

such that

$$
\mu \Theta_{k(1), \cdots, k(n), k(n+1)} = E f_{1,k(1)} \cdot \cdots \cdot f_{n,k(n)} f_{n+1,k(n+1)}
$$

(5.5.7)

for each $k_{n+1} = 1, \cdots, K_{n+1}$. Thus Condition (i) holds for $n + 1$. In addition, we can arrange these open subintervals such that

$$
\Theta_{k(1), \cdots, k(n), k(n+1)} \subset \Theta_{k(1), \cdots, k(n), j(n+1)}
$$

for each $k, j = 1, \cdots, K_{n+1}$ with $k < j$. This establishes Condition (iii) for $n + 1$. Condition (ii) also holds for $n + 1$ since, by construction, $\Theta_{k(1), \cdots, k(n+1)}$ is a subinterval of $\Theta_{k(1), \cdots, k(n)}$ for each $(k_1, \cdots, k_{n+1}) \in B_{n+1}$. Induction is completed.

6. Note that Condition (i) implies that

$$
\mu \sum_{(k_1, \cdots, k(n)) \in B(n)} \Theta_{k(1), \cdots, k(n)} = E \left( \sum_{k=1}^{K(1)} f_{1,k(1)} \right) \cdots \left( \sum_{k=1}^{K(n)} f_{n,k(n)} \right) = E 1 = 1
$$

(5.5.8)

Yuen-Kwok Chan 142 Constructive Probability
for each \( n \geq 1 \). Hence
\[
D \equiv \bigcap_{n=1}^{\infty} \bigcup_{(k(1), \ldots, k(n)) \in \mathcal{B}(n)} \Theta_{k(1), \ldots, k(n)} \tag{5.5.9}
\]
is a full subset of \([0, 1]\).

7. Let \( \theta \in D \) be arbitrary. Consider each \( n \geq 1 \). Then \( \theta \in \Theta_{k(1), \ldots, k(n)} \) for some unique sequence \( (k_1, \ldots, k_n) \in \mathcal{B}_n \) since the intervals in each union in equality \( \text{(5.5.9)} \) are mutually exclusive. By the same token, \( \theta \in \Theta_{j(1), \ldots, j(n+1)} \) for some unique \( (j_1, \ldots, j_{n+1}) \in \mathcal{B}_{n+1} \). Then \( \theta \in \Theta_{j(1), \ldots, j(n)} \) in view of Condition (ii) in Step 4 above. Hence, by uniqueness of the sequence \( (k_1, \ldots, k_n) \), we have \( (j_1, \ldots, j_n) = (k_1, \ldots, k_n) \). Now define \( k_{n+1} \equiv j_{n+1} \). It follows that \( \theta \in \Theta_{k(1), \ldots, k(n+1)} \). Thus we obtain inductively a unique sequence \( (k_p)_{p=1, 2, \ldots} \) such that \( k_p \in \{1, \ldots, K_p\} \) and \( \theta \in \Theta_{k(1), \ldots, k(p)} \) for each \( p \geq 1 \).

Since the open interval \( \Theta_{k(1), \ldots, k(n)} \) contains the given point \( \theta \), it has positive Lebesgue measure. In view of Condition (i) in Step 4 above, it follows that
\[
Ef_{1,k(1)} \cdots f_{n,k(n)} > 0, \tag{5.5.10}
\]
where \( n \geq 1 \) is arbitrary.

8. Define the function \( X_n : [0, 1] \to (S, d) \) by
\[
\text{domain}(X_n) \equiv D \subseteq \bigcup_{(k(1), \ldots, k(n)) \in \mathcal{B}(n)} \Theta_{k(1), \ldots, k(n)},
\]
and by
\[
X_n \equiv x_{n,k(n)} \quad \text{on } \partial \Theta_{k(1), \ldots, k(n)}, \quad \text{according as } k_n \leq \kappa_n \text{ or } k_n = \kappa_n + 1, \tag{5.5.11}
\]
for each \( (k_1, \ldots, k_n) \in \text{domain}(X_n) \). Then, according to Proposition \( \ref{prop:5.5.1} \), \( X_n \in M(\Theta_0, S) \). In other words, \( X_n \) is a r.v with values in the metric space \( (S, d) \). Now define the function \( X : [0, 1] \to (S, d) \) by
\[
\text{domain}(X) \equiv \{ \theta \in D : \lim_{n \to \infty} X_n(\theta) \text{ exists} \},
\]
and by
\[
X(\theta) \equiv \lim_{n \to \infty} X_n(\theta)
\]
for each \( \theta \in \text{domain}(X) \). We proceed to prove that the function \( X \) is a r.v. by showing that \( X_n \to X \) a.u.

9. To that end, let \( n \geq 1 \) be arbitrary. Define
\[
m \equiv m_n \equiv n + \lfloor \log_2(1 + \beta(2^{-n})) \rfloor_1, \tag{5.5.12}
\]
where \( \beta \) is the given modulus of tightness of the distribution \( E \) relative to the reference point \( x_0 \in S \). Then
\[
2^m > \beta(2^{-n}).
\]
CHAPTER 5. PROBABILITY SPACE

Take an arbitrary $\alpha_n \in (\beta(2^{-n}), 2^m)$. Then

$$E(d(\cdot, x_0) > \alpha_n) \leq 2^{-n}$$  \hspace{1cm} (5.5.13)

because $\beta$ is a modulus of tightness of $E$. At the same time,

$$(d(\cdot, x_0) \leq \alpha_n) \subset (d(\cdot, x_0) \leq 2^m)$$

$$\subset \bigcup_{x \in A(m)} (d(\cdot, x) \leq 2^{-m}) \subset \left(\sum_{x \in A(m)} g_{m,x} = 1\right),$$  \hspace{1cm} (5.5.14)

where the second and third inclusion are by relations [5.5.2] and [5.5.4] respectively. Define the Lebesgue measurable set

$$D_n \equiv \bigcup_{(k(1), \ldots, k(m)) \in B(m); k(m) \leq K(m)} \Theta_{k(1), \ldots, k(m)} \subset [0, 1].$$  \hspace{1cm} (5.5.15)

Then

$$\mu(D_n^c) = \sum_{(k(1), \ldots, k(m)) \in B(m); k(m) = K(m)} \mu\Theta_{k(1), \ldots, k(m)}$$

$$= \sum_{(k(1), \ldots, k(m)) \in B(m); k(m) = K(m)} Ef_{1,k(1)} \cdot \cdots \cdot Ef_{m,k(m)}$$

$$= \sum_{k(1) = 1}^{K(1)} \cdots \sum_{k(m-1) = 1}^{K(m-1)} Ef_{1,k(1)} \cdot \cdots \cdot Ef_{m-1,k(m-1)} \cdot Ef_{m,K(m)}$$

$$= Ef_{m,K(m)} = E(1 - \sum_{x \in A(m)} g_{m,x})$$

$$\leq E(d(\cdot, x_0) > \alpha_n) \leq 2^{-n},$$  \hspace{1cm} (5.5.16)

where the first inequality is thanks to relation 5.5.14 and the second is inequality 5.5.13.

10. Consider each $\theta \in D$. By Step 7, there exists a unique sequence $(k_p)_{p=1,2,\ldots}$ such that $k_p \in \{1, \ldots, K_p\}$ and $\theta \in \Theta_{k(1), \ldots, k(p)}$ for each $p \geq 1$. In particular, $\theta \in \Theta_{k(1), \ldots, k(m)}$. In view of the defining equality 5.5.15 for the set $D_n$, it follows that $k_m \leq K_m$, whence

$$f_{m,k(m)} = g_{m,x(m,k(m))},$$

according to the defining equality 5.5.5. Moreover, by Condition (ii) in Step 4 above, we have $\theta \in \Theta_{k(1), \ldots, k(q)} \subset \Theta_{k(1), \ldots, k(m)}$ for each $q \geq m$. Suppose, for the sake of a contradiction, that $k_{m+1} = K_{m+1}$. Then, by the defining equality 5.5.5 we have

$$f_{m+1,k(m+1)} = 1 - \sum_{x \in A(m+1)} g_{m+1,x}.$$

Hence inequality 5.5.10 applied to $m + 1$, yields

$$0 < Ef_{1,k(1)} \cdot \cdots \cdot Ef_{m-1,k(m-1)} g_{m,x(m,k(m))} f_{m+1,k(m+1)} \left(1 - \sum_{x \in A(m+1)} g_{m+1,x}\right)$$  \hspace{1cm} (5.5.17)
5.5. THE SKOROKHOD REPRESENTATION

On the other hand, using successively the relations \[5.5.3, 5.5.1, 5.5.2\] and \[5.5.4\] we obtain
\[
\begin{align*}
(g_{m,x(m,k(m))} > 0) & \subset (d(\cdot, x_{m,k(m)}) \leq 2^{-m+1}) \subset (d(\cdot, x_{0}) \leq 2^{m} + 2^{-m+1}) \\
& \subset (d(\cdot, x_{0}) \leq 2^{m+1}) \subset \bigcup_{x \in \mathbb{A}(m+1)} (d(\cdot, x) \leq 2^{-m-1}) \\
& \subset \left( \sum_{x \in \mathbb{A}(m+1)} g_{m+1,x} = 1 \right).
\end{align*}
\]
Hence the right-hand side of the strict inequality \[5.5.17\] vanishes, while the left-hand side is 0, a contradiction. We conclude that \(k_{m+1} \leq \kappa_{m+1}\). Repeating these steps, we obtain, for each \(q \geq m\), the inequality
\[
k_{q} \leq \kappa_{q},
\]
whence
\[
f_{q,k(q)} = g_{q,x(q,k(q))}. \tag{5.5.18}
\]
It follows from the defining equality \[5.5.11\] that
\[
X_{q}(\theta) = x_{q,k(q)}
\]
for each \(q \geq m \equiv m_{e}\), where \(\theta \in DD_{n}\) is arbitrary. Summing up, we have
\[
DD_{n} \subset \bigcap_{q=m}^{\infty} (X_{q} = x_{q,k(q)}). \tag{5.5.19}
\]

11. Continue with \(\theta \in DD_{n}\) and the corresponding unique sequence \((k_{p})_{p=1,2,\ldots}\) in the previous step. Let \(q \geq p \geq m\) be arbitrary. For abbreviation, write \(y_{p} \equiv x_{p,k(p)}\). Then inequality \[5.5.10\] and equality \[5.5.18\] together imply that
\[
Ef_{1,k(1)} \cdots f_{m-1,k(m-1)}g_{m,y(m)} \cdots g_{p,y(p)} \cdots g_{q,y(q)} > 0.
\]
Hence there exists \(z \in S\) such that
\[
(f_{1,k(1)} \cdots f_{m-1,k(m-1)}g_{m,y(m)} \cdots g_{p,y(p)} \cdots g_{q,y(q)})(z) > 0,
\]
whence \(g_{p,y(p)}(z) > 0\) and \(g_{q,y(q)}(z) > 0\). Consequently, by relation \[5.5.3\] we obtain
\[
d(y_{p}, y_{q}) \leq d(y_{p}, z) + d(z, y_{q}) \leq 2^{-p+1} + 2^{-q+1} \to 0 \tag{5.5.20}
\]
as \(p, q \to \infty\). Since \((S,d)\) is complete, we have
\[
X_{p}(\theta) \equiv x_{p,k(p)} \equiv y_{p} \to y
\]
as \(p \to \infty\), for some \(y \in S\). Hence \(\theta \in \text{domain}(X)\), with \(X(\theta) \equiv y\). Moreover, with \(q \to \infty\) in inequality \[5.5.20\] we obtain
\[
d(X_{p}(\theta), X(\theta)) \leq 2^{-p+1}, \tag{5.5.21}
\]
Yuen-Kwok Chan 145 Constructive Probability
where \( p \geq m = m_n \) and \( \theta \in DD_n \) are arbitrary. Since \( \mu(DD_n)^c = \mu D_n^c \leq 2^{-n} \) is arbitrarily small when \( n \geq 1 \) is sufficiently large, we conclude that \( X_n \to X \) a.u. relative to the Lebesgue measure \( I \), as \( n \to \infty \). It follows that the function \( X : [0,1] \to S \) is measurable.

In other words, \( X \) is a r.v.

12. It remains to verify that \( I_X = E \), where \( I_X \) is the distribution induced by \( X \) on \( S \). For that purpose, let \( h \in C(S) \) be arbitrary. We need to prove that \( I_h(X) = Eh \), where, without loss of generality, we assume that \( |h| \leq 1 \) on \( S \). Let \( \delta_h \) be a modulus of continuity of the function \( h \). Let \( \varepsilon > 0 \) be arbitrary. Let \( n \geq 1 \) be so large that (i')

\[
2^{-n} < \varepsilon \wedge \frac{1}{2} \delta_h(\frac{\varepsilon}{3}),
\]

and (ii') \( f \) is supported by \( (d(\cdot,x_0) \leq 2^n) \). Then relation 5.5.2 implies that \( f \) is supported by \( \bigcup_{x \in A(n)} (d(\cdot,x) \leq 2^{-n}) \). At the same time, by the defining equality 5.5.11 of the simple r.v. \( X_n : [0,1] \to S \), we have

\[
I_h(X_n) = \sum_{(k(1), \ldots, k(n)) \in B(n) : k(n) \leq \kappa(n)} h(x_n, k(n)) \mu \Theta_{k(1), \ldots, k(n)} + h(x_0) \mu(D_n^c)
\]

\[= \sum_{k(1) = 1}^{\kappa(1)} \cdots \sum_{k(n-1) = 1}^{\kappa(n-1)} \sum_{k(n) = 1}^{\kappa(n)} h(x_n, k(n)) \epsilon f_{1, k(1)} \cdots f_{n-1, k(n-1)} f_n, k(n) + h(x_0) \mu(D_n^c)\]

\[= \sum_{k = 1}^{\kappa(n)} h(x_n, k) \epsilon f_n, k + h(x_0) \mu(D_n^c)\]

\[= \sum_{x \in A(n)} h(x) \epsilon g_n, x + h(x_0) \mu(D_n^c)\]

where the third equality is thanks to equality 5.5.6. Hence

\[
|h(X_n) - E \sum_{x \in A(n)} h(x) g_n, x| \leq |h(x_0) \mu(D_n^c)| \leq \mu(D_n^c) \leq 2^{-n} < \varepsilon.
\]

At the same time, as \( A_n \) is a \( 2^{-n} \)-partition of unity of \( (S, d) \), with \( 2^{-n} < \frac{1}{2} \delta_h(\frac{\varepsilon}{3}) \), Proposition 5.2.6 implies that \( \left\| \sum_{x \in A(n)} h(x) g_n, x - h \right\| \leq \varepsilon \). Hence

\[
|E \sum_{x \in A(n)} h(x) g_n, x - Eh| \leq \varepsilon.
\]

Inequality 5.5.23 therefore yields

\[
|h(X_n) - Eh| < 2\varepsilon.
\]

Since \( \varepsilon > 0 \) is arbitrarily small, we have \( I_h(X_n) \to Eh \) as \( n \to \infty \). On the other hand, \( h(X_n) \to h(X) \) a.u. relative to \( I \). Hence the Dominated Convergence Theorem implies that \( I_h(X_n) \to I_h(X) \). It follows that \( Eh = Ih(X) \), where \( h \in C(S) \) is arbitrary. We conclude that \( E = I_X \).

Define \( \Phi_{\delta_h, \varepsilon}(E) = X \), and the theorem is proved. \( \Box \)
5.5. THE SKOROKHOD REPRESENTATION

Theorem 5.5.2. (Metrical Continuity of Skorokhod Representation) Let $\xi \equiv (A_n)_{n=1,2,\ldots}$ be a binary approximation of the locally compact metric space $(S, d)$ relative to the reference point $x_0 \in S$. Let $\left\| \xi \right\| \equiv (\kappa_n)_{n=1,2,\ldots}$ be the modulus of local compactness of $(S, d)$ corresponding to $\xi$. In other words, $\kappa_n \equiv |A_n|$ is the number of elements in the enumerated finite set $A_n$ for each $n \geq 1$.

Let $\mathcal{J}(S, d)$ be the set of distributions on $(S, d)$. Let $\mathcal{J}^\beta(S, d)$ be a tight subset of $\mathcal{J}(S, d)$ with a modulus of tightness $\beta$ relative to $x_0$. Recall the probability metric $\rho_{\text{rob}}$ on $\mathcal{M}(\Theta_0, S)$ defined in Definition 5.1.12. Then the Skorokhod representation

$$
\Phi_{\text{sk}, \xi} : (\mathcal{J}(S, d), \rho_{\text{Dist}, \xi}) \to (\mathcal{M}(\Theta_0, S), \rho_{\text{rob}})
$$

constructed in Theorem 5.5.1 is uniformly continuous on the subset $\mathcal{J}^\beta(S, d)$, with a modulus of continuity $\delta_{\text{sk}}(\cdot, \|\xi\|, \beta)$ depending only on $\|\xi\|$ and $\beta$.

Proof. Refer to the proof of Theorem 5.5.1 for notations. In particular, let

$$
\pi \equiv \{(g_{n,x} : x \in A_n)\}_{n=1,2,\ldots}
$$

denote the partition of unity of $(S, d)$ determined by $\xi$.

1. Let $n \geq 1$ be arbitrary. Recall from Proposition 3.2.5 that, for each $x \in A_n$, the functions $g_{n,x}$ and $\sum_{y \in A(n)} g_{n,y}$ in $C(S)$ have Lipschitz constant $2^{n+1}$ and have values in $[0,1]$. Consequently, each of the functions $f_{n,1}, \ldots, f_{n,K(n)}$ defined in formula 5.5.5 has Lipschitz constant $2^{n+1}$.

2. Let $(k_1, \cdots, k_n) \in B_n \equiv \{1, \cdots, K_1\} \times \cdots \times \{1, \cdots, K_n\}$ be arbitrary. Then the function

$$
h_{k_1, \cdots, k(n)} \equiv n^{-1} \sum_{p=1}^{n} \sum_{k=1}^{k(p)-1} f_{1,k(1)} \cdots f_{p-1,k(p-1)} f_{p,k} \in C_{ub}(S)
$$

has values in $[0,1]$. By elementary operations of Lipschitz constants, as in Exercise 3.2.1 the function $h_{k_1, \cdots, k(n)}$ has Lipschitz constant given by

$$
n^{-1} \sum_{p=1}^{n} \sum_{k=1}^{k(p)-1} (2^{1+1} + 2^{2+1} + \cdots + 2^{p+1})
$$

$$
= 2^n n^{-1} \sum_{p=1}^{n} (\kappa_p - 1)(1 + 2 + \cdots + 2^{p-1}) < 2^n n^{-1} \sum_{p=1}^{n} \kappa_p 2^p
$$

$$
< 2^n n^{-1} \kappa_n 2^{n+1} = n^{-1} 2^{n} \kappa_n.
$$

3. Now let $E, E' \in \mathcal{J}^\beta(S, d)$ be arbitrary. Let the objects $\{\Theta_{k_1, \cdots, k(n)} : (k_1, \cdots, k_n) \in B_n; n \geq 1\}$, $D$, $(X_n)_{n=1,2,\ldots}$, and $X$ be constructed as in Theorem 5.5.1 relative to $E$. Let the objects $\{\Theta'_{k_1, \cdots, k(n)} : (k_1, \cdots, k_n) \in B_n; n \geq 1\}$, $D'$, $(X'_n)_{n=1,2,\ldots}$, and $X'$ be similarly constructed relative to $E'$.
4. Let $\varepsilon > 0$ be arbitrary. Fix

$$n \equiv \lfloor 3 - \log_2 \varepsilon \rfloor_1.$$ 

Thus $2^{-n+3} < \varepsilon$. As in the proof of Theorem 5.5.1, let

$$m \equiv m_n \equiv n \lor \lfloor \log_2 (1 \lor \beta(2^{-n})) \rfloor_1,$$  \hspace{1cm} (5.5.24)

and let

$$c \equiv m^{-1} 2^{m+3} \kappa_m,$$  \hspace{1cm} (5.5.25)

where $\beta$ is the given modulus of tightness of the distributions $E$ in $\tilde{\mathcal{J}}^\beta(S,d)$ relative to the reference point $x_0 \in S$. Let

$$\alpha \equiv 2^{-n} \prod_{p=1}^m K_p^{-1} = 2^{-m} |B_m|^{-1}.$$  \hspace{1cm} (5.5.26)

By Proposition 5.3.1, there exists $\tilde{\Delta}(m^{-1} \alpha, c, \beta, \|\xi\|) > 0$ such that if

$$\rho_{Dist, \xi}(E, E') < \delta_{Sk}(\varepsilon, \|\xi\|, \beta) \equiv \Delta(m^{-1} \alpha, c, \beta, \|\xi\|),$$

then

$$|Ef - E'f| < m^{-1} \alpha$$  \hspace{1cm} (5.5.27)

for each $f \in C_{ab}(S)$ with Lipschitz constant $c > 0$ and with $|f| \leq 1$.

5. Suppose

$$\rho_{Dist, \xi}(E, E') < \delta_{Sk}(\varepsilon, \|\xi\|, \beta).$$  \hspace{1cm} (5.5.28)

We will prove that

$$\rho_{Prob}(X, X') < \varepsilon.$$ 

To that end, let $(k_1, \ldots, k_m) \in B_m$ be arbitrary. We will calculate the endpoints of the open interval

$$(a_{k(1), \ldots, k(m)}, b_{k(1), \ldots, k(m)}) \equiv \Theta_{k(1), \ldots, k(m)}.$$ 

Recall that, by construction, $\{\Theta_{k(1), \ldots, k(m-1), k_1} : 1 \leq k \leq K_m\}$ is the set of subintervals in a partition of the open interval $\Theta_{k(1), \ldots, k(m-1)}$ into mutually exclusive open subintervals, with

$$\Theta_{k(1), \ldots, k(m-1), k_1} < \Theta_{k(1), \ldots, k(m-1), k_2}$$

if $1 \leq k < j \leq K_m$. Hence the left endpoint of $\Theta_{k(1), \ldots, k(m)}$ is

$$a_{k(1), \ldots, k(m)} = a_{k(1), \ldots, k(m-1)} + \sum_{k=1}^{k(m)-1} \mu \Theta_{k(1), \ldots, k(m-1), k}$$

$$= a_{k(1), \ldots, k(m-1)} + \sum_{k=1}^{k(m)-1} Ef_{1,k(1)} \cdots f_{m-1,k(m-1)} f_{m,k},$$  \hspace{1cm} (5.5.29)

where the second equality is due to Condition (i) in Step 4 of the proof of Theorem 5.5.1. Recursively, we then obtain

$$a_{k(1), \ldots, k(m)}$$
Then define the set 

\[ a_k(1), \ldots, k(m-2) + \sum_{k=1}^{k(m-1)-1} Ef_1(k(1) \cdots f_{m-2,k(m-2)}f_{m-1,k} + \sum_{k=1}^{k(m)-1} E f_{1,k(1)} \cdots f_{m-1,k(m)}f_{m,k} = \cdots = \sum_{p=1}^{m-1} \sum_{k=1}^{k(p)-1} E f_{1,k(1)} \cdots f_{p-1,k(p-1)}f_{p,k} \equiv mE h_{k(1), \ldots, k(m)}. \]

6. Similarly, write 

\( (a'_k(1), \ldots, k(m), b'_k(1), \ldots, k(m)) \equiv \Theta'_k(1), \ldots, k(m). \)

Then 

\[ a'_k(1), \ldots, k(m) = mE' h_{k(1), \ldots, k(m)}. \]

Therefore 

\[ |a'_k(1), \ldots, k(m) - a'_k(1), \ldots, k(m)| = |m|E h_{k(1), \ldots, k(m)} - E' h_{k(1), \ldots, k(m)}| < mn^{-1}\alpha = \alpha. \quad (5.5.30) \]

where the inequality is by applying inequality 5.5.27 to the function \( f \equiv h_{k(1), \ldots, x(m)} \), which has been observed in Step 2 above to have values in \( [0,1] \) and to have Lipschitz constant \( c \equiv m^{-1/2}m^3\kappa_m \). By symmetry, we can similarly prove that 

\[ |b'_k(1), \ldots, k(m) - b'_k(1), \ldots, k(m)| < \alpha. \quad (5.5.31) \]

7. Inequality 5.5.27 in Step 11 of the proof of Theorem 5.5.1 gives 

\[ d(X_m, X) \leq 2^{-m+1}, \quad (5.5.32) \]

on \( DD_n \). Now partition the set \( B_m \equiv B_{m,0} \cup B_{m,1} \cup B_{m,2} \) into three disjoint subsets, where 

\[ B_{m,0} \equiv \{ (k_1, \ldots, k_m) \in B_m : k_m = K_m \}, \]

\[ B_{m,1} \equiv \{ (k_1, \ldots, k_m) \in B_m : k_m \leq \kappa_m : \mu \Theta_k(1), \ldots, k(m) > 2\alpha \}, \]

\[ B_{m,2} \equiv \{ (k_1, \ldots, k_m) \in B_m : k_m \leq \kappa_m : \mu \Theta_k(1), \ldots, k(m) < 3\alpha \}. \]

Define the set 

\[ H \equiv \bigcup \tilde{\Theta} \equiv \bigcup \Theta_{k(1), \ldots, k(m)} \subset [0,1], \]

where the open interval 

\[ \tilde{\Theta} \equiv (a_{k(1), \ldots, k(m)} - \alpha, b_{k(1), \ldots, k(m)} + \alpha) \]

is the \( \alpha \)-interior of \( \Theta_{k(1), \ldots, k(m)} \) for each \( (k_1, \ldots, k_m) \in B_{m,1} \). Then 

\[ H^c = \bigcup \Theta_{k(1), \ldots, k(m)} \bigcup \bigcup \Theta_{k(1), \ldots, k(m)} \bigcup \bigcup \Theta_{k(1), \ldots, k(m)}. \]

Yuen-Kwok Chan

149

Constructive Probability
Hence
\[ \mu H^c = \sum_{(k(1), \ldots, k(m)) \in B(m,1)} 2\alpha + \sum_{(k(1), \ldots, k(m)) \in B(m,2)} \mu \Theta_{k(1)} \cdots k(m) \]
\[ + \mu \bigcup_{(k(1), \ldots, k(m)) \in B(m): k(m) = k(m)} \Theta_{k(1)} \cdots k(m) \]
\[ < \sum_{(k(1), \ldots, k(m)) \in B(m,1)} 2\alpha + \sum_{(k(1), \ldots, k(m)) \in B(m,2)} 3\alpha + \mu D_n^c \]
\[ < |B_m,1|2\alpha + |B_m,2|3\alpha + 2^{-n} \]
\[ \leq |B_m|3\alpha + 2^{-n} = 3 \cdot 2^{-n} + 2^{-n} = 2^{-n+2}, \]
where the next-to-last equality is from the defining equality 5.5.26. Note for later reference that the set \( H \) depends only on \( E \), and not on \( E' \).

8. Now let \( \theta \in HDD' \) be arbitrary. Then, according to the definitions of \( H_n, D \), and \( D' \), we have
\[ \theta \in \Theta_{k(1)} \cdots k(m) \Theta_{j(1)} \cdots j(m) \]
for some \((k_1, \ldots, k_m) \in B_{m,1}\) and some \((j_1, \ldots, j_m) \in B_{m}\). Hence, in view of inequalities 5.5.30 and 5.5.31, we have
\[ \theta \in (a_{k(1)} \cdots k(m) + \alpha, b_{k(1)} \cdots k(m) - \alpha) \]
\[ \subset (a'_{k(1)} \cdots k(m), b'_{k(1)} \cdots k(m)) = \Theta'_{k(1)} \cdots k(m). \]

Consequently,
\[ \theta \in \Theta'_{k(1)} \cdots k(m) \Theta'_{j(1)} \cdots j(m). \]

The intersection of the two open intervals on the right-hand side would however be empty unless their subscripts are identical. Hence \((k_1, \ldots, k_m) = (j_1, \ldots, j_m)\). In particular, \( j_m = k_m \leq \kappa_m \), where the inequality is because \((k_1, \ldots, k_m) \in B_{m,1}\). Hence \( \theta \in D_nD'_n \) by the defining equality 5.5.15 for the sets \( D_n \) and \( D'_n \). At the same time, by the defining equality 5.5.14 for the r.v.'s \( X_m \) and \( X'_m \), we have
\[ X_m(\theta) = x_{m,k(m)} = x_{m,j(m)} = X'_m(\theta). \]

Since \( \theta \in HDD' \) is arbitrary, we have proved that (i) \( HDD' \subset D_nD'_nDD' \), and (ii) \( X_m = X'_m \) on \( HDD' \).

9. By inequality 5.5.21 in the proof of Theorem 5.5.1, we have
\[ d(X_m, X) \leq 2^{-m+1} \]
on \( D_nD'_nDD' \). Combining with Conditions (i) and (ii) in the previous step, we obtain
\[ HDD' \subset (X_m \leq X'_m) \cap (d(X_m, X) \leq 2^{-m+1}) \cap (d(X'_m, X) \leq 2^{-m+1}) \]
\[ \subset (d(X, X') \leq 2^{-m+2}) \cap (d(X, X') \leq 2^{-n+2}) \cap (d(X, X') \leq \epsilon), \]where \( D, D' \) are full sets.
5.6. INDEPENDENCE AND CONDITIONAL EXPECTATION

10. From relation 5.5.36 and inequality 5.5.33 we deduce

\[ \rho_{\text{Prob}}(X, X') = I(1 \wedge d(X, X'); H) + I(1 \wedge d(X, X'); H^c) \leq 2^{-m+2} + \mu H^c \]

\[ < 2^{-m+2} + 2^{-n+2} \leq 2^{-n+2} + 2^{-n+2} = 2^{-n+3} < \epsilon, \]

where \( E, E' \in \tilde{J}^\beta(S, d) \) are arbitrary such that \( \rho_{\text{Dist}, \xi}(E, E') < \delta_{\text{Sk}}(\epsilon, \|\xi\|, \beta) \), where \( X \equiv \Phi_{\text{Sk}, \xi}(E) \) and \( X' \equiv \Phi_{\text{Sk}, \xi}(E') \), and where \( \epsilon > 0 \) is arbitrary. Thus the mapping \( \Phi_{\text{Sk}, \xi} : (J(S, d), \rho_{\text{Dist}, \xi}) \rightarrow (M(\Theta_0, S), \rho_{\text{Prob}}) \) is uniformly continuous on the subspace \( \tilde{J}^\beta(S, d) \), with \( \delta_{\text{Sk}}(\cdot, \|\xi\|, \beta) \) as a modulus of continuity. The theorem is proved. \[ \square \]

Skorokhod’s continuity theorem in [Skorohod 1956], in terms of a.u. convergence, is a consequence of the preceding proof.

Theorem 5.5.3. (Continuity of Skorokhod representation in terms of weak convergence and a.u. convergence). Let \( \xi \) be a binary approximation of the locally compact metric space \((S, d)\), relative to the reference point \( x_0 \in S \).

Let \( E, E^{(1)}, E^{(2)}, \cdots \) be a sequence of distributions on \((S, d)\) such that \( E^{(n)} \Rightarrow E \). Let \( X \equiv \Phi_{\text{Sk}, \xi}(E) \) and \( X^{(n)} \equiv \Phi_{\text{Sk}, \xi}(E^{(n)}) \) for each \( n \geq 1 \). Then \( X^{(n)} \rightarrow X \) a.u.

Proof. Let \( \|\xi\| \) be the modulus of local compactness of \((S, d)\) corresponding to \( \xi \). By hypothesis, \( E^{(n)} \Rightarrow E \). Hence \( \rho_{\text{Dist}, \xi}(E, E^{(n)}) \rightarrow 0 \) by Proposition 5.3.3. By Proposition 5.3.10 the family \( \tilde{J}^\beta(S, d) = \{E, E^{(1)}, E^{(2)}, \cdots\} \) is tight, with some modulus of tightness \( \beta \). Let \( \epsilon > 0 \) be arbitrary. Let \( \delta_{\text{Sk}}(\epsilon, \|\xi\|, \beta) > 0 \) be defined as in Theorem 5.5.2. In Step 9 of the proof of Theorem 5.5.2, we see that there exists a Lebesgue measurable subset \( H \) of \([0, 1]\) which depends only on \( E \), with \( \mu H^c < \epsilon \), such that for each \( E' \in \tilde{J}^\beta(S, d) \) we have

\[ H \subset (d(X, X') < \epsilon) \quad \text{a.s.,} \quad (5.5.37) \]

where \( X' \equiv \Phi_{\text{Sk}, \xi}(E') \), provided that \( \rho_{\text{Dist}, \xi}(E, E') < \delta_{\text{Sk}}(\epsilon, \|\xi\|, \beta) \). Hence, if \( p \geq 1 \) is so large that \( \rho_{\text{Dist}, \xi}(E, E^{(n)}) < \delta_{\text{Sk}}(\epsilon, \|\xi\|, \beta) \) for each \( n \geq p \), then

\[ d(X, X^{(n)}) \leq \epsilon \]

a.s. on \( H^c \), for each \( n \geq p \). Consequently, \( X_n \rightarrow X \) a.u. according to Proposition 5.1.14. \[ \square \]

5.6 Independence and Conditional Expectation

The product space introduced in §4.10.6 gives a model for compounding two independent experiments into one. This section introduces the notion of conditional expectations, which will later be used for a more general method of compounding probability spaces, or, in the other direction, analyzing an r.v. in terms of simpler ones.
Definition 5.6.1. (Independent set of r.v.’s). Let \((\Omega, L, E)\) be a probability space. A finite set \(\{X_1, \cdots, X_n\}\) of r.v.’s where \(X_i\) has values in a complete metric space \((S_i, d_i)\), for each \(i = 1, \cdots, n\) is said to be independent if
\[
E f_1(X_1) \cdots f_n(X_n) = E f_1(X_1) \cdots E f_n(X_n) \tag{5.6.1}
\]
for each \(f_1 \in C_{ub}(S_1), \cdots, f_n \in C_{ab}(S_n)\). In that case we will also say that \(X_1, \cdots, X_n\) are independent. A sequence of events \(A_1, \cdots, A_n\) is said to be independent if \(1_{A(1)}, \cdots, 1_{A(n)}\) are independent r.r.v.’s.

An arbitrary set of r.v.’s is said to be independent if every finite subset is independent. \(\square\)

Proposition 5.6.2. (Independent r.v.’s from product space). Let \(F_1, \cdots, F_n\) be distributions on the locally compact metric spaces \((S_1, d_1), \cdots, (S_n, d_n)\) respectively. Let \((S, d) \equiv (S_1 \times \cdots, S_n, d_1 \otimes \cdots \otimes d_n)\) be the product metric space. Consider the product integration space
\[
(\Omega, L, E) \equiv (S, L, F_1 \otimes \cdots \otimes F_n) \equiv \bigotimes_{j=1}^n (S_j, L_j, F_j),
\]
where \((S_i, L_i, F_i)\) is the probability space that is the completion of \((S_i, C_{ub}(S_i), F_i)\), for each \(i = 1, \cdots, n\). Then the following holds.

1. Let \(i = 1, \cdots, n\) be arbitrary. Define the coordinate r.v. \(X_i : \Omega \to S_i\) by \(X_i(\omega) \equiv \omega_i\) for each \(\omega \equiv (\omega_1, \cdots, \omega_n) \in \Omega\). Then the r.v.’s \(X_1, \cdots, X_n\) are independent. Moreover, \(X_i\) induces the distribution \(F_i\) on \((S_i, d_i)\) for each \(i = 1, \cdots, n\).

2. \(F_1 \otimes \cdots \otimes F_n\) is a distribution on \((S, d)\). Specifically it is the distribution \(F\) induced on \((S, d)\) by the r.v. \(X \equiv (X_1, \cdots, X_n)\).

Proof. 1. By Proposition 4.8.7 the continuous functions \(X_1, \cdots, X_n\) on \((S, L, E)\) are measurable. Let \(f_j \in C_{ab}(S_j)\) be arbitrary, for each \(j = 1, \cdots, n\). Then
\[
E f_1(X_1) \cdots f_n(X_n) = F_1 f_1 \cdots F_n f_n \tag{5.6.2}
\]
by Fubini’s Theorem. Let \(i = 1, \cdots, n\) be arbitrary. In the special case where \(f_j \equiv 1\) for each \(j = 1, \cdots, n\) with \(j \neq i\), we obtain, from equality 5.6.2
\[
E f_i(X) = F_i f_i. \tag{5.6.3}
\]
Hence equality 5.6.2 yields
\[
E f_1(X_1) \cdots f_n(X_n) = E f_1(X_1) \cdots E f_n(X_n)
\]
where \(f_i \in C_{ab}(S_i)\) is arbitrary for each \(i = 1, \cdots, n\). Thus the r.v.’s \(X_1, \cdots, X_n\) are independent. Moreover equality 5.6.3 shows that the r.v. \(X_i\) induces the distribution \(F_i\) on \((S_i, d_i)\) for each \(i = 1, \cdots, n\).

2. Since \(X\) is an r.v. with values in \(S\), it induces a distribution \(E_X\) on \((S, d)\). Hence
\[
E_X f \equiv E f(X) = (F_1 \otimes \cdots \otimes F_n) f
\]
for each \(f \in C_{ab}(S)\). Thus \(F_1 \otimes \cdots \otimes F_n = E_X\) is a distribution \(F\) on \((S, d)\). \(\square\)
5.6. INDEPENDENCE AND CONDITIONAL EXPECTATION

**Proposition 5.6.3. (Basics of independence).** Let \((\Omega, L, E)\) be a probability space. Suppose the each \(i = 1, \cdots, n\), let \(X_i\) be a r.v. with values in a complete metric space \((S_i, d_i)\), and let \((S_i, L_{X(i)}, E_{X(i)})\) be the the probability space it induces on \((S_i, d_i)\). Suppose the r.v.'s \(X_1, \cdots, X_n\) are independent. Then, for arbitrary \(f_1 \in L_{X(1)} \cdots f_n \in L_{X(n)}\), we have

\[
E \prod_{i=1}^{n} f_i(X_i) = \prod_{i=1}^{n} E f_i(X_i). \tag{5.6.4}
\]

**Proof.** Consider each \(i = 1, \cdots, n\). Let \(f_i \in L_{X(i)}\) be arbitrary. By Definition 5.2.3 \(L_{X(i)}\) is the completion of \((\Omega, C_{ab}(S_i), E_{X(i)})\). The r.v. \(f_i \in L_{X(i)}\) is therefore the \(L_1\)-limit relative to \(E_{X(i)}\) of a sequence \((f_{ih}, h=1,2,\cdots)\) in \(C_{ab}(S_i)\) as \(h \to \infty\). Moreover, according to 5.2.6 we have \(f_i(\Omega) \in L(X_i)\) with \(E f_i(X_i) = E_{X(i)} f_i\). Hence

\[
E[f_{ih}(X_i) - f_i(X_i)] = E_X[f_{ih} - f_i] \to 0
\]

as \(h \to \infty\). By passing to subsequences if necessary, we may assume that

\[
f_{ih}(X_i) \to f_i(X_i) \quad a.u. \tag{5.6.5}
\]

as \(h \to \infty\), for each \(i = 1, \cdots, n\).

First consider the case where \(f_i \geq 0\) for each \(i = 1, \cdots, n\). Let \(a > 0\) be arbitrary. In view of the independence of the r.v.'s \(X_1, \cdots, X_n\), we have

\[
E \prod_{i=1}^{n} (0 \lor f_{ih}(X_i) \land a) = \prod_{i=1}^{n} E (0 \lor f_{ih}(X_i) \land a) \equiv \prod_{i=1}^{n} E_X (0 \lor f_{ih} \land a).
\]

In view of the a.u. convergence 5.6.5 we can let \(h \to \infty\) and apply the Dominated Convergence Theorem to obtain

\[
E \prod_{i=1}^{n} (f_i(X_i) \land a) = \prod_{i=1}^{n} E_X (f_i \land a).
\]

Now let \(a \to \infty\) and apply the Monotone Convergence Theorem to obtain

\[
E \prod_{i=1}^{n} f_i(X_i) = \prod_{i=1}^{n} E_X (f_i) = \prod_{i=1}^{n} E f_i(X_i).
\]

The same equality for arbitrary \(f_1 \in L_{X(1)} \cdots f_n \in L_{X(n)}\) follows by linearity. \(\square\)

We next define the conditional expectation of a r.r.v., as the revised expectation given the observed values of all the r.v.'s in a family \(G\).

**Definition 5.6.4. (Conditional expectation).** Let \((\Omega, L, E)\) be a probability space, and let \(L'\) be a probability subspace of \(L\). Let \(Y \in L\) be arbitrary. If there exists \(X \in L'\) such that \(E Y = E X\) for each indicator \(Z \in L'\), then we say that \(X\) is the conditional expectation of \(Y\) given \(L'\), and define \(E(Y|L') \equiv X\). We will call \(L_{|L'} \equiv \{Y \in L : E(Y|L') \text{ exists}\}\) the subspace of conditionally integrable r.r.v.'s given the subspace \(L'\).

Yuen-Kwok Chan 153 Constructive Probability
CHAPTER 5. PROBABILITY SPACE

In the special case where \( L' \equiv L(G) \) is the probability subspace generated by a given family of r.v.’s with values in some complete metric space \((S,d)\), we will simply write \( E(Y|G) \equiv E(Y|L') \) and say that \( L_G \equiv L(L') \) is the subspace of \textit{conditionally integrable} r.r.v.’s given the family \( G \). In the case where \( G \equiv \{V_1,\cdots,V_m\} \) for some \( m \geq 1 \), we write also \( E(Y|V_1,\cdots,V_m) = E(Y|G) \equiv E(Y|L') \).

In the case where \( n = 1 \), and where \( V_1 = 1_A \) for some measurable set \( A \) with \( P(A) > 0 \), it can easily be verified that, for arbitrary \( Y \in L \), the conditional \( E(Y|1_A) \) exists is given by \( E(Y|1_A) = P(A)^{-1}E(Y1_A)1_A \). In that case, we will write

\[
E_A(Y) \equiv P(A)^{-1}E(Y1_A)
\]

for each \( Y \in L \), and write \( P_A(B) \equiv E_A(1_B) \) for each measurable set \( B \). The next lemma proves that \((\Omega,L,E_A)\) is a probability space, called the \textit{conditional probability space given the event} \( A \).

More generally, if \( Y_1,\cdots,Y_n \in L_{|L'} \) then we define the vector

\[
E((Y_1,\cdots,Y_n)|L') \equiv (E(Y_1|L'),\cdots,E(Y_n|L'))
\]

of integrable r.r.v.’s in \( L' \).

Let \( A \) be an arbitrary measurable subset of \((\Omega,L,E)\). If \( 1_A \in L_{|L'} \) we will write \( P(A|L') \equiv E_A(1_B) \) and call \( P(A|L') \) the \textit{conditional probability} of the event \( A \) given the probability subspace \( L' \). If \( 1_A \in L_G \) for some given family of r.v.’s with values in some complete metric space \((S,d)\), we will simply write \( P(A|G) \equiv E(1_A|G) \). In the case where \( G \equiv \{V_1,\cdots,V_m\} \), we write also \( P(A|V_1,\cdots,V_m) \equiv E(1_A|V_1,\cdots,V_m) \).

Before proceeding, note that the statement \( E(Y|L') \equiv X \) asserts two things: that \( E(Y|L') \) \textit{exists}, and that it is equal to \( X \). We have defined the conditional expectation without the sweeping classical assertion of its existence. Before we use a particular conditional expectation, we will first supply a proof of its existence.

**Lemma 5.6.5. (Conditional probability space given an event is indeed a probability space).** Let the measurable set \( A \) be arbitrary, with \( P(A) > 0 \). Then the triple \((\Omega,L,E_A)\) is indeed a probability space.

**Proof.** We need to verify the conditions in Definition 4.3.1 for an integration space.

1. Clearly \( E_A \) is a linear function on the linear \( L \).
2. Let \( (Y_i)_{i=0,1,2,\cdots} \) be an arbitrary sequence of functions in \( L \) such that \( Y_i \) is non-negative for each \( i \geq 1 \) and such that \( \sum_{i=1}^{\infty}E_A(Y_i) < E_A(Y_0) \). Then \( \sum_{i=1}^{\infty}E(Y_i1_A) < E(Y_01_A) \) by the definition of the function \( E_A \). Hence, since \( E \) is an integration, there exists \( \omega \in \bigcap_{i=0}^{\infty} \text{domain}(Y_i1_A) \) such that \( \sum_{i=1}^{\infty}Y_i(\omega)1_A(\omega) < Y_0(\omega)1_A(\omega) \). It follows that \( 1_A(\omega) > 0 \). Dividing by \( 1_A(\omega) \), we obtain \( \sum_{i=1}^{\infty}Y_i(\omega) < Y_0(\omega) \).
3. Let \( Y \in L \) be arbitrary. Then \( E_A(Y \wedge n) = E(Y \wedge n)1_A \rightarrow E(Y)1_A \equiv E_A(Y) \) as \( n \rightarrow \infty \). Similarly, \( E_A(Y \wedge n^{-1}) = E(|Y| \wedge n^{-1})1_A \rightarrow 0 \) as \( n \rightarrow \infty \).

Summing up, all three conditions in Definition 4.3.1 are satisfied by the triple \((\Omega,L,E_A)\). Because \( L \) is complete relative to the integration \( E \), in the sense of Definition 4.4.1 so it can trivially be verified that \( L \) is complete relative to the integration \( E_A \). Because \( 1 \in L \) with \( E_A(1) = 1 \), the complete integration space \((\Omega,L,E_A)\) is a probability space.
We will show that the conditional expectation is unique if it exists, two r.v.’s considered equal if they are equal a.s. The next two proposition proves basic properties of conditional expectations. They would be trivial classically, because the principle of infinite search would imply, via the Radon-Nikodym Theorem, that \( L_{|\mathcal{U}} = L \).

**Proposition 5.6.6.** (Basics of conditional expectation). Let \((\Omega, L', E)\) be a probability subspace of a probability space \((\Omega, L, E)\). Then the following holds.

1. Suppose \( Y_1 = Y_2 \) a.s. in \( L \), and suppose \( X_1, X_2 \in L' \) are such that \( EZ_j = EZ_j \) for each \( j = 1, 2 \), for each indicator \( Z \in L' \). Then \( X_1 = X_2 \) a.s. Consequently, the conditional expectation, if it exists, is uniquely defined.

2. Suppose \( X, Y \in L_{|\mathcal{U}} \). Then \( aX + bY \in L_{|\mathcal{U}} \), and

\[
E(aX + bY|L') = aE(X|L') + bE(Y|L'),
\]

for each \( a, b \in \mathbb{R} \). If, in addition, \( X \leq Y \) a.s., then \( E(X|L') \leq E(Y|L') \) a.s. In particular, if \( |X| \in L_{|\mathcal{U}} \) also, then \( |E(X|L')| \leq E(|X|L') \) a.s.

3. \( E(E(Y|L')) = E(Y) \) for each \( Y \in L_{|\mathcal{U}} \). Moreover, \( L' \subset L_{|\mathcal{U}} \), and \( E(Y|L') = Y \) for each \( Y \in L' \).

4. Suppose \( Y \in L_{|\mathcal{U}} \). In other words, suppose the conditional expectation \( E(Y|L') \) exists. Then \( ZY \in L_{|\mathcal{U}} \), and \( E(ZY|L') = ZE(Y|L') \), for each bounded \( Z \in L' \).

5. Let \( Y \in L \) be arbitrary. Let \( G \) be an arbitrary set of r.v.‘s with values in some complete metric space \((S, d)\). Suppose there exists \( X \in L(G) \) such that

\[
EYh(V_1, \cdots, V_k) = EXh(V_1, \cdots, V_k)
\]

(5.6.6)

for each \( h \in G_{ab}(S^k) \), for each finite subset \( \{V_1, \cdots, V_k\} \subset G \), and for each \( k \geq 1 \), then \( E(Y|G) = X \).

6. Let \( L'' \) be a probability subspace with \( L'' \subset L' \). Suppose \( X \in L_{|\mathcal{U}} \) with \( Y \equiv E(X|L') \). Then \( Y \in L_{|\mathcal{U}} \), iff \( X \in L_{|\mathcal{U}} \), in which case \( E(X|L'') = E(E(X|L'|L'')). \)

7. If \( Y \in L \) and if \( Y, Z \) are independent for each indicator \( Z \in L' \), then \( E(Y|L') = EY \).

8. Let \( Y \) be a r.r.v.. with \( Y^2 \in L \). Suppose \( X \equiv E(Y|L') \) exists. Then \( X^2, (Y - X)^2 \in L \) and \( EY^2 = EX^2 + E(Y - X)^2 \). Consequently, \( EX^2 \leq EY^2 \) and \( E(Y - X)^2 \leq EY^2 \).

**Proof.** 1. Let \( t > 0 \) be arbitrary and let \( Z \equiv 1_{(t < X_1 - X_2)} \in L' \). Then

\[
tP(t < X_1 - X_2) \leq EZ(X_1 - X_2) = EZ(Y_1 - Y_2) = 0,
\]

whence \( P(t < X_1 - X_2) = 0 \). It follows that that \( 0 < X_1 - X_2 \) is a null set, and that \( X_1 \geq X_2 \) a.s. By symmetry, \( X_1 = X_2 \) a.s.
2. Suppose $X, Y \in L_{l'}$. Let $Z \in L'$ be an arbitrary indicator. Then

$$E(Z(aX + bY)) = aE(ZX) + bE(ZY)$$

$$= aE(ZE(X'|L')) + bE(ZE(Y'|L'))$$

$$= E(Z(aE(X'|L') + bE(Y'|L')))$$.

Hence

$$E(aX + bY|L') = aE(X|L') + bE(Y|L')$$.

The remainder of Assertion 2 follows from assertion 1.

3. If $Y \in L_{l'}$, then

$$E(E(Y|L')) = E(1E(Y|L')) = E(1Y) = E(Y).$$

Separately, if $Y \in L'$, then, for each indicator $Z \in L'$, we have trivially $E(ZY) = E(ZY)$, whence $E(Y|L') = Y$.

4. Suppose $Y \in L_{l'}$, with $X \equiv E(Y|L')$. Then, by definition, $EZY = EZX$ for each indicator $Z \in L'$. The equality extends to all linear combinations of integrable indicators. Since such linear combinations are dense in $L$, the equality extends, by the Dominated Convergence Theorem, to all bounded integrable r.r.v.'s $Z \in L'$. Moreover if $U, Z \in L'$ are bounded and integrable r.r.v.'s, so is $UZ$, and the previous statement implies that $E(UZY) = E(UZX)$, whence $E(UY|L') = UX = UE(Y|L')$.

5. Let $Y \in L$ be arbitrary. Suppose equality \[5.6.6\] holds. Let $Z$ be an arbitrary indicator in $L' \equiv (L, G)$. Then $Z$ is the $L_1$-limit of some sequence $(h_n(V_{n,k} | (X_n,n,k))_{n=1,2,\cdots}$ where $h_n \in C_{ab}(S^{k(n)})$ for each $n \geq 1$. Hence, by the Dominated Convergence Theorem

$$EYZ = \lim_{n \to \infty} E_Y h_n(V_{n,k} | (X_n,n,k)) = \lim_{n \to \infty} E_X h_n(V_{n,k} | (X_n,n,k)) = EXZ,$$

where the second equality is due to equality \[5.6.6\] Thus $E(Y|G) \equiv E(Y|L') = X$.

6. Let $U \in L''$ an arbitrary indicator. Then $U \in L'$. First, suppose $X \in L_{l^n}$, with $Z \equiv E(X|L'') \in L''$. Then, by assertions 4 and 3 above, we have

$$EUY \equiv E(UX|L'') = E(UE(E(X|L'')|L')) = E(UE(X|L'')) \equiv EUY,$$

whence $E(Y|L'') = Z$. Consequently,

$$E(X|L'') \equiv Z = E(Y|L'') \equiv E(E(X|L')|L'').$$

Conversely, suppose $Y \in L_{l^n}$, with $Z \equiv E(Y|L'')$. Then, since $U \in L'$ and $U \in L''$, we have $EUX = EUY = EUZ$. Hence $E(X|L'') = Z$ and $X \in L_{l^n}$.

7. Suppose $Y \in L$, and suppose $Y, Z$ are independent for each indicator $Z \in L'$. Then, for each indicator $Z \in L'$ we have

$$E(ZY) = (EZ)(EY) = E(ZYE).$$

Since trivially $EY \in L'$, it follows that $E(Y|L') = EY$.

8. Let $Y$ be a r.r.v. with $Y^2 \in L$. Suppose $X \equiv E(Y|L')$ exists. Since $Y \in L_2$, there exists a decreasing sequence $\varepsilon_1 > \varepsilon_2 > \cdots$ of positive real numbers such that
\[ EY^2 1_A < 2^{-k} \] for each measurable set \( A \) with \( P(A) < \varepsilon_k \), for each \( k \geq 1 \). Since \( X \) is a r.r.v., there exists a sequence \( 0 \equiv a_0 < a_1 < a_2 < \cdots \) of positive real numbers with \( a_k \to \infty \) such that \( P(|X| \geq a_k) < \varepsilon_k \). Let \( k \geq 1 \) be arbitrary. Then

\[ EY^2 1_{|X| \geq a(k)} < 2^{-k} \]

Write \( Z_k \equiv 1_{a(k+1) > |X| \geq a(k)} \). Then \( Z_k, XZ_k, X^2Z_k \in L' \) are bounded in absolute value by \( 1, a_{k+1}, a_k^2 \) respectively. Hence

\[
EY^2 1_{a(k+1) > |X| \geq a(k)} = E((Y - X) + X)^2 Z_k \\
= E(Y - X)^2 Z_k + 2E(Y - X)XZ_k + EX^2 Z_k \\
= E(Y - X)^2 Z_k + 2E(YXZ_k) - 2E(XXZ_k) + EX^2 Z_k \\
= E(Y - X)^2 Z_k + 2E(XXZ_k) - 2E(XXZ_k) + EX^2 Z_k \\
= E(Y - X)^2 Z_k + EX^2 Z_k,
\]

(5.6.7)

where the fourth equality is by applying Assertion 4 to \( Y \) and to the bounded r.r.v. \( XZ_k \in L' \). Since \( Y^2 \in L \) by assumption, we have

\[
\sum_{k=0}^{\infty} EX^2 1_{a(k+1) > |X| \geq a(k)} \leq \sum_{k=0}^{\infty} EY^2 1_{a(k+1) > |X| \geq a(k)} = EY^2.
\]

Consequently

\[
X^2 = \sum_{k=0}^{\infty} X^2 1_{a(k+1) > |X| \geq a(k)} \in L.
\]

Similarly, \( (Y - X) \in L^2 \). Moreover, summing equality \( 5.6.7 \) over \( k = 0, 1, \ldots \), we obtain

\[
EY^2 = E(Y - X)^2 + EX^2.
\]

Assertion 8 and the proposition are proved. \( \square \)

**Proposition 5.6.7. (Space of conditionally integrable functions given a probability subspace is closed).** Let \( (\Omega, L, E) \) be a probability space. Let \( (\Omega, L', E) \) be a probability subspace of \( (\Omega, L, E) \). Let \( L_{1L'} \) be the space of r.r.v.'s conditionally integrable given \( L' \). Then the following holds.

1. Let \( X, Y \in L \) be arbitrary. Suppose \( EUX \leq EUY \) for each indicator \( U \in L' \). Then \( EZX \leq EZY \) for each bounded nonnegative r.r.v. \( Z \in L' \).

2. Suppose \( Y \in L_{1L'} \). Then \( E|Y'| \leq E|Y| \).

3. The linear subspace \( L_{1L'} \) of \( L \) is closed relative to the \( L_1 \)-norm.

**Proof.** 1. Suppose \( EUX \leq EUY \) for each indicator \( U \in L' \). Then, by linearity, \( EVX \leq EVY \) for each nonnegative linear combination \( Y \) of indicators in \( L' \). Now consider each bounded nonnegative r.r.v. \( Z \in L' \). We may assume, without loss of generality, that \( Z \) has values in \([0, 1]\). Then \( E|Z - V_n| \to 0 \) for some sequence \( (V_n)_{n=1,2,\ldots} \) of nonnegative linear combinations of indicators in \( L' \), with values in \([0, 1]\). By passing to a
subsequence, we may assume that $V_n \to Z$ a.s. Hence, by the Dominated Convergence Theorem, we have

$$EZX = \lim_{n \to \infty} EV_nX \leq \lim_{n \to \infty} EV_nY = EZY.$$

2. Suppose $Y \in L_{L'}$, with $E(Y|L') = X \in L'$. Let $\varepsilon > 0$ be arbitrary. Then, since $X$ is integrable, there exists $a > 0$ such that $EX1_{|X| \leq a} < \varepsilon$. Then

$$E|X| = EX1_{X > a} - EX1_{X < a} + EY1_{|X| \leq a}$$

$$\leq EX1_{X > a} - EX1_{X < a} + \varepsilon$$

$$= EY1_{Y > a} - EY1_{Y < a} + \varepsilon$$

$$\leq E|Y|1_{X > a} + E|Y|1_{X < a} + \varepsilon \leq |Y| + \varepsilon,$$

where the second equality is because $Y = E(X|L')$. Since $\varepsilon > 0$ is arbitrarily small, we conclude that $E|X| \leq E|Y|$, as alleged.

3. Let $(Y_n)_{n=1,2,\ldots}$ be a sequence in $L_{L'}$ such that $E|Y_n - Y| \to 0$ for some $Y \in L$. For each $n \geq 1$, let $X_n \equiv E(Y_n|L')$. Then, By Assertion 2 above, we have

$$E|X_n - X_m| = E|E(Y_n - Y_m|L')| \leq E|Y_n - Y_m| \to 0$$

as $n, m \to \infty$. Thus $(X_n)_{n=1,2,\ldots}$ is a Cauchy sequence in the complete metric space $L'$ relative to the $L_1$-norm. It follows that $E|X_n - X| \to 0$ for some $X \in L'$, as $n \to \infty$. Hence, for each indicator $Z \in L'$, we have

$$EXZ = \lim_{n \to \infty} EX_nZ = \lim_{n \to \infty} EY_nZ = EYZ.$$

It follows that $E(Y|L') = X$ and $Y \in L_{L'}$. \qed

## 5.7 Normal Distributions

The classical development of the topics in the remainder of this chapter is exemplar of constructive mathematics. However, some tools in said development have been given many proofs, some constructive and others not. An example is the spectral theorem for symmetric matrices below. For ease of reference, we therefore present some such topics here, using only constructive proofs.

Recall some notations and basic theorems from Matrix Algebra.

### Definition 5.7.1. (Matrix notations)

For an arbitrary $m \times n$ matrix

$$\theta \equiv \begin{bmatrix} \theta_{1,1} & \cdots & \theta_{1,n} \\ \vdots & \ddots & \vdots \\ \theta_{m,1} & \cdots & \theta_{m,n} \end{bmatrix},$$

Yuen-Kwok Chan 158 Constructive Probability
of real or complex elements $\theta_{i,j}$, we will let

$$\theta^T \equiv [\theta_{i,j}]_{j=1,\ldots;n, i=1,\ldots;m} = \begin{bmatrix}
\theta_{1,1} & \cdots & \theta_{m,1} \\
\vdots & \ddots & \vdots \\
\theta_{1,n} & \cdots & \theta_{m,n}
\end{bmatrix}$$

denote the transpose, which is an $n \times m$ matrix. If $n = m$ and $\theta = \theta^T$, then $\theta$ is said to be symmetric. If $\theta_{i,j} = 0$ for each $i, j = 1, \cdots, n$ with $i \neq j$, then $\theta$ is called a diagonal matrix. For each sequence of complex numbers $(\lambda_1, \cdots, \lambda_n)$, write $\text{diag}(\lambda_1, \cdots, \lambda_n)$ for the diagonal matrix $\theta$ with $\theta_{i,i} = \lambda_i$ for each $i = 1, \cdots, n$. A matrix $\theta$ is said to be real if all its elements $\theta_{i,j}$ are real numbers. Unless otherwise specified, all matrices in the following are assumed to be real.

For an arbitrary sequence $\mu \equiv (\mu_1, \cdots, \mu_n) \in \mathbb{R}^n$, we will abuse notations and let $\bar{\mu}$ denote also the column vector

$$\bar{\mu} \equiv (\mu_1, \cdots, \mu_n) \equiv \begin{bmatrix}
\mu_1 \\
\vdots \\
\mu_n
\end{bmatrix}$$

Thus $\bar{\mu}^T = [\mu_1, \cdots, \mu_n]$. A $1 \times 1$ matrix is identified with its only entry. Hence, if $\bar{\mu} \in \mathbb{R}^n$, then

$$|\mu| \equiv ||\bar{\mu}|| \equiv \sqrt{\bar{\mu}^T \bar{\mu}} = \sqrt{\sum_{i=1}^n \mu_i^2}.$$ 

We will let $I_n$ denote the $n \times n$ diagonal matrix $\text{diag}(1, \cdots, 1)$. When the dimension $n$ is understood, we write simply $I \equiv I_n$. Likewise, we will write $0$ for any matrix whose entries are all equal to the real number $0$, with dimensions understood from the context.

The determinant of an $n \times n$ matrix $\theta$ is denoted by $\text{det} \theta$. The $n$ complex roots $\lambda_1, \cdots, \lambda_n$ of the polynomial $\text{det}(\theta - \lambda I)$ of degree $n$ are called the eigenvalues of $\theta$. Then $\text{det} \theta = \lambda_1 \cdots \lambda_n$. Let $j = 1, \cdots, n$ be arbitrary. Then there exists a nonzero column vector $x_j$, whose elements are in general complex, such that $\theta x_j = \lambda_j x_j$. The vector $x_j$ is called an eigenvector for the eigenvalue $\lambda_j$. If $\theta$ is real and symmetric, then the $n$ eigenvalues $\lambda_1, \cdots, \lambda_n$ are real.

Let $\Sigma$ be a symmetric $n \times n$ matrix whose elements are real. Then $\Sigma$ is said to be nonnegative definite if $x^T \Sigma x \geq 0$ for each $x \in \mathbb{R}^n$. In that case all its eigenvalues are nonnegative, and, for each eigenvalue, there exists a real eigenvector whose elements are real. It is said to be positive definite if $x^T \Sigma x > 0$ for each nonzero $x \in \mathbb{R}^n$. In that case all its eigenvalues are positive, whence $\Sigma$ is nonsingular, with an inverse $\Sigma^{-1}$. An $n \times n$ real matrix $U$ is said to be orthogonal if $U^T U = I$. This is equivalent to saying that the column vectors of $U$ form an orthonormal basis of $\mathbb{R}^n$. □

**Theorem 5.7.2. (Spectral Theorem for Symmetric Matrices).** Let $\theta$ be an arbitrary $n \times n$ symmetric matrix. Then the following holds.
1. There exists an orthogonal matrix $U$ such that $U^T \Theta U = \Lambda$, where
\[ \Lambda \equiv \text{diag}(\lambda_1, \cdots, \lambda_n) \]
and $\lambda_1, \cdots, \lambda_n$ are eigenvalues of $\Theta$.

2. Suppose, in addition, that $\lambda_1, \cdots, \lambda_n$ are nonnegative. Define the symmetric matrix $A \equiv U \Lambda^{\frac{1}{2}} U^T$, where $\Lambda^{\frac{1}{2}} = \text{diag}(\lambda_1^{\frac{1}{2}}, \cdots, \lambda_n^{\frac{1}{2}})$. Then $\Theta = AA^T$.

Proof. 1. Proceed by induction on $n$. The assertion is trivial if $n = 1$. Suppose the assertion has been proved for $n - 1$. Recall that, for an arbitrary unit vector $v_n$, there exist $v_1, \cdots, v_{n-1} \in \mathbb{R}^n$ such that $v_1, \cdots, v_{n-1}, v_n$ form an orthonormal basis of $\mathbb{R}^n$. Now let $v_n$ be an eigenvector of $\Theta$ corresponding to $\lambda_n$. Let $V$ be the $n \times n$ matrix whose $i$-th column is $v_i$ for each $i = 1, \cdots, n$. Then $V$ is an orthogonal matrix. Define an $(n-1) \times (n-1)$ symmetric matrix $\eta$ by $\eta_{i,j} \equiv v_i^T \Theta v_j$ for each $i, j = 1, \cdots, n-1$. By the induction hypothesis, there exists an $(n-1) \times (n-1)$ orthogonal matrix $W$ such that
\[ W^T \eta W = \Lambda_{n-1} = \text{diag}(\lambda_1, \cdots, \lambda_{n-1}) \tag{5.7.1} \]
for some $\lambda_1, \cdots, \lambda_{n-1} \in \mathbb{R}$. Define the $n \times n$ matrices
\[ W' \equiv \begin{bmatrix} w_{1,1}, & \cdots, & w_{1,n-1}, & 0 \\ \vdots & \ddots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots \\ w_{n-1,1}, & \cdots, & w_{n-1,n-1}, & 0 \\ 0, & \cdots, & 0, & 1 \end{bmatrix} \]
and $U \equiv VW'$. Then it is easily verified that $U$ is orthogonal. Moreover,
\[ U^T \Theta U = W'^T V^T \Theta V W' = W'^T \]

\[ \begin{bmatrix} v_1^T \Theta v_1, & \cdots, & v_{n-1}^T \Theta v_{n-1}, & v_n^T \Theta v_n \\ \vdots & \ddots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots \\ v_{n-1}^T \Theta v_1, & \cdots, & v_n^T \Theta v_{n-1}, & v_1^T \Theta v_n \end{bmatrix} W' \]

\[ = \begin{bmatrix} w_{1,1}, & \cdots, & w_{1,n-1}, & 0 \\ \vdots & \ddots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots \\ w_{n-1,1}, & \cdots, & w_{n-1,n-1}, & 0 \\ 0, & \cdots, & 0, & 1 \end{bmatrix} \begin{bmatrix} \eta_{1,1}, & \cdots, & \eta_{1,n-1}, & 0 \\ \vdots & \ddots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots \\ \eta_{n-1,1}, & \cdots, & \eta_{n-1,n-1}, & 0 \end{bmatrix} \begin{bmatrix} \eta_{1,1}, & \cdots, & \eta_{1,n-1}, & 0 \\ \vdots & \ddots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots \\ \eta_{n-1,1}, & \cdots, & \eta_{n-1,n-1}, & 0 \end{bmatrix} \begin{bmatrix} 0, & \cdots, & 0, & \lambda_n \end{bmatrix} \]
where the fourth equality is thanks to equality 5.7.1 Induction is completed. The equality \( U^T \theta U = \Lambda \) implies that \( \theta U U^T = U \Lambda \) and that \( \lambda_i \) is an eigenvalue of \( \theta \) with an eigenvector given by the \( i \)-th column of \( U \). Assertion 1 is thus proved.

Since
\[
\theta = U \Lambda U^T = U \Lambda^\frac{1}{2} \Lambda^\frac{1}{2} U^T = U \Lambda^\frac{1}{2} U^T U \Lambda^\frac{1}{2} U^T = AA^T,
\]
Assertion 2 is proved.

\[\square\]

**Definition 5.7.3. (Normal distribution with positive definite covariance).** Let \( n \geq 1 \) and \( \bar{\mu} \in \mathbb{R}^n \) be arbitrary. Let \( \bar{\sigma} \) be an arbitrary positive definite \( n \times n \) matrix. Then the function defined on \( \mathbb{R}^n \) by
\[
\varphi_{\bar{\mu}, \bar{\sigma}}(y) \equiv (2\pi)^{-\frac{n}{2}} (\det \bar{\sigma})^{-\frac{1}{2}} \exp \left( -\frac{1}{2} (y - \bar{\mu})^T \bar{\sigma}^{-1} (y - \bar{\mu}) \right)
\]  
(5.7.2)

for each \( y \in \mathbb{R}^n \) is a p.d.f. Let \( \Phi_{\bar{\mu}, \bar{\sigma}} \) be the corresponding distribution on \( \mathbb{R}^n \), and let \( Y \equiv (Y_1, \cdots, Y_n) \) be any r.v. with values in \( \mathbb{R}^n \) and with \( \Phi_{\bar{\mu}, \bar{\sigma}} \) as its distribution. Then \( \varphi_{\bar{\mu}, \bar{\sigma}}, \Phi_{\bar{\mu}, \bar{\sigma}}, Y \), and \( Y_1, \cdots, Y_n \) are respectively said to be the normal p.d.f., normal distribution, normally distributed, and jointly normal, with mean \( \bar{\mu} \) and covariance matrix \( \bar{\sigma} \). Proposition 5.7.6 below justifies the terminology. The p.d.f. \( \Phi_{0,I} \) and the distribution \( \Phi_{0,I} \) are said to be standard normal, where \( I \) is the identity matrix.

In the case where \( n = 1 \), define \( \sigma \equiv \sqrt{\bar{\sigma}} \) and write \( \Phi_{\bar{\mu}, \sigma^2} \) also for the P.D.F. associated with the distribution \( \Phi_{\bar{\mu}, \sigma^2} \), and call it a normal P.D.F. Thus \( \Phi_{0,1}(x) = \int_{-\infty}^x \varphi_{0,1}(u) du \) for each \( x \in \mathbb{R} \). In Definition 5.7.7 we will generalize the definition of normal distributions to an arbitrary nonnegative definite matrix \( \bar{\sigma} \). \[\square\]

**Proposition 5.7.4. (Basics of standard normal distribution).** Consider the case \( n = 1 \). Then the following holds.

1. The function \( \varphi_{0,1} \) on \( \mathbb{R} \) defined by
\[
\varphi_{0,1}(x) \equiv \frac{1}{\sqrt{2\pi}} \exp \left( -\frac{1}{2} x^2 \right)
\]
is a p.d.f. on \( \mathbb{R} \) relative to the Lebesgue measure. Thus \( \Phi_{0,1} \) is a P.D.F. on \( \mathbb{R} \).
2. Write $\Phi = \Phi_{0,1}$. We will call $\Psi \equiv 1 - \Phi : [0, \infty) \to (0, \frac{1}{2}]$ the tail of $\Phi$. Then $\Phi(-x) = 1 - \Phi(x)$ for each $x \in \mathbb{R}$. Moreover,

$$\Psi(x) \leq e^{-x^2/2}$$

for each $x \geq 0$.

3. The inverse $\overline{\Psi} : (0, \frac{1}{2}] \to [0, \infty)$ of $\Psi$ is a decreasing function from $(0,1)$ to $\mathbb{R}$ such that $\overline{\Psi}(\varepsilon) \to \infty$ as $\varepsilon \to 0$. Moreover $\overline{\Psi}(\varepsilon) \leq \sqrt{-2\log \varepsilon}$ for $\varepsilon \in (0, \frac{1}{2}]$.

Proof. 1. We calculate

$$\left( \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} e^{-x^2/2} \ dx \right)^2 = \frac{1}{2\pi} \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} e^{-(x^2+y^2)/2} \ dx \ dy$$

$$= \frac{1}{2\pi} \int_{0}^{2\pi} \int_{0}^{r} e^{-r^2/2} r \ dr \ d\theta = \frac{1}{2\pi} \int_{0}^{2\pi} \left( -e^{-r^2/2} \right)_{0}^{+\infty} \ d\theta$$

$$= \frac{1}{2\pi} \int_{0}^{2\pi} \ d\theta = 1,$$  \hspace{1cm} (5.7.3)

where the change of variables from $(x,y)$ to $(r, \theta)$ is defined by $x = r \cos \theta$ and $y = r \sin \theta$. Thus $\varphi_{0,1}$ is Lebesgue integrable, with integral equal to 1, hence a p.d.f. on $\mathbb{R}$.

In the above proof, we used a series of steps: (i) the function $e^{-x^2/2}$ is integrable relative to the Lebesgue integration $J \equiv \int \ dx$, (ii) the function $e^{-(x^2+y^2)/2}$ is integrable relative to $\int \int dxdy \equiv J \otimes J$, (iii) Fubini’s Theorem equates the double integral to successive integrals in either order, (iv) a disk $D_{a}$ with center 0 and radius $a > 0$ is integrable relative to $J \otimes J$, (v) the double integral $\int \int e^{-(x^2+y^2)/2} dxdy$ is equal to the limit of $\int \int 1_{D_{a}}(x,y) e^{-(x^2+y^2)/2} dxdy$ as $a \to \infty$, and (vi) we make a change of integration variables from $(x,y)$ to $(r, \theta)$ in the last double integral. Step (i) follows from an estimate of $|c_{a} - c_{a'}| \to 0$ as $a, a' \to \infty$, where $c_{a} \equiv \int_{a}^{a} e^{-x^2/2} \ dx$. Step (ii) is justified by Corollary 4.10.7. The use of Fubini’s Theorem in step (iii) is justified by the conclusion of step (ii). The integrability of $D_{a}$ in step (iv) follows because $D_{a} = (Z \leq a)_{1[-a,a][x[-a,a]}$ where $Z$ is the continuous function defined by $Z(x,y) \equiv \sqrt{x^2+y^2}$. Step (v) is an application of the Monotone Convergence Theorem. Step (vi), the change of integration variables from rectangular- to polar coordinates, is by Corollary 13.0.11 in the Appendix. In the remainder of this book, such slow motion, blow-by-blow justifications will mostly be left to the reader.

2. Note first that

$$\Phi(-x) \equiv \int_{-\infty}^{-x} \varphi(u) \ du$$

$$= \int_{x}^{\infty} \varphi(-v) \ dv = \int_{x}^{\infty} \varphi(v) \ dv = 1 - \Phi(x),$$

where we made a change of integration variables $v = -u$ and noted that $\varphi(-v) = \varphi(v)$.

Next, if $x \in \left[ \frac{1}{\sqrt{2\pi}}, \infty \right)$, then

$$\Psi(x) = \frac{1}{\sqrt{2\pi}} \int_{x}^{\infty} e^{-u^2/2} \ du$$
5.7. NORMAL DISTRIBUTIONS

\[
\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-u^2/2} du = \frac{1}{\sqrt{2\pi}} e^{-x^2/2} \leq e^{-x^2/2}.
\]

On the other hand, if \( x \in (0, \frac{1}{\sqrt{2\pi}}) \), then

\[
\Psi(x) \leq \Psi(0) = \frac{1}{2} < \exp(-\frac{1}{\sqrt{2\pi}})^2/2) \leq e^{-x^2/2}.
\]

Therefore, by continuity, \( \Psi(x) \leq e^{-x^2/2} \) for each \( x \in [0, \infty) \).

3. Consider any \( \varepsilon \in (0, 1) \). Define \( x \equiv -\sqrt{2\log \varepsilon} \). Then \( \Psi(x) \leq e^{-x^2/2} = \varepsilon \) by Assertion 2. Since \( \Psi \) is a decreasing function, it follows that

\[
\sqrt{-2\log \varepsilon} \equiv x = \Psi^{-1}(\varepsilon) \geq \Psi(\epsilon).
\]

Proposition 5.7.5. (Moments of standard normal r.r.v.) Suppose a r.r.v. \( X \) has
the standard normal distribution \( \Phi_{0.1} \), with p.d.f. \( \Phi_{0.1}(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2} \). Then \( X^m \) is integrable for each \( m \geq 0 \). Moreover, for each even integer \( m \equiv 2k \geq 0 \) we have

\[
EX^m = EX^{2k} = (2k - 1)(2k - 3) \cdots 3 \cdot 1 = (2k)!2^{-k}/k!,
\]

while \( EX^m = 0 \) for each odd integer \( m > 0 \).

Proof. Let \( m \geq 0 \) be any even integer. Let \( a > 0 \) be arbitrary. Then, integrating by parts, we have

\[
\frac{1}{\sqrt{2\pi}} \int_{-a}^{a} x^{m+2} e^{-x^2/2} dx = \frac{1}{\sqrt{2\pi}} \left[ (-x^{m+1} e^{-x^2/2}) \right]_{-a}^{a} + (m+1) \frac{1}{\sqrt{2\pi}} \int_{-a}^{a} x^m e^{-x^2/2} dx
\]

(5.7.4)

Since the function \( g_m \) defined by \( g_m(x) = \mathbf{1}_{[-a,a]}(x)x^m \) for each \( x \in R \) is Lebesgue measurable and is bounded, Proposition 5.4.2 implies that \( g_m \) is integrable relative to the p.d.f. \( \Phi_{0.1} \), which has \( \Phi_{0.1} \) as p.d.f.. Moreover, according to Proposition 5.4.2 equality (5.7.4) can be re-written as

\[
\int g_{m+2}(x)d\Phi_{0.1}(x) = \frac{1}{\sqrt{2\pi}} \left[ (-x^{m+1} e^{-x^2/2}) \right]_{-a}^{a} + (m+1) \int g_m(x)d\Phi_{0.1}(x)
\]

or, in view of Proposition 5.4.5 as

\[
Eg_{m+2}(X) = \frac{1}{\sqrt{2\pi}} \left[ (-x^{m+1} e^{-x^2/2}) \right]_{-a}^{a} + (m+1)Eg_m(X)
\]

(5.7.5)

The Lemma is trivial for \( m = 0 \). Suppose the Lemma has been prove for integers up to and including the even integer \( m \equiv 2k - 2 \). By the induction hypothesis, \( X^m \) is integrable. At the same time, \( g_m(X) \rightarrow X^m \) in probability as \( a \rightarrow \infty \). Hence, by the Dominated Convergence Theorem, we have \( Eg_m(X) \rightarrow EX^m \) as \( a \rightarrow \infty \). Since \( |a|^{m+1} e^{-a^2/2} \rightarrow 0 \) as \( a \rightarrow \infty \), equality (5.7.5) yields \( Eg_{m+2}(X) \rightarrow (m+1)EX^m \) as \( a \rightarrow \infty \).
The Monotone Convergence Theorem therefore implies that $X^{m+2}$ is integrable, with $EX^{m+2} = (m+1)EX^{m}$, or

$$EX^{2k} = (2k-1)EX^{2k-2} = \cdots = (2k-1)(2k-3)\cdots1 = (2k)!2^{-k}/k!$$

Since $X^{m+2}$ is integrable, so is $X^{m+1}$, according to Lyapunov’s inequality. Moreover,

$$EX^{m+1} = \int x^{m+1}d\Phi_{0,1}(x) = \int x^{m+1}\phi_{0,1}(x)dx = 0$$

since $x^{m+1}\phi_{0,1}(x)$ is an odd function of $x \in \mathbb{R}$. Induction is completed. \qed

The next proposition shows that $\phi_{\mu,\Sigma}$ and $\Phi_{\mu,\Sigma}$ in Definition 5.7.3 are well defined.

**Proposition 5.7.6.** (Basics of normal distributions with positive definite covariance). Let $n \geq 1$ and $\mu \in \mathbb{R}^n$ be arbitrary. Let $\Sigma$ be an arbitrary positive definite $n \times n$ matrix. Use the notations in Definition 5.7.3. Then the following holds.

1. $\phi_{\mu,\Sigma}$ is indeed a p.d.f. on $\mathbb{R}^n$, i.e. $\int \phi_{\mu,\Sigma}(x)dx = 1$, where $\int dx$ stands for the Lebesgue integration on $\mathbb{R}^n$. Thus the corresponding distribution $\Phi_{\mu,\Sigma}$ on $\mathbb{R}^n$ is well defined. Moreover, $\Phi_{\mu,\Sigma}$ is equal to the distribution of the r.v. $Y = \mu + AX$ where $A$ is an arbitrary $n \times n$ matrix with $\Sigma = AA^T$ and where $X$ is an arbitrary r.v. with values in $\mathbb{R}^n$ and with the standard normal distribution $\Phi_{0,1}$. In short, linear combinations of a finite set of standard normal r.r.v.’s and the constant 1 are jointly normal. More generally, linear combinations of a finite set of jointly normal r.r.v.’s are jointly normal.

2. Let $Z \equiv (Z_1, \ldots, Z_n)$ be a r.v. with values in $\mathbb{R}^n$ with distribution $\Phi_{\mu,\Sigma}$. Then $EZ = \mu$ and $E(Z - \mu)(Z - \mu)^T = \Sigma$.

3. Let $Z_1, \ldots, Z_n$ be jointly normal r.r.v.’s. Then $Z_1, \ldots, Z_n$ are independent iff they are pairwise uncorrelated. In particular, if $Z_1, \ldots, Z_n$ are jointly standard normal, then they are independent.

**Proof.** For each $x \equiv (x_1, \cdots, x_n) \in \mathbb{R}^n$, we have, by Definition 5.7.3

$$\phi_{0,l}(x) \equiv \phi_{0,l}(x) \equiv (2\pi)^{-\frac{n}{2}}\exp\left(-\frac{1}{2}x^T \Sigma^{-1} x\right)$$

$$= \prod_{i=1}^{n}\left(\frac{1}{\sqrt{2\pi}}\exp\left(-\frac{1}{2}x_i^2\right)\right) = \phi_{0,1}(x_1) \cdots \phi_{0,1}(x_n).$$

Since $\phi_{0,l}$ is a p.d.f. on $\mathbb{R}$ according to Proposition 5.7.3 above, Proposition 4.10.7 implies that the Cartesian product $\phi_{0,l}$ is a p.d.f. on $\mathbb{R}^n$. Let $X \equiv (X_1, \cdots, X_n)$ be an arbitrary r.v. with values in $\mathbb{R}^n$ and with p.d.f. $\phi_{0,l}$. Then

$$EF_1(X_1) \cdots f_n(X_n)$$

$$= \int \cdots \int f_1(x_1) \cdots f_n(x_n)\phi_{0,1}(x_1) \cdots \phi_{0,1}(x_n)dx_1 \cdots dx_n$$

$$= \prod_{i=1}^{n}\int f_i(x_i)\phi_{0,1}(x_i)dx_i = EF_1(X_1) \cdots EF_n(X_n) \quad (5.7.6)$$
5.7. NORMAL DISTRIBUTIONS

for each \( f_1, \ldots, f_n \in C(R) \). Separately, for each \( i = 1, \ldots, n \), the r.v. \( X_i \) has distribution \( \Phi_{0,1} \), whence \( X_i \) has \( m \)-th moment for each \( m \geq 0 \), with \( EX_i^m = 0 \) if \( m \) is odd, according to Proposition 5.7.3.

1. Next let \( \bar{\sigma}, \bar{\mu} \) be as given. Let \( A \) be an arbitrary \( n \times n \) matrix such that \( \bar{\sigma} = AA^T \). By 5.7.2, such a matrix \( A \) exists. Then \( \det(\bar{\sigma}) = \det(A)^2 \). Since \( \bar{\sigma} \) is positive definite, it is nonsingular and so is \( A \). Let \( X \) be an arbitrary r.v. with values in \( R^n \) and with the standard normal distribution \( \Phi_{0,1} \). Define the r.v. \( Y \equiv \bar{\mu} + AX \). Then, for arbitrary \( f \in C(R^n) \), we have

\[
Ef(Y) = Ef(\bar{\mu} + AX) = \int f(\bar{\mu} + Ax)\phi_{0,1}(x)dx
\]

\[
\equiv (2\pi)^{-\frac{n}{2}} \int f(\bar{\mu} + Ax) \exp\left(-\frac{1}{2}x^T \sigma x\right)dx
\]

\[
= (2\pi)^{-\frac{n}{2}} \det(A)^{-1} \int f(y) \exp\left(-\frac{1}{2}(y - \bar{\mu})^T A^{-1}A^{-1}(y - \bar{\mu})\right)dy
\]

\[
= (2\pi)^{-\frac{n}{2}} \det(\bar{\sigma})^{-\frac{1}{2}} \int f(y) \exp\left(-\frac{1}{2}(y - \bar{\mu})^T \sigma^{-1}(y - \bar{\mu})\right)dy
\]

\[
\equiv \int f(y)\phi_{\bar{\mu}, \bar{\sigma}}(y)dy,
\]

where the fourth equality is by the change of integration variables \( y = \bar{\mu} + Ax \). Thus \( \phi_{\bar{\mu}, \bar{\sigma}} \) is the p.d.f. on \( R^n \) of the r.v. \( Y \), and \( \Phi_{\bar{\mu}, \bar{\sigma}} \) is the distribution of \( Y \).

2. Next, let \( Z_1, \ldots, Z_n \) be jointly normal r.v.'s with distribution \( \Phi_{\bar{\mu}, \bar{\sigma}} \). By Assertion 1, there exist a standard normal r.v. \( X \equiv (X_1, \ldots, X_n) \) on some probability space \((\Omega', L', E')\), and an \( n \times n \) matrix \( AA^T = \bar{\sigma} \), such that \( E'f(\bar{\mu} + AX) = \Phi_{\bar{\mu}, \bar{\sigma}}(f) = Ef(Z) \) for each \( f \in C(R^n) \). Thus \( Z \) and \( Y \equiv \bar{\mu} + AX \) induce the same distribution on \( R^n \). Let \( i, j = 1, \ldots, n \) be arbitrary. Since \( X_i, X_j, X_iX_j \) and, therefore, \( Y_i, Y_j, Y_iY_j \) are integrable, so are \( Z_iZ_j, Z_iZ_j \), with

\[
EZ = E'Y = \bar{\mu} + AE'X = \bar{\mu},
\]

and

\[
E(Z - \bar{\mu})(Z - \bar{\mu})^T = E'(Y - \bar{\mu})(Y - \bar{\mu})^T = AE'XX^T A^T = AA^T = \bar{\sigma}.
\]

3. Suppose \( Z_1, \ldots, Z_n \) are pairwise uncorrelated. Then \( \sigma_{i,j} = E(Z_i - \bar{\mu}_i)(Z_j - \bar{\mu}_j) = 0 \) for each \( i, j = 1, \ldots, n \) with \( i \neq j \). Thus \( \bar{\sigma} \) and \( \bar{\sigma}^{-1} \) are diagonal matrices, with \( (\bar{\sigma}^{-1})_{i,i} = \sigma_{i,i} \) or 0 according as \( i = j \) or not. Hence, for each \( f_1, \ldots, f_n \in C(R) \), we have

\[
Ef_1(Z_1) \cdots f_n(Z_n)
\]

\[
= (2\pi)^{-\frac{n}{2}} (\det(\bar{\sigma}))^{-\frac{1}{2}} \int \cdots \int f(z_1) \cdots f(z_n) \exp\left(-\frac{1}{2}(z - \bar{\mu})^T \sigma^{-1}(z - \bar{\mu})\right)dz_1 \cdots dz_n
\]

\[
= (2\pi)^{-\frac{n}{2}} (\sigma_{1,1} \cdots \sigma_{n,n})^{-\frac{1}{2}} \int \cdots \int f(z_1) \cdots f(z_n) \exp\left(-\frac{1}{2}(z - \bar{\mu})^T \sigma^{-1}(z - \bar{\mu})\right)dz_1 \cdots dz_n
\]

\[
= (2\pi\sigma_{i,i})^{-\frac{1}{2}} \int f(z_i) \exp\left(-\frac{1}{2}(z_i - \bar{\mu}_i)\sigma^{-1}_{i,i}(z_i - \bar{\mu}_i)\right)dz_i.
\]

Yuen-Kwok Chan

165

Constructive Probability
normal distribution on $\mathbb{R}^n$. We conclude that $Z_1, \cdots, Z_n$ are independent if they are pairwise uncorrelated. The converse is trivial. $\square$

Next we generalize the definition of normal distribution to include the case where the covariance matrix nonnegative definite.

**Definition 5.7.7.** (Normal distribution with nonnegative definite covariance). Let $n \geq 1$ and $\mu \in \mathbb{R}^n$ be arbitrary. Let $\Sigma$ be an arbitrary nonnegative definite $n \times n$. Define the normal distribution $\Phi_{\mu, \Sigma}$ on $\mathbb{R}^n$ by

$$\Phi_{\mu, \Sigma}(f) = \lim_{\epsilon \to 0} \Phi_{\mu, \Sigma + \epsilon I}(f)$$

for each $f \in C(\mathbb{R}^n)$, where, for each $\epsilon > 0$, the function $\Phi_{\mu, \Sigma + \epsilon I}$ is the normal distribution on $\mathbb{R}^n$ introduced in Definition 5.7.4 for the positive definite matrix $\Sigma + \epsilon I$. Lemma 5.7.8 below proves that $\Phi_{\mu, \Sigma}$ well defined and is indeed a distribution.

A sequence $Z_1, \cdots, Z_n$ of r.v.’s is said to be jointly normal, with $\Phi_{\mu, \Sigma}$ as distribution, if $Z \equiv (Z_1, \cdots, Z_n)$ has the distribution $\Phi_{\mu, \Sigma}$ on $\mathbb{R}^n$.

**Lemma 5.7.8.** (Normal distribution with nonnegative definite covariance is well defined). Use the notations and assumptions in Definition 5.7.7. Then the following holds.

1. The the limit $\lim_{\epsilon \to 0} \Phi_{\mu, \Sigma + \epsilon I}(f)$ in equality (5.7.7) exists for each $f \in C(\mathbb{R}^n)$. Moreover, $\Phi_{\mu, \Sigma}$ is the distribution of $Z \equiv \mu + AX$ for some standard normal $X \equiv (X_1, \cdots, X_n)$ and some $n \times n$ matrix $A$ with $AA^T = \Sigma$.

2. If $\Sigma$ is positive definite, then $\Phi_{\mu, \Sigma}(f) = \int f(y) \phi_{\mu, \Sigma}(y) dy$, where $\phi_{\mu, \Sigma}$ was defined in Definition 5.7.3. Thus Definition 5.7.7 of $\Phi_{\mu, \Sigma}$ for a nonnegative definite $\Sigma$ is consistent with the previous Definition 5.7.4 for a positive definite $\Sigma$.

3. Let $Z \equiv (Z_1, \cdots, Z_n)$ be an arbitrary r.v. with values in $\mathbb{R}^n$ and with distribution $\Phi_{\mu, \Sigma}$. Then $Z^{(1)} \cdots Z^{(n)}$ is integrable for each $k_1, \cdots, k_n \geq 0$. In particular, $Z$ has mean $\mu$ and covariance matrix $\Sigma$.

**Proof.** 1. Let $\epsilon > 0$ be arbitrary. Then $\Sigma + \epsilon I$ is positive definite. Hence, the normal distribution $\Phi_{\mu, \Sigma + \epsilon I}$ has been defined. Separately, Theorem 5.7.2 implies that there exists an orthogonal matrix $U$ such that $U^T \Sigma U = \Lambda$, where $\Lambda \equiv \text{diag}(\lambda_1, \cdots, \lambda_n)$ is a diagonal matrix whose diagonal elements consist of the eigenvalues $\lambda_1, \cdots, \lambda_n$ of $\Sigma$. These eigenvalues are nonnegative since $\Sigma$ is nonnegative definite. Hence, again by Theorem 5.7.2 we have

$$\Sigma + \epsilon I = A_\epsilon A_\epsilon^T$$

where

$$A_\epsilon \equiv U \lambda_1^{\frac{1}{2}} \cdots \lambda_n^{\frac{1}{2}} U^T$$

where $\lambda_k^{\frac{1}{2}} = \sqrt{\lambda_k + \epsilon}, \cdots, \sqrt{\lambda_n + \epsilon}$.

Now let $X$ be an arbitrary r.v. on $\mathbb{R}^n$ with the standard normal distribution $\Phi_{0, I}$. In view of equality (5.7.8) Proposition 5.7.6 implies that $\Phi_{\mu, \Sigma + \epsilon I}$ is equal to the distribution of the r.v.

$$Y(\epsilon) \equiv \mu + A_\epsilon X.$$
Define $A \equiv U \Lambda^{1/2} U^T$, where $\Lambda^{1/2} = diag(\sqrt{\lambda_1}, \cdots, \sqrt{\lambda_n})$ and define $Y \equiv \bar{\mu} + AX$. Then
\[
E|A_\varepsilon X - AX|^2 = EX^T (A_\varepsilon - A)^T (A_\varepsilon - A)X
\]
\[
= \sum_{i=1}^{n} \sum_{j=1}^{n} \sum_{k=1}^{n} EX_{ij} U_{i,j} (\sqrt{\lambda_j + \varepsilon - \sqrt{\lambda_j})^2} U_{j,k} X_k
\]
\[
= \sum_{i=1}^{n} \sum_{j=1}^{n} U_{i,j} (\sqrt{\lambda_j + \varepsilon - \sqrt{\lambda_j})^2} U_{j,i}
\]
\[
= \sum_{j=1}^{n} (\sqrt{\lambda_j + \varepsilon - \sqrt{\lambda_j})^2} \sum_{i=1}^{n} U_{i,j} U_{j,i}
\]
\[
= \sum_{j=1}^{n} (\sqrt{\lambda_j + \varepsilon - \sqrt{\lambda_j})^2} \to 0
\]
as $\varepsilon \to 0$. Lyapunov’s inequality then implies that
\[
E|Y^{(e)} - Y| = E|A_\varepsilon X - AX| \leq (E|A_\varepsilon X - AX|^2)^{1/2} \to 0
\]
as $\varepsilon \to 0$. In other words, $Y^{(e)} \to Y$ in probability. Consequently, the distribution $\Phi_{\bar{\mu}, \bar{\sigma}}$ converges to the distribution $F_Y$ of $Y$. We conclude that the limit $\Phi_{\bar{\mu}, \bar{\sigma}}(f)$ in equality (5.7.7) exists and is equal to $EF(Y)$. In other words, $\Phi_{\bar{\mu}, \bar{\sigma}}$ is the distribution of the r.v. $Y \equiv \bar{\mu} + AX$. Moreover,
\[
AA^T = U \Lambda^{1/2} U^T U \Lambda^{1/2} U^T = U \Lambda U^T = \bar{\sigma}.
\]
Assertion 1 is proved.

2. Next suppose $\bar{\sigma}$ is positive definite. Then $\Phi_{\bar{\mu}, \bar{\sigma}} + \epsilon I \to \Phi_{\bar{\mu}, \bar{\sigma}}$ uniformly on compact subsets of $\mathbb{R}^n$. Hence
\[
\lim_{\epsilon \to 0} \Phi_{\bar{\mu}, \bar{\sigma}} + \epsilon I (f) = \lim_{\epsilon \to 0} \int f(y) \Phi_{\bar{\mu}, \bar{\sigma}} + \epsilon I (y) dy = \int f(y) \Phi_{\bar{\mu}, \bar{\sigma}} (y) dy
\]
for each $f \in C(\mathbb{R}^n)$. Therefore Definition 5.7.7 is consistent with Definition 5.7.3, proving Assertion 2.

3. Now let $Z \equiv (Z_1, \cdots, Z_n)$ be any r.v. with values in $\mathbb{R}^n$ and with distribution $\Phi_{\bar{\mu}, \bar{\sigma}}$. By Assertion 1, $\Phi_{\bar{\mu}, \bar{\sigma}}$ is the distribution of $Y \equiv \bar{\mu} + AX$ for some standard normal $X \equiv (X_1, \cdots, X_n)$ and some $n \times n$ matrix $A$ with $AA^T = \bar{\sigma}$. Thus $Z$ and $Y$ have the same distribution. Let $k_1, \cdots, k_n \geq 0$ be arbitrary. Then the r.v. $Y_1^{(1)} \cdots Y_n^{(n)}$ is a linear combination of products $X_1^{(1)} \cdots X_n^{(n)}$ integrable where $j_1, \cdots, j_n \geq 0$, each of which is integrable in view of Proposition 5.7.3 and Proposition 4.10.7. Hence $Y_1^{(1)} \cdots Y_n^{(n)}$ is integrable. It follows that $Z_1^{(1)} \cdots Z_n^{(n)}$ is integrable. $EZ = EY = \bar{\mu}$ and
\[
E(Z - \bar{\mu})(Z - \bar{\mu})^T = E(Y - \bar{\mu})(Y - \bar{\mu})^T = EAXX^T A^T = AA^T = \bar{\sigma}.
\]
In other words, $Z$ has mean $\bar{\mu}$ and covariance matrix $\bar{\sigma}$, proving Assertion 3.

Constructive Probability
CHAPTER 5. PROBABILITY SPACE

We will need some bounds related to the normal p.d.f. in later sections.
Recall from Proposition 5.7.4 the standard normal P.D.F. \( \Phi \) on \( R \), its tail \( \Psi \), and the inverse function \( \Psi \) of the latter.

**Lemma 5.7.9.** (Some bounds for normal probabilities).

1. Suppose \( h \) is a measurable function on \( R \) relative to the Lebesgue integration. If \( |h| \leq a \) on \([-\alpha, \alpha]\) and \( |h| \leq b \) on \([-\alpha, \alpha]^{\circ} \) for some \( a, b, \alpha > 0 \), then
   \[
   \int |h(x)| \phi_{0, \sigma}(x) dx \leq a + 2b \Psi(\frac{\alpha}{\sigma})
   \]
   for each \( \sigma > 0 \).

2. In general, let \( n \geq 1 \) be arbitrary. Let \( I \) denote the \( n \times n \) identity matrix. Suppose \( f \) is a Lebesgue integrable function on \( R^{n} \), with \( |f| \leq 1 \). Let \( \sigma > 0 \) be arbitrary. Define a function \( f_{\sigma} \) on \( R^{n} \) by
   \[
f_{\sigma}(x) \equiv \int_{y \in R^{n}} f(x-y) \phi_{0, \sigma}(y) dy
   \]
   for each \( x \in R^{n} \). Suppose \( f \) is continuous at some \( t \in R^{n} \). In other words, suppose, for arbitrary \( \varepsilon > 0 \), there exists \( \delta(t, \varepsilon) > 0 \) such that \( |f(t) - f(r)| < \varepsilon \) for each \( r \in R^{n} \) with \( |r-t| < \delta(t, \varepsilon) \). Let \( \varepsilon > 0 \) be arbitrary. Let \( \alpha \equiv \delta(t, \varepsilon) > 0 \) and let
   \[
   \sigma < \alpha / \Psi(\frac{1}{2}(1 - (1 - \varepsilon/4)^{2})).
   \]
   Then
   \[
   |f_{\sigma}(t) - f(t)| \leq \varepsilon.
   \]

3. Again consider the case \( n = 1 \). Let \( \varepsilon > 0 \) be arbitrary. Suppose \( \sigma > 0 \) is so small that \( \sigma < \varepsilon / \Psi(\frac{1}{2}) \). Let \( r, s \in R \) be arbitrary with \( r + 2\varepsilon < s \). Let \( f \equiv 1_{(r,s)} \). Then
   \[
   1_{(r+\varepsilon, s-\varepsilon)} - \varepsilon \leq f_{\sigma} \leq 1_{(r-\varepsilon, s+\varepsilon)} + \varepsilon.
   \]

**Proof.** 1. We estimate
   \[
   \frac{1}{\sqrt{2\pi\sigma}} \int_{-\alpha}^{\alpha} |h(x)| e^{-x^{2}/(2\sigma^{2})} dx
   \]
   \[
   \leq \frac{1}{\sqrt{2\pi\sigma}} \int_{-\alpha}^{\alpha} a e^{-x^{2}/(2\sigma^{2})} dx + \frac{1}{\sqrt{2\pi\sigma}} \int_{|x| > \alpha} b e^{-x^{2}/(2\sigma^{2})} dx
   \]
   \[
   \leq a + \frac{1}{\sqrt{2\pi}} \int_{|u| > \alpha} b e^{-u^{2}/2} du = a + 2b \Psi(\frac{\alpha}{\sigma})
   \]

2. Let \( f, t, \varepsilon, \delta(t), \alpha, \) and \( \sigma \) be as given. Then inequality 5.7.10 implies that
   \[
   (1 - (1 - \varepsilon/4)^{2}) > 2\Psi(\frac{\alpha}{\sigma}),
   \]
   whence
   \[
   2(1 - (1 - 2\Psi(\frac{\alpha}{\sigma}))^{n}) < \frac{\varepsilon}{2}.
   \]
Then, \(|f(t-u) - f(t)| < \frac{s}{8}\) for \(u \in \mathbb{R}^n\) with \(||u|| \equiv |u_1| \lor \cdots \lor |u_n| < \alpha\). By hypothesis \(\sigma \leq \alpha/\Psi(\frac{s}{8})\). Hence \(\frac{s}{8} \geq \Psi(\frac{s}{8})\) and so \(\Psi(\frac{s}{8}) \leq \frac{s}{8}\). Hence, by Assertion 1, we have

\[
|f_\alpha(t) - f(t)| = \int (f(t-u) - f(t)) \varphi_{0,\sigma_1}(u)du \\
\leq \int_{||u|| < \alpha} |f(t-u) - f(t)| \varphi_{0,\sigma_1}(u)du + \int_{||u|| \geq \alpha} |f(t-u) - f(t)| \varphi_{0,\sigma_1}(u)du \\
\leq \frac{\varepsilon}{2} + 2(1 - \int_{||u|| < \alpha} \varphi_{0,\sigma_1}(u)du) \\
= \frac{\varepsilon}{2} + 2(1 - (\Phi(\frac{\alpha}{\sigma}) - \Phi(\frac{\alpha}{\sigma}))^n) \\
= \frac{\varepsilon}{2} + 2(1 - 2\Psi(\frac{\alpha}{\sigma})^n) \\
< \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon,
\]

as desired, where the last inequality is from inequality \([5.7.11]\).

3. Define \(f_\alpha(x) \equiv \int f(x-y) \varphi_{0,\sigma}(y)dy\) for each \(x \in \mathbb{R}\). Consider each \(t \in (r+\varepsilon, s-\varepsilon]\). Then \(f\) is constant in a neighborhood of \(t\), hence continuous at \(t\). More precisely, let \(\delta_j(\theta, t) \equiv \varepsilon\) for each \(\theta > 0\). Then

\[
(t - \delta_j(\theta), t + \delta_j(\theta)) = (t - \varepsilon, t + \varepsilon) \subset (r, s) \subset (f = 1)
\]

for each \(\theta > 0\). Let \(\alpha \equiv \delta_j(\frac{s}{2}, t) \equiv \varepsilon\). Then, by hypothesis

\[
\sigma < \epsilon \Psi(\frac{\varepsilon}{8})^{-1} = \alpha/\Psi(\frac{1}{2}(1 - (1 - \frac{\varepsilon}{4}))) \quad (5.7.12)
\]

Hence, by Assertion 2, we have

\[
|f(t) - f_\alpha(t)| \leq \varepsilon,
\]

where \(t \in (r+\varepsilon, s-\varepsilon]\) is arbitrary. Since \(1_{(r+\varepsilon, s-\varepsilon)}(t) \leq f(t)\), it follows that

\[
1_{(r+\varepsilon, s-\varepsilon)}(t) - \varepsilon \leq f_\alpha(t) \quad (5.7.13)
\]

for each \(t \in (r+\varepsilon, s-\varepsilon]\). Since \(f_\alpha \geq 0\), inequality \([5.7.13]\) is trivially satisfied for \(t \in (\infty, r+\varepsilon) \cup (s-\varepsilon, \infty)\). We have thus proved that inequality \([5.7.13]\) holds on \(domain(1_{(r+\varepsilon, s-\varepsilon)}(t))\). Next consider any \(t \in (-\infty, r-\varepsilon) \cup (s+\varepsilon, \infty)\). Again, for arbitrary \(\theta > 0\) we have \(|f(t) - f(u)| = 0 < \theta\) for each \(u \in (t - \delta_j(\theta), t + \delta_j(\theta))\). Hence, by Assertion 2, we have \(f_\alpha(t) = f_\alpha(t) - f(t) < \varepsilon\). It follows that

\[
f_\alpha(t) \leq 1_{(r-\varepsilon, s+\varepsilon)}(t) + \varepsilon \quad (5.7.14)
\]

for each \(t \in (-\infty, r-\varepsilon) \cup (s+\varepsilon, \infty)\). Since \(f_\alpha \leq 1\), inequality \([5.7.14]\) is trivially satisfied for \(t \in (r-\varepsilon, s+\varepsilon]\). We have thus proved that inequality \([5.7.14]\) holds on \(domain(1_{(r-\varepsilon, s+\varepsilon)}(t))\). Assertion 3 is proved.
5.8 Characteristic Functions

In previous sections we analyzed distributions $J$ on a locally compact metric space $(S, d)$ in terms of their values $Jg$ at basis functions $g$ in a partition of unity. In the special case where $(S, d)$ is the Euclidean space $R$, the basis functions can be replaced by the exponential functions $h_\lambda$ with $\lambda \in R$, where $h_\lambda(x) = e^{i\lambda x}$, where $i = \sqrt{-1}$. The result is characteristic functions, a most useful in the study of distributions of r.r.v.’s.

The classical development of this tool in usual texts, e.g. [Chung 1968] or [Loeve 1960] is constructive, except for infrequent and superficial appeals to the principle of infinite search. The bare essentials of this material is presented here for completeness and for ease of reference. The reader who is familiar with the topic and is comfortable that the classical treatment is constructive, or easily made so, can skip over this and the next section and come back for reference.

We will be working with complex-valued measurable functions. Let $C$ denote the complex plane equipped with the usual metric.

**Definition 5.8.1. (Complex valued integrable function).** Let $I$ be an integration on a locally compact metric space $(S, d)$, and let $(S, \Lambda, I)$ denote the completion of the integration space $(S, C(S), I)$. A function $X \equiv IU + iIV : S \to C$ whose real part $U$ and imaginary part $V$ are measurable on $(S, \Lambda, I)$ is said to be measurable on $(S, \Lambda, I)$. If both $U, V$ are integrable, then $X$ is said to be integrable, with integral $IX \equiv IU + iIV$.

By separation into real and imaginary parts, the complex-valued functions immediately inherit the bulk of the theory of integration developed hitherto in this book for real-valued functions. One exception is the very basic inequality $|IX| \leq |I|X|$ when $|X|$ is integrable. Its trivial proof in the case of real valued integrable functions relies on the linear ordering of $R$, which is absent in $C$. The next lemma gives a proof for complex valued integrable functions.

**Lemma 5.8.2. ($|IX| \leq |I|X|$ for complex valued integrable function $X$).** Use the notations in Definition 5.8.1 Let $X : S \to C$ be an arbitrary complex valued function. Then the function $X$ is measurable in the sense of Definition 5.8.1 if it is measurable in the sense of Definition 5.8.1. In other words, the former is consistent with the latter. Moreover, if $X$ is measurable and if $|X| \in L$, then $X$ is integrable with $|IX| \leq |I|X|$.

**Proof.** Write $X \equiv IU + iIV$, where $U, V$ are the real and imaginary parts of $X$ respectively.

1. Suppose $X$ is measurable in the sense of Definition 5.8.1. Then $U, V : (S, \Lambda, I) \to R$ are measurable functions. Therefore the function $(U, V) : (S, \Lambda, I) \to R^2$ is measurable. At the same time, we have $X = f(U, V)$, where the continuous function $f : R^2 \to C$ is defined by $f(u, v) \equiv u + iv$. Hence $X$ is measurable in the sense of Definition 4.8.1 according to Proposition 4.8.7. Conversely, suppose $X : (S, \Lambda, I) \to C$ is measurable in the sense of Definition 4.8.1. Note that $U, V$ are continuous functions of $X$. Hence, again by Proposition 4.8.7 both $U, V$ are measurable. Thus $X$ is measurable in the sense of Definition 5.8.1.
2. Suppose $X$ is measurable and $|X| \in L$. Then, by Definition 5.8.1, both $U$ and $V$ are measurable, with $|U| \cup |V| \leq |X| \in L$, it follows that $U, V \in L$. Thus $X$ is integrable according to Definition 5.8.1.

Let $\varepsilon > 0$ be arbitrary. Then either (i) $|I|X| < 3\varepsilon$, or (ii) $|I|X| > 2\varepsilon$.

First consider Case (i). Then

$$|I|X| = |I|U + i|V| \leq |I|U| + |i|V| \leq |I|U| + |I|V| \leq 2|I|X| < |I|X| + 3\varepsilon.$$ 

Now consider Case (ii). By the Dominated Convergence Theorem, there exists $a > 0$ so small that $I(|X| \wedge a) < \varepsilon$. Then

$$I|X|1_{(|X| \leq a)} \leq I(|X| \wedge a) < \varepsilon.$$ 

(5.8.1)

Write $A \equiv (a < |X|)$. Then

$$|I|U|1_{A} - |I|U| \leq |I|U|1_{(|X| \leq a)}| \leq |I|U|1_{(|X| \leq a)}| \leq I|X|1_{(|X| \leq a)} < \varepsilon.$$ 

Similarly, $|I|V|1_{A} - |I|V| < \varepsilon$. Hence

$$|I|(X_{1}A) - |I|X| = |I|(U_{1}A - IU) + i|I|(V_{1}A - IV)| < 2\varepsilon.$$ 

(5.8.2)

Write $c \equiv I|X|1_{A}$. Then it follows that

$$c \equiv I|X|1_{A} = I|X| - I|X|1_{(|X| \leq a)} > 2\varepsilon - 2\varepsilon = 0,$$

where the inequality is on account of Condition (ii) and inequality 5.8.1. Now define a probability integration space $(S, L, E)$ using $g \equiv c^{-1}|X|1_{A}$ as a probability density function on the integration space $(S, \Lambda, I)$. Thus

$$E(Y) \equiv c^{-1}I(Y|X|1_{A})$$

for each $Y \in L$. Then

$$|c^{-1}I(X_{1}A)| \equiv |E\left(\frac{X}{|X| \vee a}1_{A}\right)| = |E\left(\frac{U}{|X| \vee a}1_{A}\right) + iE\left(\frac{V}{|X| \vee a}1_{A}\right)|$$

$$= (E\left(\frac{U}{|X| \vee a}1_{A}\right)^{2} + E\left(\frac{V}{|X| \vee a}1_{A}\right)^{2})^{\frac{1}{2}}$$

$$\leq (E\left(\frac{U^{2}}{(|X| \vee a)^{2}}1_{A}\right) + E\left(\frac{V^{2}}{(|X| \vee a)^{2}}1_{A}\right))^{\frac{1}{2}} = (E\left(\frac{|X|^{2}}{(|X| \vee a)^{2}}1_{A}\right))^{\frac{1}{2}} \leq 1,$$

where the inequality is thanks to Lyapunov. Hence $|I(X_{1}A)| \leq c \equiv I|X|1_{A}$. Inequality 5.8.2 therefore yields

$$|I|X| < |I(X_{1}A)| + 2\varepsilon \leq I|X|1_{A} + 2\varepsilon < I|X| + 3\varepsilon.$$ 

Summing up, we have $|I|X| < I|X| + 3\varepsilon$ regardless of Case (i) or Case (ii), where $\varepsilon > 0$ is arbitrary. We conclude that $I|X| \leq I|X|$. \qed
Lemma 5.8.3. (Basic inequalities for exponentials). Let $x, y, x', y' \in \mathbb{R}$ be arbitrary, with $y \leq 0$ and $y' \leq 0$. Then
\[
|e^{ix} - 1| \leq 2 \wedge |x|
\] (5.8.3)
and
\[
|e^{ix+y} - e^{ix'+y'}| \leq 2 \wedge |x-x'| + 1 \wedge |y-y'|.
\]
Proof. If $x \geq 0$, then
\[
|e^{ix} - 1|^2 = |\cos x - 1 + isinx|^2 = 2(1 - \cos x)
\]
\[
= 2 \int_0^x \sin u du \leq 2 \int_0^x u du \leq x^2.
\] (5.8.4)
Hence, by symmetry and continuity, $|e^{ix} - 1| \leq |x|$ for arbitrary $x \in \mathbb{R}$. At the same time, $|e^{ix} - 1| \leq 2$. Equality 5.8.3 follows.

Now assume $y \geq y'$.\[
|e^{ix+y} - e^{ix'+y'}| \leq |e^{ix+y} - e^{ix+y'}| + |e^{ix'+y} - e^{ix'+y'}|
\]
\[
\leq |e^{ix} - e^{ix'}| \cdot e^y + |e^y - e^{ix'}| \leq |e^{ix-x'} - 1| \cdot e^{ix'} + e^y (1 - e^{-y-y'})
\]
\[
\leq (2 \wedge |x-x'|) e^{ix'} + (1 - e^{-y-y'}) \leq 2 \wedge |x-x'| + 1 \wedge |y-y'|
\]
where the last inequality is because $y' \leq y \leq 0$ by assumption. Hence, by symmetry and continuity, the same inequality holds for arbitrary $y, y' \leq 0$.\]

Recall the matrix notations and basics from Definition 5.7.1. Moreover, we will write $|x| \equiv (x_1^2 + \cdots + x_n^2)^{1/2}$ and write $\|x\| \equiv |x_1| \vee \cdots \vee |x_n|$ for each $x \equiv (x_1, \cdots, x_n) \in \mathbb{R}^n$.

Definition 5.8.4. (Characteristic function, Fourier transform, and convolution). Let $n \geq 1$ be arbitrary.

1. Let $X \equiv (X_1, \cdots, X_n)$ be a r.v. with values in $\mathbb{R}^n$. The characteristic function of $X$ is the complex-valued function $\psi_X$ on $\mathbb{R}^n$ defined by
\[
\psi_X(\lambda) \equiv E \exp i\lambda^T X \equiv E \cos(\lambda^T X) + iE \sin(\lambda^T X).
\]
for each $\lambda \in \mathbb{R}^n$.

2. Let $J$ be an arbitrary distribution on $\mathbb{R}^n$. The characteristic function of $J$ is defined to be $\psi_J \equiv \psi_X$, where $X$ is any r.v. with values in $\mathbb{R}^n$ such that $E_X = J$. Thus
\[
\psi_J(\lambda) \equiv J h_\lambda, \text{ where } h_\lambda(x) \equiv \exp i\lambda^T X \text{ for each } \lambda, x \in \mathbb{R}^n.
\]

3. If $g$ is a complex-valued integrable function on $\mathbb{R}^n$ relative to the Lebesgue integration, the Fourier transform of $g$ is defined to be the complex valued function $\hat{g}$ on $\mathbb{R}^n$ with
\[
\hat{g}(\lambda) \equiv \int_{\mathbb{R}^n} (\exp i\lambda T x) g(x) dx
\]
for $\lambda \in \mathbb{R}^n$, where $\int \cdot dx$ signifies the Lebesgue integration on $\mathbb{R}^n$, and where $x \in \mathbb{R}^n$ is the integration variable. The convolution of two complex-valued Lebesgue integrable functions $f, g$ on $\mathbb{R}^n$ is the complex valued function $f * g$ defined by $(f * g)(x) \equiv \int_{\mathbb{R}^n} f(x-y)g(y) dy$ for each $x \in \mathbb{R}^n$.
4. Suppose \( n = 1 \). Let \( F \) be a p.d.f. on \( \mathbb{R} \). The characteristic function of \( F \) is defined as \( \psi_F \equiv \psi_J \), where \( J \equiv \int f \, dF \). If, in addition, \( F \) has a p.d.f. \( f \) on \( \mathbb{R} \), then the characteristic function of \( f \) is defined as \( \psi_f \equiv \psi_J \). In that case, \( \psi_F(\lambda) = \int e^{i\lambda t} f(t) \, dt \equiv \hat{f}(\lambda) \) for each \( \lambda \in \mathbb{R} \).

We can choose to express the characteristic function in terms of the r.v. \( X \), or in terms of the distribution \( J \), or, in the case \( n = 1 \), the p.d.f., as a matter of convenience. A theorem proved in one set of notations will be used in another set without further comment.

**Lemma 5.8.5. (Basics of convolution).** Let \( f, g, h \) be complex-valued Lebesgue integrable functions on \( \mathbb{R}^n \). Then the following holds.

1. \( f \ast g \) is Lebesgue integrable.
2. \( f \ast g = g \ast f \)
3. \( (f \ast g) \ast h = f \ast (g \ast h) \)
4. \( (af + bg) \ast h = a(f \ast h) + b(g \ast h) \) for all complex numbers \( a, b \).
5. Suppose \( n = 1 \), and suppose \( g \) is a p.d.f. If \( |f| \leq a \) for some \( a \in \mathbb{R} \) then \( |f \ast g| \leq a \). If \( f \) is real-valued with \( a \leq f \leq b \) for some \( a, b \in \mathbb{R} \), then \( a \leq f \ast g \leq b \).
6. \( \hat{f} \ast g = \hat{f} \hat{g} \)
7. \( |\hat{f}| \leq \|f\|_1 \equiv \int_{x \in \mathbb{R}^n} |f(x)| \, dx \)

**Proof.** If \( f \) and \( g \) are real-valued, then the integrability of \( f \ast g \) follows from Corollary 13.0.12 in the appendices. Assertion 1 then follows by linearity. We will prove Assertions 6 and 7, the remaining assertions left as an exercise. For Assertion 6, note that, for each \( \lambda \in \mathbb{R}^n \), we have

\[
\hat{f} \ast g(\lambda) \equiv \int (\exp i\lambda^T x)(\int f(x-y)g(y) \, dy) \, dx
\]

\[
= \int_{-\infty}^{\infty} (\int_{-\infty}^{\infty} (\exp i\lambda^T (x-y))f(x-y) \, dx)(\exp i\lambda^Ty)g(y) \, dy
\]

\[
= \int_{-\infty}^{\infty} (\int_{-\infty}^{\infty} (\exp i\lambda^Tu) f(u) \, du)(\exp i\lambda^Ty)g(y) \, dy
\]

\[
= \hat{f}(\lambda)(\exp i\lambda^Ty)g(y) \, dy = \hat{f}(\lambda)\hat{g}(\lambda),
\]

as asserted. At the same time, for each \( \lambda \in \mathbb{R}^n \), we have

\[
|\hat{f}(\lambda)| \equiv |\int_{x \in \mathbb{R}^n} (\exp i\lambda^Tx) f(x) \, dx|
\]

\[
\leq \int_{x \in \mathbb{R}^n} |(\exp i\lambda^Tx) f(x)| \, dx = \int_{x \in \mathbb{R}^n} |f(x)| \, dx,
\]

where the inequality is by Lemma 5.8.2. Assertion 7 is verified. \( \square \)
CHAPTER 5. PROBABILITY SPACE

Proposition 5.8.6. (Uniform continuity of characteristic functions). Let \( X \) be a r.v.
with values in \( \mathbb{R}^n \). Let \( \bar{B}_X \) be a modulus of tightness of \( X \). Then the following holds.

1. \(|\psi_X(\lambda)| \leq 1\) and \( \psi_{a+BX}(\lambda) = \exp(i \lambda^T a) \psi_X(\lambda^T B) \) for each \( a, \lambda \in \mathbb{R}^n \) and for each \( n \times m \) matrix \( B \).

2. \( \psi_X \) is uniformly continuous. More precisely, \( \psi_X \) has a modulus of continuity
given by \( \delta(\epsilon) = \frac{\epsilon}{\beta(\frac{\lambda}{\epsilon})} \) for \( \epsilon > 0 \).

3. If \( g \) is a Lebesgue integrable function on \( \mathbb{R}^n \), then \( \hat{g} \) is uniformly continuous.
   More precisely, for each \( \epsilon > 0 \) there exists \( \gamma = \gamma(\epsilon) > 0 \) so large that \( \int_{|x| > \gamma} |g(x)| dx < \epsilon \). Then a modulus of continuity of \( \hat{g} \) is given by \( \delta(\epsilon) = \frac{\epsilon}{\exp(k \times \gamma^2) \gamma} \) for \( \epsilon > 0 \), where \( \|g\| = \int |g(t)| dt \).

Proof. 1. For each \( \lambda \in \mathbb{R}^n \) we have \(|\psi_X(\lambda)| = |E \exp(i \lambda^T X)| \leq E|\exp(i \lambda^T X)| = E1 = 1\).
   Moreover
   \[
   \psi_{a+BX}(\lambda) = \exp(i \lambda^T a)E(i \lambda^T BX) = \exp(i \lambda^T a) \psi_X(\lambda^T B)
   \]
   for each \( a, \lambda \in \mathbb{R}^n \) and for each \( n \times m \) matrix \( B \).

2. Let \( \epsilon > 0 \). Let \( \delta(\epsilon) = \frac{\epsilon}{\beta(\frac{\lambda}{\epsilon})} \). Suppose \( h \in \mathbb{R}^n \) is such that \( |h| < \delta(\epsilon) \). Then \( \beta(\frac{\lambda}{\epsilon}) < \frac{\epsilon}{3|h|} \). Pick \( a \in (\beta(\frac{\lambda}{\epsilon}), \frac{\epsilon}{3|h|}) \). Then \( P(|X| > a) < \frac{\epsilon}{3} \) by the definition of \( \beta \). On the other hand, for each \( x \in \mathbb{R}^n \) with \( |x| \leq a \), we have \(|\exp(i h^T x) - 1| \leq |h^T x| \leq |h| a < \frac{\epsilon}{3} \).

   Hence, for each \( \lambda \in \mathbb{R}^n \),
   \[
   |\psi_X(\lambda + h) - \psi_X(\lambda)| \leq E|\exp(i \lambda^T X)(\exp(i h^T X) - 1)|
   \leq E(|\exp(i h^T X) - 1|; |X| \leq a) + 2P(|X| > a) < \frac{\epsilon}{3} + 2 \frac{\epsilon}{3} = \epsilon
   \]

3. Proceed in the same manner as above. Let \( \epsilon > 0 \). Write \( \epsilon' = \frac{\epsilon}{\|g\| + 2} \). Let \( \delta(\epsilon) = \frac{\epsilon'}{\gamma(\epsilon')} \). Suppose \( h \in \mathbb{R}^n \) is such that \( |h| < \delta(\epsilon) \). Then \( \gamma(\epsilon') < \frac{\epsilon'}{|h|} \). Pick \( a \in (\gamma(\epsilon'), \frac{\epsilon'}{|h|}) \).

   Then \( \int_{|x| > a} |g(x)| dx < \epsilon' \) by the definition of \( \gamma \). Moreover, for each \( x \in \mathbb{R}^n \) with \( |x| \leq a \), we have \(|\exp(i h^T x) - 1| \leq |h^T x| \leq |h| a < \epsilon' \). Hence, for each \( \lambda \in \mathbb{R}^n \),
   \[
   |\hat{g}(\lambda + h) - \hat{g}(\lambda)| \leq \int |\exp(i \lambda^T x)(\exp(i h^T x) - 1)g(x)| dx
   \leq \int_{|x| \leq a} |\exp(i h^T x) - 1|g(x)| dx + \int_{|x| > a} 2|g(x)| dx
   \leq \epsilon' \int |g(x)| dx + 2\epsilon' = \epsilon'(|\|g\|| + 2) = \epsilon.
   \]

\[ \square \]

Lemma 5.8.7. (Characteristic function of normal distribution). Let \( \Phi_{\mu, \Sigma} \) be an
arbitrary normal distribution on \( \mathbb{R}^n \), with mean \( \mu \) and covariance matrix \( \Sigma \). Then the
characteristic function of \( \Phi_{\mu, \Sigma} \) is given by

\[
\psi_{\mu, \Sigma}(\lambda) = \exp(i \mu^T \lambda - \frac{1}{2} \lambda^T \Sigma \lambda)
\]
for each \( \lambda \in \mathbb{R}^n \).

Yuen-Kwok Chan 174 Constructive Probability
5.8. CHARACTERISTIC FUNCTIONS

Proof. 1. Consider the special case where \( n = 1, \mu = 0, \) and \( \sigma = 1. \) Let \( X \) be a r.v. with the standard normal distribution \( \Phi_{0,1}. \) By \( 5.7.5, \) \( X^p \) is integrable for each \( p \geq 0, \) with \( m_p \equiv EX^p = (2k)!2^{-k}/k! \) if \( p \) is equal to some even integer \( 2k, \) and with \( m_p \equiv EX^p = 0 \) otherwise. Using these moment formulas, we compute the characteristic function

\[
\psi_{0,1}(\lambda) = \frac{1}{\sqrt{2\pi}} \int e^{i\lambda x} e^{-x^2/2} dx = \frac{1}{\sqrt{2\pi}} \int \sum_{p=0}^{\infty} \frac{(i\lambda x)^p}{p!} e^{-x^2/2} dx
\]

\[
= \sum_{p=0}^{\infty} \frac{(i\lambda)^p}{p!} m_p = \sum_{k=0}^{\infty} \frac{(-1)^k \lambda^{2k}}{(2k)!} m_{2k}
\]

\[
= \sum_{k=0}^{\infty} \frac{(-1)^k \lambda^{2k}}{(2k)!} (2k)! 2^{-k} / k! = \sum_{k=0}^{\infty} \frac{(-\lambda^2 / 2)^k}{k!} = e^{-\lambda^2 / 2}
\]

where Fubini’s Theorem justifies any change in the order of integration and summation.

2. Now consider the general case. By Lemma \( 5.7.8, \) \( \Phi_{\bar{\mu},\bar{\sigma}} \) is the distribution of a r.v. \( Y = \bar{\mu} + AX \) for some matrix \( A \) with \( \bar{\sigma} = AA^T \) and for some r.v. \( X \) with the standard normal p.d.f. \( \Phi_0,1 \) on \( \mathbb{R}^n, \) where \( I \) is the \( n \times n \) identity matrix. Let \( \lambda \in \mathbb{R}^n \) be arbitrary. Write \( \theta \equiv A^T \lambda. \) Then

\[
\psi_{\bar{\mu},\bar{\sigma}}(\lambda) = E \exp(i \lambda^T Y) = E \exp(i\lambda^T \bar{\mu} + i\lambda^T AX)
\]

\[
= \int_{\mathbb{R}^n} \exp(i\lambda^T \bar{\mu} + i\theta^T x) \phi_0,1(x) dx
\]

\[
= \exp(i\lambda^T \bar{\mu}) \prod_{j=1}^{n} \int \exp(i\theta^T x_j) \phi_{0,1}(x_j) dx_j
\]

where we used Theorem \( 13.0.9 \) for the change of integration variables. By Fubini’s Theorem and by the first part of this proof, this reduces to

\[
\psi_{\bar{\mu},\bar{\sigma}}(\lambda) = \exp(i\lambda^T \bar{\mu}) \prod_{j=1}^{n} \left( \int \exp(i\theta^T x_j) \phi_{0,1}(x_j) dx_j \right)
\]

\[
= \exp(i\lambda^T \bar{\mu}) \prod_{j=1}^{n} \exp(-\frac{1}{2} \theta^T \theta) = \exp(i\lambda^T \bar{\mu}) \exp(-\frac{1}{2} \theta^T \theta)
\]

\[
= \exp(i\lambda^T \bar{\mu} - \frac{1}{2} \lambda^T AA^T \lambda) = \exp(i\lambda^T \bar{\mu} - \frac{1}{2} \lambda^T \bar{\sigma} \lambda).
\]

\[ \square \]

Corollary 5.8.8. (Convolution with normal density). Suppose \( f \) is a Lebesgue integrable function on \( \mathbb{R}^n. \) Let \( \sigma > 0 \) be arbitrary. Write \( \bar{\sigma} \equiv \sigma^2 I, \) where \( I \) is the \( n \times n \) identity matrix. Define \( \bar{f}_\sigma \equiv f \ast \phi_{0,\bar{\sigma}}. \) Then

\[
f_\sigma(t) = (2\pi)^{-n} \int \exp(i\lambda^T t - \frac{1}{2} \sigma^2 \lambda^T \lambda) \hat{f}(-\lambda) d\lambda
\]

for each \( t \in \mathbb{R}^n. \)

Yuen-Kwok Chan 175 Constructive Probability
Proof. In view of Lemma 5.8.7 we have, for each \( t \in \mathbb{R}^n \),

\[
 f_\sigma(t) = \int \phi_0(\sigma^{-1}(t-x))f(x)dx
 = (2\pi\sigma^2)^{-\frac{n}{2}} \int \exp\left(-\frac{1}{2\sigma^2}y^T y\right)f(x)dy
 = (2\pi\sigma^2)^{-\frac{n}{2}} \int \exp\left(-\frac{1}{2\sigma^2}y^T y\right)f(x)dy
 = (2\pi\sigma)^{-n} \int \exp\left(-i\sigma^{-1}y^T t - \frac{1}{2}y^T y\right)f(-\sigma^{-1}y)dy
 = (2\pi)^{-n} \int \exp\left(-i\lambda^T t - \frac{1}{2}\sigma^2\lambda^T \lambda\right)f(-\lambda) d\lambda
\]

Note that in the double integral, the integrand is a continuous function in \((x,y)\) and is bounded in absolute value by a constant multiple of \(\exp\left(-\frac{1}{2}y^T y\right)f(x)\) which is, by Proposition 4.10.7, Lebesgue integrable on \(\mathbb{R}^{2n}\). This justifies the changes in order of integration, thanks to Fubini. \(\Box\)

The next theorem recovers a distribution on \(\mathbb{R}^n\) from its characteristic function.

**Theorem 5.8.9. (Inversion formula for characteristic functions).** Let \( J, J' \) be distributions on \(\mathbb{R}^n\), with characteristic functions \(\psi_J, \psi_{J'}\) respectively. Let \( f \) be an arbitrary Lebesgue integrable function on \(\mathbb{R}^n\). Let \( \hat{f} \) denote the Fourier Transform of \( f \). Let \( \sigma > 0 \) be arbitrary. Write \( \sigma \equiv \sigma^2 I \), where \( I \) is the \( n \times n \) identity matrix. Define \( f_\sigma \equiv f \ast \phi_0(\sigma) \).

Then the following holds.

1. We have
   \[
   J f_\sigma = (2\pi)^{-n} \int \exp\left(-\frac{1}{2}\sigma^2\lambda^T \lambda\right)f(-\lambda) \psi_J(\lambda) d\lambda. \tag{5.8.5}
   \]

2. Suppose \( f \in C_{ab}(\mathbb{R}^n) \) and \(|f| \leq 1\). Let \( \varepsilon > 0 \) be arbitrary. Suppose \( \sigma > 0 \) is so small that
   \[
   \sigma \leq \delta f(\frac{\varepsilon}{2})/\sqrt{-2\log\left(\frac{1}{2}(1-\frac{\varepsilon}{4})^\frac{1}{2}\right)}.
   \]
   Then
   \[
   |J f - J f_\sigma| \leq \varepsilon.
   \]
   Consequently \( J f = \lim_{\sigma \to 0} J f_\sigma \).

3. Suppose \( f \in C_{ab}(\mathbb{R}) \) is arbitrary such that \( \hat{f} \) is Lebesgue integrable on \(\mathbb{R}^n\). Then
   \[
   J f = (2\pi)^{-n} \int \hat{f}(-\lambda) \psi_J(\lambda) d\lambda.
   \]

4. If \( \psi_J \) is Lebesgue integrable on \(\mathbb{R}^n\), then \( J \) has a p.d.f. Specifically, then
   \[
   J f = (2\pi)^{-n} \int f(x) \hat{\psi}_J(-x) dx
   \]
   for each \( f \in C(\mathbb{R}^n) \).
5.8. CHARACTERISTIC FUNCTIONS

5. $J = J'$ iff $\psi_J = \psi_{J'}$.

Proof. Write $\|f\| \equiv \int |f(t)| dt < \infty$. Then $|\hat{f}| \leq \|f\|$.

1. Consider the function $Z(\lambda, x) \equiv \exp(i \lambda^T x - \frac{1}{2} \sigma^2 \lambda^T \lambda)$ on the product space $(\mathbb{R}^n, L_0, I_0) \otimes (\mathbb{R}^n, L, J)$ where $(\mathbb{R}^n, L_0, I_0)$ is the Lebesgue integration space and where $(\mathbb{R}^n, L, J)$ is the probability space that is the completion of $(\mathbb{R}^n, C_{ab}(\mathbb{R}^n), J)$. The function $Z$ is a continuous function of $(\lambda, x)$. Hence $Z$ is measurable. Moreover, $|Z| \leq U$ where $U(\lambda, x) \equiv \|f\| e^{-\sigma^2 \lambda^2/2}$ is integrable. Hence $Z$ is integrable by the Dominated Convergence Theorem.

2. Now suppose $f \in C_{ab}(\mathbb{R}^n)$ with modulus of continuity $\delta_f$ with $|f| \leq 1$. Recall that $\bar{\Psi}(0, \frac{1}{\lambda}) \rightarrow [0, \infty)$ denotes the inverse of the tail function $\Psi \equiv 1 - \Phi$ of the standard normal P.D.F. $\Phi$. Proposition [5.7.4] says that $\bar{\Psi}(\alpha) \leq \sqrt{-2 \log \alpha}$ for each $\alpha \in (0, \frac{1}{\lambda}]$. Hence

$$\sigma \leq \delta_f \frac{\epsilon}{2} / \sqrt{-2 \log \left(\frac{1}{2} (1 - \left(1 - \frac{\epsilon}{2}\right)^2\right))} \leq \delta_f \frac{\epsilon}{2} / \bar{\Psi}(\frac{1}{2} (1 - \left(1 - \frac{\epsilon}{4}\right)^2)),$$

where the first inequality is by hypothesis. Therefore Lemma [5.8.3] implies that $|f_\sigma - f| \leq \epsilon$. Consequently $|f - f_\sigma| \leq \epsilon$. Hence $f = \lim_{\sigma \rightarrow 0} f_\sigma$. This proves Assertion 2.

3. Now let $f \in C_{ab}(\mathbb{R}^n)$ be arbitrary. Then, by linearity, Assertion 2 implies that

$$\lim_{\sigma \rightarrow 0} f_\sigma = f. \quad (5.8.7)$$

$$f_\sigma = (2\pi)^{-n} \int \exp\left(-\frac{1}{2} \sigma^2 \lambda^T \lambda\right) f(-\lambda) \psi_J(\lambda) d\lambda. \quad (5.8.8)$$

Suppose $\hat{f}$ is Lebesgue integrable on $\mathbb{R}^n$. Then the integrand in equality (5.8.5) is dominated in absolute value by the integrable function $|\hat{f}|$, and converges a.u. on $\mathbb{R}^n$ to the function $\hat{f}(-\lambda) \psi_J(\lambda)$ as $\sigma \rightarrow 0$. Hence the Dominated Convergence Theorem implies that

$$\lim_{\sigma \rightarrow 0} f_\sigma = (2\pi)^{-n} \int \hat{f}(-\lambda) \psi_J(\lambda) d\lambda.$$

Combining with equality (5.8.7) Assertion 3 is proved.

4. Next consider the case where $\psi_J$ is Lebesgue integrable. Suppose $f \in C(\mathbb{R}^n)$ with $|f| \leq 1$. Then the function $U_\sigma(x, \lambda) \equiv f(x) \psi_J(\lambda) e^{-ikx - \sigma^2 \lambda^2/2}$ is an integrable function relative to the product Lebesgue integration on $\mathbb{R}^{2n}$, and is dominated in absolute value by the integrable function $f(x) \psi_J(\lambda)$. Moreover, $U_\sigma \rightarrow U_0$ uniformly on compact
subsets of \(R^{2n}\) where \(U_0(x, \lambda) \equiv f(x)\psi_j(\lambda)e^{-i\lambda x}\). Hence \(U_\sigma \rightarrow U_0\) in measure relative to \(I_0 \otimes I_0\). The Dominated Convergence Theorem therefore yields, as \(\sigma \rightarrow 0\),

\[
Jf_\sigma = (2\pi)^{-n} \int \exp(-\frac{1}{2}\sigma^2 \lambda^T \lambda) \hat{f}(-\lambda) \psi_j(\lambda) d\lambda
\]

\[
= (2\pi)^{-n} \int \exp(-\frac{1}{2}\sigma^2 \lambda^T \lambda) \psi_j(\lambda) \int \exp(-i\lambda x) f(x) dx d\lambda
\]

\[
\rightarrow (2\pi)^{-n} \int \psi_j(\lambda) \int \exp(-i\lambda x) f(x) dx d\lambda
\]

\[
= (2\pi)^{-n} \int \hat{\psi}(x) f(x) dx.
\]

On the other hand, by Assertion 2, we have \(I f_\sigma \rightarrow I f\) as \(\sigma \rightarrow 0\). Assertion 4 is proved.

5. Assertion 5 follows from Assertion 4. \(\square\)

**Definition 5.8.10. (Metric of characteristic functions).** Let \(n \geq 1\) be arbitrary. Let \(\psi, \psi'\) be arbitrary characteristic functions on \(R^n\). Define

\[
\rho_{\text{char}}(\psi, \psi') \equiv \rho_{\text{char}, n}(\psi, \psi') \equiv \sum_{j=1}^{\infty} 2^{-j} \sup_{|\lambda| \leq J_j} |\psi(\lambda) - \psi'(\lambda)|. \tag{5.8.9}
\]

Then \(\rho_{\text{char}}\) is a metric. \(\square\)

We have seen earlier that characteristic functions are continuous and bounded in absolute values by 1. Hence the supremum inside the parentheses in equality 5.8.9 exists and is bounded by 2. Thus \(\rho_{\text{char}}\) is well-defined. In view of Theorem 5.8.11 it is easily seen that \(\rho_{\text{char}}\) is a metric. Convergence relative to \(\rho_{\text{char}}\) is equivalent to uniform convergence on each compact subset of \(R^n\).

The next theorem shows that the correspondence between distributions on \(R^n\) and their characteristic functions is uniformly continuous when restricted to a tight subset.

**Theorem 5.8.11. (Continuity Theorem for characteristic functions).** Let \(\xi\) be an arbitrary binary approximation of \(R\). Let \(n \geq 1\) be arbitrary, but fixed. Let \(\xi^n = (\xi^i)_{i=1,2,\ldots, n}\) be the binary approximation of \(R^n\) which is the \(n\)-th power of \(\xi\). Let \(\|\xi^n\|\) be the modulus of local compactness of \(R^n\) associated with \(\xi^n\). Let \(\rho_{\text{Dist}, \xi^n}\) be the corresponding distribution metric on the space of distributions on \(R^n\), as in Definition 5.3.4. Let \(\mathcal{J}_0\) be a family of distributions on \(R^n\).

Let \(J, J' \in \mathcal{J}_0\) be arbitrary, with corresponding characteristic functions \(\psi, \psi'\). Then the following holds.

1. For each \(\varepsilon > 0\), there exists \(\delta_{\text{char}, \mathcal{J}_0}(\varepsilon, n) > 0\) such that if \(\rho_{\text{char}}(\psi, \psi') < \delta_{\text{char}, \mathcal{J}_0}(\varepsilon, n)\) then \(\rho_{\text{Dist}, \xi^n}(J, J') < \varepsilon\).

2. Suppose \(\mathcal{J}_0\) is tight, with some modulus of tightness \(\beta\). Then, for each \(\varepsilon > 0\), there exists \(\delta_{\text{dist}, \mathcal{J}_0}(\varepsilon, \beta, \|\xi^n\|) > 0\) such that if \(\rho_{\text{Dist}, \xi^n}(J, J') < \delta_{\text{dist}, \mathcal{J}_0}(\varepsilon, \beta)\) then \(\rho_{\text{char}}(\psi, \psi') < \varepsilon\).

3. If \((J_m)_{m=0,1,\ldots}\) is a sequence of distributions on \(R^n\) with a corresponding sequence \((\psi_m)_{m=0,1,\ldots}\) of characteristic functions such that \(\rho_{\text{char}}(\psi_m, \psi_0) \rightarrow 0\), then \(J_m \Rightarrow J_0\).

Yuen-Kwok Chan 178 Constructive Probability
5.8. CHARACTERISTIC FUNCTIONS

Proof. Let

\[
\pi_R^n \equiv \{ \{ g_{p,x} \colon x \in A_p \} \}_{p=1,2,\ldots}
\]  

be the partition of unity of \( \mathbb{R}^n \) determined by \( \xi^n \), as introduced in Definition \ref{char_func}. Thus \( \| \xi^n \| \equiv (|A_p|)_{p=1,2,\ldots} \). Let

\[
v_n \equiv \int_{|y| \leq 1} dy,
\]

the volume of the unit sphere \( \{ y \in \mathbb{R}^n \colon |y| \leq 1 \} \) in \( \mathbb{R}^n \).

1. Let \( \varepsilon > 0 \) be arbitrary. For abbreviation, write

\[
\alpha \equiv \frac{1}{8} \varepsilon.
\]

Let \( p \equiv |0 \lor (1 - \log_2 \varepsilon)|_1 \). Thus

\[
2^{-p} < \frac{\varepsilon}{2}.
\]

For each \( \theta > 0 \) define

\[
\delta_p(\theta) \equiv 2^{-p-1} \theta > 0.
\]

Recall from Proposition \ref{prop:char_func} the standard normal P.D.F. \( \Phi \) on \( \mathbb{R} \), its decreasing tail function \( \Psi : [0, \infty) \to (0, \frac{1}{2}] \), and the inverse function \( \bar{\Psi} : (0, \frac{1}{2}] \to [0, \infty) \) of the latter. Define

\[
\sigma \equiv \delta_p\left(\frac{\alpha}{\varepsilon}\right) / \sqrt{-2 \log\left(\frac{1}{2} \left(1 - \left(1 - \frac{\alpha}{\varepsilon}\right)^2\right)\right)} > 0.
\]

Define

\[
m \equiv \left[ \sigma^{-1} n^{\frac{1}{2}} \Psi\left(\frac{1}{2} \wedge v_n^{-1} \varepsilon 2^{-5} (2\pi)^{\frac{n}{2}} \sigma^{-n} n^{-1}\right)\right]_1.
\]

Thus \( m \geq 1 \) is so large that

\[
\sum_{j=1}^{2m} \frac{1}{\sigma^{n} n^{\frac{1}{2}}} < \frac{1}{8} \varepsilon.
\]

Finally, define

\[
\delta_{ch,distr}(\varepsilon) \equiv \delta_{ch,distr}(\varepsilon,n) \equiv v_n^{-1} \varepsilon 2^{-m-3} (2\pi)^{\frac{n}{2}} \sigma^{n} > 0.
\]

Now suppose the characteristic functions \( \psi, \psi' \) on \( \mathbb{R}^n \) are such that

\[
\rho_{ch}(\psi, \psi') \equiv \sum_{|\lambda| \leq m} 2^{-j} \sup_{|\lambda| \leq j} |\psi(\lambda) - \psi'(\lambda)| < \delta_{ch,distr}(\varepsilon).
\]

We will prove that \( \rho_{Distr, \xi^n}(J,J') < \varepsilon \). To that end, first note that, with \( m \geq 1 \) as defined above, the last displayed inequality implies

\[
\sup_{|\lambda| \leq m} |\psi(\lambda) - \psi'(\lambda)| < 2^m \delta_{ch,distr}(\varepsilon).
\]

Next, let \( k = 1, \ldots, p \) and \( x \in A_k \) be arbitrary. Write \( f \equiv g_{k,x} \) for abbreviation. Then, by Proposition \ref{prop:Lipschitz}, \( f \) has values in \([0,1]\) and has Lipschitz constant \( 2^{k+1} \leq 2^p + 1 \).
Consequently, \( f \) has the modulus of continuity \( \delta_p \) defined in equality 5.8.11 above. Hence, in view of equality 5.8.12 Theorem 5.8.9 implies that

\[
|Jf - Jf_{\sigma}| \leq \alpha \equiv \frac{1}{8} \varepsilon, \tag{5.8.17}
\]

and that

\[
Jf_{\sigma} = (2\pi)^{-n} \int \exp\left(-\frac{1}{2} \sigma^2 \lambda^T \lambda \right) \hat{f}(-\lambda)(\psi(\lambda) - \psi' (\lambda))d\lambda, \tag{5.8.18}
\]

where \( f_{\sigma} \equiv f \ast \phi_{0, \sigma^2 I} \), where \( I \) is the \( n \times n \) identity matrix, and where \( \hat{f} \) stands for the Fourier transform of \( f \). Moreover, by Proposition 5.2, the function \( f \equiv g_{k, \sigma} \) has the sphere \( \{ y \in \mathbb{R}^n : |y - x| \leq 2^{-k+1} \} \) as support. Therefore

\[
|\hat{f}| \leq \int f(y)dy \leq v_n (2^{-k+1})^n < v_n, \tag{5.8.19}
\]

where \( v_n \) is the volume of the unit \( n \)-sphere in \( \mathbb{R}^n \), as defined previously.

By equality 5.8.18 for \( J \) and a similar equality for \( J' \), we have

\[
|Jf_{\sigma} - J'f_{\sigma}| = (2\pi)^{-n} \int \exp\left(-\frac{1}{2} \sigma^2 \lambda^T \lambda \right) \hat{f}(-\lambda)(\psi(\lambda) - \psi'(\lambda))d\lambda
\]

\[
\leq (2\pi)^{-n} \int_{|\lambda| \leq m} \exp\left(-\frac{1}{2} \sigma^2 \lambda^T \lambda \right) \hat{f}(-\lambda)(\psi(\lambda) - \psi'(\lambda))d\lambda
\]

\[
+ (2\pi)^{-n} \int_{|\lambda| > m} \exp\left(-\frac{1}{2} \sigma^2 \lambda^T \lambda \right) \hat{f}(-\lambda)(\psi(\lambda) - \psi'(\lambda))d\lambda. \tag{5.8.20}
\]

In view of inequalities 5.8.19 and 5.8.16 the first summand in the last sum is bounded by

\[
(2\pi)^{-n} v_n 2^m \delta_{h, distr} (\varepsilon) \int \exp\left(-\frac{1}{2} \sigma^2 \lambda^T \lambda \right) d\lambda
\]

\[
\leq (2\pi)^{-n} v_n 2^m \delta_{h, distr} (\varepsilon) (2\pi)^{\frac{n}{2}} \sigma^{-n} = \frac{1}{8} \varepsilon,
\]

where the last equality is from the defining equality 5.8.14 The second summand is bounded by

\[
(2\pi)^{-n} v_n 2 \int_{|\lambda| \geq m} \exp\left(-\frac{1}{2} \sigma^2 \lambda^T \lambda \right) d\lambda
\]

\[
\leq (2\pi)^{-n} v_n 2 \int_{|\lambda| \geq m} \ldots \int_{|\lambda_1| \geq m} \exp\left(-\frac{1}{2} \sigma^2 \lambda_1^2 + \ldots + \lambda_n^2 \right) d\lambda_1 \ldots d\lambda_n
\]

\[
\leq (2\pi)^{-n} v_n 2 (2\pi)^{\frac{n}{2}} \sigma^{-n} \int_{|\lambda| \geq m} \phi_{0, 1}(\lambda_1) \ldots \phi_{0, 1}(\lambda_n) d\lambda_1 \ldots d\lambda_n
\]

\[
\leq v_n 2 (2\pi)^{-\frac{n}{2}} \sigma^{-n} \sum_{j=1}^{n} \int_{|\lambda_j| > m} \phi_{0, 1}(\lambda_j) d\lambda_j
\]

\[
= v_n 2 (2\pi)^{-\frac{n}{2}} \sigma^{-n} \sum_{j=1}^{n} \int_{|\lambda_j| > m} \phi_{0, 1}(\lambda_j) d\lambda_j
\]
5.8. CHARACTERISTIC FUNCTIONS

\[ = \nu_n 2^2 (2\pi)^{-\frac{n}{2}} \sigma^{-n} \Psi(\sigma n^{-\frac{1}{2}} m) < \frac{1}{8} \varepsilon, \]

where the last inequality follows from inequality [5.8.13]. Hence inequality [5.8.20] yields

\[ |Jf - J'f| \leq \frac{1}{8} \varepsilon + \frac{1}{4} \varepsilon = \frac{1}{4} \varepsilon. \]

Combining with inequality [5.8.17] for \( J \) and a similar inequality for \( J' \), we obtain

\[ |Jf - J'f| \leq |Jf - Jf_\alpha| + |Jf_\alpha - J'f_\alpha| + |J'f - Jf_\alpha| \]

\[ \leq \frac{1}{8} \varepsilon + \frac{1}{4} \varepsilon = \frac{1}{4} \varepsilon, \]

where \( f \equiv g_{k,x} \), where \( k = 1, \ldots, p \) and \( x \in A_p \) are arbitrary. Hence

\[ \left| \rho_{\text{Dist}, \xi}(\xi, J') - \rho_{\text{Dist}, \xi}(\xi, J) \right| = \sum_{k=1}^{\infty} 2^{-k}[|A_k|^{-1}] \sum_{x \in A(k)} |Jg_{k,x} - J'g_{k,x}|. \]

\[ \leq \sum_{k=1}^{p} 2^{-k} \varepsilon + \sum_{k=p+1}^{\infty} 2^{-k} \]

\[ \leq \frac{\varepsilon}{2} + 2^{-p} < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon. \]

Assertion 1 has been proved.

2. Conversely, let \( \varepsilon > 0 \) be arbitrary. Write \( p \equiv \lfloor 0 \vee (2 - \log_2 \varepsilon) \rfloor \). For each \( \theta > 0 \) define \( \delta_p(\theta) \equiv p^{-1} \theta \). By Proposition [5.3.11] there exists \( \Delta(\xi, \delta_p, \beta, \|\xi^n\|) > 0 \) such that if

\[ \rho_{\text{Dist}, \xi}(\xi, J') < \Delta(\frac{\varepsilon}{4}, \delta_p, \beta, \|\xi^n\|) \]

then, for each \( f \in C_{ab}(R^n) \) with modulus of continuity \( \delta_p \) and with \( |f| \leq 1 \), we have

\[ |Jf - J'f| < \frac{\varepsilon}{4}. \]  \hspace{1cm} (5.8.21)

Define

\[ \delta_{\text{dar}, \xi}(\xi, \beta, \|\xi^n\|) \equiv \Delta(\frac{\varepsilon}{4}, \delta_p, \beta, \|\xi^n\|). \]  \hspace{1cm} (5.8.22)

We will prove that \( \delta_{\text{dar}, \xi}(\xi, \beta, \|\xi^n\|) \) has the desired properties. To that end, suppose

\[ \rho_{\text{Dist}, \xi}(\xi, J') < \delta_{\text{dar}, \xi}(\xi, \beta, \|\xi^n\|) \equiv \Delta(\frac{\varepsilon}{4}, \delta_p, \beta, \|\xi^n\|). \]

Let \( \lambda \in R^n \) be arbitrary with \( |\lambda| \leq p \). Define the function

\[ h_\lambda(x) \equiv \exp(i\lambda^T x) \equiv \cos \lambda^T x + i \sin \lambda^T x \]

for each \( x \in R^n \). Then, using inequality [5.8.3], we obtain

\[ |\cos \lambda^T x - \cos \lambda^T y| \leq |\exp(i\lambda^T x) - \exp(i\lambda^T y)| \]

Yuen-Kwok Chan  \hspace{1cm} 181  \hspace{1cm} Constructive Probability
\begin{equation}
|\exp(i\lambda^T(x-y)) - 1| \leq |\lambda^T(x-y)| \leq p|x-y|,
\end{equation}
for each \(x,y \in \mathbb{R}^n\). Hence the function \(\cos(\lambda^T \cdot)\) on \(\mathbb{R}^n\) has modulus of continuity \(\delta_p\). Moreover, \(|\cos(\lambda^T \cdot)| \leq 1\). Hence, inequality (5.8.21) is applicable and yields
\begin{equation}
|J \cos(\lambda^T \cdot) - J' \cos(\lambda^T \cdot)| \leq \frac{\varepsilon}{4}.
\end{equation}

Similarly
\begin{equation}
|J \sin(\lambda^T \cdot) - J' \sin(\lambda^T \cdot)| \leq \frac{\varepsilon}{4}.
\end{equation}

Combining,
\begin{equation}
|\psi(\lambda) - \psi'(\lambda)| = |J \cos(\lambda^T \cdot) - J' \cos(\lambda^T \cdot)| + |J \sin(\lambda^T \cdot) - J' \sin(\lambda^T \cdot)| \leq \frac{\varepsilon}{2},
\end{equation}
where \(\lambda \in \mathbb{R}^n\) is arbitrary with \(|\lambda| \leq p\). We conclude that
\begin{equation}
\rho_{\text{char}}(\psi, \psi') \equiv \sum_{j=1}^{\infty} 2^{-j} \sup_{|\lambda| \leq j} |\psi(\lambda) - \psi'(\lambda)|
\leq \sum_{j=1}^{p} 2^{-j} \sup_{|\lambda| \leq j} |\psi(\lambda) - \psi'(\lambda)| + \sum_{j=p+1}^{\infty} 2^{-j/2}
\leq \frac{\varepsilon}{2} + 2^{-p+1} \leq \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.
\end{equation}

3. Finally, suppose \(\rho_{\text{char}}(\psi_m, \psi_0) \to 0\). Then, by Assertion 1, we have \(\rho_{\text{Dist}, \mathbb{E}}(J_m, J_0) \to 0\) as \(m \to \infty\). Hence Proposition 5.3.5 implies that \(J_m \Rightarrow J_0\).

The theorem is proved. \(\square\)

The following propositions relate the moments of a r.v. \(X\) to the derivatives of its characteristic function.

**Proposition 5.8.12. (Taylor expansion of characteristic functions).** Let \(n \geq 1\) be arbitrary, and let \(X\) be an arbitrary r.v. Suppose \(X^n\) is integrable, with a simple modulus of integrability \(\eta_{\text{int}}\) in the sense of Definition 4.7.3, and with \(E|X|^n \leq b\) for some \(b > 0\). Let \(\psi\) denote the characteristic function of \(X\). Define the remainder \(r_n(\lambda)\) by
\begin{equation}
\psi(\lambda) = \sum_{k=0}^{n} (i\lambda)^k EX^k / k! + r_n(\lambda)
\end{equation}
for each \(\lambda \in \mathbb{R}\). Then the following holds.

1. The characteristic function \(\psi\) has continuous derivative of order \(n\) on \(\mathbb{R}\), with
\begin{equation}
\psi^{(k)}(\lambda) = i^k EX^k e^{i\lambda x}
\end{equation}
5.8. CHARACTERISTIC FUNCTIONS

for each \( \lambda \in \mathbb{R} \) for each \( k = 0, \cdots, n \). In particular the \( k \)-th moment of \( X \) is given by \( EX^k = (-i)^k \psi^{(k)}(0) \), for each \( k = 0, \cdots, n \). Moreover, \( \psi^{(n)} \) is uniformly continuous on \( \mathbb{R} \), with a modulus of continuity \( \delta_{\psi,n} \) on \( \mathbb{R} \) defined by

\[
\delta_{\psi,n}(\varepsilon) = \frac{\varepsilon}{2b} (\eta_{intg}(\frac{\varepsilon}{2}))^{-\frac{1}{n}}
\]

for each \( \varepsilon > 0 \).

2. For each \( \lambda \in \mathbb{R} \) with

\[
|\lambda| < \frac{n! \varepsilon}{2b} (\eta_{intg}(\frac{n! \varepsilon}{2}))^{-\frac{1}{n}}
\]

we have \( |\psi_n(\lambda)| < \varepsilon |\lambda|^n \).

3. Suppose \( X^{n+1} \) is integrable. Then, for each \( t \in \mathbb{R} \), we have

\[
\psi(t) = \sum_{k=0}^{n} \psi^{(k)}(t_0)(t - t_0)^k/k! + \bar{r}_n(t)
\]

where

\[
|\bar{r}_n(t)| \leq |t - t_0|^n E|X|^{n+1}/(n+1)!
\]

Proof. We first observe that \( (e^{iax} - 1)/a \to i\lambda \) uniformly for \( x \) in any compact interval \([-t,t]\) as \( a \to 0 \). This can be shown by first noting that, for arbitrary \( \varepsilon > 0 \), Taylor’s Theorem in the Appendix implies \( |e^{iax} - 1 - iax| \leq a^2x^2/2 \) and so \( |a^{-1}(e^{iax} - 1 - i\lambda)| \leq \lambda^2/2 < \varepsilon \) for each \( x \in [-t,t] \), provided that \( a < 2\varepsilon/t^2 \).

1. Let \( \lambda \in \mathbb{R} \) be arbitrary. Proceed inductively. The assertion is trivial if \( n = 0 \). Suppose the assertion has been proved for \( k = 0, \cdots, n-1 \). Let \( \varepsilon > 0 \) be arbitrary, and let \( t \) be so large that \( P(|X| > t) < \varepsilon \). For \( a > 0 \), define \( D_a = i \lambda X^k e^{iaX}(e^{iaX} - 1)/a \). By the observation at the beginning of this proof, \( D_a \) converges uniformly to \( i^{k+1}X^{k+1}e^{i\lambda X} \) on \( (|X| \leq t) \) as \( a \to 0 \). Thus we see that \( D_a \) converges a.u. to \( i^{k+1}X^{k+1}e^{i\lambda X} \). At the same time \( |D_a| \leq |X|^k |(e^{iaX} - 1)/a| \leq |X|^{k+1} \) where \( |X|^{k+1} \) is integrable. The Dominated Convergence Theorem applies, yielding \( \lim_{a \to 0} ED_a = i^{k+1}EX^{k+1}e^{i\lambda X} \). On the other hand, by the induction hypothesis \( ED_a = a^{-1}(i^{k+1}EX^k e^{i(\lambda + a)X} - i^{k+1}EX^k e^{i\lambda X}) = a^{-1}(\psi^{(k)}(\lambda + a) - \psi^{(k)}(\lambda)) \). Combining, we see that \( \frac{d}{da} \psi^{(n)}(\lambda) \) exists and is equal to \( i^{k+1}EX^{k+1}e^{i\lambda X} \). Induction is completed.

We next prove the continuity of \( \psi^{(n)} \). To that end, let \( \varepsilon > 0 \) be arbitrary. Let \( \lambda, a \in \mathbb{R} \) be arbitrary with

\[
|a| < \delta_{\psi,n}(\varepsilon) = \frac{\varepsilon}{2b} (\eta_{intg}(\frac{\varepsilon}{2}))^{-\frac{1}{n}}.
\]

Then

\[
|\psi^{(n)}(\lambda + a) - \psi^{(n)}(\lambda)| = |EX^a e^{i(\lambda + a)X} - EX^a e^{i\lambda X}|
\]

\[
\quad \quad \quad \quad \leq E|X|^n|e^{iaX} - 1| \leq E|X|^n(2 \land |aX|)
\]

\[
\quad \quad \quad \quad \leq 2E|X|^n |(|X|^n \land \eta_{intg}(\frac{\varepsilon}{2})) + E|X|^n |(|aX|)I(|X|^n \leq \eta_{intg}(\frac{\varepsilon}{2}))
\]

\[
\quad \quad \quad \quad \leq \frac{\varepsilon}{2} + |a| (\eta_{intg}(\frac{\varepsilon}{2}))^{-\frac{1}{n}} E|X|^n \leq \frac{\varepsilon}{2} + \frac{\varepsilon}{2b} E|X|^n \leq \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.
\]
Thus $\delta_{\psi, n}$ is the modulus of continuity of $\psi^{(n)}$ on $R$. Assertion 1 is verified.

2. Assertion 2 is an immediate consequence of Assertion 1 above and Assertion 2 of Theorem 14.0.1 when we set $f \equiv \psi$, $t = \lambda$ and $t_0 = 0$ in the latter.

3. Suppose $X^{n+1}$ is integrable. Then $\psi^{(n+1)}$ exists on $R$, with $|\psi^{(n+1)}| \leq E|X|^{n+1}$ by equality \[5.8.24\]. Hence $\bar{r}_n(t) \leq E|X|^{n+1} |t - t_0|^{n+1} / (n+1)!$ according to Assertion 3 of Theorem 14.0.1.

For the proof of a partial converse, we need some basic equalities for binomial coefficients.

Lemma 5.8.13. (Binomial coefficients). For each $n \geq 1$ the sum

$$\sum_{k=0}^{n} \binom{n}{k} (-1)^k k^j = 0$$

for $j = 0, \cdots, n - 1$, and

$$\sum_{k=0}^{n} \binom{n}{k} (-1)^k k^n = (-1)^n n!.$$

Proof. Differentiate $j$ times the binomial expansion

$$(1 - e^t)^n = \sum_{k=0}^{n} \binom{n}{k} (-1)^k e^{kt}$$

to get

$$n(n-1) \cdots (n-j+1)(1-e^t)^{n-j} = \sum_{k=0}^{n} \binom{n}{k} (-1)^k k^j e^{kt},$$

and then set $t$ to 0.

Classical proofs for the next theorem in familiar texts rely on Fatou’s Lemma, which is not constructive because it trivially implies the principle of infinite search. The following proof contains an easy fix.

Proposition 5.8.14. (Moments of r.r.v. and derivatives of its characteristic function). Let $\psi$ denote the characteristic function of $X$. Let $n \geq 1$ be arbitrary. If $\psi$ has a continuous derivative of order $2n$ in some neighborhood of $\lambda = 0$, then $X^{2n}$ is integrable.

Proof. Write $\lambda_k \equiv 2^{-k}$ for each $k \geq 1$. Then

$$\frac{\sin^2(\lambda_k X)}{\lambda_k^2} = \frac{\sin^2(2\lambda_{k+1} X)}{(2\lambda_{k+1})^2} = \frac{(2 \sin(\lambda_{k+1} X) \cos(\lambda_{k+1} X))^2}{(2\lambda_{k+1})^2}$$

$$= \frac{\sin^2(\lambda_{k+1} X)}{\lambda_{k+1}^2} \cos^2(\lambda_{k+1} X) \leq \frac{\sin^2(\lambda_{k+1} X)}{\lambda_{k+1}^2}.$$

Yuen-Kwok Chan 184 Constructive Probability
for each $k \geq 1$. Thus we see that the sequence $((\sin(\frac{t}{\lambda}X))_k)^n)_{k=1,2,\ldots}$ of integrable r.r.v.'s is nondecreasing. Since $\psi^{(2n)}$ exists, we have, by Taylor’s Theorem, Theorem 14.0.1 in the Appendix,

$$
\psi(\lambda) = \sum_{j=0}^{2n} \frac{\psi^{(j)}(0)}{j!} \lambda^j + o(\lambda^{2n})
$$
as $\lambda \to 0$. Hence for any $\lambda \in \mathbb{R}$ we have

$$
E\left(\frac{\sin(\lambda X)}{\lambda}\right)^{2n} = E\left(\frac{e^{i\lambda X} - e^{-i\lambda X}}{2i\lambda}\right)^{2n} = (2i\lambda)^{-2n} E \sum_{k=0}^{2n} (-1)^k e^{i(2n-2k)\lambda X}
$$

$$
= (2i\lambda)^{-2n} \left(\sum_{k=0}^{2n} (-1)^k \psi((2n-2k)\lambda)\right)
$$

$$
= (2i\lambda)^{-2n} \left\{ \sum_{k=0}^{2n} \left(\sum_{j=0}^{2n} \frac{\psi^{(j)}(0)}{j!} (2n-2k)^j \lambda^j + o(\lambda^{2n})\right)\right\}
$$

$$
= (2i\lambda)^{-2n} \{o(\lambda^{2n}) + \sum_{j=0}^{2n} \frac{\psi^{(j)}(0)}{j!} \lambda^j \sum_{k=0}^{2n} (-1)^k (2n-2k)^j \}
$$

$$
= o(1) + (2i\lambda)^{-2n} \{\psi^{(2n)}(0) \lambda^{2n} 2^{2n}\} = (-1)^n \psi^{(2n)}(0)
$$
in view of Lemma 5.8.13. Consequently $E\left(\frac{\sin(\lambda X)}{\lambda}X\right)^{2n} \to (-1)^n \psi^{(2n)}(0)$. At the same time $\frac{\sin(\lambda t)}{\lambda} \to t$ uniformly for $t$ in any compact interval. Hence $\left(\frac{\sin(\lambda X)}{\lambda}\right)^{2n} \to X^{2n}$ a.u. as $k \to \infty$. Therefore, by the Monotone Convergence Theorem, the limit r.r.v. $X^{2n} = \lim_{k \to \infty} \left(\frac{\sin(\lambda X)}{\lambda}\right)^{2n}$ is integrable.

Proposition 5.8.15. (Product distribution and direct product of characteristic function). Let $F_1, F_2$ be distributions on $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively, with the characteristic functions $\psi_1, \psi_2$ respectively. Let the function $\psi_1 \otimes \psi_2$ be defined by

$$
(\psi_1 \otimes \psi_2)(\lambda) \equiv (\psi_1(\lambda_1), \psi_2(\lambda_2))
$$

for each $\lambda \equiv (\lambda_1, \lambda_2) \in \mathbb{R}^{n+m}$ be arbitrary, where $\lambda_1 \in \mathbb{R}^n$ and $\lambda_2 \in \mathbb{R}^m$. Let $F$ be a distribution on $\mathbb{R}^{n+m}$ with characteristic function $\psi$. Then $F = F_1 \otimes F_2$ iff $\psi = \psi_1 \otimes \psi_2$. Proof. Suppose $F = F_1 \otimes F_2$. Let $\lambda \equiv (\lambda_1, \lambda_2) \in \mathbb{R}^{n+m}$ be arbitrary, where $\lambda_1 \in \mathbb{R}^n$ and $\lambda_2 \in \mathbb{R}^m$. Let $\exp(i\lambda_1^T \cdot)$ be the function on $\mathbb{R}^{n+m}$ whose value at arbitrary $x \equiv (x_1, x_2) \in \mathbb{R}^{n+m}$, where $x_1 \in \mathbb{R}^n$ and $x_2 \in \mathbb{R}^m$, is $\exp(i\lambda_1^T x)$. Similarly let $\exp(i\lambda_2^T \cdot), \exp(i\lambda_2^T x)$ be the functions whose values at $(x_1, x_2) \in \mathbb{R}^{n+m}$ are $\exp(i\lambda_2^T x_1), \exp(i\lambda_2^T x_2)$ respectively. Then

$$
\psi(\lambda) \equiv F \exp(i\lambda^T \cdot) = F \exp(i\lambda_1^T \cdot) \exp(i\lambda_2^T \cdot)
$$

$$
= (F_1 \otimes F_2) \exp(i\lambda_1^T \cdot) \exp(i\lambda_2^T \cdot)
$$

$$
= (F_1 \exp(i\lambda_1^T \cdot)) (F_2 \exp(i\lambda_2^T \cdot))
$$

$$
= \psi_1(\lambda_1) \psi_2(\lambda_2) = (\psi_1 \otimes \psi_2)(\lambda).
$$
Thus $\psi = \psi_1 \otimes \psi_2$.

Conversely, suppose $\psi = \psi_1 \otimes \psi_2$. Let $G \equiv F_1 \otimes F_2$. Then $G$ has characteristic function $\psi_1 \otimes \psi_2$ by the previous paragraph. Thus the distributions $F$ and $G$ have the same characteristic function $\psi$. By Theorem 5.8.9 it follows that $F = G \equiv F_1 \otimes F_2$. \(\square\)

**Corollary 5.8.16. (Independence in terms of characteristic functions).** Let $X_1 : \Omega \to \mathbb{R}^n$ and $X_2 : \Omega \to \mathbb{R}^m$ be r.v.’s on a probability space $(\Omega, L, E)$, with characteristic functions $\psi_1, \psi_2$ respectively. Let $\psi$ be the characteristic function of the r.v. $X \equiv (X_1, X_2) : \Omega \to \mathbb{R}^{n+m}$. Then $X_1, X_2$ are independent iff $\psi = \psi_1 \otimes \psi_2$.

**Proof.** Let $F_1, F_2$ be the distributions induced by $X, X_1, X_2$ on $\mathbb{R}^{n+m}, \mathbb{R}^n, \mathbb{R}^m$ respectively. Then $X_1, X_2$ are independent iff $F = F_1 \otimes F_2$, by Definition 5.6.1 Since $F = F_1 \otimes F_2$ iff $\psi = \psi_1 \otimes \psi_2$, according to Proposition 5.8.15 the corollary is proved. \(\square\)

**Proposition 5.8.17. (Conditional expectation of jointly normal r.v.’s).** Let $Z_1, \ldots, Z_m, Y_1, \ldots, Y_m$ be arbitrary jointly normal r.v.’s with mean 0. Suppose the covariance matrix $\Sigma_Z \equiv EZZ^T$ of $Z \equiv (Z_1, \ldots, Z_m)$ is positive definite. Let $\Sigma_Y \equiv EYY^T$ be the covariance matrix of $Y \equiv (Y_1, \ldots, Y_m)$. Define the $n \times m$ cross-covariance matrix $c_{Z,Y} \equiv EY^T Z$, and define the $n \times m$ matrix $b_Y = \Sigma_Z^{-1} c_{Z,Y}$. Then the following holds.

1. The $m \times m$ matrix $\Sigma_{Y|Z} \equiv \Sigma_Y - c_{Z,Y}^T \Sigma_Z^{-1} c_{Z,Y}$ is nonnegative definite.

2. For each $f \in L_Y$, we have
   \[
   E(f(Y)|Z) = \Phi_{b_Y^T \Sigma_{Y|Z}} f.
   \]
   Heuristically, given $Z$, the conditional distribution of $Y$ is normal with mean $b_Y^T Z$ and covariance matrix $\Sigma_{Y|Z}$. In particular, $E(Y|Z) = b_Y^T Z = c_{Z,Y}^T \Sigma_Z^{-1} Z$.

3. The r.v.’s $V \equiv E(Y|Z)$ and $X \equiv Y - E(Y|Z)$ are independent normal r.v.’s with values in $\mathbb{R}^m$.

4. $EY^T Y = EV^T V + EX^T X$.

**Proof.** 1. Let $X = (X_1, \ldots, X_m) \equiv Y - b_Y^T Z$. Thus $Y = b_Y^T Z + X$. Then $Z_1, \ldots, Z_m, X_1, \ldots, X_m$ are jointly normal according to Proposition 5.7.6. Furthermore,

\[
EXX^T = EYY^T - EYZ^T b_Y - EY^T Z b_Y^T + EB_Y ZZ^T b_Y
\]

while the covariance matrix of $X$ is given by

\[
\Sigma_X \equiv EXX^T = EYY^T - EYZ^T b_Y - EY^T Z b_Y^T + EB_Y ZZ^T b_Y
\]

\[
= \Sigma_Y - c_{Z,Y}^T b_Y - b_Y^T c_{Z,Y} + b_Y^T \Sigma_Z b_Y
\]

\[
= \Sigma_Y - c_{Z,Y}^T \Sigma_Z^{-1} c_{Z,Y} - b_Y^T c_{Z,Y} + b_Y^T c_{Z,Y}
\]

\[
= \Sigma_Y - c_{Z,Y}^T \Sigma_Z^{-1} c_{Z,Y} \equiv \Sigma_{Y|Z},
\]

whence $\Sigma_{Y|Z}$ is nonnegative definite.
2. Hence the r.v. \( U = (Z, X) \) in \( R^{n+m} \) has mean 0 and covariance matrix

\[
\Sigma_U = \begin{bmatrix} \Sigma_Z & 0 \\ 0 & \Sigma_X \end{bmatrix} \equiv \begin{bmatrix} \Sigma_Z & 0 \\ 0 & \Sigma_{Y|Z} \end{bmatrix}.
\]

Accordingly, \( U \) has the characteristic function

\[
E \exp(i \lambda^T U) = \psi_{0, \Sigma_U}(\lambda) \equiv \exp(-\frac{1}{2} \lambda^T \Sigma_U \lambda)
\]

\[
= \exp(-\frac{1}{2} \theta^T \Sigma Z \theta) \exp(-\frac{1}{2} \gamma^T \Sigma X \gamma)
\]

\[
= E \exp(i \theta^T Z) E \exp(i \gamma^T X),
\]

for each \( \lambda \equiv (\theta_1, \ldots, \theta_n, \gamma_1, \ldots, \gamma_m) \in R^{n+m} \). It follows from Corollary 5.8.10 that \( Z, X \) are independent. In other words, the distribution \( \mathcal{L}(Z, X) \) induced by \( (Z, X) \) on \( R^{n+m} \) is given by the product distribution,

\[
\mathcal{L}(Z, X) = \mathcal{L}(Z) \otimes \mathcal{L}(X)
\]

of \( \mathcal{L}(Z), \mathcal{L}(X) \) induced on \( R^n, R^m \) respectively by \( Z, X \) respectively.

Now let \( f \in L_Y \) be arbitrary. Thus \( f(Y) \in L \). Let \( z \equiv (z_1, \cdots, z_n) \in R^n \) and \( z \equiv (x_1, \cdots, x_m) \in R^m \) be arbitrary. Define

\[
\bar{f}(z, x) \equiv f(b^T_Y z + x)
\]

and

\[
\bar{f}(z) \equiv E x \bar{f}(z, \cdot) \equiv E \bar{f}(z, x) \equiv E f(b^T_Y z + X) = \Phi_{b^T_Y \Sigma, \Sigma_{Y|Z}} f.
\]

We will prove that the r.r.v. \( \bar{f}(Z) \) is the condition expectation of \( f(Y) \) given \( Z \). To that end, let \( g \in C(R^n) \) be arbitrary. Then, by Fubini’s Theorem

\[
E f(Y) g(Z) = E \bar{f}(Z, X) g(Z) = E_{(Z, X)}(\bar{f} g) = E_Z \otimes E_X (\bar{f} g)
\]

\[
= E_Z(\mathcal{L}(\bar{f} g)) = E_Z \bar{f} g = E \bar{f}(Z) g(Z).
\]

It follows that

\[
E f(Y) g(Z) = \Phi_{b^T_Y \Sigma, \Sigma_{Y|Z}} f.
\]

In particular, \( E(Y|Z) = b^T_Y Z = c^T_Z \Sigma_Z^{-1} Z \).

3. By Step 2, the r.v.’s \( Z, X \) are independent normal. Hence the r.v.’s \( V \equiv E(Y|Z) = b^T_Y Z \) and \( X = Y - E(Y|Z) \) are independent normal.

4. Hence \( EV^T X = (EV^T)(EX) = 0 \). It follows that

\[
EY^T Y = E(V + X)^T (V + X) = EV^T V + EX^T X.
\]

\[\square\]
5.9 The Central Limit Theorem

Let \( X_1, \ldots, X_n \) be independent r.r.v.'s with mean 0 and standard deviations \( \sigma_1, \ldots, \sigma_n \) respectively. Define \( \sigma = \sigma^2 = \sigma_1^2 + \cdots + \sigma_n^2 \) and consider the distribution \( F \) of the scaled sum \( X = (X_1 + \cdots + X_n)/\sigma \). By replacing \( X_k \) with \( X_k/\sigma \) we may assume that \( \sigma = 1 \). The Central Limit Theorem says that, if each individual summand \( X_k \) is small relative to the sum \( X \), then \( F \) is close to the standard normal distribution \( \Phi_{0,1} \).

One criterion, due to Lindberg and Feller, for the summands \( X_k (k = 1, \ldots, n) \) to be individually small relative to the sum, is for

\[
\theta(r) \equiv \sum_{k=1}^{n} (E1_{|X_k| > r}X_k^2 + E1_{|X_k| \lesssim r}|X_k|^3)
\]

to be small for some \( r \geq 0 \).

**Lemma 5.9.1.** Suppose \( r \geq 0 \) is such that \( \theta(r) < \frac{1}{8} \). Then

\[
\sum_{k=1}^{n} \sigma_k^3 \leq \theta(r) \tag{5.9.1}
\]

**Proof.** Consider each \( k = 1, \ldots, n \). Then, since \( \theta(r) < \frac{1}{8} \) by hypothesis, we have \( z \equiv E1_{|X_k| > r}X_k^2 < \frac{1}{8} \) and \( a \equiv E1_{|X_k| \lesssim r}|X_k|^3 < \frac{1}{8} \). A consequence is that \( (z + a^2/3)^{3/2} \leq z + a \) which can be seen by noting that the two sides are equal at \( z = 0 \) and by comparing first derivatives relative to \( z \) on \( [0, \frac{1}{8}] \). Lyapunov’s inequality then implies that

\[
\sigma_k^3 = (EX_k^21_{(|X_k| > r)} + E|X_k|^31_{(|X_k| \lesssim r)})^{3/2} \leq (EX_k^21_{(|X_k| > r)} + (E|X_k|^31_{(|X_k| \lesssim r)})^{2/3})^{3/2} \equiv (z + a^2/3)^{3/2} \leq z + a \equiv EX_k^21_{(|X_k| > r)} + E|X_k|^31_{(|X_k| \lesssim r)}.
\]

Summing over \( k \), we obtain inequality 5.9.1. \( \square \)

**Theorem 5.9.2. (Central Limit Theorem).** Let \( f \in C(R) \) and \( \varepsilon > 0 \) be arbitrary. Then there exists \( \delta > 0 \) such that, if \( \theta(r) < \delta \) for some \( r \geq 0 \), then

\[
| \int f(x)dF(x) - \int f(x)d\Phi_{0,1}(x) | < \varepsilon. \tag{5.9.2}
\]

**Proof.** Let \( \xi_R \) be an arbitrary, but fixed, binary approximation of \( R \) relative to the reference point 0. We assume, without loss of generality, that \( |f(x)| \leq 1 \). Let \( \delta_f \) be a modulus of continuity of \( f \), and let \( b > 0 \) be so large that \( f \) has \([-b, b]\) as support. Let \( \varepsilon > 0 \) be arbitrary. By Proposition 5.3.3 there exists \( \delta_f(\varepsilon, \delta_f, b, \|\xi_R\|) > 0 \) such that, if the distributions \( F, \Phi_{0,1} \) satisfy

\[
\rho_{\xi(R)}(F, \Phi_{0,1}) < \varepsilon' \equiv \delta_f(\varepsilon, \delta_f, b, \|\xi_R\|), \tag{5.9.3}
\]

Yuen-Kwok Chan
188
Constructive Probability
5.9. THE CENTRAL LIMIT THEOREM

then inequality 5.9.2 holds. Separately, according to Corollary 5.8.11 there exists \( \delta_{ch,\text{distr}}(\varepsilon') > 0 \) such that, if the characteristic functions \( \psi_F, \psi_{0,1} \) of \( F, \Phi_{0,1} \) respectively satisfy

\[
\rho_{\text{char}}(\psi_F, \psi_{0,1}) \equiv \sum_{j=1}^{\infty} 2^{-j} \sup_{|\lambda| \leq j} |\psi_F(\lambda) - \psi_{0,1}(\lambda)| < \varepsilon'' \equiv \delta_{ch,\text{distr}}(\varepsilon'), \tag{5.9.4}
\]

then inequality 5.9.3 holds.

Now take \( m \geq 1 \) be so large that \( 2^{-m+2} \leq \varepsilon'' \), and define

\[
\delta \equiv \frac{1}{8} \lambda \left( \frac{1}{m^3} - 3 \varepsilon'' \right).
\]

Suppose \( \theta(r) < \delta \)

for some \( r \geq 0 \). Then \( \theta(r) < \frac{1}{2} \). We will show that inequality 5.9.2 holds.

To that end, let \( \lambda \in [-m, m] \) and \( k = 1, \ldots, n \) be arbitrary. Let \( \phi_k \) denote the characteristic function of \( X_k \), and let \( Y_k \) be a normal r.r.v. with mean 0, variance \( \sigma^2_k \), and characteristic function \( e^{-\frac{\sigma^2_k \lambda^2}{2}} \). Then

\[
E|Y_k|^3 = \frac{2}{\sqrt{2\pi} \sigma_k} \int_0^\infty y^3 \exp\left(\frac{-y^2}{2 \sigma_k^2}\right) dy.
\]

\[
= \frac{4 \sigma^3_k}{\sqrt{2\pi}} \int_0^\infty u \exp(-u) du = \frac{4 \sigma^3_k}{\sqrt{2\pi}} = 2 \sqrt{\frac{2}{\pi}} \sigma^3_k,
\]

where we made a change of integration variables \( u \equiv \frac{-1}{2 \sigma_k^2} y^2 \). Moreover, since \( \sum_{k=1}^n \sigma_k^2 = 1 \) by assumption, and since all characteristic functions have absolute value bounded by 1, we have

\[
|\phi_F(\lambda) - e^{-\lambda^2/2}| = \left| \prod_{k=1}^n \phi_k(\lambda) - \prod_{k=1}^n e^{-\sigma_k^2 \lambda^2/2} \right|
\]

\[
\leq \sum_{k=1}^n |\phi_k(\lambda) - e^{-\sigma_k^2 \lambda^2/2}|. \tag{5.9.5}
\]

By Proposition 5.8.12 the Taylor expansions up to degree 2 for the characteristic functions \( \phi_k(\lambda) \) and \( e^{-\sigma_k^2 \lambda^2/2} \) are equal because the two corresponding distributions have equal first and second moments. Hence the difference of the two functions is equal to the difference of the two remainders in their respective Taylor expansions. Again by Proposition 5.8.12 the remainder for \( \phi_k(\lambda) \) is bounded by

\[
\lambda^2 E X_k^2 1_{\{|X_k| > r\}} + \frac{|\lambda|^3}{3!} E|X_k|^3 1_{\{|X_k| \leq r\}}
\]

\[
\leq m^3 (E X_k^2 1_{\{|X_k| > r\}} + E|X_k|^3 1_{\{|X_k| \leq r\}}).
\]

Yuen-Kwok Chan 189 Constructive Probability
By the same token, the remainder for \( e^{-\sigma_k^2 s^2/2} \) is bounded by a similar expression, where \( X_k \) is replaced by \( Y_k \) and where \( r \geq 0 \) is replaced by \( s \geq 0 \), which becomes, as \( s \to \infty \),

\[
m^3 E|Y_k|^3 = 2\sqrt{\frac{2}{\pi}} m^3 \sigma_k^3 < 2m^3 \sigma_k^3.
\]

Combining, inequality 5.9.5 yields, for each \( \lambda \in [-m,m] \),

\[
|\varphi_r(\lambda) - e^{-\lambda^2/2}| \leq m^3 \sum_{k=1}^n (EX_k^2 1_{|X_k| > r} + E|X_k|^3 1_{|X_k| \leq r}) + 2m^3 \sum_{k=1}^n \sigma_k^3
\]

\[
\leq 3m^3 \theta(r) \leq 3m^3 \delta \leq \frac{e''}{2},
\]

where the second inequality follows from the definition of \( \theta(r) \) and from Lemma 5.9.1. Hence, since \( |\varphi_r - \varphi_{0,1}| \leq 2 \), we obtain

\[
\varphi_{\text{char}}(\varphi_r, \varphi_{0,1}) \leq \sum_{j=1}^{m} 2^{-j} \sup_{|\lambda| \leq j} |\varphi_r(\lambda) - \varphi_{0,1}(\lambda)| + 2^{-m+1}
\]

\[
\leq \frac{e''}{2} + \frac{e''}{2} = \epsilon'' = \delta_{\text{c.d.s.t.r}}(\epsilon'),
\]

establishing inequality 5.9.4. Consequently, inequality 5.9.3 and, in turn, inequality 5.9.2 follow. The theorem is proved.

**Corollary 5.9.3. (Lindberg’s Central Limit Theorem)** For each \( p = 1, 2, \cdots \), let \( n_p \geq 1 \) be arbitrary, and let \( (X_{p,1}, \cdots, X_{p,n(p)}) \) be an independent sequence of r.v.'s with mean 0 and variance \( \sigma_{p,k}^2 \) such that \( \sum_{k=1}^{n(p)} \sigma_{p,k}^2 = 1 \). Suppose for each \( r > 0 \) we have

\[
\lim_{p \to \infty} \sum_{k=1}^{n(p)} EX_{p,k}^2 1_{|X(p,k)| > r} = 0 \tag{5.9.6}
\]

Then \( \sum_{k=1}^{n(p)} X_{p,k} \) converges in distribution to the standard normal distribution \( \Phi_{0,1} \) as \( p \to \infty \).

**Proof.** Let \( \delta > 0 \) be arbitrary. According to Theorem 5.9.2, it suffices to show that there exists \( r > 0 \) such that, for sufficiently large \( p \), we have

\[
\sum_{k=1}^{n(p)} EX_{p,k}^2 1_{|X(p,k)| > r} < \frac{\delta}{2}
\]

and

\[
\sum_{k=1}^{n(p)} E|X_{p,k}|^3 1_{|X(p,k)| < r} < \frac{\delta}{2}.
\]

For that purpose, take any \( r \in (0, \frac{\delta}{2}) \). Then the first of the last two inequalities holds for sufficiently large \( p \), in view of inequality 5.9.6 in the hypothesis. The second follows from

\[
\sum_{k=1}^{n(p)} E|X_{p,k}|^3 1_{|X(p,k)| < r} \leq r \sum_{k=1}^{n(p)} EX_{p,k}^2 = r < \frac{\delta}{2}.
\]
5.10 SUPPLEMENTS AND EXERCISES

Because of the importance of the Central Limit Theorem, much work since the early development of probability theory has been dedicated to an optimal rate of convergence, culminating in the Feller’s bound: \( \sup_{t \in \mathbb{R}} |F(t) - \Phi(t)| \leq 6 \theta(r) \) for each \( r \geq 0 \). The proof on pages 544-546 of [Feller II 1971], which is a careful analysis of the difference \( \phi_k(\lambda) - e^{-\lambda^2/2} \), contains a few typos and omitted steps which serve to keep the reader on the toes. That proof contains also a superfluous assumption that the maximum distance between two P.D.F.’s is always attained at some point in \( R \). There is no constructive proof for the general validity of that assumption. There is however an easy constructive substitute which says that, if one of the two P.D.F.s is continuously differentiable, then the supremum distance exists: there is a sequence \( \{ t_n \} \) in \( R \) such that \( \lim_{n \to \infty} |F(t_n) - \Phi_{0,1}(t_n)| \) exists and bounds any \( |F(t) - \Phi_{0,1}(t)| \). This is sufficient for Feller’s proof.

5.10 Supplements and Exercises

Exercise 5.10.1. (General existence of \( E(Y|X) \) implies the principle of infinite search).

Hint. We will give a counter example where \( X \) has a p.d.f. To that end, let \( \Omega = [0,1] \times \{-1,1\} \) be equipped with the Euclidean metric. Define the distribution \( E_0 \equiv I_0 \otimes I_1 \) on \( \Omega \), where \( I_0 \) is the Lebesgue integration on \([0,1]\), and where \( I_1 \) is the probability integration on \( \{-1,1\} \) which assigns equal probabilities to each of \(-1 \) and \( 1 \). Let \( \{ r_n \}_{n=1,2,..} \) be an arbitrary 0-1 sequence with at most a 1.

For each \( n \geq 1 \), define a distribution \( E_n \) on \( \Omega \) by \( E_n Z \equiv \int_0^1 Z(x,(-1)^{[2^n x]})dx \) for each \( Z \in C(\Omega) \), where \( [a] \) stands for the integer part of a real number \( a \), whence \( [2^n x] \) is defined for a.e. \( x \in [0,1] \). Then \( |E_n Z - E_0 Z| \to 0 \) for each \( Z \in C(\Omega) \). Hence

\[
EZ \equiv E_0 Z + \sum_{n=1}^\infty r_n (E_n Z - E_0 Z)
\]

exists. Then \( (\Omega,C(\Omega),E) \) is an integration space with \( E1 = 1 \). Therefore its completion \( (\Omega,E) \) is a probability space. We have also

\[
|E_m Z - EZ| \leq |E_m Z - E_0 Z| + \sum_{n=1}^\infty r_n (E_n Z - E_0 Z) \to 0 \quad \text{as} \quad m \to \infty.
\]

Let \( X,Y \) be the first and second coordinate functions: \( X(x,y) = x \) and \( Y(x,y) = y \) for each \((x,y) \in \Omega \). It can easily be shown that \( E_0(Y|X) = 0 \) and \( E_n(Y|X) = (-1)^{2^n X} \) for each \( n \geq 1 \). Moreover \( X \) has a p.d.f.: \( Ef(X) = \int_0^1 f(t) dt \).

Assume that \( E(Y|X) \) exists. Let \( a \in (0,1) \) be such that \( A = (E(Y|X) > a) \) is measurable. Either \( P(A) > 0 \) or \( P(A) < \frac{1}{2} \).

Suppose \( P(A) > 0 \). Then

\[
EY1_A = E(E(Y|X)1_A) = E(E(Y|X)1_{E(Y|X)>a}) > aP(A) > 0
\]
At the same time, \( E_0Y1_A = E_0(E_0(Y|X)1_A) = 0 \). Therefore \( \sum_{n=1}^{\infty} r_n(E_nY1_A - E_0Y1_A) = EY1_A > 0 \), and so there exists an \( n \)-th summand in the series which is positive. Hence that \( r_n > 0 \) for some \( n \geq 1 \).

Suppose, on the other hand, that \( P(A) < \frac{1}{2} \). Suppose \( r_n > 0 \) for some \( n \). Then \( E = E_n \). Hence \( A = (E_n(Y|X) > a) \) and so \( P(A) = P((-1)^{2|X|}) = \frac{1}{2} \), a contradiction. Hence \( r_n = 0 \) for each \( n \).

Thus from the general existence of \( E(Y|X) \) we have deduced the principle of infinite search. \( \square \)

**Exercise 5.10.2. (Constructively, existence of \( E(Z|X) \) does not imply that of \( E(|Z||X|) \).)**

Let \( X, Y \) be the r.r.v.'s as constructed in the preceding exercise. Let \( V \) be a r.r.v. independent of \( X, Y \) such that \( P(V = 1) = P(V = -1) = \frac{1}{2} \). Define \( Z = V(1 + Y) \). Then \( E(Z|X) = 0 \). At the same time, \( |Z| = (1 + Y) \). Hence the existence of \( E(|Z||X) \) would imply that of \( E(Y|X) \). Combining with Exercise 5.10.1, we see that a proof that existence of \( E(Z|X) \) implies that of \( E(|Z||X) \) would also prove the principle of infinite search.

**Exercise 5.10.3. (Integration of complex valued functions).** Let \( f \) be a complex-valued integrable function on and integration space \( (\Omega, L, I) \). Then \(|f| \leq |f|\).

**Proof.** Let \( g \) and \( h \) denote the real and imaginary parts of \( f \) respectively. Thus \( f \equiv g + ih \). By hypothesis both \( g \) and \( h \) are integrable relative to \( I \). Hence, by definition, \( f \) is integrable. Moreover,

\[
|f|^2 \equiv |g + ih|^2 \leq |g|^2 + |h|^2 \leq |g|^2 + |h|^2 = |f|^2.
\]

\( \square \)

**Exercise 5.10.4. (Weak Convergence is equivalent to convergence at all bounded continuous functions).** Let \((S,d)\) be a locally compact metric space. Let \( I, I_n \in Q_S \) for each \( n \geq 1 \). Prove that \( I_n \Rightarrow I \) iff \( I_n f \to I f \) for each \( f \in C_b(S) \).

**Hint.** Suppose \( I_n \Rightarrow I \). Equivalently \( I_n g \to I g \) for each \( g \in C(S) \). Moreover \( \{I, I_1, I_2, \cdots \} \) is tight. Consider \( f \in C_b(S) \). Without loss of generality, assume that \( 0 \leq f \leq 1 \). Let \( \varepsilon > 0 \) be arbitrary. Let \( x_0 \in S \) be fixed and let \( a > 0 \) be so large that \( g \equiv 1 \wedge (a - d(\cdot, x_0))_+ \) has \( 0 \leq 1 - lg < \varepsilon \). Then \( 0 \leq I f - I g = I f(1 - g) \leq 1 - lg < \varepsilon \). Since \( g, f g \in C(S) \), there exists \( m \) so large that \( |I_n f - I g| < \varepsilon \) and \( |I_n f g - I f g| < \varepsilon \) for each \( n \geq m \). Consider any \( n \geq m \). We then have \( 0 \leq 1 - I_n g \leq 1 - lg + |I_n g - lg| < 2\varepsilon \). Consequently \( 0 \leq I_n f - I_n g \leq I_n (1 - g) < 2\varepsilon \). Combining, we have \( |I_n f - I f| \leq |I_n f - I_n g| + |I_n f g - I f g| + |I f g - I f| < 4\varepsilon \). Since \( \varepsilon > 0 \) is arbitrary, we have proved that \( I_n g \to I g \) for each \( g \in C(S) \) implies \( I_n f \to I f \) for each \( f \in C_b(S) \). The converse is trivial since \( C(S) \subset C_b(S) \). \( \square \)
Part III

Stochastic Process
Chapter 6

Random Fields and Stochastic Processes

In this chapter, unless otherwise specified, \((S,d)\) will denote a locally compact metric space, with an arbitrary, but fixed, reference point \(x_0\).

6.1 Random Field and Finite Joint Distributions

In this section, we introduce random fields, their marginal distributions, and some notions of their continuity. and let \(\Omega\) be a set. Let \((\Omega, L, E)\) be a probability space.

**Definition 6.1.1. (Random Fields).** Suppose a function 
\[ X : Q \times \Omega \to S \]
is such that, for each \(t \in Q\), the function \(X_t \equiv X(t, \cdot)\) is a r.v. on \(\Omega\) with values in \(S\). Then \(X\) is called a random field, or r.f. for abbreviation, with sample space \(\Omega\), with parameter set \(Q\), and with state space \(S\). To be precise, we will sometimes write \[ X : Q \times (\Omega, L, E) \to (S,d). \]

We will let \(\tilde{R}(Q \times \Omega, S)\) denote the set of such r.f.’s. Two r.f.’s \(X, Y \in \tilde{R}(Q \times \Omega, S)\) are considered equal if \(X_t = Y_t\) a.s. on \(\Omega\), for each \(t \in Q\).

Let \(X \in \tilde{R}(Q \times \Omega, S)\) be arbitrary. For each \(\omega \in \Omega\) such that \(domain(X(\cdot, \omega))\) is nonempty, the function \(X(\cdot, \omega)\) is called a sample function. If \(K\) is a subset of \(Q\), then we write \[ X|K \equiv X|(K \times \Omega) : K \times \Omega \to S, \]
and call the r.f. \(X|K\) the restriction of \(X\) to \(K\).

In the special case where the parameter set \(Q\) is a subset of \(R\), the r.f. \(X\) is called a stochastic process, or simply a process. In that case, the variable \(t \in Q\) is often called the time parameter. 

\[ 195 \]
When the parameter set $Q$ is countably infinite, we can view a r.f. with state space $(S,d)$ as a r.v. with values in $(S^\infty,d^\infty)$.

**Lemma 6.1.2.** *(Random field with countable parameter set can be regarded as a r.v. with values in the path space, and conversely).* Let $X : Q \times (\Omega,L,E) \to (S,d)$ be an arbitrary r.f. where the parameter set $Q = \{t_1,t_2,\cdots\}$ is countably infinite. Then the function $(X_{t_1},X_{t_2},\cdots) : \Omega \to S^Q$ is a r.v. on $(\Omega,L,E)$ with values in the complete metric space $(S^Q,d^Q)$. The converse also holds.

**Proof.** 1. Suppose $X : Q \times (\Omega,L,E) \to (S,d)$ is a r.f. Let $x_0$ be an arbitrary, but fixed, reference point in $S$. Let $f \in C_{ub}(S^m,d^m)$ be arbitrary, with a modulus of continuity $\delta_f$. Let $\epsilon > 0$ be arbitrary. Let $m \geq 1$ be so large that $2^{-m} < \delta_f(\epsilon)$. Define a function $f_m$ on $S^m$ by

$$f_m(x_1,\cdots,x_m) \equiv f(x_1,\cdots,x_m,x_0,\cdots)$$

for each $(x_1,\cdots,x_m) \in S^m$. Then it is easily verified that $f_m \in C_{ub}(S^m,d^m)$. Hence $f_m(X_{t_1(1)},\cdots,X_{t_1(m)}) \in L$. At the same time,

$$d^m((X_{t_1(1)},X_{t_1(2)},\cdots),(X_{t_1(1)},\cdots,X_{t_1(m)},x_0,\cdots))$$

$$= \sum_{k=m+1}^{\infty} 2^{-k}d(X_{t_1(k)},x_0) \leq \sum_{k=m+1}^{\infty} 2^{-k} = 2^{-m} < \delta_f(\epsilon).$$

Consequently

$$|f(X_{t_1(1)},X_{t_1(2)},\cdots) - f_m(X_{t_1(1)},\cdots,X_{t_1(m)})| < \epsilon.$$ 

Thus $f(X_{t_1(1)},X_{t_1(2)},\cdots)$ is the uniform limit of a sequence in $L$, hence is itself a member of $L$. Since the complete metric space $(S^\infty,d^\infty)$ is bounded, Proposition 5.1.4 implies that the function $(X_{t_1(1)},X_{t_1(2)},\cdots)$ is a r.v.

2. Conversely, suppose $X \equiv (X_{t_1(1)},X_{t_1(2)},\cdots)$ is a r.v. on $(\Omega,L,E)$ with values in the complete metric space $(S^Q,d^Q)$. Let $n \geq 1$ be arbitrary. Define the function $f : (S^Q,d^Q) \to (S,d)$ by $f(x_1,x_2,\cdots,x_n) \equiv x_n$ for each $(x_1,x_2,\cdots,x_n) \in (S^Q,d^Q)$. Then it can easily be verified that the function $f$ is uniformly continuous and is bounded on bounded subsets of $(S^Q,d^Q)$. Hence Proposition 4.8.7 implies that $f \circ X \equiv X_{t_1(n)}$ is a r.v. on $(\Omega,L,E)$ with values in $(S,d)$. Since $n \geq 1$ is arbitrary, we conclude that $X : Q \times (\Omega,L,E) \to (S,d)$ is a r.f.

In general, when the parameter set $Q$ is a metric space, we introduce three notions of continuity of a r.f. They correspond to the terminology in [Neveu 1965]. For ease of presentation, we restrict our attention to the special case where $Q$ is bounded. The generalization to a locally compact metric space is straightforward.

**Definition 6.1.3.** *(Continuity of r.f. on a bounded metric parameter space).* Let $X : Q \times \Omega \to S$ be a r.f., where $(S,d)$ is a locally compact metric space and where $(Q,d_Q)$ is a bounded metric space. Thus $d_Q \leq b$ for some $b \geq 0$.

1. Suppose, for each $\epsilon > 0$, there exists $\delta_{r.f.}(\epsilon) > 0$ such that

$$E(1 \wedge d(X_t,X_s)) \leq \epsilon$$

Yuen-Kwok Chan 196 Constructive Probability
for each \( s,t \in Q \) with \( d_Q(t,s) < \delta_c(p)(\varepsilon) \). Then the r.f. \( X \) is said to be \textit{continuous in probability}, with the operation \( \delta_c(p) \) as a \textit{modulus of continuity in probability}. We will let \( R_{c(p)}(Q \times \Omega, S) \) denote the set of r.f.'s which are continuous in probability, with the given bounded metric space as parameter space.

2. Suppose \( \text{domain}(X(\cdot, \omega)) \) is dense in \( Q \) for a.e. \( \omega \in \Omega \). Suppose, in addition, that for each \( \varepsilon > 0 \), there exists \( \delta_{auc}(\varepsilon) > 0 \) such that, for each \( s \in Q \), there exists a measurable set \( D_s \subseteq \text{domain}(X_s) \) with \( P(D_s^c) < \varepsilon \) such that for each \( \omega \in D_s \) and for each \( t \in \text{domain}(X(\cdot, \omega)) \) with \( d_Q(t,s) < \delta_{auc}(\varepsilon) \), we have

\[
d(X(t,\omega),X(s,\omega)) \leq \varepsilon.
\]

Then the r.f. \( X \) is said to be \textit{continuous a.u.}, with the operation \( \delta_{auc} \) as a \textit{modulus of continuity a.u.} on \( Q \).

3. Suppose, for each \( \varepsilon > 0 \), there exist \( \delta_{auc}(\varepsilon) > 0 \) and a measurable set \( D \) with \( P(D^c) < \varepsilon \) such that

\[
d(X(t,\omega),X(s,\omega)) \leq \varepsilon,
\]

and \( s,t \in \text{domain}(X(\cdot, \omega)) \) with \( d_Q(t,s) < \delta_{auc}(\varepsilon) \), for each \( \omega \in D \). Then the r.f. \( X \) is said to be \textit{a.u. continuous}, with the operation \( \delta_{auc} \) as a \textit{modulus of a.u. continuity}. \( \square \)

The reader can give simple examples of stochastic processes which are continuous in probability but not continuous a.u., and of processes which are continuous a.u. but not a.u. continuous.

**Definition 6.1.4.** \textit{(Continuity of r.f. on an arbitrary metric parameter space).} Let \( X : Q \times \Omega \to S \) be a r.f., where \((S,d)\) is a locally compact metric space and where \((Q,d_Q)\) is an arbitrary metric space.

The r.f. \( X \) is said to be \textit{continuous in probability} if, for each bounded subset \( K \) of \( Q \), the restricted r.f. \( X|K : K \times \Omega \to S \) is continuous in probability.

The r.f. \( X \) is said to be \textit{continuous a.u.} if, for each bounded subset \( K \) of \( Q \), the restricted r.f. \( X|K : K \times \Omega \to S \) is continuous a.u.

The r.f. \( X \) is said to be \textit{a.u. continuous} if, for each bounded subset \( K \) of \( Q \), the restricted r.f. \( X|K : K \times \Omega \to S \) is a.u. continuous. \( \square \)

**Proposition 6.1.5.** \textit{(Alternative definitions of r.f. continuity).} Let \( X : Q \times \Omega \to S \) be a r.f., where \((S,d)\) is a locally compact metric space and where \((Q,d_Q)\) is a bounded metric space. Then the following holds.

1. Suppose \( X \) is continuous in probability, with a modulus of continuity in probability \( \delta_c(p) \). Let \( \varepsilon > 0 \) be arbitrary. Define \( \delta_c(p)(\varepsilon) \equiv \delta_c(p)(2^{-2}(1 + \varepsilon)^2) > 0 \). Then, for each \( s,t \in Q \) with \( d_Q(t,s) < \delta_c(p)(\varepsilon) \), there exists measurable set \( D_{t,s} \) with \( PD_{t,s} \leq \varepsilon \) such that

\[
d(X(t,\omega),X(s,\omega)) \leq \varepsilon
\]

for each \( \omega \in D_{t,s} \). Conversely, if there exists an operation \( \delta_c(p) \) with the above described properties, then the r.f. \( X \) is continuous in probability, with a modulus of continuity in probability \( \delta_c(p) \) defined by \( \delta_c(p)(\varepsilon) \equiv \delta_c(p)(\frac{\varepsilon}{2}) \) for each \( \varepsilon > 0 \).
2. X is continuous a.u. iff, for each \( \varepsilon > 0 \) and \( s \in Q \) there exists a measurable set \( D_s \subseteq \text{domain}(X_s) \) with \( P(D_s^c) < \varepsilon \), such that, for each \( \alpha > 0 \), there exists \( \delta_{\text{can}}'(\alpha, \varepsilon) > 0 \) such that

\[
d(X(t, \omega), X(s, \omega)) \leq \alpha
\]

for each \( t \in Q \) with \( d_Q(t, s) < \delta_{\text{can}}'(\alpha, \varepsilon) \), for each \( \omega \in D_s \).

3. X is a.u. continuous iff, for each \( \varepsilon > 0 \), there exists a measurable set \( D \) with \( P(D^c) < \varepsilon \), such that, for each \( \alpha > 0 \), there exists \( \delta_{\text{can}}'(\alpha, \varepsilon) > 0 \) such that

\[
d(X(t, \omega), X(s, \omega)) \leq \alpha
\]

for each \( s, t \in \text{domain}(X_s) \cap \text{domain}(X_t) \) with \( d_Q(t, s) < \delta_{\text{can}}'(\alpha, \varepsilon) \), for each \( \omega \in D \). Moreover, if such an operation \( \delta_{\text{can}}' \) exists, then X has a modulus of a.u. continuity given by \( \delta_{\text{can}}(\varepsilon, \varepsilon) \equiv \delta_{\text{can}}'(\alpha, \varepsilon) \) for each \( \varepsilon > 0 \).

**Proof.** As usual, write \( \widehat{d} \equiv 1 \land d \).

1. Suppose X is continuous in probability, with a modulus of continuity in probability \( \delta_{\text{cp}} \). Let \( \varepsilon > 0 \) be arbitrary. Write \( \varepsilon' \equiv 1 \land \varepsilon \). Suppose \( s, t \in Q \) are arbitrary with

\[
d_Q(t, s) < \delta_{\text{cp}}(\varepsilon) \equiv \delta_{\text{cp}}(2^{-2}(1 \land \varepsilon)^2) \equiv \delta_{\text{cp}}(2^{-2}\varepsilon^2).
\]

Then, by Definition 6.1.3 of \( \delta_{\text{cp}} \) as a modulus of continuity in probability, we have

\[
E\widehat{d}(X_t, X_s) \leq 2^{-2}\varepsilon^2 < \varepsilon^2.
\]

Take any \( \alpha \in (1^{-1}\varepsilon', \varepsilon') \) such that the set \( D_{t,s} \equiv (\widehat{d}(X_t, X_s) \leq \alpha) \) is measurable. Then Chebychev’s inequality implies that \( P(D_{t,s}^c) < \alpha < \varepsilon' \leq \varepsilon \). Moreover, for each \( \omega \in D_{t,s} \), we have \( \widehat{d}(X(t, \omega), X(s, \omega)) \leq \alpha < \varepsilon' \leq \varepsilon \). Thus the operation \( \delta_{\text{cp}} \) has the properties described in Assertion 1.

Conversely, suppose \( \delta_{\text{cp}} \) is an operation with the properties described in Assertion 1. Let \( \varepsilon > 0 \) be arbitrary. Let \( s, t \in Q \) be arbitrary with \( d_Q(t, s) < \delta_{\text{cp}}(\varepsilon) \). Then, by hypothesis, there exists a measurable subset \( D_{t,s} \) with \( PD_{t,s}^c \leq \frac{1}{2} \varepsilon \) such that, for each \( \omega \in D_{t,s} \), we have \( d(X(t, \omega), X(s, \omega)) \leq \frac{1}{2} \varepsilon \). It follows that \( E(1 \land d(X_t, X_s)) \leq \frac{1}{2} \varepsilon + PD_{t,s}^c \leq \varepsilon \). Thus X is continuous in probability.

2. Suppose X is continuous a.u., with \( \delta_{\text{can}} \) as a modulus of continuity a.u. Let \( \varepsilon > 0 \) and \( s \in Q \) be arbitrary. Then there exists, for each \( k \geq 1 \), a measurable set \( D_{s,k} \) with \( P(D_{s,k}^c) < 2^{-k} \varepsilon \) such that, for each \( \omega \in D_{s,k} \), we have

\[
d(X(t, \omega), X(s, \omega)) \leq 2^{-k} \varepsilon
\]

for each \( t \in Q \) with \( d_Q(t, s) < \delta_{\text{can}}(2^{-k} \varepsilon) \). Let \( D_s \equiv \bigcap_{k=1}^{\infty} D_{s,k} \). Then \( P(D_s^c) < \sum_{k=1}^{\infty} 2^{-k} \varepsilon = \varepsilon \). Now let \( \alpha > 0 \) be arbitrary. Let \( k \geq 1 \) be so large that \( 2^{-k} < \alpha \), and let

\[
\delta_{\text{can}}'(\alpha, \varepsilon) \equiv \delta_{\text{can}}(2^{-k} \varepsilon).
\]

Consider each \( \omega \in D_s \) and \( t \in Q \) with \( d_Q(t, s) < \delta_{\text{can}}'(\alpha, \varepsilon) \). Then \( \omega \in D_{s,k} \) and \( d_Q(t, s) < \delta_{\text{can}}(2^{-k} \varepsilon) \). Hence

\[
d(X(t, \omega), X(s, \omega)) \leq 2^{-k} \varepsilon < \alpha.
\]
6.1. RANDOM FIELD AND FINITE JOINT DISTRIBUTIONS

Thus the operation \( \delta'_{\text{auc}} \) has the described properties in Assertion 2.

Conversely, let \( \delta'_{\text{auc}} \) be an operation with the properties described in Assertion 2. Let \( \epsilon > 0 \) be arbitrary. Let \( s \in Q \) be arbitrary. Then there exists a measurable set \( D_k \) with \( P(D_k^c) < \epsilon \) such that, for each \( \omega \in D_k \), and \( t \in Q \) with \( d_Q(t,s) < \delta'_{\text{auc}}(\epsilon) \), we have \( d(X(t,\omega),X(s,\omega)) \leq \epsilon \). Thus the r.f. \( X \) is continuous a.u., with the operation \( \delta_{\text{auc}} \) as a modulus of continuity a.u. Assertion 2 is proved.

3. For Assertion 3, proceed almost verbatim as in the above proof of Assertion 2. Suppose the r.f. \( X \) is a.u. continuous, with \( \delta_{\text{auc}} \) as a modulus of a.u. continuity. Let \( \epsilon > 0 \) be arbitrary. Then there exists, for each \( k \geq 1 \), a measurable set \( D_k \) with \( P(D_k^c) < 2^{-k}\epsilon \) such that, for each \( \omega \in D_k \), we have

\[
d(X(t,\omega),X(s,\omega)) \leq 2^{-k}\epsilon
\]

for each \( s,t \in Q \) with \( d_Q(t,s) < \delta_{\text{auc}}(2^{-k}\epsilon) \). Let \( D \equiv \bigcap_{k=1}^{\infty} D_k \). Then \( P(D^c) = \sum_{k=1}^{\infty} 2^{-k}\epsilon = \epsilon \). Let \( \alpha > 0 \) be arbitrary. Let \( k \geq 1 \) be so large that \( 2^{-k} < \alpha \), and let

\[
\delta_{\text{auc}}(\alpha,\epsilon) = \delta_{\text{auc}}(2^{-k}\epsilon).
\]

Consider each \( \omega \in D \) and \( s,t \in Q \) with \( d_Q(t,s) < \delta_{\text{auc}}(\alpha,\epsilon) \). Then \( \omega \in D_k \) and \( d_Q(t,s) < \delta_{\text{auc}}(2^{-k}\epsilon) \). Hence

\[
d(X(t,\omega),X(s,\omega)) \leq 2^{-k}\epsilon < \alpha.
\]

Thus the operation \( \delta_{\text{auc}}' \) has the properties described in Assertion 3.

Conversely, let \( \delta_{\text{auc}}' \) be an operation with the properties described in Assertion 3. Let \( \epsilon > 0 \) be arbitrary. Then there exists a measurable set \( D \) with \( P(D^c) < \epsilon \) such that, for each \( \omega \in D \), and \( s,t \in Q \) with \( d_Q(t,s) < \delta_{\text{auc}}'(\epsilon,\epsilon) \equiv \delta_{\text{auc}}'(\epsilon) \), we have \( d(X(t,\omega),X(s,\omega)) \leq \epsilon \). Thus the r.f. \( X \) is a.u. continuous, with the operation \( \delta_{\text{auc}}' \) as a modulus of a.u. continuity. Assertion 3 is proved.

Proposition 6.1.6. (a.u. Continuity implies continuity a.u., etc.) Let \( X : Q \times \Omega \to S \) be a r.f., where \( (S,d) \) is a locally compact metric space and where \( (Q,d_Q) \) is a bounded metric space. Then a.u. continuity of \( X \) implies a.u. continuity which in turn implies continuity in probability.

Proof. Let \( \epsilon > 0 \) be arbitrary. Suppose \( X \) is a.u. continuous, with modulus of a.u. continuity given by \( \delta_{\text{auc}} \). Let \( D \) be a measurable set satisfying Condition 3 in Definition 6.1.3. Then \( D_k \equiv D \) satisfies Condition 2 in Definition 6.1.3. Accordingly, \( X \) is continuous a.u.

Now suppose \( X \) is continuous a.u., with modulus of a.u. continuity given by \( \delta_{\text{auc}} \). Let \( D_k \) be a measurable set satisfying Condition 2 in Definition 6.1.3. Then \( D_{k,s} \equiv D_s \) satisfies the conditions in Assertion 1 of Proposition 6.1.5, provided that we define \( \delta_{cp} \equiv \delta_{\text{auc}} \). Accordingly, \( X \) is continuous in probability.

Definition 6.1.7. (Marginal distributions of a r.f.). Let \( X : Q \times \Omega \to S \) be a r.f. Let \( n \geq 1 \) be arbitrary, and let \( t = (t_1, \cdots, t_n) \) be an arbitrary sequence in \( Q \). Let \( F_{t(1),\cdots,t(n)} \) denote the distribution induced on \( (S^n,d^{(n)}) \) by the r.v. \((X_{t(1)},\cdots, X_{t(n)})\). Then

\[
F_{t(1),\cdots,t(n)}(f) \equiv Ef(X_{t(1)},\cdots, X_{t(n)}) \tag{6.1.1}
\]

Yuen-Kwok Chan 199 Constructive Probability
CHAPTER 6. RANDOM FIELDS AND STOCHASTIC PROCESSES

for each \( f \in C_{ub}(S^n) \). We call the indexed family
\[
F \equiv \{ F_{(t_1),\cdots,(t_n)} : n \geq 1 \text{ and } t_1, \cdots, t_n \in Q \}
\]
the family of marginal distributions of \( X \). We will say that the r.f. \( X \) extends the family \( F \) of finite joint distributions, and that \( X \) is an extension of \( F \).

Let \( X' : Q \times \Omega' \rightarrow S \) be a r.f. with sample space \((\Omega', L', E')\). Then \( X \) and \( X' \) are said to be equivalent if their marginal distributions at each finite sequence in \( Q \) are the same. In other words, \( X \) and \( X' \) are said to be equivalent if
\[
E\{f(X_{(t_1)}, \cdots, X_{(t_n)})\} = E'\{f(X'_{(t_1)}, \cdots, X'_{(t_n)})\}
\]
for each \( f \in C_{ub}(S^n) \), for each sequence \((t_1, \cdots, t_n)\) in \( Q \), for each \( n \geq 1 \). In short, two r.f.’s are equivalent if they extend the same family of finite joint distributions. \( \square \)

6.2 Consistent Family of Finite Joint Distributions

In the last section, we saw that each r.f. gives rise to a family of marginal distributions. Conversely, we seek conditions for a family \( F \) of finite joint distributions to be the family of marginal distributions of some r.f. We will presently show that a necessary condition is consistency, to be defined next. In the following chapters we will present various sufficient conditions on \( F \) for the construction of r.f.’s with \( F \) as the family of marginal distributions and with desired properties of sample functions.

**Definition 6.2.1.** (Consistent family of f.j.d.’s). Let \( Q \) be a set. Suppose, for each \( n \geq 1 \) and for each finite sequence \( t_1, \cdots, t_n \) in \( Q \), a distribution \( F_{(t_1),\cdots,(t_n)} \) is given on the locally compact metric space \((S^n, d^{(n)})\), which will be called a finite joint distribution, or f.j.d. for short. Then the indexed family
\[
F \equiv \{ F_{(t_1),\cdots,(t_n)} : n \geq 1 \text{ and } t_1, \cdots, t_n \in Q \}
\]
is said to be a consistent family of f.j.d.’s with parameter set \( Q \) and state space \( S \), if the following Kolmogorov consistency condition is satisfied.

Let \( n, m \geq 1 \) be arbitrary. Let \( t \equiv (t_1, \cdots, t_m) \) be an arbitrary sequence in \( Q \), and let \( i \equiv (i_1, \cdots, i_n) \) be an arbitrary sequence in \( \{1, \cdots, m\} \). Define the continuous function \( i^* : S^n \rightarrow S^m \) by
\[
i^*(x_1, \cdots, x_n) \equiv (x_{i_1}, \cdots, x_{i_n}) \tag{6.2.1}
\]
for each \( (x_1, \cdots, x_n) \in S^n \), and call \( i^* \) the dual function of the sequence \( i \). Then, for each \( f \in C_{ub}(S^n) \), we have
\[
F_{(t_1),\cdots,(t_n)}(f \circ i^*) = F_{(t_{i(1)}),\cdots,(t_{i(n)})}(f), \tag{6.2.2}
\]
or, in short,
\[
F_t(f \circ i^*) = F_{i^*(t)}(f).
\]

We will let \( \hat{F}(Q,S) \) denote the set of consistent families of f.j.d.’s with parameter set \( Q \) and state space \( S \). When there is little risk of confusion, we will call a consistent family of f.j.d.’s simply a consistent family. \( \square \)
Note that for an arbitrary \( f \in C_{ub}(S^m) \) we have \( f \circ i^* \in C_{ub}(S^m) \) and so \( f \circ i^* \) is integrable relative to \( F_{r(1),\ldots,r(m)} \). Hence the left-hand side of equality (6.2.2) makes sense.

When the parameter set is a countable discrete subset of \( \mathbb{R} \), we have the following proposition with a simple sufficient condition for the construction of a consistent family of f.j.d.’s.

First some notations.

**Definition 6.2.2. (Notations for sequences).** Given any sequence \( (a_1, \cdots, a_m) \) of objects, we will use the shorter notation \( a \) for the sequence. We will use the shorter notation \( \kappa \sigma \) for the composite of two functions \( \sigma : A \to B \) and \( \kappa : B \to C \). Separtately, for each \( m \geq n \geq 1 \), define the sequence
\[
\kappa \equiv \kappa_{n,m} : \{1, \cdots, m-1\} \to \{1, \cdots, m\}
\]
by
\[
\kappa \equiv (\kappa_1, \cdots, \kappa_{m-1}) \equiv (1, \cdots, \tilde{n}, \cdots, m) \equiv (1, \cdots, n-1, n+1, \cdots, m),
\]
where the caret on the top of an element in a sequence signifies the omission of that element. Let \( \kappa^* \equiv \kappa_{n,m}^* \), denote the dual function of sequence \( \kappa \). Thus
\[
\kappa^* x = \kappa^*(x_1, \cdots, x_m) \equiv x \kappa = (x_{\kappa(1)}, \cdots, x_{\kappa(m-1)}) = (x_1, \cdots, \tilde{x}_n, \cdots, x_m)
\]
for each \( x \equiv (x_1, \cdots, x_m) \in S^m \). In words, the function \( \kappa_{n,m}^* \) deletes the \( n \)-th entry of the sequence \( (x_1, \cdots, x_m) \).

**Lemma 6.2.3. (Consistency when parameter set is discrete subset of \( R \)).** Let \( (S,d) \) be a locally compact metric space. Let \( Q \) be an arbitrary metrically discrete subset of \( \mathbb{R} \). Suppose, for each \( m \geq 1 \) and nonincreasing sequence \( r \equiv (r_1, \cdots, r_m) \in Q \), a distribution \( F_{r(1),\ldots,r(m)} \) on \( (S^m,d^m) \) is given, such that
\[
F_{r(1),\ldots,r(n)-1,r(m)} f = F_{r(1),\ldots,r(m)} (f \circ \kappa_{n,m}^*), \tag{6.2.3}
\]
or, equivalently,
\[
F \circ \kappa_{n,m} f = F (f \circ \kappa_{n,m}^*), \tag{6.2.4}
\]
for each \( f \in C_{ub}(S^{m-1}) \), for each \( n = 1, \cdots, m \). Then the family
\[
F \equiv \{ F_{r(1),\ldots,r(n)} : n \geq 1; r_1 \leq \cdots \leq r_n \text{ in } Q \}
\]
of f.j.d.’s can be uniquely extended to a consistent family of f.j.d.’s
\[
F \equiv \{ F_{s(1),\ldots,s(m)} : m \geq 1; s_1, \cdots, s_m \in Q \} \tag{6.2.5}
\]
with parameter \( Q \).

**Proof.** 1. Let the integers \( m, n \), with \( m \geq n \geq 1 \), and the increasing sequence \( r \equiv (r_1, \cdots, r_m) \) in \( Q \) be arbitrary. Let \( r' \equiv (r'_1, \cdots, r'_n) \) be an arbitrary subsequence of \( r \).
Then \( m > h \equiv m - n \geq 0 \). Moreover, \( r' \) can be obtained by deleting \( h \) elements in the sequence \( r \). Specifically, \( r' = \kappa^* r = \kappa r \), where
\[
\kappa \equiv \kappa_n(h, m) \kappa_n(h-1, m-1) \cdots \kappa_n(1, m-h) : \{1, \ldots, m-h\} \rightarrow \{1, \ldots, m\}
\]
if \( h > 0 \), and where \( \kappa \) is the identity function if \( h = 0 \). Hence, by repeated application of equality [6.2.3] in the hypothesis, we obtain
\[
F_{r'} f = F_{r'} \kappa f = F_r (f \circ \kappa^*)
\]
for each \( f \in C(S^{m-h}) \).

2. Let the sequence \( s = (s_1, \ldots, s_p) \) in \( Q \) be arbitrary. Let \( r = (r_1, \ldots, r_m) \) be an arbitrary increasing sequence in \( Q \) such that \( s \) is a sequence in \( \{ r_1, \ldots, r_m \} \). Then, because the sequence \( r \) is increasing, there exists a unique function \( \sigma : \{1, \ldots, p\} \rightarrow \{1, \ldots, m\} \) such that \( s = r \sigma \). Let \( f \in C_{ub}(S^p, d^p) \) be arbitrary. Define
\[
F_{s(1), \ldots, s(p)} f \equiv F_{s} (f \circ \sigma^*)
\]
Equation 6.2.6

We will verify that \( F_{s} f \) is well defined. To that end, let \( r' = (r'_1, \ldots, r'_m) \) be a second increasing sequence in \( Q \) such that \( s \) is a sequence in \( \{ r'_1, \ldots, r'_m \} \), and let \( \sigma' : \{1, \ldots, p\} \rightarrow \{1, \ldots, m'\} \) be the corresponding function such that \( s = r' \sigma' \). We need to verify that \( F_{s} (f \circ \sigma^*) = F_{s} (f \circ \sigma'^*) \). To that end, let \( \tilde{r} = (r_1, \ldots, r_m) \) be an arbitrary supersequence of \( r \) and \( r' \). Then, \( s = r \sigma = \tilde{r} \kappa \sigma \), while \( s = r' \sigma' = \tilde{r} \kappa \sigma' \). Hence, by uniqueness, we have \( \kappa \sigma = \kappa' \sigma' \). Consequently,
\[
F_{r} (f \circ \sigma^*) = F_{r} (f \circ \sigma'^* \circ \kappa^*) = F_{r} (f \circ \sigma'^*) = F_{r} (f \circ \sigma'^*)
\]
This shows that \( F_{s} f \) is well defined in equality 6.2.6. The same equality says that \( F_{s} \) is the distribution induced by the r.v. \( \sigma^* : (S^m, C_{ub}(S^m, d^m), F_{r}) \rightarrow (S^p, d^p) \), where \( C_{ub}(S^m, d^m) \) stands for the completion of \( C(S^m, d^m) \) relative to the distribution \( F_r \). In particular, \( F_{s(1), \ldots, s(p)} \equiv F_{s} \) is a distribution.

3. Next, let \( s = (s_1, \ldots, s_q) \) be arbitrary sequence in \( Q \), and let \( (s(1), \ldots, s(q)) \) be an arbitrary subsequence of \( s \). Write \( i \equiv (i_1, \ldots, i_p) \). Let the increasing sequence \( r = (r_1, \ldots, r_m) \) be arbitrary such that \( s \) is a sequence in \( \{ r_1, \ldots, r_m \} \), and let \( \sigma : \{1, \ldots, q\} \rightarrow \{1, \ldots, m\} \) such that \( s = r \sigma \). Then \( si = r \sigma i \). Hence, for each \( f \in C_{ub}(S^p, d^p) \), we have
\[
F_{s} f \equiv F_{s} (f \circ \sigma^*) \equiv F_{s} (f \circ \sigma^*)
\]
Thus the family
\[
F \equiv \{ F_{s(1), \ldots, s(q)} : p \geq 1; s_1, \ldots, s_p \in Q \}
\]
of f.j.d.'s is consistent.

4. Lastly, let \( s = (s_1, \ldots, s_q) \) be arbitrary increasing sequence in \( Q \). Write \( r \equiv s \). Then \( s = r \sigma \) where \( \sigma : \{1, \ldots, q\} \rightarrow \{1, \ldots, q\} \) is the identity function. Hence
\[
F_{s(1), \ldots, s(q)} f \equiv F_{r(1), \ldots, r(q)} (f \circ \sigma^*) = F_{s(1), \ldots, s(q)} f
\]
for each \( f \in C_{ub}(S^q, d^q) \). In other words, \( F_{s(1), \ldots, s(q)} \equiv F_{s(1), \ldots, s(q)} \). Thus the family \( F \) is an extension of the family \( F \), and we can simply write \( F \) for \( F \). The lemma is proved. \( \square \)
The next lemma extends the consistency condition \([6.2.2]\) to integrable functions.

**Proposition 6.2.4.** (Consistency condition extends to integrable functions). Suppose the consistency condition \([6.2.2]\) holds for each \(f \in C_{ub}(S^n)\) and for the family \(F\) of j.d.'s. Then a real valued function \(f\) on \(S^n\) is integrable relative to \(F_{(t(1),\ldots,t(i(n)))}\) iff \(f \circ i^*\) is integrable relative to \(F_{(t(1),\ldots,t(m))}\), in which case condition \([6.2.2]\) holds for \(f\).

**Proof.** Since \(i^*: (S^m,d^{(m)}) \to (S^n,d^{(n)})\) is uniformly continuous, \(i^*\) is a r.v. on the completion of \((S^m,C(S^m),F_{(t(1),\ldots,t(m))})\) and has values in \(S^n\), whence it induces a distribution on \(S^n\). Equality \([6.2.2]\) then implies that the distribution thus induced is equal to \(F_{(t(1),\ldots,t(i(n)))}\). Therefore, according to Proposition \([5.2.6]\) a function \(f: S^n \to R\) is integrable relative to \(F_{(t(1),\ldots,t(i(n)))}\) iff \(f(i^*)\) is integrable relative to \(F_{(t(1),\ldots,t(m))}\), in which case

\[
F_{(t(1),\ldots,t(i(n)))}f = F_{(t(1),\ldots,t(m))}f(i^*) \equiv F_{(t(1),\ldots,t(m))}f \circ i^*.
\]

\[\square\]

**Proposition 6.2.5.** (Marginal distributions are consistent). Let \(X: Q \times \Omega \to S\) be a r.f. Then the family \(F\) of marginal distributions of \(X\) is consistent.

**Proof.** Let \(n,m \geq 1\) and \(f \in C_{ub}(S^n)\) be arbitrary. Let \(t = (t_1,\ldots,t_m)\) be an arbitrary sequence in \(Q\), and let \(i = (i_1,\ldots,i_n)\) be an arbitrary sequence in \(\{1,\ldots,m\}\). Using the defining equalities \([6.1.1]\) and \([6.2.1]\) we obtain

\[
F_{(t(1),\ldots,t(m))}(f \circ i^*) = E((f \circ i^*)(X_{t(1)},\ldots,X_{t(m)}))
\]

\[
= E(f(X_{t(i(1))},\ldots,X_{t(i(n))})) = F_{(t(1),\ldots,t(i(n)))}f.
\]

Thus the consistency condition \([6.2.2]\) holds.

\[\square\]

**Definition 6.2.6.** (Restriction to a subset of the parameter set). Let \((S,d)\) be a locally compact metric space. Recall that \(\hat{F}(Q,S)\) is the set of consistent families of j.d.'s with parameter set \(Q\) and state space \(S\). Let \(Q'\) be any subset of \(Q\). For each \(F \in \hat{F}(Q,S)\) define

\[
F|Q' = \Phi_{Q'|Q}(F) = \{F_{(s(1),\ldots,s(n))}: n \geq 1; s_1,\ldots,s_n \in Q'\}
\]

and call \(F|Q'\) the restriction of the consistent family \(F\) to \(Q'\). The function

\[
\Phi_{Q'|Q}: \hat{F}(Q,S) \to \hat{F}(Q',S)
\]

will be called the restriction mapping of consistent families with parameter set \(Q\) to consistent families with parameter set \(Q'\).

Let \(\hat{F}_0 \subset \hat{F}(Q,S)\) be arbitrary. Denote its image under the mapping \(\Phi_{Q'|Q}\) by

\[
\hat{F}_0|Q' = \Phi_{Q'|Q}(\hat{F}_0) = \{F|Q': F \in \hat{F}_0\},
\]

and call \(\hat{F}_0|Q'\) the restriction of the set \(\hat{F}_0\) of consistent families to \(Q'\).

\[\square\]

We next introduce a metric on the set \(\hat{F}(Q,S)\) when \(Q\) is countably infinite.

Yuen-Kwok Chan 203 Constructive Probability
Definition 6.2.7. (Marginal metric on set of consistent families of f.j.d.’s with countably infinite parameter set). Let \((S, d)\) be a locally compact metric space, with a binary approximation \(\xi\) relative to some fixed reference point \(x_0\). Let \(n \geq 1\) be arbitrary. Recall that \(\xi^n\) is the \(n\)-th power of \(\xi\), and is a binary approximation of \((S^n, d^n)\) relative to \(x_0^{(n)} = (x_0, \ldots, x_0) \in S^n\), as in Definition 5.3.4. Recall from Definition 5.3.5 that sequential convergence relative to \(\rho_{\text{Dist}, \xi^n}\) on the set of distributions on \((S^n, d^n)\), and, from Proposition 5.3.5, that sequential convergence relative to \(\rho_{\text{Dist}, \xi^n}\) is equivalent to weak convergence.

Let \(Q \equiv \{t_1, t_2, \ldots\}\) be an enumerated, countably infinite, parameter set. Recall that \(\hat{F}(Q, S)\) is the set of consistent families of f.j.d.’s with parameter set \(Q\) and state space \(S\). Define a metric \(\hat{\rho}_{\text{Marg}, \xi, Q}\) on \(\hat{F}(Q, S)\) by

\[
\hat{\rho}_{\text{Marg}, \xi}(F, F') \equiv \hat{\rho}_{\text{Marg}, \xi, Q}(F, F') \equiv \sum_{n=1}^{\infty} 2^{-n} \rho_{\text{Dist}, \xi^n}(F_t(1), \ldots, F_t(n), F'_t(1), \ldots, F'_t(n))
\]  

(6.2.9)

for each \(F, F' \in \hat{F}(Q, S)\). The next lemma proves that \(\hat{\rho}_{\text{Marg}, \xi}\) metric on families of f.j.d.’s with countable parameters is indeed a metric. We will call \(\hat{\rho}_{\text{Marg}, \xi}\) the marginal metric for the set \(\hat{F}(Q, S)\) of consistent families of f.j.d.’s, relative to the binary approximation \(\xi\) of the locally compact state space \((S, d)\). Note that \(\hat{\rho}_{\text{Marg}, \xi} \leq 1\) because \(\rho_{\text{Dist}, \xi^n} \leq 1\) for each \(n \geq 1\). We emphasize that the metric \(\hat{\rho}_{\text{Marg}, \xi, Q}\) depends on the ordering in the enumerated set \(Q\). Two different enumeration leads to two different metrics, which are however equivalent. We drop the subscript \(Q\) when it is understood from context.

As observed above, sequential convergence relative to \(\rho_{\text{Dist}, \xi^n}\) is equivalent to weak convergence of distributions on \((S^n, d^n)\), for each \(n \geq 1\). Hence, for each sequence \((F(m))_{m=0,1,2,\ldots} \in \hat{F}(Q, S)\), we have \(\hat{\rho}_{\text{Marg}, \xi}(F(m), F(0)) \rightarrow 0\) iff \(F(m)_{t(1), \ldots, t(n)} \Rightarrow F(0)_{t(1), \ldots, t(n)}\) as \(m \rightarrow \infty\), for each \(n \geq 1\).

\[\Box\]

Lemma 6.2.8. The marginal metric \(\hat{\rho}_{\text{Marg}, \xi} \equiv \hat{\rho}_{\text{Marg}, \xi, Q}\) defined in Definition 6.2.7 is indeed a metric.

Proof. 1. Symmetry and triangle inequality for \(\hat{\rho}_{\text{Marg}, \xi}\) follow from their respective counterparts for \(\rho_{\text{Dist}, \xi^n}\) for each \(n \geq 1\) in the defining equality 6.2.9.

2. Suppose \(F = F'\). Then each summand in the right-hand side of equality 6.2.9 vanishes. Consequently \(\hat{\rho}_{\text{Marg}, \xi}(F, F') = 0\). Conversely, suppose \(F, F' \in \hat{F}(Q, S)\) are such that \(\hat{\rho}_{\text{Marg}, \xi}(F, F') = 0\). For each \(n \geq 1\), the defining equality 6.2.9 implies that \(\rho_{\text{Dist}, \xi^n}(F_{t(1), \ldots, t(n)}, F'_{t(1), \ldots, t(n)}) = 0\). Hence, since \(\rho_{\text{Dist}, \xi^n}\) is a metric, we have \(F_{t(1), \ldots, t(n)} = F'_{t(1), \ldots, t(n)}\), for each \(n \geq 1\). Now let \(m \geq 1\) and \(s_1, \ldots, s_m \in Q\) be arbitrary. Then there exists \(n \geq 1\) so large that \(s_k = t_{i(k)}\) for some \(i_k \in \{1, \ldots, n\}\), for each \(k = 1, \ldots, m\). By the consistency condition 6.2.2

\[F_{s(1), \ldots, s(m)} f = F_{t(i(1)), \ldots, t(i(m))} f = F_{t(i(1)), \ldots, t(i(m))}(f \circ F_t^n) = F'_{t(i(1)), \ldots, t(i(m))} f = F'_{s(1), \ldots, s(m)} f\]

for each \(f \in C_{ab}(S^n)\). We thus see that \(F_{s(1), \ldots, s(m)} = F'_{s(1), \ldots, s(m)}\) as distributions on \(S^n\) for each \(s_1, \ldots, s_m \in Q\). In other words, \(F = F'\). Summing up, \(\hat{\rho}_{\text{Marg}, \xi}\) is a metric. \[\Box\]
6.2. CONSISTENT FAMILY OF FINITE JOINT DISTRIBUTIONS

Definition 6.2.9. (Continuity in probability of consistent families). Let $(S,d)$ be a locally compact metric space. Write $\hat{d} = 1 \wedge d$. Let $(Q,d_Q)$ be a metric space. Recall that $\hat{F}(Q,S)$ is the set of consistent families of f.j.d.'s with parameter space $Q$ and state space $(S,d)$. Let $F \in \hat{F}(Q,S)$ be arbitrary.

1. Suppose $(Q,d_Q)$ is bounded. Suppose, for each $\varepsilon > 0$, there exists $\delta_{CP}(\varepsilon) > 0$ such that

$$F_{fjd} \leq \varepsilon$$

for each $s,t \in Q$ with $d_Q(s,t) < \delta_{CP}(\varepsilon)$. Then the consistent family $F$ of f.j.d.'s is said to be \textit{continuous in probability}, with $\delta_{CP}$ as a \textit{modulus of continuity in probability}.

2. More generally, let the metric space $(Q,d_Q)$ be arbitrary, not necessarily bounded. Then the consistent family $F$ of f.j.d.'s is said to be \textit{continuous in probability} if, for each bounded subset $K$ of $Q$, the restricted consistent family $F|K$ is continuous in probability. We will let $\hat{F}_{CP}(Q,S)$ denote the subset of $\hat{F}(Q,S)$ whose members are continuous in probability. □

Lemma 6.2.10. (Continuity in probability extends to f.j.d.'s of higher dimensions). Let $(S,d)$ be a locally compact metric space. Let $(Q,d_Q)$ be a bounded metric space. Suppose the consistent family $F$ of f.j.d.'s with state space $S$ and parameter space $Q$ is continuous in probability, with a modulus of continuity $\delta_{CP}$.

Let $m \geq 1$ be arbitrary. Let $f \in C_{ub}(S^m,d^m)$ be arbitrary with a modulus of continuity $\delta_f$ and with $|f| \leq 1$. Let and $\varepsilon > 0$ be arbitrary. Then there exists $\delta_{f,jd}(\varepsilon,m,\delta_f,\delta_{CP}) > 0$ such that, for each $s_1, \cdots, s_m, t_1, \cdots, t_m \in Q$ with

$$\bigvee_{k=1}^m d_Q(s_k,t_k) < \delta_{f,jd}(\varepsilon,m,\delta_f,\delta_{CP}),$$

(6.2.10)

we have

$$|F(s_1,\cdots,s(m))f - F(t_1,\cdots,t(m))f| \leq \varepsilon.$$  

(6.2.11)

Proof. Let $m \geq 1$ and $f \in C_{ub}(S^m,d^m)$ be as given. Write

$$\alpha \equiv \frac{1}{8}m^{-1}\varepsilon(1 + \delta_f(\frac{\varepsilon}{2}))$$

and define

$$\delta_{f,jd}(\varepsilon,m,\delta_f,\delta_{CP}) \equiv \delta_{CP}(\alpha).$$

Suppose $s_1, \cdots, s_m, t_1, \cdots, t_m \in Q$ satisfy inequality (6.2.10) Then

$$\bigvee_{k=1}^m d_Q(s_k,t_k) < \delta_{CP}(\alpha).$$

(6.2.12)

Let $i \equiv (1, \cdots, m)$ and $j \equiv (m+1, \cdots, 2m)$. Thus $i$ and $j$ are sequences in $\{1, \cdots, 2m\}$. Let $x \in S^{2m}$ be arbitrary. Then

$$(f \circ i^*)(x_1,\cdots,x_{2m}) \equiv f(x_{i(1)},\cdots,x_{i(m)}) = f(x_1,\cdots,x_m)$$

and

$$(f \circ j^*)(x_1,\cdots,x_{2m}) \equiv f(x_{j(1)},\cdots,x_{j(m)}) = f(x_{m+1},\cdots,x_{2m}),$$

Yuen-Kwok Chan 205 Constructive Probability
Chap 6. Random Fields and Stochastic Processes

where $i^*, j^*$ are as defined in Definition 6.2.1 relative to $i, j$ respectively. Consider each $k = 1, \ldots, m$. Let $h \equiv (k, m + k)$. Thus $h$ is a sequence in $\{1, \ldots, 2m\}$. Let

$$(r_1, \ldots, r_{2m}) \equiv (s_1, \ldots, s_m, t_1, \ldots, t_m).$$

Then

$$F_{r(1), \ldots, r(2m)}(\tilde{d} \circ h^*) = F_{r(h(1)), r(h(2))}\tilde{d} = F_{r(k), r(m+k)}\tilde{d} \leq \alpha,$$

where the inequality follows from inequality 6.2.12 in view of the definition of $\delta_{C_p}$ as a modulus of continuity in probability of the family $F$. Now take any

$$\delta_0 \in \left(\frac{1}{2}(1 \wedge \delta_f(\frac{\varepsilon}{2})), 1 \wedge \delta_f(\frac{\varepsilon}{2})\right).$$

Let

$$A_k \equiv \{x \in \mathcal{S}^{2m} : \tilde{d}(x_k, x_{m+k}) > \delta_0\} = (\tilde{d} \circ h^* > \delta_0) \subset \mathcal{S}^{2m}.$$ 

In view of inequality 6.2.13 Chebychev’s inequality yields

$$F_{r(1), \ldots, r(2m)}(A_k) = F_{r(1), \ldots, r(2m)}(\tilde{d} \circ h^* > \delta_0) < \delta_0^{-1} \alpha < 2(1 \wedge \delta_f(\frac{\varepsilon}{2}))^{-1} = \frac{1}{4}m^{-1}\varepsilon\alpha^{-1} = \frac{1}{4}m^{-1}\varepsilon.$$

Let $A \equiv \bigcup_{k=1}^{m} A_k \subset \mathcal{S}^{2m}$. Then

$$F_{r(1), \ldots, r(2m)}(A) \leq \sum_{k=1}^{m} F_{r(1), \ldots, r(2m)}(A_k) \leq \frac{1}{4}\varepsilon.$$

Now consider each $x \in A^c$. We have

$$1 \wedge d(x_k, x_{m+k}) \equiv \tilde{d}(x_k, x_{m+k}) \leq \delta_0 < 1$$

for each $k = 1, \ldots, m$, whence

$$d^m((x_1, \ldots, x_m), (x_{m+1}, \ldots, x_{2m})) \equiv \bigvee_{k=1}^{m} d(x_k, x_{m+k}) \leq \delta_0 < \delta_f(\frac{\varepsilon}{2}).$$

Consequently

$$|(f \circ i^*)(x) - (f \circ j^*)(x)| = |f(x_1, \ldots, x_m) - f(x_{m+1}, \ldots, x_{2m})| < \frac{\varepsilon}{2}$$

for each $x \in A^c$. By hypothesis, $|f| \leq 1$. Hence

$$|F_{r(1), \ldots, r(m)}f - F_{r(1), \ldots, r(n)}f| = |F_{r(i(1)), \ldots, r(i(n))}f - F_{r(j(1)), \ldots, r(j(n))}f|$$

$$= |F_{r(1), \ldots, r(2m)}(f \circ i^*) - F_{r(1), \ldots, r(2m)}(f \circ j^*)|$$

$$= |F_{r(1), \ldots, r(2m)}(f \circ i^* - f \circ j^*)|$$

$$\leq \frac{\varepsilon}{2}F_{r(1), \ldots, r(2m)}(A^c) + 2F_{r(1), \ldots, r(2m)}(A)$$

$$\leq \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.$$

as desired.

\[\square\]
Definition 6.2.11. (Metric space of consistent families which are continuous in probability). Let \((S,d)\) be a locally compact metric space, with a reference point \(x_0 \in S\) and a binary approximation \(\xi \equiv (A_n)_{n=1,2,\ldots}\) relative to \(x_0\). Let \((Q,d_Q)\) be a locally compact metric space. Let \(Q_\infty \equiv \{q_1,q_2,\cdots\}\) be an arbitrary enumerated, countably infinite, and dense subset of \(Q\).

Recall that \(\hat{F}(Q,S)\) is the set of consistent families of f.j.d.'s with parameter set \(Q\) and state space \(S\). Let \(\hat{F}_c(Q,S)\) denote the subset of \(\hat{F}(Q,S)\) whose members are continuous in probability.

Relative to the countably infinite parameter subset \(Q_\infty\) and the binary approximation \(\xi\), define a metric \(\hat{\rho}_{C_P,\xi,Q,Q_\infty}\) on \(\hat{F}_c(Q,S)\) by

\[
\hat{\rho}_{C_P,\xi,Q,Q_\infty}(F,F') \equiv \hat{\rho}_{\text{Marg},\xi,Q,Q_\infty}(F|Q_\infty,F'|Q_\infty) \\
= \sum_{n=1}^{\infty} 2^{-n} p_{\text{Dist},\xi^n}(F_q(1),\ldots,q(n)\rightarrow F'_q(1),\ldots,q(n))
\]

(6.2.16) for each \(F,F' \in \hat{F}_c(Q,S)\), where \(\hat{\rho}_{\text{Marg},\xi,Q,Q_\infty}\) is the marginal metric on \(\hat{F}(Q_\infty,S)\) introduced in Definition 6.2.7. In other words,

\[
\hat{\rho}_{C_P,\xi,Q,Q_\infty}(F,F') \equiv \hat{\rho}_{\text{Marg},\xi,Q,Q_\infty}(\Phi_{Q,Q_\infty}(F),\Phi_{Q,Q_\infty}(F'))
\]

for each \(F,F' \in \hat{F}_c(Q,S)\). The next lemma shows that \(\hat{\rho}_{C_P,\xi,Q,Q_\infty}\) is indeed a metric.

Then, trivially, the mapping

\[
\Phi_{Q,Q_\infty} : (\hat{F}_c(Q,S),\hat{\rho}_{C_P,\xi,Q,Q_\infty}) \rightarrow (\hat{F}_c(Q_\infty,S),\hat{\rho}_{\text{Marg},\xi,Q,Q_\infty})
\]

is an isometry. Note that \(0 \leq \hat{\rho}_{C_P,\xi,Q,Q_\infty} \leq 1\).

**Lemma 6.2.12.** The function \(\hat{\rho}_{C_P,\xi,Q,Q_\infty}\) defined in Definition 6.2.7 is a metric on \(\hat{F}_c(Q,S)\).

**Proof.** Suppose \(F,F' \in \hat{F}_c(Q,S)\) are such that \(\hat{\rho}_{C_P,\xi,Q,Q_\infty}(F,F') = 0\). By the defining equality (6.2.15), we have \(\hat{\rho}_{\text{Marg},\xi,Q,Q_\infty}(F|Q_\infty,F'|Q_\infty) = 0\). Hence, since \(\hat{\rho}_{\text{Marg},\xi,Q,Q_\infty}\) is a metric on \(\hat{F}(Q_\infty,S)\), we have \(F|Q_\infty = F'|Q_\infty\). In other words,

\[
F_q(1),\ldots,q(n) = F'_q(1),\ldots,q(n)
\]

for each \(n \geq 1\). Hence, for each \(m \geq 1\) and each \(s_1,\ldots,s_m \in Q_\infty\), we can let \(n \geq 1\) be so large that \(\{s_1,\ldots,s_m\} \subset \{q_1,\ldots,q_n\}\) and obtain, consistency of \(F\),

\[
F_s(1),\ldots,s(m) = F'_s(1),\ldots,s(m)
\]

(6.2.16)

Now let \(m \geq 1\) and \(t_1,\ldots,t_m \in Q\) be arbitrary. Let \(f \in C(S^m)\) be arbitrary. For each \(i = 1,\ldots,m\), let \((a_i^{(p)})_{p=1,2,\ldots}\) be a sequence in \(Q_\infty\) with \(d_Q(a_i^{(p)},r_i) \rightarrow 0\) as \(p \rightarrow \infty\). Then there exists a bounded subset \(K \subset Q\) such that \((t_1,\ldots,t_m)\) and \((a_i^{(p)})_{p=1,2,\ldots,j=1,\ldots,m}\) are in \(K\). Since \(F|K\) is continuous in probability, we have, by Lemma 6.2.10

\[
F_s(1),\ldots,s(m) \rightarrow F_{t(1),\ldots,t(m)}f
\]
where we write $s(p,i) = s_{j(p)}^i$ to lessen the burden on subscripts. Similarly,

$$F_{s(p,1),\ldots,s(p,m)}'f \to F_{t(1),\ldots,t(m)}'f,$$

On the other hand

$$F_{s(p,1),\ldots,s(p,m)}f = F_{s(p,1),\ldots,s(p,m)}'f$$

in view of equality 6.2.16. Combining,

$$F_{t(1),\ldots,t(m)}f = F_{t(1),\ldots,t(m)}'f.$$

We conclude that $F = F'$.

Conversely, suppose $F = F'$. Then trivially $\hat{\rho}_{C_p,\xi, Q|Q|}(F,F') = 0$ from equality 6.2.15. The triangle inequality and symmetry of $\hat{\rho}_{C_p,\xi, Q|Q|}$ follow from equality 6.2.15 and from the fact that $\rho_{Dist,\xi^n}$ is a metric for each $n \geq 1$. Summing up, $\hat{\rho}_{C_p,\xi, Q|Q|}$ is a metric.

### 6.3 Daniell-Kolmogorov Extension

In this and the next section, let $Q \equiv \{t_1,t_2,\cdots\}$ denote a countable parameter set. For simplicity of presentation, and without loss of generality, we will assume that $t_n = n$ for each $n \geq 1$. Thus

$$Q \equiv \{t_1,t_2,\cdots\} \equiv \{1,2,\cdots\}.$$

However we state the theorems in terms of a more general countable set $Q \equiv \{t_1,t_2,\cdots\}$, for ease of later reference when more structure on the set $Q$ is introduced, when, for example, the set $Q$ is the set of dyadic rationals in $[0,\infty)$.

Recall that $\hat{F}(Q,S)$ is the set of consistent families of f.j.d.’s with parameter set $Q$ and the locally compact state space $(S,d)$. We will prove the Daniell-Kolmogorov Extension Theorem, which constructs, for each member $F \in \hat{F}(Q,S)$, a probability space $(S^n,L,E)$ and a r.f. $U : Q \times (S^n,L,E) \to S$ with marginal distributions given by $F$.

Furthermore, we will prove the uniform metrical continuity of the Daniell-Kolmogorov Extension, with a modulus of continuity dependent only on a modulus of local compactness $||\xi||$ of $(S,d)$. Said metrical continuity implies continuity relative to weak convergence.

Recall that $\lfloor \cdot \rfloor_1$ is an operation which assigns to each $c \geq 0$ an integer $\lfloor c \rfloor_1$ in the interval $(c,c+2)$. As usual, for arbitrary symbols $a$ and $b$, we will write $a_b$ and $a(b)$ interchangeable.

**Definition 6.3.1.** (Path space, coordinate function, and distributions on path space). Let $S^Q \equiv \prod_{t \in Q} S$ denote the space of functions from $Q$ to $S$, called the path space. Relative to the enumerated set $Q$, define a complete metric $d^Q$ on $S^Q$, by

$$d^Q(x,y) \equiv \sum_{i=0}^{\infty} 2^{-i}(1 \land d(x_{t(i)}, y_{t(i)}))$$

Yuen-Kwok Chan 208 Constructive Probability
for arbitrary \( x, y \in S^0 \). Define the function \( U : Q \times S^0 \rightarrow S \) by \( U(r, v) \equiv v_r \) for each \((r, v) \in Q \times S^0\). The function \( U \) is called the coordinate function \( Q \times S^0 \). Note that \( d^Q \leq 1 \) and that \((S^0, d^Q)\) is compact if \((S, d)\) is compact.

Conforming to usage in Definition 6.2.1, we will let \( \hat{f}(S^0, d^Q) \) denote the set of distributions on the complete path space \((S^0, d^Q)\).

\[ \square \]

**Theorem 6.3.2. (Compact Daniell-Kolmogorov Extension).** Suppose the metric space \((S, d)\) is compact. Then there exists a function

\[ \mathfrak{T}_{DK} : \hat{f}(Q, S) \rightarrow \hat{f}(S^0, d^Q) \]

such that, for each consistent family of f.d.'s \( F \in \hat{f}(Q, S) \), the distribution \( E \equiv \mathfrak{T}_{DK}(F) \) satisfies the conditions (i) the coordinate function

\[ U : Q \times (S^0, L, E) \rightarrow (S, d) \]

is a r.f., where \( L \) is the completion of \( C(S^0, d^Q) \) relative to the distribution \( E \), and (ii) the r.f. \( U \) has marginal distributions given by the family \( F \).

The function \( \mathfrak{T}_{DK} \) will be called the Compact Daniell-Kolmogorov Extension.

**Proof.** Note that, since \((S, d)\) is compact by hypothesis, its countably infinite power \((S^0, d^Q) = (S^\omega, d^\omega)\) is compact.

1. Consider each \( F = \{ F_1, \ldots, F_k : k \geq 1 \} \in \hat{f}(Q, S) \). Let \( f \in C(S^\omega, d^\omega) \) be arbitrary, with a modulus of continuity \( \delta_f \). For each \( n \geq 1 \), define the function \( f_n \in C(S^\omega, d^\omega) \) by

\[ f_n(x_1, x_2, \ldots, x_n) \equiv f(x_1, x_2, \ldots, x_n, x_0, \ldots) \quad (6.3.1) \]

for each \((x_1, x_2, \ldots, x_n) \in S^\omega\). Consider each \( m \geq n \geq 1 \) so large that \( 2^{-n} < \delta_f(\varepsilon) \).

Define the function \( f_{n,m} \in C(S^\omega, d^\omega) \) by

\[ f_{n,m}(x_1, x_2, \ldots, x_m) \equiv f_n(x_1, x_2, \ldots, x_n) \equiv f(x_1, x_2, \ldots, x_n, x_0, \ldots) \quad (6.3.2) \]

for each \((x_1, x_2, \ldots, x_m) \in S^\omega\). Consider the initial-section subsequence \( i \equiv (i_1, \ldots, i_n) \equiv (1, \ldots, n) \) of the sequence \((1, \ldots, m)\). Let \( i^* : S^m \rightarrow S^\omega \) be the dual of the sequence \( i \), as in Definition 6.2.1. Then, for each \((x_1, \ldots, x_m) \in S^m\), we have

\[ f_{n,m}(x_1, x_2, \ldots, x_m) \equiv f_n(x_1, x_2, \ldots, x_n) = f_n(x_{i(1)}, x_{i(2)}, \ldots, x_{i(n)}) = f_n \circ i^*(x_1, x_2, \ldots, x_m) \]

In short,

\[ f_{n,m} = f_n \circ i^* \]

whence, by the consistency of the family \( F \) of f.d.'s, we obtain

\[ F_1, \ldots, m f_{n,m} = F_1, \ldots, m f_n \circ i^* = F_{i(1), \ldots, i(n)} f_n = F_{1, \ldots, n} f_n. \quad (6.3.3) \]

At the same time,

\[ d^\omega((x_1, x_2, \ldots, x_m, x_0, \ldots), (x_1, x_2, \ldots, x_n, x_0, \ldots)) \]

Yuen-Kwok Chan 209 Constructive Probability
for each \((x_1, x_2, \cdots, x_m) \in S^m\). Hence

\[
[f_m(x_1, x_2, \cdots, x_m) - f_{n,m}(x_1, x_2, \cdots, x_m)]
\]

for each \((x_1, x_2, \cdots, x_m) \in S^m\). Consequently, \(|F_{1,\ldots,n}f_m - F_{1,\ldots,n}f_n| \leq \varepsilon\). Combined with equality \(6.3.3\) this yields

\[
|F_{1,\ldots,n}f_m - F_{1,\ldots,n}f_n| \leq \varepsilon, \quad (6.3.4)
\]

where \(m \geq n \geq 1\) are arbitrary with \(2^{-n} < \delta_f(\varepsilon)\). Thus we see that the sequence \((F_{1,\ldots,n}f_n)_{n=1,2,\ldots}\) of real numbers is Cauchy, and has a limit. Define

\[
Ef \equiv \lim_{n \to \infty} F_{1,\ldots,n}f_n. \quad (6.3.5)
\]

Letting \(m \to \infty\) in inequality \(6.3.4\) we obtain

\[
|Ef - F_{1,\ldots,n}f_n| \leq \varepsilon, \quad (6.3.6)
\]

where \(n \geq 1\) is arbitrary with \(2^{-n} < \delta_f(\varepsilon)\).

3. We proceed to prove that \(E\) is an integration on the compact metric space \((S^m, d^m)\) in the sense of Definition \([4.2.1]\). We will first verify that the function \(E\) is linear. To that end, let \(f, g \in C(S^m, d^m)\) and \(a, b \in \mathbb{R}\) be arbitrary. For each \(n \geq 1\), define the function \(f_n\) relative to \(f\) as in equality \(6.3.1\). Similarly define the functions \(g_n, (af + bg)_n\) relative to the functions \(g, af + bg\) respectively. Then the defining equality \(6.3.1\) implies that \((af + bg)_n = af_n + bg_n\) for each \(n \geq 1\). Hence

\[
E(af + bg) \equiv \lim_{n \to \infty} F_{1,\ldots,n}(af + bg)_n = \lim_{n \to \infty} F_{1,\ldots,n}(af_n + bg_n)
\]

\[
= a \lim_{n \to \infty} F_{1,\ldots,n}f_n + b \lim_{n \to \infty} F_{1,\ldots,n}g_n, \equiv aEf + bEg. \quad \text{(6.3.7)}
\]

Thus \(E\) is a linear function. Moreover, in the special case where \(f \equiv 1\), we have

\[
Ef \equiv \lim_{n \to \infty} F_{1,\ldots,n}f_n = \lim_{n \to \infty} F_{1,\ldots,n}1 = 1 > 0. \quad (6.3.8)
\]

Inequality \(6.3.7\) immediately shows that the triple \((S^m, C(S^m, d^m), E)\) satisfies Condition (i) of Definition \([4.2.1]\). It remains to verify also Condition (ii), the positivity condition, of Definition \([4.2.1]\). To that end, let \(f \in C(S^m, d^m)\) be arbitrary with \(Ef > 0\). Then, by equality \(6.3.3\) we have \(F_{1,\ldots,n}f_n > 0\) for some \(n \geq 1\). Hence, since \(F_{1,\ldots,n}\) is a distribution, there exists \((x_1, x_2, \cdots, x_n) \in S^n\) such that \(f_n(x_1, x_2, \cdots, x_n) > 0\). Therefore

\[
f(x_1, x_2, \cdots, x_n, x_0, \cdots) \equiv f_n(x_1, x_2, \cdots, x_n) > 0.
\]
Thus the positivity condition is also verified. Accordingly, \( E \) is an integration on the compact metric space \((S^\infty, d^\infty)\).

4. Since the compact metric space \((S^\infty, d^\infty)\) is bounded, and since \(E1 = 1\), Lemma 3.2.2 implies that \(E\) is a distribution on \((S^\infty, d^\infty)\), and that the completion \((S^\infty, L, E)\) of the integration space \((S^\infty, C(S^\infty, d^\infty), E)\) is a probability space. In symbols, \(E \in \hat{I}(S^\infty, d^\infty)\). Define \(\mathcal{F}_{DK}(F) \equiv E\). Thus we have constructed the function \(\hat{F}(Q, S) \rightarrow \hat{I}(S^\infty, d^\infty)\).

5. It remains to show that the coordinate function \(U : Q \times (S^\infty, L, E) \rightarrow S\) is a r.f. with marginal distributions given by the family \(F\). To that end, let \(m \geq n \geq 1\) and \(g \in C(S^\infty, d^\infty)\) be arbitrary. Define a function \(f \in C(S^\infty, d^\infty)\) by

\[
f(x_1, x_2, \cdots) \equiv g(x_1, \cdots, x_n)
\]

for each \(x \equiv (x_1, x_2, \cdots) \in S^\infty\), and define the function \(f_m\) relative to \(f\) as in equality 6.3.1. Thus

\[
f_m(x_1, x_2, \cdots, x_m) \equiv f(x_1, x_2, \cdots, x_m, x_{m+1}, x_{m+2}, \cdots) \equiv g(x_1, \cdots, x_n),
\]

for each \((x_1, x_2, \cdots, x_m) \in S^m\). Consequently,

\[
f_m(x_1, x_2, \cdots, x_m) = g(x_1, \cdots, x_n) = f_n(x_1, x_2, \cdots, x_n) = f_n \circ i^*(x_1, x_2, \cdots, x_m)
\]

for each \((x_1, x_2, \cdots, x_m) \in S^m\), where \(i \equiv (i_1, \cdots, i_n) \equiv (1, \cdots, n)\) is the initial-section subsequence of the sequence \((1, \cdots, m)\), and where \(i^* : S^m \rightarrow S^n\) be is the dual of the sequence \(i\). In short, \(f_m = f_n \circ i^*\). At the same time,

\[
g(U_1, \cdots, U_n)(x) \equiv g(U_1(x), \cdots, U_n(x)) = g(x_1, \cdots, x_n) = f(x)
\]

for each \(x \equiv (x_1, x_2, \cdots) \in S^\infty\). In short, \(g(U_1, \cdots, U_n) = f\). Combining,

\[
E_g(U_1, \cdots, U_n) = Ef \equiv \lim_{m \rightarrow \infty} F_1, \cdots, m f_m = \lim_{m \rightarrow \infty} F_1, \cdots, m f_n \circ i^* = F_1, \cdots, n f_n = F_1, \cdots, n g,
\]

where \(n \geq 1\) and \(g \in C(S^\infty, d^\infty)\) are arbitrary, and where the fourth equality is by the consistency of the family \(F\) of f.j.d.’s. Equality 6.3.10 implies that \((U_1, \cdots, U_n)\) is a r.v. on the sample space \((S^\infty, L, E)\), with values in \((S^\infty, d^\infty)\) and with distribution \(F_1, \cdots, n\). It follows that \(U_n\) is a r.v. on the sample space \((S^\infty, L, E)\), with values in \(S\), where \(n \geq 1\) is arbitrary. Summing up, we conclude that the coordinate function

\[
U : Q \times (S^\infty, L, E) \rightarrow S
\]

is a r.f. Equality 6.3.10 says that \(U\) has marginal distributions given by the family \(F\). The theorem is proved.

We proceed to prove the continuity of the Compact Daniell-Kolmogorov Extension relative to the two metrics specified next.

**Definition 6.3.3.** (Specification of binary approximation of state space, and related marginal metric on the set of consistent families of f.j.d.’s). Let \(\xi \equiv (A_k)_{k=1,2}\) be an arbitrary binary approximation of the locally compact state space \((S, d)\) relative to
the reference point \( x_0 \), in the sense of Definition \[5.1.1\]. Recall that \( \tilde{F}(Q,S) \) is then equipped with the marginal metric \( \hat{\rho}_{\text{Marg},\xi,Q} \) defined relative to \( \xi \) in Definition \[6.2.7\] and that sequential convergence relative to this metric \( \hat{\rho}_{\text{Marg},\xi,Q} \) is equivalent to weak convergence of corresponding sequences of f.j.d.’s.

\[\square\]

**Definition 6.3.4.** (Specification of binary approximation of compact path space, and distribution metric on the set of distributions on said path space). Suppose the state space \( (S,d) \) is compact. Let \( \xi \equiv (A_k)_{k=1,2} \) be an arbitrary binary approximation of \( (S,d) \) relative to the reference point \( x_0 \). Recall that, since the metric space \( (S^\infty,d^e) \) is compact, the countable power \( \xi^\infty \equiv (B_k)_{k=1,2} \) of \( \xi \) is defined and is a binary approximation of \( (S^\infty,d^e) \), according to Definition \[3.1.6\] and Lemma \[5.1.7\]. Recall that, since \( (S,d) \) is compact by assumption, the set \( \hat{J}(S^\infty,d^e) \) of distributions is equipped with the distribution metric \( \hat{\rho}_{\text{Dist},\xi^\infty} \), defined relative to \( \xi^\infty \) in Definition \[5.3.4\] and that sequential convergence relative to this metric \( \hat{\rho}_{\text{Dist},\xi^\infty} \) is equivalent to weak convergence. Note that the metric \( \hat{\rho}_{\text{Dist},\xi^\infty} \) is defined only when the state space \( (S,d) \) is compact. Write \( \hat{\rho}_{\text{Dist},\xi^\infty} \equiv \hat{\rho}_{\text{Dist},\xi^\infty} \).

**Theorem 6.3.5.** (Continuity of the Compact Daniell-Kolmogorov Extension). Suppose \( (S,d) \) is compact. Let \( \xi \equiv (A_k)_{k=1,2} \) be an arbitrary binary approximation of \( (S,d) \) relative to the reference point \( x_0 \). Then the Compact Daniell-Kolmogorov Extension

\[ \mathcal{F}_\text{DK} : (\tilde{F}(Q,S),\hat{\rho}_{\text{Marg},\xi,Q}) \rightarrow (\hat{J}(S^\infty,d^e),\hat{\rho}_{\text{Dist},\xi^\infty}) \]

constructed in Theorem \[6.3.2\] is uniformly continuous, with modulus of continuity \( \hat{\delta}_\text{DK}(\cdot,\|\xi\|) \) dependent only on the modulus of local compactness \( \|\xi\| \equiv (|A_k|)_{k=1,2} \) of the compact metric space \( (S,d) \).

**Proof.** 1. Let \( \epsilon \in (0,1) \) be arbitrary. For abbreviation, write \( c \equiv 2^4 \epsilon^{-1} \) and \( \alpha \equiv 2^{-1} \epsilon \). Let \( m \equiv \lceil \log_2 (2\epsilon^{-1}) \rceil \). Define the operation \( \delta_\epsilon \) by

\[ \delta_\epsilon(\epsilon') \equiv c^{-1} \epsilon' \]  \[ (6.3.11) \]

for each \( \epsilon' > 0 \). Take \( n \geq 1 \) so large that

\[ 2^{-n} < \frac{1}{3} \epsilon^{-1} \alpha = \delta_\epsilon(\frac{\alpha}{3}). \]

Note that, by the definition of the operation \( \lfloor \cdot \rfloor \), we have \( 2\epsilon^{-1} < 2^m < 2\epsilon^{-1} \cdot 2^2 = \frac{4}{\epsilon} \).

Hence

\[ 2^{m+1} < c \]

and

\[ 2^{-m} < \frac{1}{2} \epsilon. \]

2. Let \( F,F' \in \tilde{F}(Q,S) \) be arbitrary, with \( F \equiv \{F_{1,\ldots,k} : k \geq 1\} \) and \( F' \equiv \{F'_{1,\ldots,k} : k \geq 1\} \). Consider the distributions \( F_{1,\ldots,n} \in F \) and \( F'_{1,\ldots,n} \in F' \). Since, by hypothesis \( d \leq 1 \), we have the product metric \( d^\infty \leq 1 \) also. Hence, trivially, the distributions \( F_{1,\ldots,n},F'_{1,\ldots,n} \)
6.3. DANIELL-KOLMOGOROV EXTENSION

on \((S^n, d^n)\) have modulus of tightness equal to 1. Let \(\xi^n\) be the power \(n\)-th power of \(\xi\), as in Definition 5.1.4. Thus \(\xi^n\) is a binary approximation for \((S^n, d^n)\). Recall the distribution metric \(\rho_{\text{Dist}, \xi^n}\) relative to \(\xi^n\) on the set of distributions on \((S^n, d^n)\), as introduced in Definition 5.3.4. Then Assertion 1 of Proposition 5.3.11 applies to the compact metric space \((S^n, d^n)\) and the distribution metric \(\rho_{\text{Dist}, \xi^n}\), to yield

\[
\Delta = \Delta(\alpha, \delta, 1, \|\xi^n\|) > 0
\]

(6.3.12)
such that, if

\[
\rho_{\text{Dist}, \xi^n}(F_1, \ldots, n, F'_1, \ldots, n) < \Delta,
\]

then

\[
|F_1, \ldots, n g - F'_1, \ldots, n g| < \frac{\alpha}{3}
\]

(6.3.13)
for each \(g \in C(S^n, d^n)\) with \(|g| \leq 1\) and with modulus of continuity \(\delta_c\). Recall from Lemma 5.1.5 that the modulus of local compactness \(\|\xi^n\|\) of \((S^n, d^n)\) is determined by the modulus of local compactness \(\|\xi\|\) of \((S, d)\). Hence we can define

\[
\bar{\delta}_{DK}(\epsilon) \equiv \bar{\delta}_{DK}(\epsilon, \|\xi^n\|) \equiv 2^{-n} \Delta > 0.
\]

(6.3.14)

We will prove that \(\bar{\delta}_{DK}\) is a modulus of continuity of the Compact Daniell-Kolmogorov Extension \(\bar{\delta}_{DK}\).

3. Suppose, for that purpose, that

\[
\sum_{k=1}^{n} 2^{-k} \rho_{\text{Dist}, \xi^n}(F_1, \ldots, n, F'_1, \ldots, n) \equiv \hat{\rho}_{\text{Marg}, \xi^n}(F, F') < \bar{\delta}_{DK}(\epsilon).
\]

(6.3.15)
We need to show that, then,

\[
\rho_{\text{Dist}, \xi^n}(E, E') < \epsilon
\]
where \(E \equiv \bar{\delta}_{DK}(F)\) and \(E' \equiv \bar{\delta}_{DK}(F')\).

4. To that end, let

\[
\pi \equiv \{(g_{k,x} : x \in B_k)\}_{k=1,2,\ldots}
\]
be the partition of unity of the compact metric space \((S^n, d^n)\) determined by its binary approximation \(\xi^n \equiv (B_k)_{k=1,2,\ldots}\), as in Definition 5.2.4. In other words, the family \(\{g_{k,x} : x \in B_k\}\) of basis functions is the \(2^{-k}\)-partition of unity of \((S^n, d^n)\) determined by the enumerated finite subset \(B_k\), for each \(k \geq 1\). Moreover, according to Definition 5.3.4 we have

\[
\rho_{\text{Dist}, \xi^n}(E, E') \equiv \sum_{k=1}^{n} 2^{-k} |B_k|^{-1} \sum_{x \in B(k)} |E g_{k,x} - E' g_{k,x}|
\]

(6.3.16)

5. Next note that inequality 6.3.15 immediately yields

\[
\rho_{\text{Dist}, \xi^n}(F_1, \ldots, n, F'_1, \ldots, n) < 2^n \bar{\delta}_{DK}(\epsilon) = \Delta.
\]

(6.3.17)
Consider each \(k = 1, \ldots, m\). Let \(x \in B_k\) be arbitrary. Proposition 5.2.3 says that the basis function \(g_{k,x}\) has values in \([0, 1]\), and has Lipschitz constant \(2^{k+1}\) on \((S^n, d^n)\), where

Yuen-Kwok Chan  213  Constructive Probability
$2^{k+1} \leq 2^{m+1} < c$. Hence the function $g_{k,x}$ has Lipschitz constant $c$, and, equivalently, has the modulus of continuity $\delta_c$. Now define the function $g_{k,x,n} \in C(S^n,d^n)$ by

$$g_{k,x,n}(y_1,\cdots,y_n) = g_{k,x}(y_1,\cdots,y_n,x_0,x_0,\cdots)$$

for each $(y_1,\cdots,y_n) \in S^n$. Then, for each $(z_1, z_2, \cdots, z_n), (y_1, y_2, \cdots, y_n) \in (S^n,d^n), we have

$$|g_{k,x,n}(z_1, z_2, \cdots, z_n) - g_{k,x,n}(y_1, y_2, \cdots, y_n)|$$

$$\equiv |g_{k,x}(z_1, z_2, \cdots, z_n,x_0,\cdots) - g_{k,x}(y_1, y_2, \cdots, y_n,x_0,\cdots)|$$

$$\leq 2^{k+1}d^n((z_1, z_2, \cdots, z_n,x_0,\cdots),(y_1, y_2, \cdots, y_n,x_0,\cdots))$$

$$< c \sum_{k=1}^{n} 2^{-k}d(z_k,y_k) \leq c n d(z_k,y_k)$$

$$\equiv c d^n((z_1, z_2, \cdots, z_n),(y_1, y_2, \cdots, y_n)).$$

Thus the function $g_{k,x,n}$ also has Lipschitz constant $c$, and, equivalently, has the modulus of continuity $\delta_c$. In addition, $|g_{k,x}| \leq 1$, whence $|g_{k,x,n}| \leq 1$. In view of inequality [6.3.17] all the conditions for inequality [6.3.13] have now been verified for the function $g_{k,x,n}$. Accordingly,

$$|F_{1,\cdots,n}g_{k,x,n} - F_{1,\cdots,n}g_{k,x,n}| < \frac{\alpha}{3}.$$

At the same time, since $2^{-n} < \delta_c(\frac{\alpha}{3}), where \delta_c is a modulus of continuity of the function $g_{k,x,n}$. inequality [6.3.6] in the proof of Theorem [6.3.2] applies to the functions $g_{k,x}, g_{k,x,n}$ in the place of $f,f_n$, and to the constant $\frac{\alpha}{3}$ in the place of $\varepsilon$, to yield

$$|Eg_{k,x} - F_{1,\cdots,n}g_{k,x,n}| \leq \frac{\alpha}{3}, \tag{6.3.18}$$

with a similar inequality when $E,F$ are replaced by $E',F'$ respectively. The triangle inequality therefore leads to

$$|Eg_{k,x} - E'g_{k,x}| \leq |F_{1,\cdots,n}g_{k,x,n} - F_{1,\cdots,n}g_{k,x,n}| + \frac{2}{3} \alpha < \frac{\alpha}{3} + \frac{2}{3} \alpha = \alpha, \tag{6.3.19}$$

where $k=1,\cdots,m$ and $x \in B_k$ are arbitrary. It follows that

$$\rho_{Dist,\xi}((\Phi_{DK}(F),\Phi_{DK}(F')) = \rho_{Dist,\xi}(E,E') \equiv \sum_{k=1}^{\infty} 2^{-k}|B_k|^{-1} \sum_{x \in B(k)} |Eg_{k,x} - E'g_{k,x}|$$

$$\leq \sum_{k=1}^{m} 2^{-k} + \alpha + 2^{-m} < \alpha + \frac{1}{2} \varepsilon = \varepsilon,$$

where $F,F' \in \hat{F}(Q,S)$ are arbitrary with $\rho_{Marg,\xi,Q}(F,F') < \delta_{DK}(\varepsilon,\|\xi\|)$, where $\varepsilon > 0$ is arbitrary. Thus the Compact Daniell-Kolmogorov Extension

$$\Phi_{DK} : (\hat{F}(Q,S),\rho_{Marg,\xi,Q}) \rightarrow (\hat{F}(S^Q,d^Q),\rho_{Dist,\xi})$$

is uniformly continuous on $\hat{F}(Q,S)$, with modulus of continuity $\delta_{DK}(\cdot,\|\xi\|)$. The theorem is proved. \qed

Yuen-Kwok Chan

214

Constructive Probability
To generalize Theorems 6.3.2 and 6.3.5 to a locally compact, but not necessarily compact, state space \((S,d)\), we (i) identify each consistent family of f.j.d.’s on the latter with one on the one-point compactification \((\bar{S},d)\) whose f.j.d.’s assign probability 1 to powers of \(S\), (ii) apply Theorems 6.3.2 and 6.3.5 to the compact state space \((\bar{S},d)\), resulting in distributions on the path space \((\bar{S}^\infty,d^\infty)\), and (iii) prove that these distributions assign probability 1 to the path subspace \((S^\infty,d^\infty)\), and can therefore be regarded as distributions on the latter.

The remainder of this section makes this precise.

**Lemma 6.3.6.** (Identifying each consistent family of f.j.d.’s with state space \(S\) with a consistent family of f.j.d.’s with state space \(\bar{S} \equiv S \cup \{\Delta\}\)). Suppose \((S,d)\) is locally compact, not necessarily compact. There exists an injection

\[
\psi : \hat{F}(Q,S) \rightarrow \hat{F}(Q,\bar{S})
\]

such that, for each \(F \equiv \{F_1,\ldots,n : n \geq 1\} \in \hat{F}(Q,S)\), with \(F \equiv \{F_1,\ldots,n : n \geq 1\} = \psi(F)\), we have

\[
\hat{F}_{1,\ldots,n} = \hat{F}_{1,\ldots,n}(\hat{F}(S^n))
\]

for each \(\hat{F} \in C(S^n,\hat{F}(S^n))\), for each \(n \geq 1\). Moreover, for each \(F \in \hat{F}(Q,S)\), with \(\hat{F} = \psi(F)\), and for each \(n \geq 1\), the set \(S^n\) is a full subset of \(S^\infty\) relative to the distribution \(\hat{F}_{1,\ldots,n}\) on \((S^\infty,\hat{F}(S^\infty))\).

Henceforth, we will identify \(F\) with \(\hat{F} \equiv \psi(F)\). In words, each consistent family of f.j.d.’s with state space \(S\) is regarded as a consistent family of f.j.d.’s with state space \(\bar{S}\) which assign probability 1 to powers of \(S\). Thus

\[
\hat{F}(Q,S) \subset \hat{F}(Q,\bar{S}).
\]

**Proof.** Consider each \(F \equiv \{F_1,\ldots,n : n \geq 1\} \in \hat{F}(Q,S)\). Let \(n \geq 1\) be arbitrary. Let \(\hat{F} \in C(S^n,\hat{F}(S^n))\) be arbitrary. Then \(\hat{F}|_{S^n} \in C_{ab}(S^n,d^n)\) by Corollary 3.3.5. Hence \(\hat{F}|_{S^n}\) is integrable relative to the distribution \(\hat{F}_{1,\ldots,n}\) on \((S^n,d^n)\), according to Definition 5.2.1. Therefore we can define

\[
\hat{F}_{1,\ldots,n} = \hat{F}_{1,\ldots,n}(\hat{F}|_{S^n}).
\]

Since \(\hat{F}_{1,\ldots,n}\) is a distribution, the right-hand side is a linear function of \(\hat{F}\). Hence \(\hat{F}_{1,\ldots,n}\) is a linear function on \(C(S^n,\hat{F}(S^n))\). Suppose \(\hat{F}_{1,\ldots,n} > 0\). Then \(\hat{F}_{1,\ldots,n}(\hat{F}|_{S^n}) > 0\). Again, since \(\hat{F}_{1,\ldots,n}\) is a distribution, it follows that there exists \(x \in S\) such that \(\hat{F}|_{S^n}(x) > 0\). Thus \(\hat{F}_{1,\ldots,n}\) is an integration on the compact metric space \((S^n,\hat{F}(S^n))\). Moreover \(\hat{F}_{1,\ldots,n} = 1\). Therefore \(\hat{F}_{1,\ldots,n}\) is a distribution.

2. Next, we need to verify that the family \(\hat{F} \equiv \{\hat{F}_{1,\ldots,n} : n \geq 1\}\) is consistent. To that end, let \(m \geq n \geq 1\) be arbitrary. Let \(i \equiv (i_1,\ldots,i_n) \equiv (1,\ldots,m)\) be the initial subsequence \((1,\ldots,m)\). Let \(i^* : S^n \rightarrow S^m\) be its dual function. Then trivially \((\hat{F} \circ i^*)|_{S^m} = (\hat{F}|_{S^m}) \circ i^*\) on \(S^m\). Hence

\[
\hat{F}_{1,\ldots,m}(\hat{F} \circ i^*) = \hat{F}_{1,\ldots,m}(\hat{F} \circ i^*)|_{S^m} = \hat{F}_{1,\ldots,m}(\hat{F} \circ i^*)|_{S^m} = \hat{F}_{1,\ldots,m}(\hat{F}|_{S^m}) \circ i^* = \hat{F}_{1,\ldots,m}(\hat{F}|_{S^m}) \circ i^* = \hat{F}_{1,\ldots,m}(\hat{F}|_{S^m}) = \hat{F}_{1,\ldots,m}(\hat{F}|_{S^m})
\]

Yuen-Kwok Chan 215 Constructive Probability
where the third equality follows from the consistency of the family $F$. Thus the family 

$$F \equiv \psi(F) \equiv \{ F_{1,\ldots,n} : n \geq 1 \}$$

of f.j.d.’s with state space $(\mathcal{S}, \mathcal{A})$ is consistent. In other words, $\psi(F) \in \hat{\mathcal{F}}(Q, \mathcal{S})$. From the defining equality $\psi(F) \equiv \{ F_{1,\ldots,n} : n \geq 1 \}$ we see that, if $F = F' \in \hat{\mathcal{F}}(Q, \mathcal{S})$ then $\psi(F) = \psi(F')$. We conclude that $\psi$ is a well defined function.

3. Now suppose $F, F' \in \hat{\mathcal{F}}(Q, \mathcal{S})$ are such that $F \equiv \psi(F) \equiv F' \equiv \hat{\mathcal{F}}$. Let $n \geq 1$ be arbitrary. Consider each $f \in C(\mathcal{S}^n, d^n)$. Then, by Corollary 3.3.5 there exists $\hat{f} \in C(\mathcal{S}^n, d^n)$ such that $f = \hat{f}|\mathcal{S}^n$. The defining equality $\psi(F) \equiv \{ F_{1,\ldots,n} : n \geq 1 \}$ therefore implies that 

$$F_{1,\ldots,n}(f) = F_{1,\ldots,n}(\hat{f}|\mathcal{S}^n) = F_{1,\ldots,n}(\hat{f})$$

$$= \hat{F}_{1,\ldots,n}(\hat{f}) = \hat{F}_{1,\ldots,n}(F_{1,\ldots,n}(\hat{f})) = \hat{F}_{1,\ldots,n}(f).$$

By Lemma 5.3.3, it follows that $F_{1,\ldots,n} = \hat{F}_{1,\ldots,n}$ as distributions, where $n \geq 1$ is arbitrary. Hence $F = F'$. Thus $\psi$ is an injection. The lemma is proved. 

Lemma 6.3.7. (Identifying each distribution in $\mathfrak{F}_{\text{DK}}(\hat{\mathcal{F}}(Q, \mathcal{S}))$ with a distribution on the path space $(S^0, d^0)$). Since $(\mathcal{S}, \mathcal{A})$ is a compact metric space, Theorem 6.3.2 yields the Compact Daniell-Kolmogorov Extension

$$\mathfrak{F}_{\text{DK}} : \hat{\mathcal{F}}(Q, \mathcal{S}) \to \mathfrak{J}(S^0, d^0)$$

Since $\hat{\mathcal{F}}(Q, \mathcal{S}) \subset \mathfrak{F}(Q, \mathcal{S})$ according to Lemma 6.3.6 the image $\mathfrak{F}_{\text{DK}}(\hat{\mathcal{F}}(Q, \mathcal{S}))$ is well defined and is a subset of $\mathfrak{J}(S^0, d^0)$. Define

$$\mathfrak{J}_{\text{DK}}(S^0, d^0) \equiv \mathfrak{F}_{\text{DK}}(\hat{\mathcal{F}}(Q, \mathcal{S})) \subset \mathfrak{J}(S^0, d^0).$$

(6.3.23)

Let $E \in \mathfrak{J}_{\text{DK}}(S^0, d^0)$ be arbitrary. In other words, $E = \mathfrak{F}_{\text{DK}}(F)$ for some $F \in \hat{\mathcal{F}}(Q, \mathcal{S})$. Then $S^0$ is a full subset relative to the distribution $E$. Define

$$\varphi(E) \equiv E \equiv E|_{\mathfrak{C}_{\text{ub}}(S^0, d^0)}.$$ 

(6.3.24)

Then the following holds.

1. $\varphi(E) \equiv E \in \mathfrak{J}(S^0, d^0)$.

2. The coordinate function $U : Q \times (S^0, L, E) \to (S, d)$ is a r.f. with marginal distributions given by the family $F$, where $(S^0, L, E)$ is the completion of $(S^0, C_{\text{ub}}(S^0, d^0), E)$.

3. The function

$$\varphi : \mathfrak{J}_{\text{DK}}(S^0, d^0) \to \mathfrak{J}(S^0, d^0)$$

(6.3.25)

thus defined is an injection.

Henceforth, we will identify $E$ with $E \equiv \varphi(E)$. In words, each distribution on the path space $(S^0, d^0)$ which is the image under the mapping $\mathfrak{F}_{\text{DK}}$ of some family of f.j.d.’s with state space $(S, d)$ will be identified with a distribution on the path space $(S^0, d^0)$. Thus

$$\mathfrak{J}_{\text{DK}}(S^0, d^0) \subset \mathfrak{J}(S^0, d^0) \cap \mathfrak{J}(S^0, d^0).$$

Yuen-Kwok Chan
6.3. DANIELL-KOLMOGOROV EXTENSION

Proof. 1. Let $\mathcal{T} \in \mathcal{F}_{\mathcal{D}}(S^0, d^0)$ be arbitrary. Then, by the defining equality [6.3.23], there exists $F \in \mathcal{F}(Q, S)$ such that $E = \mathcal{F}_{\mathcal{D}}(F)$, where $F' \equiv \psi(F)$. Theorem [6.3.2] applied to the compact metric space $(S, d)$ and the consistent family $\mathcal{F}$ of f.i.d.s with state space $(S, d)$, says that the coordinate function

$$\mathcal{U} : Q \times (S^0, \mathcal{L}, E) \to (S, \mathcal{F})$$

is a r.f. with marginal distributions given by the family $\mathcal{F}$, where $(S^0, \mathcal{L}, E)$ is the completion of $(S^0, C(S^0, d^0), E)$.

Note that each function $f \in C_{\mathcal{D}}(S^0, d^0)$ can be regarded as a function on $S^0$ with $\text{domain}(f) \equiv S^0 \subset S^0$. We will prove that $S^0$ is a full set in $(S^0, \mathcal{L}, E)$, and that $C_{\mathcal{D}}(S^0, d^0) \subset \mathcal{L}$. We will then show that the restricted function $E = \mathcal{F}C_{\mathcal{D}}(S^0, d^0)$ is a distribution on $(S^0, d^0)$.

2. To that end, let $n, m \geq 1$ be arbitrary. Define the function

$$h_m \equiv 1 \land (1 + m - d(\cdot, x_m))_+ \in C(S, d).$$

Define the function $\tilde{h}_n \in C(S, d)$ by $\tilde{h}_n(y) \equiv h_m(y)$ or $\tilde{h}_n(y) \equiv 0$ according as $y \in S$ or $y = \Delta$. Then $h_m = \tilde{h}_n|S$. Moreover, for each point $y \in (S, d)$ we have $\tilde{h}_n(y) = 1$ if $m \geq 1$ is sufficiently large. At the same time, $\tilde{h}_n(\Delta) = 0$ for each $m \geq 1$. It follows that $\lim_{m \to \infty} \tilde{h}_n(\mathcal{U}_n)(y) = 1$ or $0$ according as $\mathcal{U}_n(y) \in S$ or $\mathcal{U}_n(y) = \Delta$, for each $y \in \text{domain}(\mathcal{U}_n)$. In short,

$$\lim_{m \to \infty} \mathcal{U}_n = 1_{(\mathcal{U}(n) \in S)}$$

on $\text{domain}(\mathcal{U}_n)$. Moreover,

$$\mathcal{E}h_m(\mathcal{U}_n) = \mathcal{F}h_m \equiv F_n(\tilde{h}_m|S) = F_nh_m \uparrow 1$$

as $m \to \infty$, where the first equality is because the r.f. $\mathcal{U}$ has marginal distributions given by the family $\mathcal{F}$, where the second equality is by the defining formula [6.3.20] of the family $\mathcal{F} \equiv \psi(F)$, and where the convergence is because $F_n$ is a distribution on the locally compact metric space $(S, d)$. The Monotone Convergence Theorem therefore implies that the indicator $1_{(\mathcal{U}(n) \in S)}$ is integrable on $(S', \mathcal{L}, E)$, with integral 1. Thus $(\mathcal{U}_n \in S)$ is a full subset of the probability space $(S', \mathcal{L}, E)$, where $n \geq 1$ is arbitrary. Since, by the definition of the coordinate function $\mathcal{U}$, we have

$$S^\infty = \bigcap_{m=1}^{\infty} \{(x_1, x_2, \cdots) \in S^\infty : x_m \in S\}$$

$$= \bigcap_{m=1}^{\infty} \{(x_1, x_2, \cdots) \in S^\infty : \mathcal{U}_m(x_1, x_2, \cdots) \in S\} = \bigcap_{m=1}^{\infty} (\mathcal{U}_m \in S),$$

it follows that $S^\infty$ is the intersection of a sequence of full subsets, and is itself a full subset of $(S^\infty, \mathcal{L}, E)$.

3. Now note that $U_n = \mathcal{U}_n$ on the full subset $S^\infty$ of $(S', \mathcal{L}, E)$, where

$$U : Q \times S^\infty \to S$$

Yuen-Kwok Chan 217 Constructive Probability
is the coordinate function as in Definition 6.3.1 where \( n \geq 1 \) is arbitrary. It follows that \( U \) is a r.f. on \((S', \mathcal{T}, \mathcal{E})\) with values in the metric space \((S, d)\).

4. Next consider each \( n \geq 1 \), \( \tilde{f} \in C_{ab}(S', d) \) and \( f \in C_{ab}(S^n, d^n) \), such that \( \tilde{f}|^{S'} = f \). Then
\[
f(U_1, \ldots, U_n) \in C_{ab}(S^n, d^n). \tag{6.3.26}
\]
Separately, according to Proposition 4.8.17 the function \((U_1, \ldots, U_n)\) on \((S', \mathcal{T}, \mathcal{E})\) is a r.v. with values in \((S^n, d^n)\). Hence \( f(U_1, \ldots, U_n) \in \mathcal{L} \) by Proposition 4.8.7. Therefore
\[
\tilde{f}(U_1, \ldots, U_n)|^{S^n} = f(U_1, \ldots, U_n) \in \mathcal{L}. \tag{6.3.27}
\]
Combining,
\[
Ef(U_1, \ldots, U_n) = \mathcal{E}_f(U_1, \ldots, U_n) = \mathcal{E}\tilde{f}(U_1, \ldots, U_n) = \mathcal{E}_1, \ldots, \mathcal{E}_n(f), \tag{6.3.28}
\]
where the first equality is by the equality 6.3.24 and relation 6.3.27, where the second equality is from equality 6.3.22, where the third equality is because the r.f. \( U : \Omega \times (S', \mathcal{T}, \mathcal{E}) \to (S, d) \) has marginal distributions given by the family \( \mathcal{E} \), and where the fourth equality is by the defining equality 6.3.20 in Lemma 6.3.6.

5. We proceed to prove that the function \( E \) is a distribution on the complete metric space \((S^n, d^n)\). To that end, let \( f \in C_{ab}(S^n, d^n) \) be arbitrary, with a modulus of continuity \( \delta_f \), and with \( |f| \leq b \) for some \( b > 0 \). We will prove that \( f \in \mathcal{L} \). Define the function \( \mathcal{F} : S \to R \) by domain \( \mathcal{F} \equiv S^n \) and by \( \mathcal{F}(x) = f(x) \) for each \( x \in S^n \).

Let \( \varepsilon > 0 \) be arbitrary. Let \( n \geq 1 \) be so large that \( 2^{-n} < \delta_f(\varepsilon) \). Define \( f_n \in C_{ab}(S^n, d^n) \) by
\[
f_n(x_1, x_2, \ldots, x_n) \equiv f(x_1, x_2, \ldots, x_n, x_0, x_0, \ldots) \tag{6.3.29}
\]
for each \( (x_1, x_2, \ldots, x_n) \in S^n \). Then
\[
d^n(((x_1, x_2, \ldots, x_n, x_0, x_0, \ldots), (x_1, x_2, \ldots)) \leq \sum_{i=n+1}^{\infty} 2^{-i} = 2^{-n} < \delta_f(\varepsilon)
\]
for each \( x = (x_1, x_2, \ldots) \in S^n \). Hence
\[
|f_n(U_1, \ldots, U_n) - f(x_1, x_2, \ldots)| = |f_n(x_1, x_2, \ldots, x_n) - f(x_1, x_2, \ldots)|
\]
\[
= |f(x_1, x_2, \ldots, x_n, x_0, x_0, \ldots) - f(x_1, x_2, \ldots)| < \varepsilon
\]
for each \( x = (x_1, x_2, \ldots) \in S^n \). In other words,
\[
|f_n(U_1, \ldots, U_n) - f| < \varepsilon \tag{6.3.30}
\]
on the full set \( S^n \), where \( n \geq 1 \) is arbitrary with \( 2^{-n} < \delta_f(\varepsilon) \). Thus
\[
f_n(U_1, \ldots, U_n) \to f \tag{6.3.31}
\]
in probability on \((S^n, \mathcal{T}, \mathcal{E})\). At the same time, since \( f_n \in C_{ab}(S^n, d^n) \), we have \( f_n(U_1, \ldots, U_n) \in \mathcal{L} \) according to relation 6.3.27 while \( |f| \leq b \) and \( |f_n| \leq b \) for each \( n \geq 1 \). Therefore, in
view of the convergence relation \(6.3.31\) the Dominated Convergence Theorem implies that \(f \in \mathcal{L}\), and that

\[
E f = \lim_{n \to \infty} E f_n(U_1, \cdots, U_n) = \lim_{n \to \infty} \mathcal{E} f_n(U_1, \cdots, U_n) = \mathcal{E} f ,
\]

where the second equality is by applying equality \(6.3.28\) to \(f_n\) for each \(n \geq 1\). Since \(f \in C_{ab}(S^\omega, d^\omega)\) is arbitrary, we see that \(C_{ab}(S^\omega, d^\omega) \subseteq \mathcal{L}\).

6. We will now verify that \((S^\omega, C_{ab}(S^\omega, d^\omega), E)\) is an integration space. First note that the space \(C_{ab}(S^\omega, d^\omega)\) is linear, contains constants, and is closed to the operations of absolute values and minimums. Linearity of the function \(E\) follows from that of \(\mathcal{E}\), in view of equality \(6.3.32\). Now suppose a sequence \((g_i)_{i=0,1,2,\ldots}\) of functions in \(C_{ab}(S^\omega, d^\omega)\) is such that \(g_i\) is non-negative for each \(i \geq 1\) and such that \(\sum_{i=1}^\infty E g_i < E g_0\). Then, by equality \(6.3.32\) we have \(\sum_{i=1}^\infty E g_i < \mathcal{E} g_0\). Hence, since \(E\) is an integration, there exists a point \(x \in \bigcap_{i=0}^\infty \text{domain}(g_i)\) such that \(\sum_{i=1}^\infty g_i(x) < g_0(x)\). Thus the positivity condition in Definition \(4.3.1\) has been verified for the function \(E\). Now let \(g \in C_{ab}(S^\omega, d^\omega)\) be arbitrary. Then \(E(g \wedge k) = E(g \wedge k) \to \mathcal{E} g\) as \(k \to \infty\), where the convergence is because \(\mathcal{E}\) is an integration. Similarly, \(E(|g| \wedge k^{-1}) \to 0\) as \(k \to \infty\). Thus all the conditions in Definition \(4.3.1\) have been verified for \((S^\omega, C_{ab}(S^\omega, d^\omega), E)\) to be an integration space.

7. Since \(d^\omega \leq 1\) and \(1 = \mathcal{E} 1 = 1\), Assertion 2 of Lemma \(5.2.2\) implies that the integration \(E\) is a distribution on the complete metric space \((S^\omega, d^\omega)\). In other words, \(\varphi(\mathcal{E}) = E \in \mathcal{J}(S^0, d^0)\). We see that the function \(\varphi\) is well defined. Moreover, let \((S^\omega, L, E)\) be the completion of the integration space \((S^\omega, C_{ab}(S^\omega, d^\omega), E)\). Then equality \(6.3.25\) implies that the coordinate function \(U\) is a r.f. on the sample space \((S^\omega, L, E)\) and with marginal distributions given by the family \(F\).

8. It remains to prove that \(\varphi\) is an injection. To that end, let a second distribution \(\mathcal{E}' \in \mathcal{J}_{DK}(S^0, d^0)\) be arbitrary. Suppose \(E \equiv \varphi(\mathcal{E}) = \varphi(\mathcal{E}') \equiv E'\). Let \(\mathcal{J} \in (S^0, d^0)\) be arbitrary. Then \(f \equiv \mathcal{J}|S^\omega \in C_{ab}(S^\omega, d^\omega)\). Then equality \(6.3.32\) yields

\[
\mathcal{E}\mathcal{J} = \mathcal{E} f = E f = E' f = E'\mathcal{J} = \mathcal{E}\mathcal{J},
\]

where the first and last equality are because \(\mathcal{J} = f\) on the full subset \(S^\omega\) relative to \(\mathcal{E}\) and to \(\mathcal{E}'\). Thus \(\mathcal{E} = \mathcal{E}'\) as distributions on the compact metric space \((S^0, d^0)\). We conclude that the function \(\varphi\) is an injection. The lemma is proved.

We are now ready to prove the Daniell-Kolmogorov Extension Theorem, where the state space is required only to be locally compact.

**Theorem 6.3.8.** (Daniell-Kolmogorov Extension, and its continuity). Suppose \((S,d)\) is locally compact, not necessarily compact, with a binary approximation \(\xi\). Recall the set 

\[
\mathcal{J}_{DK}(S^0, d^0) \subset \mathcal{J}(S^0, d^0) \cap \mathcal{J}(S^0, d^0)
\]

of distributions, defined in Lemma \(6.3.7\). Then the following holds.
1. (Existence). There exists a function

\[ \Phi_{DK}: \tilde{F}(Q, S) \rightarrow \tilde{J}_{DK}(S^Q, d^Q) \]

such that, for each consistent family \( F \in \tilde{F}(Q, S) \) of f.j.d.'s, the distribution \( E \equiv \Phi_{DK}(F) \) satisfies the conditions (i) the coordinate function

\[ U: Q \times (S^Q, L, E) \rightarrow S \]

is a r.f., where \( L \) is the completion of \( C_{\text{dist}}(S^Q, d^Q) \) relative to the distribution \( E \), and (ii) the r.f. \( U \) has marginal distributions given by the family \( F \). The function \( \Phi_{DK} \) will be called the Daniell-Kolmogorov Extension.

2. (Continuity). Let \( \tilde{\xi} \) be the compactification of the given binary approximation \( \xi \), as constructed in Corollary 3.3.4. Thus \( \tilde{\xi} \) is a binary approximation of \((\tilde{S}, \tilde{F})\) relative to the fixed reference point \( x_0 \in S \). Since the metric space \((\tilde{S}, \tilde{F})\) is compact, the countable power \( \tilde{\xi}^\infty \equiv (\tilde{B}_k)_{k=1,2} \) of \( \tilde{\xi} \) is defined and is a binary approximation of \((\tilde{S}^\infty, \tilde{F}^\infty)\), according to Definition 3.1.6. Recall that the set \( \tilde{J}(\tilde{S}^\infty, \tilde{F}^\infty) \) is then equipped with the distribution metric \( \rho_{\text{dist}} \tilde{\xi}^\infty \) defined relative to \( \tilde{\xi}^\infty \), according to Definition 5.3.4 and that convergence of a sequence of distributions on \((\tilde{S}^\infty, \tilde{F}^\infty)\) relative to the metric \( \rho_{\text{dist}} \tilde{\xi}^\infty \) is equivalent to weak convergence. Write \( \rho_{\text{dist}} \tilde{\xi}^\infty \equiv \rho_{\text{dist}, \tilde{\xi}^\infty} \). Since \( \tilde{J}_{DK}(S^Q, d^Q) \) is a subset of \( \tilde{J}(\tilde{S}^\infty, \tilde{F}^\infty) \), we have a metric subspace \((\tilde{J}_{DK}(S^Q, d^Q), \rho_{\text{dist}, \tilde{\xi}^\infty})\). Then the Daniell-Kolmogorov Extension

\[ \Phi_{DK}: (\tilde{F}(Q, S), \tilde{\rho}_{\text{marg}, \tilde{\xi}, Q}) \rightarrow (\tilde{J}_{DK}(S^Q, d^Q), \rho_{\text{dist}, \tilde{\xi}^\infty}) \]

is uniformly continuous, with a modulus of continuity \( \delta_{DK}(\cdot, \| \tilde{\xi} \|) \) dependent only on the modulus of local compactness \( \| \tilde{\xi} \| \equiv (|A_k|)_{k=1,2} \) of the locally compact state space \((S, d)\).

Proof. 1. Apply Theorems 6.3.2 and 6.3.5 to the compact metric space \((\tilde{S}, \tilde{F})\) to obtain the Compact Daniell-Kolmogorov Extension

\[ \overline{\Phi}_{DK}: (\tilde{F}(Q, S), \tilde{\rho}_{\text{marg}, \tilde{\xi}, Q}) \rightarrow (\tilde{J}(\tilde{\xi}^\infty, \tilde{F}^\infty), \rho_{\text{dist}, \tilde{\xi}^\infty}), \]

which is uniformly continuous with modulus of continuity \( \overline{\delta}_{DK}(\cdot, \| \tilde{\xi} \|) \) dependent only on the modulus of local compactness \( \| \tilde{\xi} \| \) of the compact metric space \((\tilde{S}, \tilde{F})\).

2. By the defining equality \( 6.3.23 \) in Lemma 6.3.7, we have

\[ \overline{\Phi}_{DK}(\tilde{F}(Q, S)) \equiv \tilde{J}_{DK}(S^Q, d^Q), \]

(6.3.34)

where \( \tilde{F}(Q, S) \) is a subset of \( \tilde{F}(Q, S) \). Hence we can define the restricted mapping

\[ \Phi_{DK} \equiv \overline{\Phi}_{DK}|\tilde{F}(Q, S): (\tilde{F}(Q, S), \tilde{\rho}_{\text{marg}, \tilde{\xi}, Q}) \rightarrow (\tilde{J}_{DK}(S^Q, d^Q), \rho_{\text{dist}, \tilde{\xi}^\infty}), \]

(6.3.35)

which inherits the continuity and modulus of continuity \( \overline{\delta}_{DK}(\cdot, \| \tilde{\xi} \|) \) from \( \overline{\Phi}_{DK} \). Thus the mapping \( \Phi_{DK} \) is uniformly continuous. According to Corollary 3.3.6, \( \| \tilde{\xi} \| \) in turn
depends only on the modulus of local compactness $\|\xi\|$ of the locally compact metric space $(S, d)$. Hence we can define

$$\delta_{DK}(\cdot, \|\xi\|) \equiv \Phi_{DK}(\cdot, \|\xi\|),$$

and $\Phi_{DK}$ has the modulus of continuity $\delta_{DK}(\cdot, \|\xi\|)$ which depends only on $\|\xi\|$.

3. Let $F \in \tilde{F}(Q, S)$ be arbitrary. Let $E \equiv \Phi_{DK}(F)$. Then $E = \Phi_{DK}(F)$ by the defining equality \[6.3.35\] of the function $\Phi_{DK}$. Hence Assertion 2 of Lemma \[6.3.7\] is applicable to $E \equiv E = \Phi_{DK}(F)$ and $F \in \tilde{F}(Q, S)$, and says that the coordinate function $U : Q \times (S^O, L, E) \to (S, d)$ is a r.f. with marginal distributions given by the family $F$, where $(S^O, L, E)$ is the completion of $(S^O, C_\mathbb{R}(S^O, d^O), E)$.

The theorem is proved.

\[ \Box \]

6.4 Daniell-Kolmogorov-Skorokhod Extension

We use the notations as in the previous section. In particular, $Q \equiv \{t_1, t_2, \cdots\}$ denotes a countable parameter set, and, for simplicity of presentation, and without loss of generality, we assume that $t_n = n$ for each $n \geq 1$. Thus

$$Q \equiv \{t_1, t_2, \cdots\} \equiv \{1, 2, \cdots\}.$$  

For two consistent families $F$ and $F'$ of f.j.d.'s with the parameter set $Q$ and the locally compact state space $(S, d)$, the Daniell-Kolmogorov Extension in the previous section produces two corresponding distributions $E$ and $E'$ on the path space $(S^\infty, d^\infty)$, such that the families $F$ and $F'$ of f.j.d.'s are the marginal distributions of the r.f.'s $U : Q \times (S^O, L, E) \to (S, d)$ and $U : Q \times (S^O, L', E') \to (S, d)$, receptively, even as the underlying coordinate function $U$ remains the same.

In contrast, Theorem 3.1.1 in \[Skorohod 1956\] combines the Daniell-Kolmogorov Extension with Skorokhod’s Representation Theorem, presented as Theorem \[5.5.1\] in the present work, and produces (i) as the sample space, the fixed probability space

$$(\Theta_0, L_0, I_0) \equiv ([0, 1], L_0, \int \cdot dx)$$

based on the uniform distribution $\int \cdot dx$ on the unit interval $[0, 1]$, and (ii) for each $F \in \tilde{F}(Q, S)$, a r.f. $Z : Q \times (\Theta_0, L_0, I_0) \to (S, d)$ with marginal distributions given by $F$. The sample space is fixed, but two different families $F$ and $F'$ of f.j.d.'s result in two different r.f.'s $Z$ and $Z'$. Theorem 3.1.1 in \[Skorohod 1956\] shows that the Daniell-Kolmogorov-Skorokhod Extension thus obtained is continuous relative to weak convergence in $\tilde{F}(Q, S)$. Because the r.f.’s produced can be regarded as r.v.’s on the same probability space $(\Theta_0, L_0, I_0)$ with values in the path space $(S^O, d^O)$, we will have at our disposal the familiar tools of making new r.v.’s, including the taking of continuous function of given r.v.’s and the taking of limits in various senses. These operations on such r.v.’s would be clumsy or impossible in terms of distributions on the path space, . This will be clear as we go along.

Note that, in Theorem \[5.5.1\] of the present work, we recast the aforementioned Skorokhod’s Representation Theorem in terms of partitions of unity in the sense of

Yuen-Kwok Chan 221 Constructive Probability
Definition 6.4.1. (Metric space of r.f.’s with countable parame-
ter set). Suppose the state space \((S,d)\) is locally compact, not necessarily compact. Let \((\Omega, L, E)\) be an arbitrary probability space. Recall that \(\hat{M}(\Omega, S^0)\) inherits from \(M(\Omega, S^0)\) the probability metric \(\rho_{Prob}\), defined in Definition 5.1.10. More precisely, define

\[
\hat{\rho}_{\text{Prob}, Q}(Z, Z') = \rho_{\text{Prob}}(Z, Z') = E(1 \land d^Q(Z, Z'))
\]

for each \(Z, Z' \in \hat{M}(\Omega, S^0) = M(\Omega, S^0)\). Note that \(\hat{\rho}_{\text{Prob}, Q} \leq 1\).

In view of the right-hand side of the defining equality \((6.4.1)\) the metric \(\hat{\rho}_{\text{Prob}, Q}\) is determined by the enumeration \((t_1, t_2, \ldots)\) of the countably infinite set \(Q\). A different enumeration would produce a different, albeit equivalent, metric. We omit the subscript \(Q\) for the enumerated set only when it is understood from context.

Note that equality \((6.4.1)\) implies that sequential convergence of r.f.’s in \(\hat{M}(\Omega, S^0)\) relative to the metric \(\rho_{\text{Prob}}\) is equivalent to convergence in probability and, therefore, to the weak convergence of the sequence, when the r.f.’s are viewed as r.v.’s. \(\Box\)

Theorem 6.4.2. (Compact Daniell-Kolmogorov-Skorokhod Extension). Suppose \((S,d)\) is compact. Let \(\xi \equiv (\xi_t)_{t=1, 2, \ldots}\) be an arbitrary binary approximation of state space \((S,d)\). Then there exists a function

\[
\Phi_{DKS, \xi} : \hat{M}(Q, S) \to \hat{M}(Q \times \Theta_0, S)
\]

such that, for each \(F \in \hat{M}(Q, S)\), the r.f. \(Z \equiv \Phi_{DKS, \xi}(F) : Q \times \Theta_0 \to S\) has marginal distributions given by the family \(F\). The function \(\Phi_{DKS, \xi}\) constructed in the proof below will be called the Daniell-Kolmogorov-Skorokhod Extension relative to the binary approximation \(\xi\) of \((S,d)\).

Proof. 1. Consider the Compact Daniell-Kolmogorov Extension

\[
\Phi_{DK} : \hat{M}(Q, S) \to \hat{M}(S^0, d^Q),
\]

which maps each consistent family \(F \in \hat{M}(Q, S)\) of f.j.d.’s to a distribution \(E \equiv \Phi_{DK}(F)\) on \((S^0, d^Q)\), such that (i) the coordinate function \(U : Q \times (S^0, L, E) \to S\) is a r.f., where
6.4. DANIELL-KOLMOGOROV-SKOROKHOD EXTENSION

$L$ is the completion of $C(S^0,d^0)$ relative to the distribution $E$, and (ii) $U$ has marginal distributions given by the family $F$.

2. Since the path space $(S,d)$ is compact by hypothesis, the countable power $ξ^∞≡(B_k)_{k=1,2}$ of $ξ$ is defined and is a binary approximation of $(S^0,d^0)≡(S^∞,d^∞)$, according to Definition 5.1.6. Recall that the set $J(S^0,d^0)$ is then equipped with the distribution metric $ρ_{Dist,ξ^∞}$ defined relative to $ξ^∞$, according to Definition 5.3.4 and that convergence of a sequence of distributions on $(S^0,d^0)$ relative to the metric $ρ_{Dist,ξ^∞}$ is equivalent to weak convergence. Write $ρ_{Dist,ξ^∞}≡ρ_{Dist,ξ^0}$.

2. Recall from 5.1.10 that $M(Θ_0,S^0)$ denotes the set of r.v.’s $Z≡(Z_1, Z_2, ⋯)$ defined relative to the metric $ρ_{Dist,ξ^0}$. According to Definition 3.1.6. Recall that the Skorokhod representation $Ω$ constructed the Skorokhod representation $Φ$ such that, for each distribution $E$ in $J(S^0,d^0)$, with values in the compact path space $(S^0,d^0)$. Theorem 5.5.1 constructed the Skorokhod representation $Φ_{Sk,ξ^∞}:J(S^0,d^0)→M(Θ_0,S^0)$ such that, for each distribution $E$ in $J(S^0,d^0)$, with $Z≡Φ_{Sk,ξ^∞}(E)$, we have

$$E=I_0Z,$$  

where $I_0Z$ is the distribution induced on the compact metric space $(S^0,d^0)$ by the r.v. $Z$, in the sense of 5.2.3.

3. We will now verify that the composite function

$$Φ_{DKS,ξ^∞}≡Φ_{Sk,ξ^∞}◦Φ_{DK}:𝒮(Q,S)→M(Θ_0,S^0)$$  

has the desired properties. To that end, let the consistent family $F∈𝒮(Q,S)$ of f.j.d.’s be arbitrary. Let $Z≡Φ_{DKS,ξ^∞}(F)$. Then $Z≡Φ_{Sk,ξ^∞}(E)$ for some $E≡Φ_{DK}(F)$. We need only verify that the r.v. $Z=(Z_1, Z_2, ⋯)$ in $M(Θ_0,S^0)$, when viewed as a r.f. $Z:Q×(Θ_0,L_0, I_0)→(S,d)$, has marginal distributions given by the family $F$.

4. To that end, let $n≥1$ and $g∈C(S^n,d^n)$ be arbitrary. Define the function $f∈C(S^∞,d^∞)$ by

$$f(x_1, x_2, ⋯, x_n)$$  

for each $(x_1, x_2, ⋯, x_n)∈S^n$. Then, for each $x≡(x_1, x_2, ⋯, x_n)∈S^∞$, we have, by the definition of the coordinate function $U$,

$$f(x)=f(x_1, x_2, ⋯, x_n)=f(U_1(x), U_2(x), ⋯, x_n)=g(U_1, ⋯, U_n)(x).$$  

Therefore

$$I_0f(Z_1, ⋯, Z_n) = I_0f(Z_1, Z_2, ⋯) = I_0f(Z) = I_0Zf$$

$$=Ef = E g(U_1, ⋯, U_n) = F_{1, ⋯, n}g,$$  

where the third equality is by the definition of the induced distribution $I_0Z$, the fourth follows from equality 6.4.2, the fifth is by equality 6.4.4 and the last is by Condition (ii) in Step 1. Since $n≥1$ and $g∈C(S^n,d^n)$ are arbitrary, we conclude that the r.f. $Φ_{DKS,ξ^∞}(F)=Z$ has marginal distributions given by the family $F$. The theorem is proved. □
CHAPTER 6. RANDOM FIELDS AND STOCHASTIC PROCESSES

Theorem 6.4.3. (Continuity of Compact Daniell-Kolmogorov-Skorokhod Extension). Use the same assumptions and notations as in Theorem 6.4.2. In particular, suppose the state space \((S,d)\) is compact. Recall that the modulus of local compactness of \((S,d)\) corresponding to the binary approximation \(ξ \equiv (A_p)_{p=1,2,\ldots}\) is defined as the sequence

\[\|ξ\| \equiv (|A_p|)_{p=1,2,\ldots}\]

of integers. Then the Compact Daniell-Kolmogorov-Skorokhod Extension

\[\Phi_{DKS,ξ} : \Phi_{DK}(\hat{R}(Q,S),\hat{ρ}_{Dist,ξ,0}) \rightarrow (\tilde{R}(Q,ρ_{Prob,ξ}),\tilde{ρ}_{Prob,ξ})\]  

(6.4.6)

is uniformly continuous with a modulus of continuity \(\delta_{DKS}(\cdot,\|ξ\|)\) dependent only on \(\|ξ\|\). The marginal metric \(\hat{ρ}_{Dist,ξ,0}\) and the probability metric \(\hat{ρ}_{Prob,ξ}\) were introduced in Definitions 6.2.7 and 6.4.1 respectively.

Proof. 1. By the defining equality 6.4.3 in Theorem 6.4.2, we have

\[\Phi_{DKS,ξ} \equiv \Phi_{Sk,ξ} \circ \Phi_{DK},\]  

(6.4.7)

where the Compact Daniell-Kolmogorov Extension

\[\Phi_{DK} : \Phi_{DK}(\hat{R}(Q,S),\hat{ρ}_{Dist,ξ,0}) \rightarrow (\tilde{R}(Q,ρ_{Dist,ξ}),\tilde{ρ}_{Dist,ξ})\]  

is uniformly continuous according to Theorem 6.3.5 with modulus of continuity

\[\delta_{DK}(\cdot,\|ξ\|)\]

dependent only on the modulus of local compactness \(\|ξ\| \equiv (|A_k|)_{k=1,2,\ldots}\) of the compact metric space \((S,d)\).

2. Separately, the metric space \((S,d)\) is compact by hypothesis. Hence its countable power \((S^0,d^0)\) is defined and is a binary approximation of \((S^0,d^0)\). Moreover, since \(d^0 \leq 1\), the set \(\tilde{J}(S^0,d^0)\) of distributions on \((S^0,d^0)\) is trivially tight, with the modulus of tightness \(β = 1\). Hence Theorem 5.5.2 is applicable to the metric space \((S^0,d^0)\) along with its binary approximation \(ξ^0\), and implies that the Skorokhod representation

\[\Phi_{Sk,ξ} : \tilde{J}(S^0,d^0),\rho_{Dist,ξ^0}) \rightarrow (M(Θ_0,S),ρ_{Prob})\]

is uniformly continuous, with a modulus of continuity \(δ_{Sk}(\cdot,\|ξ^0\|,1)\) depending only on \(\|ξ^0\|\). Equivalently,

\[\Phi_{Sk,ξ} : \tilde{J}(S^0,d^0),\rho_{Dist,ξ^0}) \rightarrow (\tilde{R}(Q,ρ_{Prob,S}),ρ_{Prob})\]

is uniformly continuous, with a modulus of continuity \(δ_{Sk}(\cdot,\|ξ^0\|,1)\).

3. Combining, we see that the composite function \(\Phi_{DKS,ξ}\) in equality 6.4.6 is uniformly continuous, with a modulus of continuity given by the composite operation

\[\delta_{DKS}(\cdot,\|ξ\|) \equiv \delta_{DK}(δ_{Sk}(\cdot,\|ξ^0\|,1),\|ξ\|),\]

where we observe that the modulus of local compactness \(\|ξ^0\|\) of the countable power \((S^0,d^0)\) is determined by the modulus of local compactness \(\|ξ\|\) of the compact metric space \((S,d)\), according to Lemma 3.1.7. The theorem is proved.
Now the Daniell-Kolmogorov-Skorokhod Extension Theorem, where the state space is required only to be locally compact.

**Theorem 6.4.4.** (Daniell-Kolmogorov-Skorokhod Extension, and its continuity). Suppose \((S,d)\) is locally compact, not necessarily compact, with a binary approximation \(\xi\). Then the following holds.

1. **(Existence).** There exists a function \(\Phi_{DKS,\xi} : \tilde{F}(Q,S) \to R(Q \times \Theta_0, S)\) such that, for each \(F \in \tilde{F}(Q,S)\), the r.f. \(Z \equiv \Phi_{DKS,\xi}(F) : Q \times \Theta_0 \to S\) has marginal distributions given by the family \(F\). The function \(\Phi_{DKS,\xi}\) will be called the Daniell-Kolmogorov-Skorokhod Extension relative to the binary approximation \(\xi\) of \((S,d)\).

2. **(Continuity).** The Daniell-Kolmogorov-Skorokhod Extension

\[
\Phi_{DKS,\xi} : (\tilde{F}(Q,S), \hat{\rho}_{\text{Marg},\xi,Q}) \to (\tilde{R}(Q \times \Theta_0, S), \tilde{\rho}_{\text{Prob},Q})
\]

is uniformly continuous, with a modulus of continuity \(\delta_{DKS}(\cdot, \|\xi\|)\) dependent only on the modulus of local compactness \(\|\xi\| \equiv (|A_k|)_{k=1,2}\) of the locally compact state space \((S,d)\).

**Proof.** 1. Let \(\tilde{\xi}\) be the compactification of the given binary approximation \(\xi\), as constructed in Corollary 3.3.6. Thus \(\tilde{\xi}\) is a binary approximation of \((\overline{S},\overline{d})\) relative to the fixed reference point \(x_0 \in S\). Since the metric space \((\overline{S},\overline{d})\) is compact, the countable power \(\tilde{\xi}^\omega\) of \(\tilde{\xi}\) is defined and is a binary approximation of \((\overline{S},\overline{d})\), according to Definition 3.1.6. Apply Theorems 6.4.2 and 6.4.3 to the compact metric space \((\overline{S},\overline{d})\) to obtain the Compact Daniell-Kolmogorov-Skorokhod Extension

\[
\Phi_{DKS,\xi} : (\tilde{F}(Q,\overline{S}), \hat{\rho}_{\text{Marg},\xi,Q}) \to (\tilde{R}(Q \times \Theta_0, \overline{S}), \tilde{\rho}_{\text{Prob},Q}),
\]

which is uniformly continuous with a modulus of continuity \(\delta_{DKS}(\cdot, \|\tilde{\xi}\|)\) dependent only on \(\|\tilde{\xi}\|\). Specifically,

\[
\Phi_{DKS,\xi} = \Phi_{Sk_{\xi}} \circ \Phi_{DK},
\]

where

\[
\Phi_{DK} : (\tilde{F}(Q,\overline{S}), \hat{\rho}_{\text{Marg},\xi,Q}) \to (\tilde{J}(\overline{S}^Q,\overline{d}^Q), \tilde{\rho}_{\text{Dist},\overline{S}^Q})
\]

and

\[
\Phi_{Sk_{\xi}} : \tilde{J}(\overline{S}^Q,\overline{d}^Q) \to (M(\Theta_0,\overline{S}^Q), \rho_{\text{Prob}})
\]

2. Since \(\tilde{F}(Q,S)\) is a subset of \(\tilde{F}(Q,\overline{S})\), we can define the restricted mapping

\[
\Phi_{DKS,\xi} \equiv \Phi_{DKS,\xi}^*(\tilde{F}(Q,S), (\tilde{F}(Q,S), \hat{\rho}_{\text{Marg},\xi,Q}) \to (\tilde{R}(Q \times \Theta_0, \overline{S}), \tilde{\rho}_{\text{Prob}}),
\]

which inherits the continuity and modulus of continuity \(\delta_{DKS}(\cdot, \|\tilde{\xi}\|)\) from \(\Phi_{DKS,\xi}\). Thus the mapping \(\Phi_{DKS,\xi}\) is uniformly continuous. According to Corollary 3.3.6, \(\|\tilde{\xi}\|\)
in turn depends only on the modulus of local compactness $\|\xi\|$ of the locally compact metric space $(S,d)$. Hence we can define
\[
\delta_{\text{DKS}}(\cdot,\|\xi\|) = \overline{\delta}_{\text{DKS}}(\cdot,\|\xi\|).
\]
Then $\Phi_{\text{DKS},\xi}$ has the modulus of continuity $\delta_{\text{DKS}}(\cdot,\|\xi\|)$ which depends only on $\|\xi\|$. 

3. Let $F \in \widehat{F}(Q,S)$ be arbitrary. Write $Z = \Phi_{\text{DKS},\xi}(F)$. It remains to prove that $Z \in \widehat{R}(Q \times \Theta_{0},S)$ and that it has marginal distributions given by the family $F$. To that end, note that, since $\Phi_{\text{DKS},\xi} \equiv \overline{\Phi}_{\text{DKS},\xi}\overline{F}(Q,S)$, we have $Z = \overline{\Phi}_{\text{DKS},\xi}(F)$. Moreover, write $E \equiv \overline{\Phi}_{\text{DKS}}(F) \in \widehat{J}(S^{Q},d^{Q})$. Then, by the defining equality (6.4.3) for the function $\overline{\Phi}_{\text{DKS},\xi}$, we have
\[
Z \equiv \Phi_{\text{DKS},\xi}(F) = \Phi_{\overline{\Phi}_{\text{DKS},\xi}}(E) \in M(\Theta_{0},\mathbb{S}^{Q}).
\]
Furthermore, Theorem 5.5.1 defined and constructed the Skorokhod representation $\Phi_{\overline{\Phi}_{\text{DKS},\xi}}$, such that the r.v.
\[
Z \equiv \Phi_{\overline{\Phi}_{\text{DKS},\xi}}(E) : (\Theta_{0},L_{0},I_{0}) \rightarrow (\mathbb{S}^{Q},d^{Q})
\]
induces the distribution $E$ on the metric space $(\mathbb{S}^{Q},d^{Q})$. In other words, $Ef = I_{0}f(Z)$ for each $f \in C(\mathbb{S}^{Q},d^{Q})$. In particular,
\[
Ef(U_{1},\ldots,U_{n}) = I_{0}\overline{g}(Z_{1},\ldots,Z_{n}) \quad (6.4.10)
\]
for each $g \in C_{ub}(S^{n},d^{n})$, for each $n \geq 1$. Here $U : Q \times S^{Q} \rightarrow S$ is the coordinate function.

On the other hand, Theorem 6.3.8 says that $\Phi_{\text{DK}} \equiv \overline{\Phi}_{\text{DK}}\overline{F}(Q,S)$, whence
\[
E \equiv \overline{\Phi}_{\text{DK}}(F) = \Phi_{\text{DK}}(F) \in \widehat{J}(S^{Q},d^{Q}),
\]
and that (i) the coordinate function
\[
U : Q \times (S^{Q},L,E) \rightarrow (S,d)
\]
is a r.f., where $L$ is the completion of $C_{ub}(S^{Q},d^{Q})$ relative to the distribution $E$, and (ii) the r.f. $U$ has marginal distributions given by the family $F$. Hence
\[
Ef(U_{1},\ldots,U_{n}) = F_{1,\ldots,n}\overline{g} \quad (6.4.11)
\]
for each $g \in C_{ub}(S^{n},d^{n})$, for each $n \geq 1$. Combining equalities (6.4.10) and (6.4.11) we obtain
\[
I_{0}\overline{g}(Z_{1},\ldots,Z_{n}) = F_{1,\ldots,n}\overline{g}
\]
for each $g \in C_{ub}(S^{n},d^{n})$, for each $n \geq 1$. Summing up, we conclude that
\[
Z : Q \times (\Theta_{0},L_{0},I_{0}) \rightarrow (S,d)
\]
is a r.f. with marginal distributions given by the consistent family $F$ of f.j.d.’s. The theorem is proved.$\square$

226

Constructive Probability
As a corollary, we prove Skorokhod’s sequential continuity theorem, essentially
Theorem 3.1.1 in [Skorohod 1956].

**Theorem 6.4.5. (Sequential continuity of the Daniell-Komogorov-Skorokhod Ex-
tension).** Let \( F^{(0)}, F^{(1)}, F^{(2)}, \cdots \) be an arbitrary sequence in \( \bar{F}(Q, S) \) such that
\[
\hat{\rho}_{\text{Marg}, Q}(F^{(p)}, F^{(0)}) \to 0. \quad (6.4.12)
\]
For each \( p \geq 0 \), write
\[
Z^{(p)} = \Phi_{\text{DKS}, Q}(F^{(p)}) \in (\bar{R}(Q \times \Theta_0, S), \rho_{\text{Prob}}) = M(\Theta_0, S^Q)
\]
Then
\[
Z^{(p)} \to Z^{(0)} \quad \text{a.u.}
\]
as r.v.‘s on \((\Theta_0, L_0, I_0)\) with values in the path space \((S^Q, d^Q)\).

**Proof.** Let \( p \geq 0 \) be arbitrary. Write \( Z^{(p)} = \Phi_{\text{DKS}, Q}(F^{(p)}) \) and write \( \Phi^{(p)} = \Phi_{\text{DK}}(F^{(p)}) \in J(S^Q, d^Q) \). Then
\[
Z^{(p)} = \Phi_{\text{DKS}, Q}(F^{(p)}) = \Phi_{\text{Sk}, Q}(\Phi_{\text{DK}}(F^{(p)})) = \Phi_{\text{Sk}, Q}(\Phi^{(p)}). \quad (6.4.13)
\]
Since
\[
\Phi_{\text{DK}} : (\bar{F}(Q, S), \hat{\rho}_{\text{Marg}, Q}) \to (J(S^Q, d^Q), \rho_{\text{Dist}, Q})
\]
is uniformly continuous, convergence relation \(6.4.12\) implies \( \rho_{\text{Dist}, Q}(\Phi^{(p)}, \Phi^{(0)}) \to 0 \). At the same time, the metric space \((S^Q, d^Q)\) is compact. Hence Theorem \(5.5.3\) is applicable, and implies that
\[
\Phi_{\text{Sk}, Q}(\Phi^{(p)}) \to \Phi_{\text{Sk}, Q}(\Phi^{(0)}) \quad \text{a.u.}
\]
on \((\Theta_0, L_0, I_0)\). In view of equality \(6.4.13\) this can be rewritten as
\[
Z^{(p)} \to Z^{(0)} \quad \text{a.u.}
\]
as r.v.‘s on \((\Theta_0, L_0, I_0)\) with values in \((S^Q, d^Q)\). In other words,
\[
\Phi^{(p)}(Z^{(p)}, Z^{(0)}) \to 0 \quad \text{a.u.} \quad (6.4.14)
\]

5. We proceed to show that
\[
d^\infty(Z^{(p)}, Z^{(0)}) \to 0 \quad \text{a.u.} \quad (6.4.15)
\]
To that end, let \( n \geq 1 \) be arbitrary. Then there exists \( b > 0 \) so large that
\[
I_0 B^c < 2^{-n}
\]
where
\[
B \equiv \left( \bigvee_{k=1}^n d(Z^{(0)}(\xi_k), x) \leq b \right). \quad (6.4.16)
\]
Let \( h \equiv n \lor |\log_2 b| \). In view of the a.u. convergence [6.4.14] there exist \( m \geq h \) and a measurable subset \( A \) of \((\Theta_0, L_0, I_0)\) with

\[
I_0 A^c < 2^{-n}
\]

such that

\[
1_A \sum_{k=1}^\infty 2^{-k} I(\hat{Z}^{(p)}(\theta), \hat{Z}^{(0)}(\theta)) \leq 2^{-2h-1}|A_0|^{-2}
\]  

(6.4.17)

for each \( p \geq m \).

6. Now consider each \( \theta \in AB \) and each \( k = 1, \cdots, n \). Then, by inequality [6.4.17] we have

\[
\hat{d}(\hat{Z}^{(p)}(\theta), \hat{Z}^{(0)}(\theta)) \leq 2^k 2^{-2h-1}|A_0|^{-2} \leq 2^{-h-1}|A_0|^{-2},
\]  

(6.4.18)

while equality [6.4.16] yields

\[
d(\hat{Z}^{(0)}(\theta), x_0) \leq b < 2^h.
\]  

(6.4.19)

According to Assertion (ii) of Theorem [3.3.4] regarding the one-point compactification \((\overline{S}, \overline{d})\) of \((S, d)\) relative to the binary approximations \( \xi \equiv (A_p)_{p=1,2,\cdots} \), if \( y \in (d(\cdot, x_0) \leq 2^h) \) and \( z \in S \) are such that

\[
\overline{d}(y, z) < 2^{-h-1}|A_0|^{-2},
\]

then

\[
d(y, z) < 2^{-h+2}.
\]

Hence inequalities [6.4.18] and [6.4.19] together yield

\[
d(\hat{Z}^{(p)}(\theta), \hat{Z}^{(0)}(\theta)) < 2^{-h+2} \leq 2^{-n+2},
\]

where \( \theta \in AB \), and \( k = 1, \cdots, n \) are arbitrary. Consequently, recalling the notation \( \hat{d} \equiv 1 \land \overline{d} \), we obtain

\[
1_{AB} \sum_{k=1}^\infty 2^{-k} \hat{d}(\hat{Z}^{(p)}(\theta), \hat{Z}^{(0)}(\theta)) \leq 1_{AB} \sum_{k=1}^n 2^{-k} \hat{d}(\hat{Z}^{(p)}(\theta), \hat{Z}^{(0)}(\theta)) + \sum_{k=n+1}^\infty 2^{-k} 
\]

\[
\leq 1_{AB} \sum_{k=1}^n 2^{-k} 2^{-n+2} + \sum_{k=n+1}^\infty 2^{-k} < 2^{-n+2} + 2^{-n} < 2^{-n+1},
\]

where \( 2^{-n+1} \) and \( I_0(AB)^c < 2^{-n+1} \) are arbitrarily small. Hence, by Proposition [5.1.14] we have

\[
\sum_{k=1}^\infty 2^{-k} \hat{d}(\hat{Z}^{(p)}(\theta), \hat{Z}^{(0)}(\theta)) \to 0 \text{ a.u.}
\]

Equivalently,

\[
d^w(\hat{Z}^{(p)}, \hat{Z}^{(0)}) \to 0 \text{ a.u.}
\]  

(6.4.20)

In other words, \( Z^{(p)} \to Z^{(0)} \) a.u. in \( M(\Theta_0, S^w) \), as alleged.

\[\square\]
Chapter 7

Measurable Random Field

7.1 Measurable R.F.’s which are Continuous in Probability

In this chapter, let $(S,d)$ be a locally compact metric space, not necessarily a linear space or ordered. Let $(Q,d_Q)$ be a compact metric space endowed with an arbitrary, but fixed, integration.

Consider each consistent family $F$ of f.j.d.’s with parameter space $Q$ and state space $S$ which is continuous in probability, we will construct a measurable r.f. $X : Q \times \Omega \to S$ which extends $F$, in a sense to be defined presently. We will also prove that the construction is metrically continuous.

In the special case where $S \equiv [-\infty, \infty]$ and where $Q$ is a subinterval of $[-\infty, \infty]$, where the symbol $[-\infty, \infty]$ stands for a properly defined and metrized two-point compactification of the real line, the main theorem in Section III.4 of [Neveu 1965], gives a classical construction. The construction in [Neveu 1965] uses a sequence of step processes on half open intervals, and then uses the limit supremum of this sequence as the desired measurable process $X$. Existence of a limit supremum is, however, by invoking principle of infinite search, and not constructive.

[Potthoff 2009] gives a constructive proof of existence in the case where $S \equiv [-\infty, \infty]$ and where $(Q,d_Q)$ is a metric space, by using linear combinations, with stochastic coefficients, of certain deterministic basis functions, as successive $L_1$-approximations to the desired measurable random field $X$, obviating the use of any limit supremum. These deterministic basis functions are continuous on $(Q,d_Q)$ with values in the state space $[0, 1]$, and are from a partition of unity of $(Q,d_Q)$.

In the general case, where neither a linear structure nor an ordering is available on the state space $(S,d)$, the aforementioned limit supremum or linear combinations of basis functions would not be available. We will go around these difficulties by replacing the linear combinations with stochastic interpolations of the basis functions, essentially by continuously varying the probability weighting of basis functions. This method of construction of measurable processes, and the subsequent theorem of metrical continuity of the construction, in epsilon-delta terms, seem hitherto unknown.
Let \( \Omega \) be a probability space. Recall from Definition 6.1.1 the space \( \hat{\Omega} \) of the results to a locally compact parameter space (the locally compact state space each member in a sequence space which is the completion of \( (Q, C(Q, d_Q), I) \). This distribution provides measurable sets and measurable functions, thereby facilitating the definition of measurability. It is otherwise unimportant, and will be called a reference distribution.

The assumption of compactness of \( (Q, d_Q) \) simplifies presentation. The generalization of the results to a locally compact parameter space \( (Q, d_Q) \) is easy, by considering each member in a sequence \( (Q_i)_{i=1,2,...} \) of compact and integrable subsets which forms an \( I \)-basis of \( Q \). This generalization is straightforward and left to the reader.

Definition 7.1.2. (Metric space of measurable r.f.’s) Let \( (Q, L, E) \) be an arbitrary probability space. Recall from Definition 6.1.1 the space \( \hat{R}(Q \times \Omega, S) \) of r.f.’s \( X : Q \times (\Omega, L, E) \rightarrow (S, d) \), with sample space \( (\Omega, L, E) \), the compact parameter space \( Q \), and the locally compact state space \( (S, d) \). Recall from Definition 5.1.10 the metric space \( (M(Q \times \Omega, S), \rho_{Prob}) \) of r.v.’s on the product probability space \( (Q \times \Omega, L \otimes L, \otimes E) \) with values in the state space \( (S, d) \). We will say that a r.f. \( X \in \hat{R}(Q \times \Omega, S) \) is measurable if \( X \in M(Q \times \Omega, S) \). We will write

\[
\hat{R}_{Meas}(Q \times \Omega, S) \equiv \hat{R}(Q \times \Omega, S) \cap M(Q \times \Omega, S)
\]

for the space of measurable r.f.’s. Note that \( \hat{R}_{Meas}(Q \times \Omega, S) \) then inherits the probability metric \( \rho_{Prob} \) on \( M(Q \times \Omega, S) \), which is defined, according to Definition 5.1.10 by

\[
\rho_{Prob}(X, Y) \equiv I \otimes E(1 \wedge d(X, Y))
\]

for each \( X, Y \in M(Q \times \Omega, S) \).

Definition 7.1.3. (Two metrics on the space of measurable r.f.’s which are continuous in probability). Recall from Definition 6.1.3 the set \( \hat{R}_{Cp}(Q \times \Omega, S) \) of r.f.’s which are continuous in probability. Let

\[
\hat{R}_{Meas,Cp}(Q \times \Omega, S) \equiv \hat{R}_{Meas}(Q \times \Omega, S) \cap \hat{R}_{Cp}(Q \times \Omega, S)
\]

be the subset of the metric space \( (\hat{R}_{Meas}(Q \times \Omega, S), \rho_{Prob}) \) whose members are continuous in probability. As a subset, it inherits the probability metric \( \rho_{Prob} \) from the latter. Define a second metric \( \rho_{Sup,Prob} \) on this set \( \hat{R}_{Meas,Cp}(Q \times \Omega, S) \) by

\[
\rho_{Sup,Prob}(X, Y) \equiv \sup_{t \in Q} E(1 \wedge (X_t, Y_t))
\]
for each $X, Y \in \tilde{R}_{\text{Meas}, C_\rho}(Q \times \Omega, S)$. Note in the above definition that $E(1 \wedge (X_i, Y_i))$ is a continuous function on the compact metric space $(Q, d_Q)$, on account of continuity in probability, whence the supremum exists. Note also that defining formulas (7.1.1) and (7.1.2) implies that $\rho_{\text{Prob}} \leq \rho_{\text{Sup}, \text{Prob}}$. In words, $\rho_{\text{Sup}, \text{Prob}}$ is a stronger metric than $\rho_{\text{Prob}}$ on the space of measurable r.f. which are continuous in probability.

□

Definition 7.1.4. (Specification of a countable dense subset of the parameter space, and a partition of unity of $Q$). By Definition 7.1.1 $\xi_Q \equiv (B_n)_{n=1, 2, \ldots}$ is an arbitrary, but fixed, binary approximation of the compact metric space $(Q, d_Q)$ relative to the reference point $q_0 \in Q$. Thus $B_1 \subset B_2 \subset \cdots$ is a sequence of metrically discrete and enumerated finite subsets of $Q$, with $B_n \equiv \{q_{n, 1}, \cdots, q_{n, \gamma(n)}\}$ for each $n \geq 1$.

1. Define the set

$$Q_\infty \equiv \{t_1, t_2, \cdots\} \equiv \bigcup_{n=1}^{\infty} B_n.$$ (7.1.3)

Note that, by assumption, $d_Q \leq 1$. Hence, for each $n \geq 1$, we have, by Definition 3.1.1 of a binary approximation,

$$Q = (d_Q(\cdot, q_0) \leq 2^n) \subset \bigcup_{q \in B(n)} (d_Q(\cdot, q) \leq 2^{-n}).$$ (7.1.4)

Hence $Q_\infty \equiv \bigcup_{n=1}^{\infty} B_n$ is a metrically discrete, countably infinite, and dense subset of $(Q, d_Q)$. Moreover, we can fix an enumeration of $Q_\infty$ in such a manner that

$$\{t_1, t_2, \cdots, t_{\gamma(n)}\} = B_n \equiv \{q_{n, 1}, \cdots, q_{n, \gamma(n)}\},$$

where $\gamma_n \equiv |B_n|$, for each $n \geq 1$.

2. Let

$$\pi_Q \equiv \{(\lambda_{n, q} : q \in B_n)\}_{n=1, 2, \ldots}$$

be the partition of unity of $(Q, d_Q)$ determined by $\xi_Q$. Let $n \geq 1$ be arbitrary. Then, for each $q \in B_n$, the basis function $\lambda_{n, q} \in C(Q, d_Q)$ has values in $[0, 1]$ and has support $(d_Q(\cdot, q) \leq 2^{-n+1})$. Moreover

$$Q \subset \bigcup_{q \in B(n)} (d_Q(\cdot, q) \leq 2^{-n}) \subset \left( \sum_{q \in B(n)} \lambda_{n, q} = 1 \right),$$ (7.1.5)

where the second inclusion is according to Proposition 3.2.5. Define the auxiliary continuous functions $\lambda_{n, 0}^+ \equiv 0$, and

$$\lambda_{n, k}^+ \equiv \sum_{i=1}^{k} \lambda_{n, q(n, i)}$$

for each $k = 1, \cdots, \gamma_n$. Then

$$0 \equiv \lambda_{n, 0}^+ \leq \lambda_{n, 1}^+ \leq \cdots \leq \lambda_{n, \gamma(n)}^+ = 1.$$
In the following, recall some miscellaneous short-hand notations. For an arbitrary integrable set $A$ in a complete integration space $(\Omega, L, E)$, we write $EA$, $E(A)$, and $E 1_A$ interchangeably. Thus, if $(\Omega, L, E)$ is a probability space, then $EA \equiv P(A)$ is the probability of $A$. Recall also that $[\cdot]_1$ is the operation which assigns to each $a \in R$ an integer $[a]_1 \in (a, a + 2)$. As usual, we write $\tilde{d} \equiv 1 \land d$, and write a subscripted expression $x_j$ interchangeably with $x(y)$.

**Theorem 7.1.5. (Extension of measurable r.f. with parameter set $Q_{\infty}$ to the full parameter set $Q$, given continuity in probability).** Consider the locally compact metric space $(S, d)$, without necessarily any linear structure or ordering. Let $(\Omega_0, L_0, E_0)$ be an arbitrary probability space. Recall the space $\hat{R}_{C_p}(Q_{\infty} \times \Omega_0, S)$ of r.f.'s which are continuous in probability over the parameter subspace $(Q_{\infty}, d_Q)$. Recall the space $\hat{R}_{Meas, C_p}(Q \times \Omega, S)$ of r.f.'s which are defined and continuous in probability on the full parameter space $(Q, d_Q)$.

Then there exists a probability space $(\Omega, L, E)$, and a function

$$\Phi_{meas, \xi}(Q) : \hat{R}_{C_p}(Q_{\infty} \times \Omega_0, S) \rightarrow \hat{R}_{Meas, C_p}(Q \times \Omega, S)$$

such that, for each $Z \in \hat{R}_{C_p}(Q_{\infty} \times \Omega_0, S)$ with a modulus of continuity in probability $\xi_{C_p}$, the r.f.

$$X \equiv \Phi_{meas, \xi}(Q)(Z) : Q \times (\Omega, L, E) \rightarrow S$$

satisfies the following conditions.

1. For a.e. $\theta \in \Theta_1$, we have $X_s(\theta, \cdot) = Z_s$ a.s. on $\Omega_0$ for each $s \in Q_{\infty}$.
2. The r.f. $X|Q_{\infty}$ is equivalent to $Z$.
3. The r.f. $X$ is measurable and continuous in probability, with the same modulus of continuity in probability $\xi_{C_p}$ as $Z$.
4. There exists a full subset $D$ of $(\Omega, L, E)$ such that, for each $\omega \in D$, and for each $t \in Q$, there exists a sequence $(s_j)$ in $Q_{\infty}$ with $d_Q(t, s_j) \rightarrow 0$ and $d(X(t, \omega), X(s_j, \omega)) \rightarrow 0$ as $j \rightarrow \infty$.

**Proof.** 1. Let

$$(\Theta_1, L_1, I_1) \equiv ([0,1], L_1, \int \cdot d \theta)$$

denote the Lebesgue integration space based on the interval $[0,1]$. Define the product sample space

$$(\Omega, L, E) \equiv (\Theta_1, L_1, I_1) \otimes (\Omega_0, L_0, E_0).$$

2. Consider each r.f. $Z \in \hat{R}_{C_p}(Q_{\infty} \times \Omega_0, S)$, with a modulus of continuity in probability $\xi_{C_p}$. Define the full subset

$$D_0 \equiv \bigcap_{q \in Q_{\infty}} \text{domain}(Z_q) \subset \Omega_0.$$

3. Augment each sample from $\Omega_0$ with a secondary sample from $\Theta_1$. More precisely, define a function

$$\tilde{Z} : Q_{\infty} \times \Omega \rightarrow S$$
7.1. MEASURABLE R.F.'S WHICH ARE CONTINUOUS IN PROBABILITY

by

\[ \text{domain}(Z) \equiv Q_{\infty} \times \Theta_1 \times D_0 \]

and

\[ \tilde{Z}(q, \theta, \omega_0) \equiv Z(q, \omega_0) \]

for each \((q, \theta, \omega_0) \in \text{domain}(Z)\). Then, for each \(q \in Q_{\infty}\), the function \(\tilde{Z}_q\) is a r.v. on \(\Omega\), according to Propositions 4.8.17 and 4.8.7. Thus \(\tilde{Z}\) is a r.f. We proceed to extend the r.f. \(\tilde{Z}\), by a sequence of stochastic interpolations, to a measurable r.f. \(X : Q \times \Omega \to S\).

4. To that end, let \(m \geq 1\) and \(k = 1, \cdots, \gamma_m\) be arbitrary, where \(\gamma_m\) is as in Definition 1.14. Define

\[ \Delta_{m,k} \equiv \{ (t, \theta) \in Q \times \Theta_1 : \theta \in (\lambda_{m,k+1}(t), \lambda_{m,k}(t)) \} \cdot \]

Relation 7.1.5 says that \(\lambda_{m,\gamma_m} = 1\). Hence Proposition 4.10.19 implies that the sets \(\Delta_{m,1}, \cdots, \Delta_{m,\gamma_m}\) are mutually disjoint integrable subsets of \(Q \times \Theta_1\), and that their union \(\bigcup_{j=1}^{\gamma_m} \Delta_{m,j}\) is a full subset. Define a function \(X^{(m)} : Q \times \Omega \to S\) by

\[ \text{domain}(X^{(m)}) \equiv \bigcup_{i=1}^{\gamma_m} \Delta_{m,i} \times D_0, \]

and by

\[ X^{(m)}(t, \omega) \equiv \tilde{Z}(q_{m,i}, \omega) \equiv Z(q_{m,i}, \omega_0) \tag{7.1.6} \]

for each \((t, \omega) \equiv (t, \theta, \omega_0) \in \Delta_{m,i} \times D_0\), for each \(i = 1, \cdots, \gamma_m\). Since the measurable sets \(\Delta_{m,1} \times D_0, \cdots, \Delta_{m,\gamma_m} \times D_0\) are mutually exclusive in \(Q \times \Omega\), with union equal to a full subset, the function \(X^{(m)} : Q \times \Omega \to S\) is measurable on \((Q \times \Omega, \Lambda \otimes L, I \otimes \mathcal{E})\), by Proposition 4.8.5.

5. Now let \(t \in Q\) be arbitrary. Define the open interval

\[ \Delta_{m,k,t} \equiv (\lambda_{m,k-1}^+(t), \lambda_{m,k}^+(t)) \equiv \{ \theta \in \Theta_1 : \theta \in (\lambda_{m,k-1}(t), \lambda_{m,k}(t)) \} \tag{7.1.7} \]

Then \(\bigcup_{i=1}^{\gamma_m} \Delta_{m,i,t}\) is a full subset of \(\Theta_1 \equiv [0, 1]\). Hence \(\Delta_{m,1,t} \times D_0, \cdots, \Delta_{m,\gamma_m,t} \times D_0\) are mutually exclusive measurable subsets of \(\Omega\) whose union is a full subset of \(\Omega\). Furthermore, by the definition of \(X^{(m)}\) in Step 2, we have

\[ X^{(m)}(t, \omega) \equiv \tilde{Z}(q_{m,i}, \omega) \equiv Z(q_{m,i}, \omega_0) \tag{7.1.8} \]

for each \((\theta, \omega_0) \in \Delta_{m,i,t} \times D_0\), for each \(i = 1, \cdots, \gamma_m\). Hence \(X^{(m)} : \Omega \to S\) is a r.v. by Proposition 4.8.5. Thus we see that \(X^{(m)} : Q \times \Omega \to S\) is a r.f. By Step 2, \(X^{(m)}\) is a measurable function. Therefore \(X^{(m)}\) is a measurable r.f.

Intuitively, for each \(t \in Q\), the r.v. \(X^{(m)}_t\) is set to the r.v. \(Z_{q_{m,i}}(t)\) with probability \(|\Delta_{m,i,t}| = \lambda_{m,q_{m,i}}(t)\), for each \(i = 1, \cdots, \gamma_m\). In this sense, \(X^{(m)}\) is a stochastic interpolation of \(Z_{q_{m,i}}(t)\), for each \(i = 1, \cdots, \gamma_m\). Note that the probabilities \(\lambda_{m,q_{m,i}}(t), \cdots, \lambda_{m,q_{m,\gamma_m}}(t)\) are continuous functions of \(t\). We will later prove that the r.f. \(X^{(m)}\) is continuous in probability, even though its sample functions are piecewise constant.

Yuen-Kwok Chan 233 Constructive Probability
6. We will first construct an a.u. convergent subsequence of \( (X^{(m)})_{m=1,2,...} \). Let \( m_0 \equiv 0 \). Let \( j \geq 1 \) be arbitrary. Write, for abbreviation,
\[
\varepsilon_j \equiv 2^{-j}. 
\]
(7.1.9)

Let
\[
n_j \equiv j \vee [(2 - \log_2 \delta_{cp}(\varepsilon_j))]_1. 
\]
(7.1.10)

Recursively on \( j \geq 1 \), define
\[
m_j \equiv m_{j-1} \vee n_j. 
\]
(7.1.11)

Define
\[
X \equiv \lim_{j \to \infty} X^{(m(j))}. 
\]
(7.1.12)

A priori, the limit need not exist anywhere. We will show that actually \( X^{(m(j))} \to X \) a.u. for each \( t \in Q \), and that therefore \( X \) is a well defined function and is a r.f.

7. To that end, let \( j \geq 1 \) be arbitrary. Then \( m_j \geq n_j \geq j \). Consider each \( t \in Q \) and \( s \in Q \) with
\[
d_Q(s,t) < 2^{-1} \delta_{cp}(\varepsilon_j). 
\]
(7.1.13)

Consider each \( \theta \in \bigcup_{i=1}^{\gamma(m(j))} \Delta_{m(j),i,t} \). Then, for each \( \omega_0 \in D_0 \), we have
\[
(\theta, \omega_0) \in \bigcup_{i=1}^{\gamma(m(j))} \Delta_{m(j),i,t} \times D_0 \equiv \text{domain}(X^{(m(j))}),
\]
and
\[
\hat{d}(\hat{Z}_\theta(\theta, \omega_0), X^{(m(j))}(\theta, \omega_0)) 
= \sum_{i=1}^{\gamma(m(j))} 1_{\Delta_{m(j),i,t}}(\theta) \hat{d}(Z_{\theta}(\omega_0), X^{(m(j))}_i(\theta, \omega_0)) 
= \sum_{i=1}^{\gamma(m(j))} 1_{\Delta_{m(j),i,t}}(\theta) \hat{d}(Z_{\theta}(\omega_0), Z_{q(m(j),i)}(\omega_0)), 
\]
(7.1.14)

where the last inequality follows from the defining formula\[7.1.8\] Hence, since \( D_0 \) is a full set, we obtain
\[
E_{\theta} \hat{d}(\hat{Z}_\theta(\theta, \cdot), X^{(m(j))}(\theta, \cdot)) = \sum_{i=1}^{\gamma(m(j))} 1_{\Delta_{m(j),i,t}}(\theta) E_{\theta} \hat{d}(Z_{\theta}, Z_{q(m(j),i)}).
\]
(7.1.15)

Suppose the summand with index \( i \) on the right-hand side is positive. Then \( \Delta_{m(j),i,t} \equiv (\lambda_{m(j),i-1}(t), \lambda_{m(j),i}(t)) \) is a non-empty open interval. Hence
\[
\lambda_{m(j),i-1}(t) < \lambda_{m(j),i}(t).
\]
Equivalently, \( \lambda_{m(j),i}(t) > 0 \). At the same time, the continuous function \( \lambda_{m(j),i}(t) \) on \( Q \) has support \( (d_Q(\cdot, q_{m(j),i}) \leq 2^{-m(j)+1}) \), as observed in the remarks preceding this theorem. Consequently,
\[
d_Q(t, q_{m(j),i}) \leq 2^{-m(j)+1}. 
\]
(7.1.16)
7.1. MEASURABLE R.F.'S WHICH ARE CONTINUOUS IN PROBABILITY

Inequalities 7.1.13 and 7.1.16 together imply that

\[ d_Q(s, q_{m(j), i}) \leq d_Q(s, t) + d_Q(t, q_{m(j), i}) < \frac{1}{2} \delta_{C_p}(\varepsilon_j) + 2^{-m(j)+1} \]

\[ < \frac{1}{2} \delta_{C_p}(\varepsilon_j) + \frac{1}{2} \delta_{C_p}(\varepsilon_j) < \delta_{C_p}(\varepsilon_j), \quad (7.1.17) \]

where the third inequality follows from defining formulas 7.1.10 and 7.1.11. By the definition of \( \delta_{C_p} \) as a modulus of continuity in probability of \( Z \) on \( Q_\infty \), inequality 7.1.17 yields

\[ E_0 \hat{d}(Z_s, Z_{q_{m(j), i}}) \leq \varepsilon_j. \]

Summing up, the above inequality holds for the \( i \)-th summand in the right-hand side of equality 7.1.15 if said \( i \)-th summand is positive. Equality 7.1.15 therefore results in

\[ E_0 \hat{d}(\tilde{Z}_s, X_t(m(j))) \leq \varepsilon_j \gamma(m(j)) \sum_{i=1}^{\gamma(m(j))} 1_{\Delta(m(j), i, t)}(\theta) = \varepsilon_j, \quad (7.1.18) \]

where \( \theta \) is an arbitrary member of the full set \( \bigcup_{i=1}^{\gamma(m(j))} \Delta_{m(j), i, t} \). Therefore, by Fubini’s Theorem,

\[ E \hat{d}(\tilde{Z}_s, X_t(m(j))) = I_1 \otimes E_0 \hat{d}(\tilde{Z}_s, X_t(m(j))) \leq \varepsilon_j, \quad (7.1.19) \]

where \( t \in Q \) and \( s \in Q_\infty \) are arbitrary with

\[ d_Q(s, t) < \frac{1}{2} \delta_{C_p}(\varepsilon_j). \]

8. Now let \( j \geq 1 \) and \( t \in Q \) be arbitrary. Take any \( s \in Q_\infty \) such that

\[ d_Q(s, t) < \frac{1}{2} \delta_{C_p}(\varepsilon_j) \wedge \frac{1}{2} \delta_{C_p}(\varepsilon_{j+1}). \]

Then it follows from inequality 7.1.19 that

\[ E \hat{d}(X_t(m(j)), X_t(m(j+1))) \leq E \hat{d}(\tilde{Z}_s, X_t(m(j))) + E \hat{d}(\tilde{Z}_s, X_t(m(j+1))) \leq \varepsilon_j + \varepsilon_{j+1} \equiv 2^{-j} + 2^{-j-1} < 2^{-j+1}, \quad (7.1.20) \]

where \( t \in Q \) and \( j \geq 1 \) are arbitrary. Hence, by Assertion 5 of Proposition 5.1.11, the function \( X_t \equiv \lim_{j \to \infty} X_t(m(j)) \) is a r.v., and

\[ X_t(m(j)) \to X_t \quad a.u. \]

We conclude that

\[ X : Q \times \Omega \to S \]

is a r.f.
9. We will now show that $X$ is a measurable r.f. Note that, by Fubini’s Theorem, inequality 7.1.20 implies

\[ (I \otimes E) \hat{d}(X^{(m(j))}, X^{(m(j+1))}) \leq 2^{-j+1} \]

(7.1.21)

for each $j \geq 1$. Since $X^{(m(j))}$ is a measurable function on $(Q \times \Omega, \Lambda \otimes L, I \otimes E)$, for each $j \geq 1$, Assertion 5 of Proposition 5.1.11 implies that $X^{(m(j))}_i \rightarrow X$ a.u. on $(Q \times \Omega, \Lambda \otimes L, I \otimes E)$, and that $X \equiv \lim_{j \to \infty} X^{(m(j))}_i$ is a measurable function on $(Q \times \Omega, \Lambda \otimes L, I \otimes E)$. Thus $X$ is a measurable r.f.

10. Define the full subset

\[ D_1 = \bigcap_{I \in Q(\omega)} \bigcap_{n=1}^{\infty} \bigcup_{i=1}^{\gamma(n)} \Delta_{n,i} \]

of $\Theta_1 \equiv [0, 1]$. Let $\theta \in D_1$ be arbitrary. For each $s \in Q_\infty$, letting $j \to \infty$ in inequality 7.1.19 with $t = s$, we obtain $E_0 \hat{d}(\tilde{Z}_s, X_s(\theta, \cdot)) = 0$, whence

\[ Z_s = \tilde{Z}_s(\theta, \cdot) = X_s(\theta, \cdot) \quad \text{a.s.} \quad (7.1.22) \]

on $(\Omega_0, L_0, E_0)$. Condition 1 in the conclusion of the theorem is proved.

11. Now let $K \geq 1$, $f \in C_{ab}(S^K)$, and $s_1, \ldots, s_K \in Q_\infty$ be arbitrary. Then, in view of equality 7.1.22 Fubini’s Theorem implies

\[ Ef(X_{s(1)}, \ldots, X_{s(K)}) = (I \otimes E_0)f(X_{s(1)}, \ldots, X_{s(K)}) = E_0f(Z_{s(1)}, \ldots, Z_{s(K)}). \]

Thus the r.f.’s $X|Q_\infty$ and $Z$ are equivalent, establishing Condition 2 in the conclusion of the theorem.

12. We will prove that $X$ is continuous in probability. For that purpose, let $\varepsilon > 0$ be arbitrary. Let $j \geq 1$ and $t, t' \in Q$ be arbitrary with

\[ d_Q(t, t') < \delta_{C_P}(\varepsilon). \]

Since $Q_\infty$ is dense in $Q$, there exist $s, s' \in Q_\infty$ with $d_Q(s, s') < \delta_{C_P}(\varepsilon)$ and

\[ d_Q(t, s) \cup d_Q(t', s') < \frac{1}{2} \delta_{C_P}(\varepsilon). \]

It follows that $E_0 \hat{d}(Z_s, Z_{s'}) \leq \varepsilon$. We can then apply inequality 7.1.19 to obtain

\[ E\hat{d}(X_t^{(m(j))}, X_{t'}^{(m(j))}) \leq E\hat{d}(X_t^{(m(j))}, \tilde{Z}_s) + E\hat{d}(\tilde{Z}_s, Z_{t'}) + E\hat{d}(\tilde{Z}_{t'}, X_{t'}^{(m(j))}). \]

\[ \leq \varepsilon_j + (I \otimes E_0) \hat{d}(1_{\Theta(1)} \otimes Z_s, 1_{\Theta(1)} \otimes Z_{t'}) + \varepsilon_j \]

\[ = \varepsilon_j + E_0 \hat{d}(Z_s, Z_{t'}) + \varepsilon_j \leq \varepsilon_j + \varepsilon + \varepsilon_j, \]

where the equality is thanks to Fubini’s Theorem. Letting $j \to \infty$ yields

\[ E\hat{d}(X_t, X_{t'}) \leq \varepsilon, \]

Yuen-Kwok Chan 236 Constructive Probability
7.1. MEASURABLE R.F.'S WHICH ARE CONTINUOUS IN PROBABILITY

where \( \varepsilon > 0 \) is arbitrarily small. Summing up, the r.f. \( X \) is continuous in probability on \( Q \), with \( \Delta_{p} \) as a modulus of continuity in probability. Condition 3 has been established.

13. For each \( s \in Q_{\infty} \), letting \( j \to \infty \) in inequality (7.1.19) with \( t = s \), we obtain

\[
E\hat{d}(\bar{Z}_{s},X_{s}) = E_{0}\hat{d}(\bar{Z}_{s},X_{s}) = 0. \tag{7.1.23}
\]

Hence

\[
D_{2} = \bigcap_{s \in Q(\infty)} \bar{Z}_{s} = X_{s} \tag{7.1.24}
\]
is a full subset of \( (\Omega,L,E) \). Define the full subset

\[
D \equiv D_{2} \cap (D_{1} \times D_{0}) \cap \bigcap_{s \in Q(\infty)} \bigcup_{j=1}^{\infty} \text{domain}(X^{(m(j))})
\]
of the sample space \( (\Omega,L,E) \).

Consider each \( \omega \equiv (\theta,\omega_{0}) \in D \subset D_{2} \). Then \( \theta \in D_{1} \) and \( \omega_{0} \in D_{0} \). Let

\[
t \in \text{domain}(X(\cdot,\omega))
\]
be arbitrary. In other words, \( (t,\omega) \in \text{domain}(X) \). Hence, by the defining equality (7.1.12) we have

\[
X(t,\omega) = \lim_{j \to \infty} X^{(m(j))}(t,\omega). \tag{7.1.25}
\]

Let \( \varepsilon > 0 \) be arbitrary. Let \( J \geq 1 \) be so large that

\[
(t,\omega) \in \text{domain}(X^{(m(j))}) \equiv \bigcup_{i=1}^{\gamma(m(j))} \Delta_{m(j),i} \times D_{0} \tag{7.1.26}
\]

and

\[
d(X(t,\omega),X^{(m(j))}(t,\omega)) < \varepsilon
\]
for each \( j \geq J \). Now consider each \( j \geq J \). By relation (7.1.26), there exists \( i_{j} = 1,\cdots,\gamma_{m(j)} \) such that

\[
(t,\theta,\omega_{0}) \equiv (t,\omega) \in \Delta_{m(j),i_{j}} \times D_{0}.
\]

Hence

\[
X^{(m(j))}(t,\omega) = \bar{Z}(q_{m(j),i_{j}},\omega) = X(q_{m(j),i_{j}},\omega), \tag{7.1.27}
\]

where the first equality follows from equality (7.1.6) and the second from equality (7.1.23) and from the membership \( \omega \in D_{2} \). At the same time, since \( t \in \Delta_{m(j),i_{j}} \), we have

\[
d_{Q}(t,q_{m(j),i_{j}}) \leq 2^{-m(j)+1} \tag{7.1.28}
\]
according to inequality (7.1.16). Summing up, for each \( \omega \) in the full set \( D \), and for each \( t \in Q \), the sequence \( (s_{j}) \equiv (q_{m(j),i_{j}}) \) in \( Q_{\infty} \) is such that

\[
d_{Q}(t,s_{j}) \to 0
\]
and

\[
d(X(t,\omega),X(s_{j},\omega)) \to 0.
\]
Thus Condition 4 of the conclusion of the theorem has also been proved.

\[\square\]

Yuen-Kwok Chan
Recall the set \( \hat{F}(Q,S) \) of consistent families of f.j.d.’s with the parameter set \( Q \) and state space \( S \). Recall the subset \( \hat{F}_{CP}(Q,S) \) whose members are continuous in probability, equipped with the metric \( \rho_{CP,\hat{\xi},Q|Q(\infty)} \) defined in Definition [6.2.11] by

\[
\rho_{CP,\hat{\xi},Q|Q(\infty)}(F,F') = \rho_{\text{Marg},\hat{\xi},Q}(F|Q(\infty),F'|Q(\infty)) = \sum_{n=1}^{\infty} 2^{-n} \rho_{\text{Dist},\hat{\xi}}(F_{q_1},\ldots,q(n),F'_{q_1},\ldots,q(n))
\]

for each \( F,F' \in \hat{F}_{CP}(Q,S) \).

The measurable extension of a consistent family of f.j.d.’s which is continuous in probability is another immediate corollary of Theorem [6.4.2].

**Theorem 7.1.6. (Construction of measurable r.f. from family of consistent f.j.d.’s which is continuous in probability).** Consider the locally compact metric space \((S,d)\), without necessarily any linear structure or ordering. Let

\[
(\Theta_0, L_0, I_0) = ([0,1], L_0, \int d\theta)
\]

denote the Lebesgue integration space based on the interval \([0,1]\). Then there exists a function

\[
\Phi_{\text{meas},\hat{\xi},\hat{\xi}}: \hat{F}_{CP}(Q,S) \to \hat{R}_{\text{Meas},CP}(\Theta_0 \times \Omega, S)
\]

such that, for each \( F \in \hat{F}_{CP}(Q,S) \), the measurable r.f.

\[
X \equiv \Phi_{\text{meas},\hat{\xi},\hat{\xi}}(F): Q \times (\Theta_0, L_0, I_0) \to S
\]

has marginal distributions given by the family \( F \).

We will refer to the function \( \Phi_{\text{meas},\hat{\xi},\hat{\xi}}(Q) \) as the measurable extension relative to the binary approximations \( \hat{\xi} \) and \( \hat{\xi}_Q \) of \((S,d)\) and \((Q,d_Q)\) respectively.

**Proof.** 1. Let \( \Phi_{Q,Q(\infty)}: \hat{F}_{CP}(Q,S) \to \hat{F}_{CP}(Q(\infty),S) \) be the function defined by

\[
\Phi_{Q,Q(\infty)}(F) = F|Q(\infty)
\]

for each \( F \in \hat{F}_{CP}(Q,S) \). Let \( \Phi_{\text{DKS},\hat{\xi}} \) be the Daniell-Kolmogorov-Skorokhod extension as constructed in Theorem [6.4.4]. Let \( \Phi_{\text{meas},\hat{\xi}}(Q) \) be the function constructed in Theorem [6.4.4].

2. We will prove that the composite function

\[
\Phi_{\text{meas},\hat{\xi},\hat{\xi}}(Q) = \Phi_{\text{meas},\hat{\xi}}(Q) \circ \Phi_{\text{DKS},\hat{\xi}} \circ \Phi_{Q,Q(\infty)}
\]

has the desired properties. To that end, let \( F \in \hat{F}_{CP}(Q,S) \) be arbitrary, with a modulus of continuity of probability \( \delta_{CP} \). Then \( F|Q(\infty) \) is also continuous in probability, with the same modulus of continuity of probability \( \delta_{CP} \). Let

\[
Z \equiv \Phi_{\text{DKS},\hat{\xi}}(F|Q(\infty))
\]
be the Daniell-Kolmogorov-Skorokhod extension of $F|Q_\infty$ relative to the binary approximation $\hat{\xi}$ of $(S,d)$. Thus
\[
Z : Q_\infty \times (\Theta_0, L_0, I_0) \to S
\]
is a r.f. with marginal distributions given by $F|Q_\infty$. It follows that the r.f. $Z$ has modulus of continuity of probability $\delta_{CP}$. Hence Theorem [7.1.5] applies, and yields the measurable r.f.
\[
X \equiv \Phi_{meas, \hat{\xi}}(Q)(Z) : Q \times (\Theta_0, L_0, I_0) \to S.
\]
Now define
\[
\Phi_{meas, \hat{\xi}}(Q)(F) \equiv X = \Phi_{meas, \hat{\xi}}(Q) \circ \Phi_{DKS, \hat{\xi}} \circ \Phi_{Q, Q(\infty)}(F).
\]
According to Theorem [7.1.5] $X$ is continuous in probability with the same modulus of continuity of probability $\delta_{CP}$. Moreover, $X|Q_\infty$ is equivalent to $Z$. Hence $X|Q_\infty$ has marginal distributions given by $F|Q_\infty$.

4. It remains to prove that the r.f. $X$ has marginal distributions given by $F$. To that end, consider each $k \geq 1$, $r_1, \ldots, r_k \in Q$, $s_1, \ldots, s_k \in Q_\infty$, and $f \in C_{ab}(S^k, d^k)$. Then
\[
I_0 f(X_{s(1)}, \ldots, X_{s(k)}) = I_0 f(Z_{r(1)}, \ldots, Z_{r(k)}) = F_{s(1), \ldots, s(k)} f.
\]
Now let $s_k \to r_k$ in $Q$ for each $k = 1, \ldots, k$. Then the left-hand side converges to $I_0 f(X_{r(1)}, \ldots, X_{r(k)})$, on account of the continuity in probability of $X$. The right-hand side converges to $F_{r(1), \ldots, r(k)} f$ by the continuity in probability of $F$, according to Lemma [6.2.10] Hence
\[
I_0 f(X_{r(1)}, \ldots, X_{r(k)}) = F_{r(1), \ldots, r(k)} f.
\]
The theorem is proved.

We will next prove the metrical continuity of the mapping $\Phi_{meas, \hat{\xi}}(Q)$. Recall from Definition [6.2.11] the metric $\tilde{\rho}_{CP, \hat{\xi}}(Q|Q(\infty))$ on the space $\hat{F}_{CP}(Q, S)$.

**Theorem 7.1.7.** (Continuity of construction of measurable r.f.’s) Let $\hat{F}_{CP, \delta_{CP}}(Q, S)$ be an arbitrary subset of $\hat{F}_{CP}(Q, S)$ whose members have a common modulus of continuity in probability $\delta_{CP}$. Recall that
\[
(\Theta_0, L_0, I_0) \equiv ([0, 1], L_0, \int \cdot \, d\theta)
\]
denote the Lebesgue integration space based on the interval $[0, 1]$.

Then the construction
\[
\Phi_{meas, \hat{\xi}}(Q) : (\hat{F}_{CP}(Q, S), \tilde{\rho}_{CP, \hat{\xi}}(Q|Q(\infty))) \to (\hat{R}_{Meas, CP}(Q \times \Theta_0, S), \rho_{Sup, Prob})
\]
(7.1.31) in Theorem [7.1.6] is uniformly continuous on the subset $\hat{F}_{CP, \delta_{CP}}(Q, S)$, with a modulus of continuity $\delta_{f, d, meas}(\cdot, \delta_{CP}, \|\hat{\xi}\|, \|\hat{\xi}_Q\|)$ dependent only on $\delta_{CP}, \|\hat{\xi}\|$, and $\|\hat{\xi}_Q\|$.

Yuen-Kwok Chan 239 Constructive Probability
CHAPTER 7. MEASURABLE RANDOM FIELD

Proof. Refer to the proofs of Theorem 7.1.5 and Theorem 7.1.6 where the defining equality \( \Phi_{\text{meas}, \xi}(Q) \mid \tilde{F}_{CP, \delta(CP)}(Q, S) = \Phi_{\text{meas}, \xi}(Q) \circ \Phi_{DKS, \xi} \circ (\Phi_{Q, Q(\omega)} \mid \tilde{F}_{CP, \delta(CP)}(Q, S)) \). (7.1.32)

For the uniform continuity of \( \Phi_{\text{meas}, \xi}(Q) \mid \tilde{F}_{CP, \delta(CP)}(Q, S) \), we need only verify the continuity of the three functions on the right-hand side, and compound their moduli of continuity.

1. By Definition 6.2.11 the function

\[
\Phi_{Q, Q(\omega)} : (\tilde{F}_{CP}(Q, S), \rho_{\text{meas}}) \to (\tilde{F}(Q, S), \rho_{\text{meas}}),
\]

defined by \( \Phi_{Q, Q(\omega)}(F) = F|_{Q_\omega} \) for each \( F \in \tilde{F}_{CP}(Q, S) \), is metric preserving. It is therefore uniformly continuous, with a trivial modulus of continuity \( \delta_{Q, Q(\omega)}(\varepsilon) \equiv \varepsilon \) for each \( \varepsilon > 0 \).

2. Let \( F \in \tilde{F}_{CP, \delta(CP)}(Q, S) \) be arbitrary. By hypothesis, \( F \) is continuous in probability on \( Q_\omega \) with a modulus of continuity \( \delta_{CP} \). Hence its restriction \( F|_{Q_\omega} \) is trivially continuous in probability on \( Q_\omega \), with the same modulus of continuity \( \delta_{CP} \). According to Theorem 6.4.4, the Daniell-Kolmogorov-Skorokhod Extension

\[
\Phi_{DKS, \xi} : (\tilde{F}(Q, S), \rho_{\text{Marg}}) \to (\tilde{F}(Q \times \Theta_0, S), \rho_{Q \times \Theta(0), S})
\]
is uniformly continuous on the subset

\[
\tilde{F}_{CP, \delta(CP)}(Q, S)|_{Q_\omega} \equiv \Phi_{Q, Q(\omega)}(\tilde{F}_{CP, \delta(CP)}(Q, S)),
\]

with a modulus of continuity \( \delta_{DKS}(\cdot, \|\xi\|) \) dependent only on the modulus of local compactness \( \|\xi\| = (\|A_k\|)_{k=1,2} \) of the locally compact space \( (S, d) \).

3. It remains to verify that the function

\[
\Phi_{\text{meas}, \xi}(Q) : (\tilde{F}(Q, S), \rho_{Q \times \Theta(0), S}) \to (\tilde{F}(Q \times \Theta_0, S), \rho_{Q \times \Theta(0), S})
\]
is uniformly continuous on the subset

\[
\tilde{F}_0 \equiv \Phi_{DKS, \xi}(\tilde{F}_{CP, \delta(CP)}(Q, S)|_{Q_\omega}) \equiv \Phi_{DKS, \xi}(\Phi_{Q, Q(\omega)}(\tilde{F}_{CP, \delta(CP)}(Q, S))).
\]

4. As in the proof of Theorem 7.1.5 define, for each \( j \geq 1 \),

\[
\varepsilon_j \equiv 2^{-j}, \quad (7.1.33)
\]

\[
n_j \equiv j \vee [(2 - \log_2 \delta_{CP}(\varepsilon_j))], \quad (7.1.34)
\]

and

\[
m_j \equiv m_{j-1} \vee n_j, \quad (7.1.35)
\]

where \( m_0 \equiv 0 \).

5. Now let \( \varepsilon > 0 \) be arbitrary. Let

\[
j \equiv \lfloor 0 \vee (4 - \log_2 \varepsilon) \rfloor.
\]

Yuen-Kwok Chan 240 Constructive Probability
Then $2^{-j} < 2^{-4} \varepsilon$. Define
\[ \delta_{\text{meas}}(\varepsilon, \delta_{\mathcal{C}_p}, \| \xi \|) = 2^{-\gamma(m(j))} \varepsilon^2. \]

Let $Z, Z' \in \mathcal{R}_0$ be arbitrary such that
\[ \rho_{Q \times \Theta_0, S}(Z, Z') < \delta_{\text{meas}}(\varepsilon, \delta_{\mathcal{C}_p}, \| \xi \|). \quad (7.1.36) \]
We will verify that $\rho_{\text{Sup}, \text{Prob}}(\Phi_{\text{meas}, \xi_Q}(Z), \Phi_{\text{meas}, \xi_Q}(Z')) < \varepsilon$.

6. Write $X \equiv \Phi_{\text{meas}, \xi_Q}(Z)$, and $X' \equiv \Phi_{\text{meas}, \xi_Q}(Z')$. Thus $Z, Z' : Q \times \Theta_0 \rightarrow S$ are r.f.'s, and $X, X' : Q \times \Theta_0 \rightarrow S$ are measurable r.f.'s. As in the proof of Theorem 7.1.5 define the full subset
\[ D_0 = \bigcap_{q \in Q^{(m)}} \text{domain}(Z_q) \]
of $\Theta_0 \equiv \Theta_0 \equiv [0, 1]$. Similarly, define the full subset $D_0' = \bigcap_{q \in Q^{(m)}} \text{domain}(Z_q')$
of $\Theta_0$. Then $D_0D_0'$ is a full subset of $\Theta_0$. Note that inequality $\ref{7.1.36}$ is equivalent to
\[ I_0 \sum_{i=1}^n 2^{-i} \tilde{d}(Z_{t(i)}, Z'_{t(i)}) < 2^{-\gamma(m(j))} \varepsilon^2. \quad (7.1.37) \]

Hence, by Chebychev’s inequality, there exists a measurable set $A \subset \Theta_0$ with
\[ I_0 A^c < 2^{-2} \varepsilon, \]
such that
\[ \sum_{i=1}^n 2^{-i} \tilde{d}(Z(t_i, \omega_0), Z'(t_i, \omega_0)) \leq 2^{-\gamma(m(j))} \varepsilon, \quad (7.1.38) \]
for each $\omega_0 \in A$.

7. Let $\omega_0 \in AD_0D_0'$ be arbitrary. Then inequality $\ref{7.1.38}$ trivially implies that
\[ \gamma(m(j)) \sum_{i=1}^n \tilde{d}(Z(t_i, \omega_0), Z'(t_i, \omega_0)) \leq 2^{-2} \varepsilon. \quad (7.1.39) \]

Let $t \in Q$ be arbitrary. Recall that
\[ \tilde{\Delta} = \bigcup_{i=1}^{\gamma(m(j))} \Delta_{n, i, \theta} \equiv \bigcup_{i=1}^{\gamma(m(j))} (\lambda_{n, i-1}^+(t), \lambda_{n, i}^-(t)) \]
is a full subset of $\Theta_1 \equiv [0, 1]$. Let $\theta \in \tilde{\Delta}$ be arbitrary. Then $\theta \in \Delta_{n, i, \theta}$ for some $i = 1, \cdots, \gamma(m(j))$. Hence $(\theta, \omega_0) \in \Delta_{n, i, \theta} \times D_0D_0'$. Therefore the defining equality $\ref{7.1.8}$ in the proof of Theorem 7.1.5 says that
\[ X_i^{(m(j))}(\theta, \omega_0) = Z(q_{m, i, \theta}) \quad (7.1.40) \]

Yuen-Kwok Chan 241 Constructive Probability
Combining the last three displayed inequalities, we obtain
\[ X_i^{(m(j))}(\theta, \Omega_b) = Z'(q_m, \Omega_b). \] (7.1.41)

Consequently, in view of inequality \[ 7.1.39 \] we have
\[
\delta_d(X_i^{(m(j))}(\theta, \Omega_b), X_i^{(m(j))}(\theta, \Omega_b)) \\
= \delta_d(Z(q_m, \Omega_b), Z'(q_m, \Omega_b)) \leq 2^{-2} \varepsilon,
\] (7.1.42)
where \((\theta, \Omega_b) \in \bar{\Delta} \times AD_0 D_0'\) is arbitrary. Since \(\varepsilon \leq 1\), it follows that
\[
I_0 \delta_d(X_i^{(m(j))}, X_i^{(m(j))}) = I_0 \delta_d(X_i^{(m(j))}, X_i^{(m(j))}) 1_{\bar{\Delta} \times AD_0 D_0'} + I_0 1_{\bar{\Delta} \times AD_0 D_0'} = 2^{-2} \varepsilon + I_0 1_{\bar{\Delta} \times AD_0 D_0'} < 2^{-2} \varepsilon + 2^{-2} \varepsilon = 2^{-1} \varepsilon.
\]

8. Separately, inequality \[ 7.1.20 \] in the proof of Theorem \[ 7.1.5 \] implies that
\[
I_0 \delta_d(X_i^{(m(j))}, X_i^{(m(j))}) \leq \sum_{j=0}^{m} 2^{-j+1} = 2^{-j+2},
\]
and, similarly, that
\[
I_0 \delta_d(X_i^{(m(j))}, X_i') < 2^{-j+2}.
\]
Combining the last three displayed inequalities, we obtain
\[
I_0 \delta_d(X_i, X_i') < 2^{-1} \varepsilon + 2^{-j+2} + 2^{-j+2} = 2^{-1} \varepsilon + 2^{-j+3},
\]
where \(t \in Q\) is arbitrary. Therefore
\[
\rho_{\text{Sup,Prob}}(X, X') = \sup_{t \in Q} I_0 \delta_d(X_i, X_i') \leq 2^{-1} \varepsilon + 2^{-j+3} < 2^{-1} \varepsilon + 2^{-1} \varepsilon = \varepsilon.
\]

In other words,
\[
\rho_{\text{Sup,Prob}}(\Phi_{\text{meas}, \xi}(Q), \Phi_{\text{meas}, \xi}(Q')) < \varepsilon,
\]
as alleged. Thus \(\delta_{\text{meas}}(\cdot, \delta_c p, \|\xi_Q\|)\) is a modulus of continuity of \(\Phi_{\text{meas}, \xi}(Q)\) on
\[
\tilde{R}_0 = \Phi_{DKS, \xi}(\tilde{F}_{c, p, \delta(c_p)}(Q, S)| Q \omega) \Phi_{DKS, \xi}(\Phi_{Q, Q(\omega)}(\tilde{F}_{c, p, \delta(c_p)}(Q, S))).
\]

9. Combining, we conclude that the composite function \(\Phi_{\text{meas}, \xi}(Q)| \tilde{R}_0\) in equality \[ 7.1.32 \] is uniformly continuous, with the composite modulus of continuity
\[
\delta_{f \text{meas}}(\cdot, \delta_c p, \|\xi\|, \|\xi_Q\|) = \delta_{Q, Q(\omega)}(\delta_{DKS}(\delta_{\text{meas}}(\varepsilon, \delta_c p, \|\xi_Q\|), \|\xi\|)))
\]

as desired.
7.2 Measurable Gaussian Random Fields

Let \((Q, d_Q)\) be a compact metric space, with \(d_Q \leq 1\) and with an arbitrary, but fixed, distribution \(I\). As an application of the Theorems 7.1.6, we will construct a measurable Gaussian r.f. \(X : Q \times \Omega \to R\) from its continuous mean and covariance functions, and will prove the continuity of this construction. For that purpose we need only prove that from the mean and covariance functions we can construct a consistent family of normal f.j.d.’s which is continuous in probability, and that the construction is continuous.

**Definition 7.2.1. (Gaussian r.f.)** A r.f. \(X : Q \times \Omega \to R\) is said to be Gaussian if it has marginal distributions which are normal. The functions \(\mu(t) \equiv EX_t\) and \(\sigma(t) \equiv E(X_t - EX_j)(X_s - EX_j)\) are called the mean and covariance functions, respectively, of the r.f. \(X\).

Without loss of generality, we will treat only the case where the r.f. is centered, with \(EX_t = 0\) for each \(t \in Q\). The more general case where the mean is a non-trivial continuous function \(\mu\) follows by adding \(\mu\) to a centered r.f. \(X\).

Recall the matrix terminologies in Definition 5.7.1.

**Definition 7.2.2. (Nonnegative definite functions).** Let \(D\) be an arbitrary nonempty set. Write \(D^2 \equiv D \times D\). Let \(\sigma : D^2 \to [0, \infty)\) be an arbitrary symmetric function. If, for each \(m \geq 1\) and for each \(r_1, \cdots, r_m \in D\), the square matrix \(\sigma(r_k, r_h)_{k=1, \cdots, m; h=1, \cdots, m}\) is nonnegative definite, then \(\sigma\) is said to be a nonnegative definite function on the set \(D^2\).

If, for each \(m \geq 1\) and for each \(r_1, \cdots, r_m \in D\), the matrix \(\sigma(r_k, r_h)_{k=1, \cdots, m; h=1, \cdots, m}\) is positive definite, then \(\sigma\) is said to be a positive definite function on the set \(D^2\).

In the rest of this chapter, let \(\xi\) and \(\xi_Q \equiv (B_n)_{n=1, 2, \cdots}\) be arbitrary, but fixed, binary approximations of the Euclidean state space \((S, d) \equiv (R, d)\) and and the compact parameter space \((Q, d_Q)\) respectively, as specified in Definitions 7.1.1 and 7.1.4 respectively. Recall the enumerated, countably infinite, dense subset

\[
Q_\infty \equiv \{t_1, t_2, \cdots\} \equiv \bigcup_{n=1}^{\infty} B_n
\]

(7.2.1)

of \(Q\), where \(B_n \equiv \{q_n, 1, \cdots, q_n, \gamma(n)\} = \{t_1, \cdots, t_{\gamma(n)}\}\) as sets, for each \(n \geq 1\).

**Proposition 7.2.3. (Consistency of family of normal f.j.d.’s generated by covariance function).** Let \(\sigma : Q \times Q \to [0, \infty)\) be a continuous nonnegative definite function. For each \(m \geq 1\) and each \(r_1, \cdots, r_m \in Q\), write the nonnegative definite matrix

\[
\underline{\sigma} \equiv \begin{bmatrix} \sigma(r_k, r_h) & \cdots & \sigma(r_k, r_m) \\ \cdots & \cdots & \cdots \\ \sigma(r_1, r_h) & \cdots & \sigma(r_1, r_m) \end{bmatrix}_{k=1, \cdots, m; h=1, \cdots, m},
\]

(7.2.2)

and define

\[
F_{(r_1), \cdots, (r_m)}^\sigma \equiv F_{0, \underline{\sigma}},
\]

(7.2.3)

where \(F_{0, \underline{\sigma}}\) is the normal distribution with mean 0 and covariance matrix \(\underline{\sigma}\). Then the following holds.

1. The family

\[
F^\sigma \equiv F_{\text{covar}, f, d}(\sigma) \equiv \{F_{(r_1), \cdots, (r_m)}^\sigma : m \geq 1; r_1, \cdots, r_m \in Q\}
\]

(7.2.4)
CHAPTER 7. MEASURABLE RANDOM FIELD

of f.j.d.’s is consistent.

2. The consistent family \( F^\sigma \) is continuous in probability. In symbols, \( F^\sigma \in \hat{L}_c(Q,R) \). Specifically, suppose \( \sigma_0 \) is a modulus of continuity of \( \sigma \) on the compact metric space \((Q^2,d_Q)\). Then \( F^\sigma \) has a modulus of continuity in probability defined by

\[
\tilde{\sigma}_C(p) \equiv \delta_{C^p}(\varepsilon,\sigma_0) \equiv \delta_0(\frac{1}{2}\varepsilon^2)
\]

for each \( \varepsilon > 0 \).

Proof. 1. Let \( m \geq 1 \) be arbitrary. Let \( \sigma \equiv (\sigma_1,\cdots,\sigma_m) \) be an arbitrary sequence in \( Q \), and let \( f \equiv (j_1,\cdots,j_m) \) be an arbitrary sequence in \( \{1,\cdots,m\} \). Let the matrix \( \sigma \) be defined as in equality 7.2.2 above. By Lemma 5.7.8, \( F^\sigma_{r(1),\cdots,r(m)} = \Phi_0,\sigma \) is the distribution of a r.v. \( Y = AZ \), where \( A \) is an \( m \times m \) matrix such that \( \sigma \equiv AA^T \), and where \( Z \) is a standard normal r.v. on some probability space \((\Omega,L,E)\), with values in \( R^m \). Let the dual function \( j^*: R^m \to R^m \) be defined by

\[
j^*(x_1,\cdots,x_m) \equiv (x_{j(1)},\cdots,x_{j(n)})
\]

for each \( x \equiv (x_1,\cdots,x_m) \in R^m \). Then \( j^*(x) = Bx \) for each \( x \in R^m \), where the \( n \times m \) matrix

\[
B \equiv [b_{k,h}]_{k=1,\cdots,n;h=1,\cdots,m},
\]

is defined by \( b_{k,h} \equiv 1 \) or 0 according as \( h = j_k \) or \( h \neq j_k \). Let \( \bar{A} = BA \). Define the \( n \times n \) matrix

\[
\bar{\sigma} \equiv \bar{A}A^T = BAA^T B^T = B\sigma B^T = [\sigma(r_{j(h)},r_{j(h)})]_{k=1,\cdots,n;h=1,\cdots,n}.
\]

Then, by the defining formula [7.2.3]

\[
F^\sigma_{r(j(1)),\cdots,r(j(n))} = \Phi_0,\bar{\sigma}.
\]

At the same time, the r.v.

\[
\tilde{Y} \equiv j^*(Y) = BY = BAZ \equiv \bar{A}Z
\]

has the normal characteristic function defined by

\[
E(\exp i\lambda^T AZ) = \exp(-\frac{1}{2}\lambda^T A\bar{A}^T \lambda) = \exp(-\frac{1}{2}\lambda^T \bar{\sigma} \lambda)
\]

for each \( \lambda \in R^n \). Hence \( \tilde{Y} \) has the normal distribution \( \Phi_0,\bar{\sigma} \). Combining, we see that, for each \( f \in C(R^n) \),

\[
F^\sigma_{r(1),\cdots,r(m)}(f \circ j^*) = E(f \circ j^*(Y)) = E(f(\tilde{Y}) = \Phi_0,\sigma(f) = F^\sigma_{r(j(1)),\cdots,r(j(n))}f.
\]

We conclude that the family \( F^\sigma \) of f.j.d.’s is consistent.

2. Now consider the case where \( m = 2 \). Consider each \( r_1, r_2 \in Q \) with

\[
d_Q(r_1,r_2) < \delta_{C^p}(\varepsilon) \equiv \delta_0(\frac{1}{2}\varepsilon^2).
\]

Yuen-Kwok Chan 244 Constructive Probability
Let \( d \) denote the Euclidean metric for \( R \). As in Step 1, there exists a r.v. \( Y \equiv (Y_1, Y_2) \) with values in \( R^2 \) with the normal distribution \( \Phi_{0, \varpi} \), where \( \varpi \equiv [\sigma(r_k, r_h)]_{k=1,2, h=1,2} \). Then

\[
\begin{align*}
F_{\sigma}(1\land d)(1 \land d) &= \Phi_{0, \varpi}(1 \land d) \\
&\leq \Phi_{0, \sigma d} = E[Y_1 - Y_2] \leq \sqrt{E(Y_1 - Y_2)^2} \\
&= \sqrt{\sigma(r_1, r_1) - 2\sigma(r_1, r_2) + \sigma(r_2, r_2)} \\
&\leq \sqrt{|\sigma(r_1, r_1) - \sigma(r_1, r_2)| + |\sigma(r_2, r_2) - \sigma(r_1, r_2)|} \\
&\leq \sqrt{\frac{1}{2} \varepsilon^2 + \frac{1}{2} \varepsilon^2} = \varepsilon,
\end{align*}
\]

where the second inequality is Lyapunov’s inequality, and the last is due to inequality \( 7.2.5 \). Thus \( F^\sigma \) is continuous in probability, with \( \delta^p(\cdot, \delta_0) \) as a modulus of continuity in probability. \( \Box \)

Recall from Definition \( 6.2.11 \) the metric space \( (\hat{F}_p^\sigma(Q, R), \hat{\rho}_p^\sigma, \xi, Q(\xi)) \) of consistent families of f.j.d.’s with parameter space \( (Q, d_Q) \) and state space \( R \).

**Proposition 7.2.4.** (Normal f.j.d.’s depend continuously on covariance function). Let \( G \) denote the set of continuous nonnegative definite functions \( \sigma : Q \times Q \to R \). Equip \( G \) with the metric \( d_G \) defined by

\[
d_G(\sigma, \sigma') = \sup_{(t, s) \in Q \times Q} |\sigma(t, s) - \sigma'(t, s)|
\]

for each \( \sigma, \sigma' \in G \). Then the function

\[
\Phi_{\text{covar, f.j.d}} : (G, d_G) \to (\hat{F}_p^\sigma(Q, R), \hat{\rho}_p^\sigma, \xi, Q(\xi))
\]

in Proposition \( 7.2.3 \) is uniformly continuous, with a modulus of continuity \( \delta_{\text{covar, f.j.d}} \) defined in equality \( 7.2.5 \) in the proof below.

**Proof.** 1. Let \( \varepsilon > 0 \) be arbitrary. Let \( n \geq 1 \) be arbitrary. By Theorem \( 5.8.11 \) there exists \( \delta_{\text{dist, distr}}(\varepsilon, n) > 0 \) such that, for arbitrary distributions \( J, J' \) on \( R^n \) whose respective characteristic functions \( \psi, \psi' \) satisfy

\[
\rho_{\text{ch, n}}(\psi, \psi') \equiv \sum_{j=1}^{\infty} 2^{-j} \sup_{|\lambda| \leq j} |\psi(\lambda) - \psi'(\lambda)| < \delta_{\text{dist, distr}}(\varepsilon, n),
\]

we have

\[
\rho_{\text{Dist, distr}}(J, J') < \varepsilon,
\]

where \( \rho_{\text{Dist, distr}} \) is the metric on the space of distributions on \( R^n \), as in Definitions \( 5.3.4 \).

2. Let \( \varepsilon > 0 \) be arbitrary. Let \( m \geq 1 \) be so large that \( 2^{-m+1} < \varepsilon \). Let \( K \geq 1 \) be so large that

\[
2^{-K+1} < \alpha = 1 \land e^{-1} \bigwedge_{n=1}^{m} \delta_{\text{dist, distr}}(\xi, n).
\]

Yuen-Kwok Chan 245 Constructive Probability
CHAPTER 7. MEASURABLE RANDOM FIELD

Then, since $0 \leq \alpha \leq 1$, basic calculus shows that $e^\alpha - 1 \leq \alpha(e - 1)$. Define

$$
\delta_{\text{covar},fjd}(\varepsilon) \equiv 2K^{-2}m^{-2}\alpha.
$$

(7.2.8)

We will verify that $\delta_{\text{covar},fjd}$ is the desired modulus of continuity of $\Phi_{\text{covar},fjd}$.

3. To that end, let $\sigma, \sigma' \in G$ be arbitrary such that

$$
da_G(\sigma, \sigma') < \delta_{\text{covar},fjd}(\varepsilon).
$$

(7.2.9)

Let $F^\sigma \equiv \Phi_{\text{covar},fjd}(\sigma)$ and $F'^\sigma \equiv \Phi_{\text{covar},fjd}(\sigma')$ be constructed as in Theorem 7.2.5. We will show that $\tilde{\rho}_{C_p,\xi}(\varepsilon) \equiv (F^\sigma, F'^\sigma) < \varepsilon$.

4. First note that inequality (7.2.9) is equivalent to

$$
\sup_{(t,s) \in \mathcal{Q} \times \mathcal{Q}} |\sigma(t,s) - \sigma'(t,s)| < 2K^{-2}m^{-2}\alpha.
$$

(7.2.10)

Next, let $n = 1, \cdots, m$ be arbitrary. The joint normal distribution $F^\sigma_{t(1), \cdots, t(n)}$ has characteristic function defined by

$$
\chi'^\sigma_{t(1), \cdots, t(n)}(\lambda) \equiv \exp\left(-\frac{1}{2} \sum_{k=1}^{n} \lambda_k \sigma(t_k, t_h)\lambda_h\right)
$$

for each $\lambda \equiv (\lambda_1, \cdots, \lambda_n) \in \mathbb{R}^n$, with a similar equality for $\sigma'$. It follows that

$$
\rho_{\text{char}}(\chi'^\sigma_{t(1), \cdots, t(n)}, \chi^\sigma_{t(1), \cdots, t(n)}) \equiv \sum_{j=1}^{\infty} 2^{-j} \sup_{|\lambda| \leq j} |\chi^\sigma_{t(1), \cdots, t(n)}(\lambda) - \chi'^\sigma_{t(1), \cdots, t(n)}(\lambda)|

< \sup_{|\lambda| \leq K} |\chi^\sigma_{t(1), \cdots, t(n)}(\lambda) - \chi'^\sigma_{t(1), \cdots, t(n)}(\lambda)| + \sum_{j=K+1}^{\infty} 2^{-j} \cdot 2

= \sup_{|\lambda| \leq K} |\exp(-\frac{1}{2} \sum_{k=1}^{n} \lambda_k \sigma(t_k, t_h)\lambda_h) - \exp(-\frac{1}{2} \sum_{k=1}^{n} \lambda_k \sigma'(t_k, t_h)\lambda_h)| + 2^{-K+1}.

By the real variable inequality $|e^{-x} - e^{-y}| = e^{-y}|e^{-x+y} - 1| \leq e^{x-y} - 1$ for arbitrary $x, y \geq 0$, the last displayed expression is bounded by

$$
\sup_{|\lambda| \leq K} \left(\exp\left(\frac{1}{2} \sum_{k=1}^{n} \sum_{h=1}^{n} |\lambda_k(\sigma(t_k, t_h) - \sigma'(t_k, t_h))\lambda_h| - 1\right) + 2^{-K+1}\right)

 \leq \left(\exp\left(\frac{K^2}{2} \sum_{k=1}^{n} \sum_{h=1}^{n} |\sigma(t_k, t_h) - \sigma'(t_k, t_h)| - 1\right) + 2^{-K+1}\right)

 \leq \left(\exp\left(\frac{K^2}{2} \sum_{k=1}^{n} \sum_{h=1}^{n} 2K^{-2}m^{-2}\alpha - 1\right) + 2^{-K+1}\right)

 \leq \left(e^{\alpha - 1} + 2^{-K+1} \leq \alpha(e - 1) + \alpha e \leq \delta_{\varepsilon,\text{dist}}(\frac{\varepsilon}{2}, n),

Yuen-Kwok Chan 246 Constructive Probability
where the second inequality is from inequality \(7.2.10\) above. Hence, according to inequality \(7.2.7\) we have

\[
\rho_{\text{Dist}, \xi^n}(F_{\sigma}^{t_1}, \ldots, F_{\sigma}^{t_n}, F_{\sigma}^{s_1}, \ldots, F_{\sigma}^{s_n}) < \frac{\varepsilon}{2},
\]

where \(n = 1, \ldots, m\) is arbitrary. Therefore, according to Definition \(6.2.11\)

\[
\tilde{p}_{\text{CP}, \xi, \Omega(t)}(F_{\sigma}^{t_1}, F_{\sigma}^{t_2}, \ldots, F_{\sigma}^{t_n}, F_{\sigma}^{s_1}, F_{\sigma}^{s_2}, \ldots, F_{\sigma}^{s_m})
\]

\[
\leq m \sum_{n=1}^{m} 2^{-n} \rho_{\text{Dist}, \xi^n}(F_{\sigma}^{t_1}, \ldots, F_{\sigma}^{t_n}, F_{\sigma}^{s_1}, \ldots, F_{\sigma}^{s_m})
\]

\[
\leq m \sum_{n=1}^{m} 2^{-n} n + 2^{-m} + \frac{\varepsilon}{2} = \frac{\varepsilon}{2} < \varepsilon,
\]

(7.2.11)

where we used the bounds \(0 \leq \rho_{\text{Dist}, \xi^n} \leq 1\) for each \(n \geq 1\).

Since \(\varepsilon > 0\) is arbitrarily small, we conclude that the function \(\Phi_{\text{covar}, fjd}\) is uniformly continuous, with modulus of continuity \(\delta_{\text{covar}, fjd}\).

Now we can mechanically apply the theorems in the previous section. As in the previous section, let

\[\Theta_0, L_0, I_0 \equiv (\Theta_1, L_1, I_1) \equiv ([0, 1], L_1, \int d\theta)\]

be the Lebesgue integration space based on the interval \([0, 1]\), and let

\[\Omega, L, E \equiv (\Theta_1, L_1, E_1) \otimes (\Theta_0, L_0, E_0)\]

**Theorem 7.2.5. (Construction of measurable Gaussian r.f. from continuous covariance function).** Let \(\sigma : Q \times Q \rightarrow R\) be a continuous nonnegative definite function. Then there exists a measurable Gaussian r.f.

\[X \equiv \Phi_{\text{covar}, fjd}(\sigma) \circ \Phi_{\text{covar}, fjd}(\sigma) : Q \times \Omega \rightarrow R\]

which is continuous in probability, and which is such that \(EX_0 = 0\) and \(EX_0 X_s = \sigma(t,s)\) for each \(t, s \in Q\). We will call the function \(\Phi_{\text{covar}, fjd}(\sigma)\) the measurable Gaussian extension relative to the binary approximations \(\xi\) and \(\xi_0\).

**Proof.** By Proposition \(7.2.3\) the family \(F_{\sigma} \equiv \Phi_{\text{covar}, fjd}(\sigma)\) of normal f.j.d.’s is consistent and continuous in probability. Hence Theorem \(7.1.6\) is applicable to \(F_{\sigma}\) and yields the measurable r.f.

\[X \equiv \Phi_{\text{covar}, fjd}(\sigma) \circ \Phi_{\text{covar}, fjd}(\sigma),\]

with marginal distributions given by \(F_{\sigma}\). Since \(F_{\sigma}\) is continuous in probability by Proposition \(7.2.3\) so is \(X\). \(\square\)
Recall from Definition 7.1.3 the metric space \( \hat{\mathcal{R}}_{\text{Meas},\mathcal{C}_p}(Q \times \Omega, R), \rho_{\text{Sup,Prob}} \) of measurable r.f.’s \( X : Q \times \Omega \rightarrow R \) which are continuous in probability. Thus
\[
\rho_{\text{Sup,Prob}}(X, Y) \equiv \sup_{t \in Q} E 1 \wedge |X_t - Y_t|
\]
for each \( X, Y \in \hat{\mathcal{R}}_{\text{Meas},\mathcal{C}_p}(Q \times \Omega, R) \).

**Theorem 7.2.6. (Continuity of the construction of measurable Gaussian r.f.’s).** Use the same assumptions and notations as in Proposition 7.2.4 and Theorem 7.2.5. Suppose \( G_0 \) is a subset of the set \( G \) of continuous nonnegative definite functions \( \sigma : Q \times Q \rightarrow R \) whose members share a common modulus of continuity \( \delta_0 \) on \( Q \times Q \). Suppose, in addition, that there exists \( b_0 \geq 0 \) such that \( \sigma(t, t) \leq b_0 \) for each \( t \in Q \), for each \( \sigma \in G_0 \).

Then the measurable Gaussian extension
\[
\Phi_{\text{cov,gauss}, \xi}(Q) : (G, d_G) \rightarrow (\hat{\mathcal{R}}_{\text{Meas},\mathcal{C}_p}(Q \times \Omega, R), \rho_{\text{Sup,Prob}})
\]
constructed in Theorem 7.2.5 is uniformly continuous on the subset \( G_0 \) of \( G \), with a modulus of continuity \( \delta_{\text{cov,gauss}}(\cdot, \delta_0, b_0, ||\xi||, ||\hat{\xi}||) \).

**Proof.**

1. By the construction in Theorem 7.2.5,
\[
\Phi_{\text{cov,gauss}, \xi}(Q) \equiv \Phi_{\text{meas, \xi}}(Q) \circ \Phi_{\text{cov, fjd}}.
\]

2. By Lemma 7.2.4 the function
\[
\Phi_{\text{cov, fjd}} : (G, d_G) \rightarrow (\hat{\mathcal{F}}_{\mathcal{C}_p}(Q, R), \hat{\rho}_{\mathcal{C}_p, \xi}(Q(\omega)))
\]
is uniformly continuous, with a modulus of continuity \( \delta_{\text{cov, fjd}} \).

3. By Proposition 7.2.3 the members of \( \hat{\mathcal{F}}_{\mathcal{C}_p, \delta(\mathcal{C})}(Q, S) \equiv \Phi_{\text{cov, fjd}}(G_0) \) share the same modulus of continuity in probability defined by \( \delta_{\mathcal{C}_p}(\epsilon, \delta_0) \equiv \delta_0(\frac{1}{2} \epsilon^2) \) for each \( \epsilon > 0 \).

4. Hence \( \hat{\mathcal{F}}_{\mathcal{C}_p, \delta(\mathcal{C})}(Q, S) \) satisfies the conditions in the hypothesis of Theorem 7.1.7. According to Assertion 2 of Theorem 7.1.7, the function
\[
\Phi_{\text{meas, \xi}}(Q) : (\hat{\mathcal{F}}_{\mathcal{C}_p, \delta(\mathcal{C})}(Q, S), \hat{\rho}_{\mathcal{C}_p, \xi}(Q(\omega))) \rightarrow (\hat{\mathcal{R}}_{\text{Meas},\mathcal{C}_p}(Q \times \Omega, R), \rho_{\text{Sup,Prob}})
\]
is uniformly continuous on \( \hat{\mathcal{F}}_{\mathcal{C}_p, \delta(\mathcal{C})}(Q, S) \), with a modulus of continuity
\[
\delta_{\text{fjd,meas}}(\cdot, \delta_{\mathcal{C}_p}, \beta, ||\xi||, ||\hat{\xi}||).
\]

5. Combining, the composite function \( \Phi_{\text{cov,gauss}, \xi}(Q) \) is uniformly continuous, with a modulus of continuity defined by the composite operation
\[
\delta_{\text{cov,gauss}}(\epsilon, \delta_0, b_0, ||\xi||, ||\hat{\xi}||) \equiv \delta_{\text{cov, fjd}}(\delta_{\text{fjd,meas}}(\epsilon, \delta_{\mathcal{C}_p}(\cdot, \delta_0), \beta, ||\xi||, ||\hat{\xi}||))
\]
for each \( \epsilon > 0 \). □
Chapter 8

Martingales

In this chapter, we define a martingale \( X \equiv \{ X_t : t = 1, 2, \ldots \} \) for modeling one’s fortune in a fair game of chance. Then we will prove the basic theorems on martingales which have wide-ranging applications. Among these is the a.u. convergence of \( X_t \) as \( t \to \infty \). Our proof is constructive and quantifies rates of convergence by means of a maximal inequality. There are proofs in traditional texts which also are constructive and quantify rates similarly by means of maximal inequalities. These traditional maximal inequalities, however, require the integrability of \( |X_t|^p \) for some \( p > 1 \), or at least the integrability of \( |X_t| \log |X_t| \). For the separate case of \( p = 1 \), the classical proof of a.u. convergence is by a separate inference from certain upcrossing inequalities. Such inference is essentially equivalent to the principle of infinite search, and is not constructive.

In contrast, the maximal inequality we present requires only the integrability of \( |X_t| \). Therefore, thanks to Lyapunov’s inequality, it is at once applicable to the case of integrable \( |X_t|^p \) for any given \( p \geq 1 \), without having to first determine whether \( p > 1 \) or \( p = 1 \).

For readers who are uninitiated in the subject, the previous paragraphs are perhaps confusing, but will become clear as we proceed. For the rich body of classical results on, and applications of, martingales, see e.g. [Doob 1953, Chung 1968, Durrett 1984].

**Definition 8.0.1. (Assumptions and Notations).** In this chapter, let \((S, d)\) be a locally compact metric space with an arbitrary, but fixed, reference point \( x_0 \). Let \((\Omega, L, E)\) be an arbitrary probability space. Unless otherwise specified, a r.v. refers to a measurable function with values in \( S \).

If \((\Omega, L', E)\) is a probability subspace of \((\Omega, L, E)\), we will simply call \( L' \) a probability subspace of \( L \) when \( \Omega \) and \( E \) are understood. Let \( Q \) denote an arbitrary nonempty subset of \( R \), called the time parameter set.

For abbreviation, we will write \( A \in L \) if \( A \) is a measurable subset of \((\Omega, L, E)\). Thus \( A \in L \) iff \( 1_A \in L \), in which case we will write \( P(A), PA, E1_A, \) and \( EA \) interchangeably, and write \( E(X:A) \equiv E1_A \) for each \( X \in L \). As usual, we write a subscripted expression \( x_y \) interchangeably with \( x(y) \).
8.1 Filtrations

Let $Q$ denote an arbitrary nonempty subset of $R$.

**Definition 8.1.1. (Filtration).** Suppose that, for each $t \in Q$, there exists a probability subspace $(\Omega, L^{(t)}, E)$ of $(\Omega, L, E)$, such that $L^{(t)} \subseteq L^{(s)}$ for each $t, s \in Q$ with $t \leq s$. Then the family $\mathcal{L} \equiv \{L^{(t)} : t \in Q\}$ is called a filtration in $(\Omega, L, E)$ with time parameter set $Q$. The filtration $\mathcal{L}$ is said to be right continuous if, for each $t \in Q$, we have

$$L^{(t)} = \bigcap_{s \in Q, s > t} L^{(s)}.$$

Suppose, in addition, that $\bar{Q}$ is a subset of $Q$. Then a stochastic process $X : \bar{Q} \times \Omega \to S$ is said to be adapted to the filtration $\mathcal{L}$ if $X_t$ is a r.v. on $(\Omega, L^{(t)}, E)$ for each $t \in Q$.

The probability space $L^{(t)}$ can be regarded as the observable history up to the time $t$. Thus a process $X$ adapted to $\mathcal{L}$ is such that $X_t$ is observable at the time $t$, for each $t \in Q$. Note that if all points in the set $Q$ are isolated points in $\bar{Q}$, then each filtration $\mathcal{L}$ with time parameter set $Q$ is right continuous.

**Definition 8.1.2. (Natural filtration of a stochastic process).** Let $X : Q \times \Omega \to S$ be an arbitrary stochastic process. For each $t \in Q$, define the set

$$G^{(X,t)} = \{X_r : r \in Q; r \leq t\},$$

and let

$$L^{(X,t)} = L(X_r : r \in Q; r \leq t) \equiv L(G^{(X,t)})$$

be the probability subspace of $L$ generated by the set $G^{(X,t)}$ of r.v.'s. Then the family $\mathcal{L}_X \equiv \{L^{(X,t)} : t \in Q\}$ is called the natural filtration of the process $X$.

**Lemma 8.1.3. (A natural filtration is indeed a filtration).** Let $X : Q \times \Omega \to S$ be an arbitrary stochastic process. Then the natural filtration $\mathcal{L}_X$ of $X$ is a filtration to which the process $X$ is adapted.

**Proof.** For each $t \leq s$ in $Q$ we have $G^{(X,t)} \subseteq G^{(X,s)}$ whence $L^{(X,t)} \subseteq L^{(X,s)}$. Thus $\mathcal{L}_X$ is a filtration. Let $t \in Q$ be arbitrary. Then $f(X_t) \in L(G^{(X,t)}) \subseteq L^{(X,t)}$ for each $f \in C_{ab}(S, \mathcal{L})$. At the same time, because $X_t$ is a r.v. on $(\Omega, L, E)$, we have $P(d(X_t, x_0) \geq a) \to 0$ as $a \to \infty$. Hence $X_t$ is a r.v. on $(\Omega, L^{(X,t)}, E)$ according to Proposition 5.1.4. Thus the process $X$ is adapted to the its natural filtration $\mathcal{L}_X$.

**Definition 8.1.4. (Right-limit extension and right continuity of a filtration).** Suppose (i) $\underline{Q} = (0, \infty)$ or (ii) $\underline{Q} \equiv [0, a]$ for some $a > 0$. Suppose $Q$ is a subset which is dense in $\underline{Q}$ and which, in Case (ii), contains the end point $a$. Let $\mathcal{L} \equiv \{L^{(t)} : t \in Q\}$ be an arbitrary filtration of a given probability space $(\Omega, L, E)$.

In Case (i) define, for each $t \in \underline{Q}$, the probability subspace

$$L^{(t+)} \equiv \bigcap\{L^{(s)} : s \in Q \cap (t, \infty)\}.$$  

(8.1.1)

Yuen-Kwok Chan 250 Constructive Probability
of $L$. In Case (ii) define, for each $t \in \overline{Q}$, the probability subspace

$$L^{(t+)} \equiv \bigcap \{L^{(s)} : s \in \overline{Q} \cap (t, a] \cup \{a\}\}.$$ (8.1.2)

Then the filtration $\mathscr{L}^+ \equiv \{L^{(t+)} : t \in \overline{Q}\}$ is called the right-limit extension of the filtration $\mathscr{L}$.

If $Q = \overline{Q}$ and $L^{(t)} = L^{(t+)}$ for each $t \in \overline{Q}$, then $\mathscr{L}$ is said to be a right continuous filtration.

$\square$

**Lemma 8.1.5. (Right-limit extension of a filtration is right continuous).** In the notations of Definition 8.1.4, we have $(\mathscr{L}^+)^+ = \mathscr{L}^+$. In words, the right-limit extension of the filtration $\mathscr{L} \equiv \{L^t : t \in Q\}$ is right continuous.

**Proof.** We will give the proof only for the case where $\overline{Q} = [0, \infty)$, the proof for the case where $\overline{Q} = [0, a]$ being similar. To that end, let $t \in \overline{Q}$ be arbitrary. Then

$$(L^{(t+)}^+) \equiv \bigcap \{L^{(s)} : s \in \overline{Q} \cap (t, \infty)\}$$

$$\equiv \bigcap \{\bigcap \{L^{(u)} : u \in Q \cap (s, \infty)\} : s \in \overline{Q} \cap (t, \infty)\}$$

$$\equiv \bigcap \{L^{(u)} : u \in Q \cap (t, \infty)\} = L^{(t+)}.$$

where the third equality is because $u \in Q \cap (t, \infty)$ iff $u \in Q \cap (s, \infty)$ for some $s \in Q \cap (t, \infty)$, thanks to the assumption that $Q$ is dense in $\overline{Q}$. $\square$

### 8.2 Stopping Times

**Definition 8.2.1. (r.r.v. with values in a subset of $R$).** Let $A$ denote an arbitrary nonempty subset of $R$. We say that a r.r.v. $\eta$ has values in the subset $A$ if $(\eta \in A)$ is a full set. $\square$

**Lemma 8.2.2. (r.r.v. with values in an increasing sequence in $R$).** Let the subset $A \equiv \{t_0, t_1, \cdots\} \subset R$ be arbitrary such that $t_{n-1} < t_n$ for each $n \geq 1$. Then a r.r.v. $\eta$ has values in $A$ iff (i) $(\eta = t_n)$ is measurable for each $n \geq 0$, and (ii) $\sum_{n=1}^\infty P(\eta = t_n) = 1$.

**Proof.** Recall Definition 4.8.10 of regular points of a real-valued measurable function. Suppose the r.r.v. $\eta$ has values in $A$. For convenience, write $t_{-1} \equiv t_0 - (t_1 - t_0)$. Consider each $t_n \in A$ with $n \geq 0$. Write $\Delta_n \equiv (t_n - t_{n-1}) \wedge (t_{n+1} - t_n) > 0$. Then there exist regular points $t, s$ of the r.r.v. $\eta$ such that

$$t_{n-1} < t_n - \Delta_n < s < t_n < t < t + \Delta_n < t_{n+1}.$$ Then $(\eta = t_n) = (\eta \leq t) (\eta \leq s)^c (\eta \in A)$. Since $(\eta \leq t)$, $(\eta \leq s)$ , and $(\eta \in A)$ are measurable subsets, it follows that the set $(\eta = t_n)$ is measurable. At the same time $P(\eta \leq t_n) \uparrow 1$ as $m \to \infty$ since $\eta$ is a r.r.v. Hence

$$\sum_{n=1}^m P(\eta = t_n) = P(\eta \leq t_n) \uparrow 1$$

Yuen-Kwok Chan 251 Constructive Probability
as \( m \to \infty \). In other words, \( \sum_{n=1}^{\infty} P(\eta = t_n) = 1 \). Thus we have proved that if the r.r.v. \( \eta \) has values in \( A \) then Conditions (i) and (ii) holds. The converse is trivial. \( \square \)

**Definition 8.2.3.** (Stopping time, space of integrable observables at a stopping time, and simple stopping time). Let \( Q \) denote an arbitrary nonempty subset of \( R \). Let \( \mathcal{L} \) be an arbitrary right continuous filtration with time parameter set \( Q \). Then a r.r.v. \( \tau \) with values in \( Q \) is called a stopping time relative to the filtration \( \mathcal{L} \) if

\[
(\tau \leq t) \in L^{(t)}
\]

for each regular point \( t \in Q \) of the r.r.v. \( \tau \). We will omit the reference to \( \mathcal{L} \) when it is understood from context, and simply say that \( \tau \) is a stopping time. Each r.v. relative to the probability subspace

\[
L^{(\tau)} = \{ Y \in L : Y 1_{(\tau \leq t)} \in L^{(t)} \text{ for each regular point } t \in Q \text{ of } \tau \}
\]

is said to be observable at the stopping time \( \tau \). Each member of \( L^{(\tau)} \) is called integrable observable at the stopping time \( \tau \).

Let \( X : Q \times \Omega \to S \) be an arbitrary stochastic process adapted to the filtration \( \mathcal{L} \). Define the function \( X_\tau \) by

\[
domain(X_\tau) \equiv \{ \omega \in domain(\tau) : (\tau(\omega), \omega) \in domain(X) \},
\]

and by

\[
X_\tau(\omega) \equiv X(\tau(\omega), \omega)
\]

for each \( \omega \in domain(X_\tau) \). Then the function \( X_\tau \) is called the observable of the process \( X \) at the stopping time \( \tau \). In general, \( X_\tau \) need not be a well defined r.v. We will need to prove that \( X_\tau \) is a well defined r.v. in each application before using it as such.

A stopping time \( \tau \) with values in some discrete finite subset of \( Q \), is called a simple stopping time. \( \square \)

We leave it as an exercise to verify that \( L^{(\tau)} \) is indeed a probability subspace. A trivial example of a stopping time is a deterministic time \( \tau \equiv s \), where \( s \in Q \) is arbitrary.

The next lemma generalizes the defining equality \[8.2.1\] and will be convenient.

**Lemma 8.2.4.** (Basic properties of stopping times). Suppose \( Q = [0, 1] \) or \( Q = [0, \infty) \). \( \mathcal{L} \) be an arbitrary right continuous filtration with time parameter set \( Q \). Let \( \tau \) be a stopping time relative to the filtration \( \mathcal{L} \). Let \( t \in Q \) be an arbitrary regular point of the r.r.v. \( \tau \). Then \( (\tau < t), (\tau = t) \in L^{(t)} \).

**Proof.** Let \( (s_k)_{k=1,2,\ldots} \) be an increasing sequence of regular points in \( Q \) of \( \tau \) such that \( s_k \uparrow t \) and such that \( P(\tau \leq s_k) \uparrow P(\tau \leq t) \). In other words \( E[1_{\tau \leq s(k)}] \to 0 \). Since \( \tau \) is a stopping time relative to a filtration \( \mathcal{L} \), we have \( 1_{\tau \leq s(k)} \in L^{(s(k))} \subset L^{(t)} \) for each \( k \geq 1 \). Hence \( 1_{\tau \leq t} \in L^{(t)} \) and \( 1_{\tau = t} = 1_{\tau \leq t} - 1_{\tau < t} \in L^{(t)} \). Equivalently, \( (\tau < t), (\tau = t) \in L^{(t)} \). \( \square \)

**Definition 8.2.5.** (Specialization to a discrete parameter set). In the remainder of this section, assume that the parameter set \( Q \equiv \{ 0, \Delta, 2\Delta, \ldots \} \) is equally spaced, with some fixed \( \Delta > 0 \), and let \( \mathcal{L} \equiv \{ L^{(t)} : t \in Q \} \) be an arbitrary, but fixed, filtration in \( (\Omega, L, E) \) with parameter \( Q \). Note that the filtration is then trivially right continuous.
Proposition 8.2.6. (Basic properties of stopping times, discrete case). Let $\tau$ and $\tau'$ be stopping times with values in $Q \equiv \{0, \Delta, 2\Delta, \cdots\}$, relative to the filtration $\mathcal{L}$. For each $n \geq -1$, write $t_n \equiv n\Delta$ for convenience. Then the following holds.

1. Let $\eta$ be a r.v. with values in $Q$. Then $\eta$ is a stopping time iff $(\eta = t_n) \in L^{(i(n))}$ for each $n \geq 0$.
2. $\tau \land \tau'$, $\tau \lor \tau'$ are stopping times.
3. If $\tau \leq \tau'$ then $L^{(\tau)} \subset L^{(\tau')}$. 
4. Let $X : Q \times \Omega \to S$ be an arbitrary stochastic process adapted to the filtration $\mathcal{L}$. Then $X_t$ is a well defined r.v. on the probability space $(\Omega, L^{(t)}, E)$.

Proof. 1. By Lemma 8.2.2, the set $(\eta = t_n)$ is measurable for each $n \geq 0$, and $\sum_{n=1}^{\infty} P(\eta = t_n) = 1$. Suppose $\eta$ is a stopping time. Let $n \geq 0$ be arbitrary. Then $(\eta \leq t_n) \in L^{(i(n))}$. Moreover, if $n \geq 1$, then $(\eta \leq t_{n-1})' \subset L^{(i(n-1))} \subset L^{(i(n))}$. If $n = 0$, then $(\eta \leq t_{n-1})' = (\eta \geq 0)$ is a full set, whence $(\eta \geq 0) \in L^{(0)}$. Combining, we see that $(\eta = t_n) = (\eta \leq t_n)(\eta \leq t_{n-1})' \in L^{(i(n))}$. We have proved the “only if” part of Assertion 1.

Conversely, suppose $(\eta = t_n) \in L^{(i(n))}$ for each $n \geq 0$. Let $t \in Q$ be arbitrary. Then $t = t_m$ for some $m \geq 0$. Hence $(\eta \leq t) = \bigcup_{n=0}^{m} (\eta = t_n)$, where, by assumption, $(\eta = t_n) \in L^{(i(n))} \subset L^{(i(m))}$ for each $n = 0, \cdots, m$. Thus we see that $(\eta \leq t)$, where $t \in Q$ is arbitrary. We conclude that $\eta$ is a stopping time.

2. Let $t = t_n$ be arbitrary. Then

$$(\tau \land \tau' \leq t) = (\tau \leq t) \cup (\tau' \leq t) \in L^{(t)},$$

and

$$(\tau \lor \tau' \leq t) = (\tau \leq t)(\tau' \leq t) \in L^{(t)}.$$

Thus $\tau \land \tau'$ and $\tau \lor \tau'$ are stopping times.

3. Let $Y \in L^{(\tau)}$ be arbitrary. Consider each $t \in Q$. Then, since $\tau \leq \tau'$,

$$Y 1_{(\tau \leq t)} = \sum_{t \in Q} Y 1_{(\tau = t)} 1_{(\tau \leq t)} = \sum_{t \in [0, t] \cap Q} Y 1_{(\tau = t)} 1_{(\tau \leq t)} \in L^{(t)}.$$ 

Thus $Y \in L^{(\tau)}$, where $Y \in L^{(t)}$ is arbitrary. We conclude that $L^{(\tau)} \subset L^{(\tau')}$. 

4. Let $X : Q \times \Omega \to S$ be an arbitrary stochastic process adapted to the filtration $\mathcal{L}$. Define the full sets $A \equiv \bigcap_{n=0}^{\infty} \text{domain}(X_{t_n})$ and $B \equiv \bigcup_{n=0}^{\infty} (\tau = t_n)$. Consider each $\omega \in AB$. Then $(\tau(\omega), \omega) = (t_n, \omega) \in \text{domain}(X)$ on $(\tau = t_n)$ for each $n \geq 0$. In short, $X_{\tau}$ is defined and is equal to the r.v. $X_{t_n}$ on $(\tau = t_n)$, for each $n \geq 0$. Since $X_{t_n}$ is a full set, the function $X_{\tau}$ is therefore a r.v. according to Proposition 4.8.5.

Simple first exit times from a time-varying neighborhood, introduced next, are examples of simple stopping times.

Definition 8.2.7. (Simple first exit time). Let $Q' \equiv \{s_0, \cdots, s_n\}$ be a finite subset of $Q \equiv \{0, \Delta, 2\Delta, \cdots\}$, where $(s_0, \cdots, s_n)$ is an increasing sequence. Let $\mathcal{L}' \equiv \{L^{(t)} : t \in Q\}$ be a filtration.
CHAPTER 8. MARTINGALES

1. Let \( x : Q' \to S \) be an arbitrary function. Let \( b : Q' \to (0, \infty) \) be an arbitrary function such that, for each \( r, s \in Q' \), we have \( b(s) \leq d(x_s, x_r) \) or \( b(s) > d(x_s, x_r) \). Let \( t \in Q' \) be arbitrary. Define

\[
\eta_{b,b,Q'}(x) \equiv \sum_{r \in Q': 2 \leq r} r 1_{\{(d(x_{s}),x_t)) > b(r)\}} \prod_{s \in Q': 1 \leq s < r} 1_{\{(d(x_{s}),x_t)) \leq b(s)\}} + s_n \prod_{s \in Q': 1 \leq s \leq r} 1_{\{(d(x_{s}),x_t)) \leq b(s)\}}.
\]  

(8.2.3)

In words, \( \eta_{b,b,Q'}(x) \) is the first time \( r \in [t, s_n]Q' \) such that \( x_r \) is at a distance greater than \( b(r) \) from the initial position \( x_t \), with \( \eta_{b,b,Q'}(x) \) set to the final time \( s_n \in Q' \) if no such \( r \) exists. Then \( \eta_{b,b,Q'}(x) \) is called the simple first exit time for the function \( x|_{[t,s_n]Q'} \) to exit the time-varying \( b \)-neighborhood of \( x_t \). In the special case where \( b(r) = \alpha \) for each \( r \in Q' \) for some constant \( \alpha > 0 \), we will write simply \( \eta_{b,a,Q'}(x) \) for \( \eta_{b,b,Q'}(x) \).

2. More generally, let \( X : Q' \times \Omega \to S \) be an arbitrary process adapted to the filtration \( \mathcal{F} \). Let \( b : Q' \to (0, \infty) \) be an arbitrary function such that, for each \( t, r, s \in Q' \), the real number \( b(s) \) is a regular point for the r.r.v. \( d(X_t, X_r) \). Let \( t \in Q' \) be arbitrary. Define the r.r.v. \( \eta_{b,b,Q'}(X) \) on \( \Omega \) defined by

\[
\eta_{b,b,Q'}(X) \equiv \sum_{r \in Q': 2 \leq r} r 1_{\{(d(X_{s,t})) > b(r)\}} \prod_{s \in Q': 1 \leq s < r} 1_{\{(d(X_{s,t})) \leq b(s)\}} + s_n \prod_{s \in Q': 1 \leq s \leq r} 1_{\{(d(X_{s,t})) \leq b(s)\}}.
\]  

(8.2.4)

is a r.r.v. called the simple first exit time for the process \( X|_{[t,s_n]Q'} \) to exit the time-varying \( b \)-neighborhood of \( X_t \). When there is little risk of confusion as to the identity of the process \( X \), we will omit the reference to \( X \), write \( \eta_{b,b,Q'} \) for \( \eta_{b,b,Q'}(X) \), and abuse notations by writing \( \eta_{b,b,Q'}(\omega) \) for \( \eta_{b,b,Q'}(X(\omega)) \), for each \( \omega \in \cap_{q \in Q' \text{ domain}(X_t)} \).

\[\square\]

The next proposition verifies that \( \eta_{b,b,Q'}(X) \) is a simple stopping time relative to the filtration \( \mathcal{F} \). It also proves some simple properties that are intuitively obvious when described in words.

Proposition 8.2.8. (Basic properties of simple first exit times). Let \( Q' \equiv \{s_0, \ldots, s_n\} \) be a finite subset of \( Q \), where \( \{s_0, \ldots, s_n\} \) is an increasing sequence. Use the assumptions and notations in Part 2 of Definition [8.2.7]. Let \( t, s \in Q' \equiv \{s_0, \ldots, s_n\} \) be arbitrary. Let \( \omega \in \text{domain}(\eta_{b,b,Q'}) \) be arbitrary. Then the following holds.

1. \( t \leq \eta_{b,b,Q'}(\omega) \leq s_n \).

2. The r.r.v. \( \eta_{b,b,Q'} \) is a simple stopping time relative to the filtration \( \mathcal{F} \).

3. If \( \eta_{b,b,Q'}(\omega) < t_n \) then \( \text{d}(X(t, \omega), X(\eta_{b,b,Q'}(\omega)), \omega) > b(\eta_{b,b,Q'}(\omega)) \). In words, if the simple first exit time occurs before the final time, then the sample path exits successfully at the simple first exit time.

4. If \( t \leq s < \eta_{b,b,Q'}(\omega) \), then \( \text{d}(X(t, \omega), X(s, \omega)) \leq b(s) \). In words, before the simple first exit time, the sample path remains in the \( b \)-neighborhood. Moreover, if

\[\text{d}(X(\eta_{b,b,Q'}(\omega), \omega), X(t, \omega)) \leq b(\eta_{b,b,Q'}(\omega))\]
then
\[ d(X(s, \omega), X(t, \omega)) \leq b(s) \]
for each \( s \in Q' \) with \( t \leq s \). In words, if the sample path is in the \( b \)-neighborhood at the simple first exit time, then it is in the \( b \)-neighborhood at any time prior to the simple first exit time.

Conversely, if \( r \in (t, s_n)Q' \) is such that \( d(X(t, \omega), X(s, \omega)) \leq b(s) \) for each \( s \in (t, r)Q' \), then \( r < \eta_{b,b,Q}(\omega) \). In words, if the sample path stays within the \( b \)-neighborhood up to and including a certain time, then the simple first exit time can come only after that time.

5. Suppose \( s_0 = s_{k(0)} < s_{k(1)} < \cdots < s_{k(p)} = s_n \) is a subsequence of \( s_0 < s_1 < \cdots < s_n \). Define \( Q'' \equiv \{s_{k(1)}, \ldots, s_{k(p)}\} \). Let \( t \in Q'' \subset Q' \) be arbitrary. Then \( \eta_{b,b,Q''} \leq \eta_{b,b,Q'} \).

In other words, if the process \( X \) is sampled at more time points, then the simple first exit time can occur no later.

**Proof.** By hypothesis, the process \( X \) is adapted to the filtration \( \mathcal{L}' \).

1. Assertion 1 is obvious from the defining equality 8.2.4.

2. By equality 8.2.4 for each \( r \in \{t, \cdots, s_{n-1}\} \), we have
\[
(\eta_{b,b,Q'} = r) = (d(X_r, X_t) > b(r)) \bigcap_{s \in Q' \cap t \leq s < r} (d(X_s, X_t) \leq b(s)) 
\]
\[
\in L^r \subset L^{s(n)}.
\]

Consequently,
\[
(\eta_{b,b,Q'} = s_n) = \bigcap_{r \in Q' \cap t \leq s(n)} (\eta_{b,b,Q'} = r)^c \in L^{s(n)}.
\]

Hence \( \eta_{b,b,Q'} \) is a simple stopping time relative to \( \mathcal{L}' \) with values in \( Q' \), according to Proposition 8.2.6.

3. Assertion 3 is obvious from the defining equality 8.2.4.

4. Suppose \( t < s < r \equiv \eta_{b,b,Q'}(\omega) \). Then
\[
d(X(t, \omega), X(s, \omega)) \leq b(s) \tag{8.2.6}
\]
by equality 8.2.5. The last inequality is trivially satisfied if \( t = s \). Hence if \( r \equiv \eta_{b,b,Q'}(\omega) = s_n \) with \( d(X(t, \omega), X(r, \omega)) \leq b(r) \) then inequality 8.2.6 holds for each \( s \in Q' \) with \( t \leq s \leq r \).

Conversely, suppose \( r \in Q' \) is such that \( t \leq r < s_n \) and such that
\[
d(X(t, \omega), X(s, \omega)) \leq b(s) \tag{8.2.6}
\]
for each \( s \in (t, r)Q' \). Suppose \( s \equiv \eta_{b,b,Q'}(\omega) \leq r < s_n \). Then \( d(X(t, \omega), X(s, \omega)) > b(s) \) by Assertion 3, a contradiction. Hence \( \eta_{b,b,Q'}(\omega) > r \). Assertion 4 is verified.

5. Let \( t \in Q'' \subset Q' \) be arbitrary. Suppose, for the sake of a contradiction, that \( s \equiv \eta_{b,b,Q''}(\omega) < \eta_{b,b,Q'}(\omega) \leq s_n \). Then \( t < s \) and \( s \in Q'' \subset Q' \). Hence, by Assertion 4 applied to the time \( s \) and to the simple first exit time \( \eta_{b,b,Q'} \), we have
\[
d(X(t, \omega), X(s, \omega)) \leq b(s).
\]
On the other hand, by Assertion 3 applied to the time $s$ and to the simple first exit time $\eta_{t,b,Q}$, we have
\[
\mathbb{P}(X(t, \omega), X(s, \omega)) > b(s),
\]
a contradiction. Hence $\eta_{t,b,Q}(\omega) \geq \eta_{t,b,Q}(\omega)$. Assertion 5 is proved.

\section{Martingales}

\textbf{Definition 8.3.1. (Martingale and Submartingale).} Let $Q$ be an arbitrary nonempty subset of $R$. Let $\mathcal{L} \equiv \{L^t : t \in Q\}$ be an arbitrary right continuous filtration in $(\Omega, L, \mathbb{P})$. Let $X : Q \times \Omega \to R$ be a stochastic process such that $X_t \in L^t$ for each $t \in Q$.

1. The process $X$ is called a\textit{ martingale} relative to $\mathcal{L}$ if, for each $t, s \in Q$ with $t \leq s$, we have $E[X_t | L^t] = E[X_s | L^t]$ for each indicator $Z \in L^t$. Accordingly to Definition\textsuperscript{5.6.4}, the last condition is equivalent to $E[X_t | L^t] = E[X_s | L^t]$ for each $t, s \in Q$ with $t \leq s$.

2. The process $X$ is called a\textit{ wide-sense submartingale} relative to $\mathcal{L}$ if, for each $t, s \in Q$ with $t \leq s$, we have $E[X_t | L^t] \leq E[X_s | L^t]$ for each indicator $Z \in L^t$. If, in addition, $E[X_t | L^t]$ exists for each $t, s \in Q$ with $t \leq s$, then $X$ is called a\textit{ submartingale} relative to $\mathcal{L}$.

3. The process $X$ is called a\textit{ wide-sense supermartingale} relative to $\mathcal{L}$ if, for each $t, s \in Q$ with $t \leq s$, we have $E[X_t | L^t] \geq E[X_s | L^t]$ for each indicator $Z \in L^t$. If, in addition, $E[X_t | L^t]$ exists for each $t, s \in Q$ with $t \leq s$, then $X$ is called a\textit{ supermartingale} relative to $\mathcal{L}$.

When there is little risk of confusion, we will omit the explicit reference to the given filtration $\mathcal{L}$.

Clearly a submartingale is also a wide-sense submartingale. The two notions are classically equivalent because, classically, with the benefit of the principle of infinite search, the conditional expectation always exists. Hence, any result that we prove for wide-sense submartingales holds classically for submartingales.

\textbf{Proposition 8.3.2. (Martingale basics).} Let $X : Q \times \Omega \to R$ be an arbitrary process adapted to the right continuous filtration $\mathcal{L} \equiv \{L^t : t \in Q\}$. Unless otherwise specified, all martingales and wide-sense submartingales are relative to the filtration $\mathcal{L}$. Then the following holds.

1. The process $X$ is a martingale iff it is both a wide-sense submartingale and a wide-sense supermartingale.

2. The process $X$ is a wide-sense supermartingale iff $-X$ is a wide-sense submartingale.

3. The expectation $E[X_t]$ is constant for $t \in Q$ if $X$ is a martingale. Moreover, $E[X_t]$ is nondecreasing in $t$ if $X$ is a wide-sense submartingale.

4. Suppose $X$ is a martingale. Then $|X|$ is a wide-sense submartingale. In particular, $E|X_t|$ is nondecreasing in $t \in Q$.

5. Suppose $X$ is a martingale. Let $a \in Q$ be arbitrary. Then the family $\{X_t : t \in \langle -\infty, a \rangle Q\}$ is uniformly integrable.
6. Let $\mathcal{F} = \{ L(t) : t \in Q \}$ be an arbitrary filtration such that $L(t) \subset L(s)$ for each $t \leq s$. Suppose $X$ is a wide-sense submartingale relative to the filtration $\mathcal{F}$. Then $X$ is a wide-sense submartingale relative to the filtration $\mathcal{F}$. The same assertion holds for martingales.

7. Suppose $X$ is a wide-sense submartingale relative to the filtration $\mathcal{F}$. Then it is a wide-sense submartingale relative to the natural filtration $\mathcal{F}_X = \{ L^{(X)}(t) : t \in Q \}$ of the process $X$.

**Proof.** 1. Assertions 1-3 being trivial, we will prove Assertions 4-7 only.

2. To that end, let $t, s \in Q$ with $t \leq s$ be arbitrary. Let the indicator $Z \in L(t)$ and the real number $\epsilon > 0$ be arbitrary. Then

$$E(|X_t|Z; X_t > \epsilon) \geq E(X_tZ; X_t > \epsilon) = E(|X_t|Z; X_t > \epsilon),$$

where the first equality is from the definition of a martingale. Since $-X$ is also a martingale, we have similarly

$$E(|X_t|Z; X_t < -\epsilon) \geq E(-X_tZ; X_t < -\epsilon) = E(|X_t|Z; X_t < -\epsilon).$$

Adding the last two displayed inequalities, we obtain

$$E(|X_t|Z) \geq E(|X_t|Z; X_t > \epsilon) + E(|X_t|Z; X_t < -\epsilon) \geq E(|X_t|Z; X_t > \epsilon) + E(|X_t|Z; X_t < -\epsilon) = E(|X_t|Z) - E(|X_t|Z; |X_t| \leq \epsilon).$$

Since

$$E(|X_t|Z; |X_t| \leq \epsilon) \leq E(|X_t|Z; |X_t| \leq \epsilon) \to 0$$
as $\epsilon \to 0$, we conclude that

$$E(|X_t|Z) \geq E(|X_t|Z),$$

where $t, s \in Q$ with $t \leq s$ and the indicator $Z \in L(t)$ are arbitrary. Thus the process $|X|$ is a wide-sense submartingale. Assertion 4 is proved.

2. Suppose $X$ is a martingale. Consider each $a \in Q$ be arbitrary. Let $t \in Q$ be arbitrary with $t < a$, and let $\epsilon > 0$ be arbitrary. Then, since $X_a$ is integrable, there exists $\delta = \delta_X(a) > 0$ so small that $E|X_a|1_A \leq \epsilon$ for each measurable set $A$ with $P(A) < \delta$. Now let $\gamma = \beta(\epsilon) \equiv E|X_a|\delta^{-1}$ be arbitrary. Then, by Chebychev’s inequality,

$$P(|X| > \gamma) \leq E|X|\gamma^{-1} \leq E|X_a|\gamma^{-1} < \delta,$$

where the second inequality is because $|X|$ is a wide-sense submartingale by Assertion 4. Hence

$$E|X|1_{|X| > \gamma} \leq E|X_a|1_{|X| > \gamma} < \epsilon,$$

where the first inequality is because $|X|$ is a wide-sense submartingale. Since $t \in Q$ is arbitrary with $t \leq a$, we conclude that the family $\{ X_t : t \in (-\infty, a]\}$ is uniformly integrable, with a simple modulus of uniform integrability $\beta$. Assertion 5 has been verified.
3. To prove Assertion 6, assume that the process $X$ is a wide-sense submartingale relative to the filtration $\mathcal{F}$. Let $t, s \in \Omega$ with $t \leq s$ be arbitrary. Consider each indicator $Z \in L(t)$. Then $Z \in L(t)$ by the assumption on $\mathcal{F}$. Hence $EZ_t \leq EZ_s$, where the indicator $Z \in L(t)$ is arbitrary. Thus $X$ is a wide-sense submartingale relative to $\mathcal{L}$. The proof for martingales is similar. Assertion 6 is proved.

4. It remains to prove Assertion 7. To that end, suppose $X$ is a wide-sense submartingale relative to $\mathcal{L}$. Note that, for each $t \in \Omega$, we have $X_t \in L(t)$ for each $r \in [0, t]$. Hence $L^{(s, t)} = L(X_t : r \in [0, t]) \subset L(t)$. Hence Assertion 6 implies that $X$ is a wide-sense submartingale relative to $\mathcal{L}_X$. The proof for martingales is similar. Assertion 7 and the proposition are proved.

**Definition 8.3.3. (Specialization to a discrete parameter set).** In the remainder of this section, unless otherwise specified, assume the parameter set $\Omega \equiv \{0, \Delta, 2\Delta, \cdots\}$ with some fixed $\Delta > 0$, and let $\mathcal{L} \equiv \{L(t) : t \in \Omega\}$ be an arbitrary, but fixed, filtration in $(\Omega, L, E)$ with parameter $\Omega$. Note that the filtration $\mathcal{L}$ is then trivially right continuous. For ease of notations, we will assume, without loss of generality, by a change of units if necessary, that $\Delta = 1$.

If a martingale $X_t$ is used to model a gambler’s fortune at the current time $t$, then the conditional expectation of said fortune at a later time $s$ given all information up to and including the current time $t$, is exactly his or her current fortune. Thus a martingale $X$ is a model for a fair game of chance. Similarly, a submartingale can be used to model a favorable game.

**Theorem 8.3.4. (Doob decomposition).** Let $Y : \{0, 1, 2, \cdots\} \times (\Omega, L, E) \to R$ be a process which is adapted to the filtration $\mathcal{L} \equiv \{L(n) : n \geq 0\}$. Suppose the conditional expectation $E(Y_m|L(n))$ exists for each $m \geq 0$ with $n \leq m$. For each $n \geq 0$, define

$$X_n \equiv Y_0 + \sum_{k=1}^{n} (Y_k - E(Y_k|L^{(k-1)})). \tag{8.3.1}$$

and

$$A_n \equiv \sum_{k=1}^{n} (E(Y_k|L^{(k-1)}) - Y_{k-1}). \tag{8.3.2}$$

where an empty sum is by convention equal to 0. Then $X : \{0, 1, 2, \cdots\} \times \Omega \to R$ is a martingale relative to the filtration $\mathcal{L}$. Moreover, $A_n \in L^{(n-1)}$ and $Y_n = X_n + A_n$ for each $n \geq 1$.

**Proof.** From the defining equality (8.3.1) we see that $X_n \in L(n)$ for each $n \geq 1$. Hence the process $X : \{0, 1, 2, \cdots\} \times \Omega \to R$ is adapted to the filtration $\mathcal{L}$. Let $m > n \geq 1$ be arbitrary. Then

$$E(X_m|L(n)) = E(\{X_n + \sum_{k=n+1}^{m} (Y_k - E(Y_k|L^{(k-1)}))|L(n)\})$$

$$= X_n + \sum_{k=n+1}^{m} (E(Y_k|L(n)) - E(E(Y_k|L^{(k-1)})|L(n)))$$

Yuen-Kwok Chan 258 Constructive Probability
where we used basic properties of conditional expectations in Proposition 5.6.6. Thus the process \( X \) is a martingale relative to the filtration \( \mathcal{L} \). Moreover, \( A_n \in L^{(n-1)} \) because all the summands in the defining equality 8.3.2 are members of \( L^{(n-1)} \).

Intuitively, Theorem 8.3.4 says that a multi-round game \( Y \) can be turned into a fair game \( X \) by charging a fair price determined at each round as the conditional expectation of payoff at the next round, with the cumulative cost of entry equal to \( A_n \) by the time \( n \).

The next theorem of Doob and its corollary are key to the analysis of martingales. It proves that, under reasonable conditions, a fair game can never be turned to a favorable one by sampling at a sequence of stopping times, or by stopping at some stopping time which cannot see the future. The reader can look up “gambler’s ruin” in the literature for a counterexample where said reasonable conditions is not assumed, where a fair coin tossing game can be turned into an almost sure win by stopping when and only when the gambler is ahead by one dollar. This latter strategy sounds intriguing except for the lamentable fact that, to achieve an almost sure winning against a house with infinite capital, the strategy would require the gambler to stay in the game for unbounded number of rounds and to have infinite capital to avoid bankruptcy.

The next theorem and its proof are essentially restatements of parts of Theorems 9.3.3 and 9.3.4 in [Chung 1968], except that, for the case of wide-sense submartingales, we add a condition to make the theorem constructive.

**Theorem 8.3.5. (Doob’s optional sampling theorem).** Let

\[ X : \{0, 1, 2, \cdots\} \times (\Omega, L, E) \to R \]

be a wide-sense submartingale relative to a filtration \( \mathcal{L} \equiv \{ L^{(k)} : k \geq 0 \} \). Let \( \tau \equiv (\tau_n)_{n=1,2,\ldots} \) be a nondecreasing sequence of stopping times with values in \( \{0, 1, 2, \cdots\} \) relative to the filtration \( \mathcal{L} \). Define the function \( X_\tau : \{0, 1, 2, \cdots\} \times (\Omega, L, E) \to R \) by

\[ X_\tau(n) \equiv X_\tau(n-1) \]

for each \( n \geq 0 \). Suppose one of the following three conditions holds.

(i) The function \( X_\tau(n) \) is an integrable r.r.v. for each \( n \geq 0 \), and the family \( \{X_n : n \geq 0\} \) of r.r.v.'s is uniformly integrable.

(ii) For each \( m \geq 1 \), there exists some \( M_m \geq 0 \) such that \( \tau_m \leq M_m \).

(iii) The given process \( X \) is a martingale, and the family \( \{X_n : n \geq 0\} \) of r.r.v.'s is uniformly integrable.

Then \( X_\tau \) is a wide-sense submartingale relative to the filtration \( \mathcal{L}_\tau \equiv \{ L^{(\tau(n))} : n \geq 0 \} \). If the given process \( X \) is a martingale, then \( X_\tau \) is a martingale relative to the filtration \( \mathcal{L}_\tau \).

**Proof.** Recall that \( Q \equiv \{0, 1, 2, \cdots\} \). Let \( m \geq n \) and the indicator \( Z \in L^{(\tau(n))} \) be arbitrary. We need to prove that the function \( X_\tau(n) \) is integrable, and that

\[ E(X_\tau(m)Z) \geq E(X_\tau(n)Z). \]  

First we will prove that \( X_\tau(n) \) is integrable.

1. Suppose Condition (i) holds. Then the function \( X_\tau(n) \) is integrable by assumption.
2. Suppose Condition (ii) holds. Then the function

\[ X_{\tau(n)} = \sum_{u=0}^{M(n)} X_{\tau(n)} 1_{\tau(n)=u} = \sum_{u=0}^{M(n)} X_u 1_{\tau(n)=u} \]

is a finite sum of integrable r.r.v., hence \( X_{\tau(n)} \) is itself an integrable r.r.v.

3. Suppose Condition (iii) holds. Then \( X \) is a martingale. Hence \( |X| \) is a wide-

sense submartingale and \( E|X| \) is nondecreasing in \( t \in Q \), according to Assertion 4 of Proposition 8.3.2. Consider each \( v, v' \in Q \) with \( v \leq v' \). Then it follows that

\[ \sum_{u=v}^{v'} E|X_{\tau(n)}|1_{\tau(n)=u} = \sum_{u=v}^{v'} E|X_u|1_{\tau(n)=u} \leq \sum_{u=v}^{v'} E|X_{\tau(n)}|1_{\tau(n)=u} \]

where the inequality is because the indicator

\[ \tau_{n+1} = \tau_n + 1 \]

4. Thus we see that \( X \) is an integrable r.r.v. under any one of the three Conditions

(i-iii). It remains to prove 8.3.3. To that end, let \( \kappa \geq 0 \) be arbitrary with \( u \leq v \). Then \( Z1_{\tau(n)=u} \in L^{(n)} \subset L^{(v)} \). Hence

\[ Y_{u,v} = X_u Z1_{\tau(n)=u} \in L^{(v)}. \]

Moreover,

\[ E\tau_{n+1} 1_{\tau(n)\geq v} = E\tau_{n+1} 1_{\tau(n)=u} 1_{\tau(n)\geq v} \]

\[ = E\tau_{n+1} 1_{\tau(n)=u} 1_{\tau(n)\geq v} + E\tau_{n+1} 1_{\tau(n)\geq v+1} \]

\[ = E\tau_{n+1} Z1_{\tau(n)\geq v} + E\tau_{n+1} Z1_{\tau(n)\geq v+1} \]

where the inequality is because the indicator

\[ Z1_{\tau(n)\geq v} = Z1_{\tau(n)\geq v+1} \]

and because \( X \) is, by hypothesis, a wide-sense submartingale. In short

\[ E\tau_{n+1} 1_{\tau(n)\geq v} \leq E\tau_{n+1} Z1_{\tau(n)\geq v} + E\tau_{n+1} 1_{\tau(n)\geq v+1} \]

where \( v \in [u, \infty) Q \) is arbitrary. Let \( \kappa \geq 0 \) be arbitrary. Applying inequality 8.3.5 successively to \( v = u, u+1, u+2, \ldots, u+\kappa \), we obtain

\[ E\tau_{n+1} 1_{\tau(n)\geq u} \leq E\tau_{n+1} Z1_{\tau(n)\geq u} + E\tau_{n+1} 1_{\tau(n)\geq u+1} \]

\[ \leq E\tau_{n+1} Z1_{\tau(n)\geq u} + E\tau_{n+1} Z1_{\tau(n)\geq u+1} + E\tau_{n+1} 1_{\tau(n)\geq u+2} \]

\[ \leq \cdots \]
8.3. MARTINGALES

\[ \leq EX_{\tau(m)}Z_{1_{\tau(n)=u}} \sum_{v \in [u, u+\kappa]|Q} 1_{\tau(m)=v} + EY_{u, u+(\kappa+1)} 1_{\tau(m) \geq u+(\kappa+1)} \]

\[ = EX_{\tau(m)}Z_{1_{\tau(n)=u}} 1_{u \leq \tau(m) \leq u+\kappa} + EX_{u+(\kappa+1)} 1_{\tau(n)=u} 1_{\tau(m) = u+(\kappa+1)} \]

\[ = EX_{\tau(m)}Z_{1_{\tau(n)=u}} 1_{\tau(m) \leq u+\kappa} + EX_{u+(\kappa+1)} Z_{1_{\tau(n)=u}} 1_{\tau(m) \geq u+(\kappa+1)}. \]

\[ = EY_{u, u+\kappa} Z_{1_{\tau(n)=u}} - EX_{\tau(m)} 1_{A(\kappa)} + EX_{u+(\kappa+1)} 1_{A(\kappa)}. \]

where \( A(\kappa) \) is the measurable set whose indicator is \( 1_{A(\kappa)} \equiv Z_{1_{\tau(n)=u}} 1_{\tau(m) \geq u+(\kappa+1)} \) and whose probability is therefore bounded by

\[ P(A(\kappa)) \leq P(t_n \geq u + (\kappa + 1)). \]

Now let \( \kappa \to \infty \). Then \( P(A(\kappa)) \to 0 \) because \( X_{\tau(m)} \) is an integrable r.v., as proved in Steps 1-3. Consequently, the second summand on the right-hand side of inequality 8.3.6 tends to 0. Now consider the third summand on the right-hand side of inequality 8.3.6

Suppose Condition (ii) holds. Then, as soon as \( u + (\kappa + 1) \geq M_m \), we have \( P(A(\kappa)) = 0 \), whence said two summands vanish as \( \kappa \to \infty \). Suppose, alternatively, Condition (i) or (iii) holds, then the last summand tends to 0, thanks to the uniform integrability of the family \( \{X_t : t \in [0, \infty)\} \) of r.v.‘s guaranteed by Condition (i) or (iii).

Summing up, the second and third summand both tend to 0 as \( \kappa \to \infty \), with only the first summand on the right-hand side of inequality 8.3.6 surviving, to yield

\[ EY_{u, u+\kappa} 1_{\tau(m) \geq u} \leq EX_{\tau(m)}Z_{1_{\tau(n)=u}}. \]

Equivalently,

\[ EX_{u} Z_{1_{\tau(n)=u}} 1_{\tau(m) \geq u} \leq EX_{\tau(m)}Z_{1_{\tau(n)=u}}. \]

Since \( \tau_n = u \) \( \subset (\tau_n \geq u) \), this last inequality simplifies to

\[ EX_{u} Z_{1_{\tau(n)=u}} 1_{\tau(m) = u} \leq EX_{\tau(m)}Z_{1_{\tau(n)=u}}, \]

where \( u \in Q = \{0, 1, 2, \cdots\} \) is arbitrary. Summation over \( u \in Q \) then yields the desired equality 8.3.3. Thus \( X_{\tau} \) is a wide-sense submartingale relative to the filtration \( L^\tau = \{L^{\tau(n)} : n = 0, 1, \cdots\} \). The first part of the conclusion of the theorem, regarding wide-sense submartingales, has been proved.

5. Finally, suppose the given wide-sense submartingale \( X \) is actually a martingale. Then \( -X \) is a wide-sense submartingale, and so by the preceding arguments, both the processes \( X_{\tau} \) and \( -X_{\tau} \) are wide-sense submartingale relative to the filtration \( L^\tau \).

Combining, we conclude that \( X_{\tau} \) is a martingale if \( X \) is a martingale, provided that one of the three Conditions (i-iii) holds. The theorem is proved. \( \square \)

**Corollary 8.3.6. (Doob’s optional stopping theorem for a finite game).** Let \( n \geq 1 \) be arbitrary. Write \( Q' = \{0, 1, \cdots, n\} \equiv \{t_0, t_1, \cdots, t_n\} \subset Q \). Let \( X : Q \times \Omega \to R \) be a process adapted to the filtration \( L \equiv \{L^{(t)} : t \in Q\} \). Let \( \tau \) be an arbitrary simple stopping time relative to \( L \) with values in \( Q' \). Define the r.v.

\[ X_\tau = \sum_{t \in Q'} X_t 1_{(\tau = t)} \in L^{(\tau)}. \]
CHAPTER 8. MARTINGALES

Define the process $X': \{0, 1, 2\} \times \Omega \to R$ by

$$(X_0', X_1', X_2') \equiv (X_{\tau(0)} X_{\tau(1)} X_{\tau(n)}).$$

Define the filtration $\mathcal{L}' \equiv \{L^{(i)} : i = 0, 1, 2\}$ by

$$(L^{(0)}, L^{(1)}, L^{(2)}) \equiv (L^{(0)}, L^{(\tau)}, L^{(\tau(n))}).$$

Then the following holds.

1. If the process $X$ is a wide-sense submartingale relative to $\mathcal{L}$, then the process $X'$ is a wide-sense submartingale relative to the filtration $\mathcal{L}'$.

2. If the process $X$ is a martingale relative to $\mathcal{L}$, then the process $X'$ is a martingale relative to $\mathcal{L}'$.

Proof. Extend the process $X$ to the parameter set $Q \equiv \{0, 1, \cdots\}$ by $X_t \equiv X_{\tau(n)}$ for each $t \in \{0, 1, \cdots\}$. Likewise extend the filtration $\mathcal{L}$ by defining $L^{(i)} \equiv L^{(\tau(n))}$ for each $t \in \{0, 1, \cdots\}$. Trivially we can verify that the extended process $X : \{0, 1, \cdots\} \times \Omega \to R$ retains the same property of being a martingale or wide-sense submartingale, respectively, as the given process being a martingale or wide-sense submartingale, relative to the extended filtration $\mathcal{L}$. Now define a sequence $\mathcal{T} \equiv (\tau_0, \tau_1, \cdots)$ of stopping times by $\tau_0 \equiv \tau_0, \tau_1 \equiv \tau, \text{ and } \tau_m \equiv \tau_1$ for each $m \geq 2$. Then it can easily be verified that the sequence $\mathcal{T}$ satisfies Condition (ii) of Theorem [8.3.5]. Hence the process $X_\tau$ defined in Theorem [8.3.5] is a martingale if $X$ is a martingale, and is a wide-sense submartingale if $X$ is a wide-sense submartingale. Since

$$(X_0', X_1', X_2') \equiv (X_{\tau(0)} X_{\tau(1)} X_{\tau(n)}) = (X_{\tau(0)} X_{\tau(1)} X_{\tau(2)})$$

and

$$(L^{(0)}, L^{(1)}, L^{(2)}) \equiv (L^{(0)}, L^{(\tau)}, L^{(\tau(n))}) = (L^{(\tau(0))}, L^{(\tau(1))}, L^{(\tau(2))}),$$

the conclusion of the corollary follows. $\square$

8.4 Convexity and Martingale Convergence

Next consider the a.u. convergence of martingales, and of wide-sense submartingales in general. Suppose $X : \{1, 2, \cdots\} \times \Omega \to R$ is a martingale relative to some filtration $\mathcal{L} \equiv \{L^{(n)} : n = 1, 2, \cdots\}$. A classical theorem says that, if $E[X_n]$ is bounded as $n \to \infty$, then $X_n$ converges a.u. as $n \to \infty$. The theorem can be proved, classically, by the celebrated upcrossing inequality of Doob, thanks to the principle of infinite search. See, for example, [Durrett 1984]. While the upcrossing inequality is constructive, the inference of a.u. convergence from it is not.

As a matter of fact, the following example shows that the martingale convergence theorem, as stated above, implies the principle of infinite search. Let $(a_n)_{n=1,2,\cdots}$ be an arbitrary nondecreasing sequence in $\{0, 1\}$. Let $Y$ be an arbitrary r.r.v. which takes the value $-1$ or $+1$ with equal probabilities. For each $n \geq 1$ define $X_n \equiv 1 + a_n Y$. Then the process $X : \{1, 2, \cdots\} \times \Omega \to \{0, 1, 2\}$ is a martingale relative to its natural filtration, with $E[X_n] = EX_n = 1$ for each $n \geq 1$. Suppose $X_n \to X$ a.u. Then there
exists \( b \in (0, 1) \) such that the set \( (X < b) \) is measurable. Then either (i) \( P(X < b) < \frac{1}{b} \) or (ii) \( P(X < b) > 0 \). In Case (i), we must have \( a_n = 0 \) for each \( n \geq 1 \). In Case (ii), because of a.u. convergence, there exists \( b' \in (b, 1) \) such that \( P(X_n < b') > 0 \) for some \( n \geq 1 \), whence \( a_n = 1 \) for some \( n \geq 1 \). Since the nondecreasing sequence \( (a_n)_{n=1,2,...} \) is arbitrary, we have deduced the principle of infinite search from said classical theorem of martingale convergence.

Thus the boundlessness \( X_n \) together with the constancy of \( E|X_n| \) is not sufficient for the constructive a.u. convergence. Boundedness is not the issue. Convexity is. The function \( |x| \) simply does not have any positive convexity away from \( x = 0 \).

With strictly convex functions \( \lambda(x) \), to be presently defined, which have positive and continuous second derivatives, as a natural alternative to the function \( |x| \), we will generalize Bishop’s maximal inequality for martingales, Theorem 3 in Chapter 8 of [Bishop 1967], to wide-sense submartingales. We then use the convergence of \( E\lambda(X_n) \), as the criterion for a.u. convergence, obviating the use of upcrossing inequalities. We will actually use a specific strictly convex function \( \lambda \) such that \( |\lambda(x)| \leq 3|x| \) for each \( x \in \mathbb{R} \). Then the boundlessness and convergence of \( E\lambda(X_n) \) follows, classically, from the boundlessness of \( E|X_n| \). Thus we will have a criterion for constructive a.u. convergence which, from the classical viewpoint, imposes no additional condition beyond the boundlessness of \( E|X_n| \). The proof, being constructive, produces rates of a.u. convergence.

**Definition 8.4.1. (Strictly convex function).** A continuous function \( \lambda : \mathbb{R} \to \mathbb{R} \) is said to be strictly convex if it has a positive and continuous second derivative \( \lambda'' \) on \( \mathbb{R} \).

This definition generalizes the admissible functions in Chapter 8 of [Bishop 1967]. The conditions of symmetry and nonnegativity of \( \lambda \) are dropped, so that we can admit an increasing function \( \lambda \). Correspondingly, we need to generalize Bishop’s version of Jensen’s inequality, Lemma 2 in Chapter 8 of [Bishop 1967], to the following theorem.

**Theorem 8.4.2. (Bishop-Jensen inequality).** Let \( \lambda : \mathbb{R} \to \mathbb{R} \) be a strictly convex function. Let the continuous function \( \theta \) be defined by \( \theta(x) = \inf_{y \in [-x,x]} \lambda''(y) > 0 \) for each \( x > 0 \). Define the continuous function \( g : \mathbb{R}^2 \to [0, \infty) \) by

\[
g(x_0, x_1) = \frac{1}{2}(x_1 - x_0)^2 \theta(|x_0| \vee |x_1|)
\]

(8.4.1)

for each \((x_0, x_1) \in \mathbb{R}^2\). Let \( X_0 \) and \( X_1 \) be integrable r.r.v.’s on \((\Omega, \mathcal{L}, P)\) such that \( \lambda(X_0), \lambda(X_1) \) are integrable. Suppose either (i) \( E(X_1|X_0) = X_0 \), or (ii) the strictly convex function \( \lambda : \mathbb{R} \to \mathbb{R} \) is nondecreasing and \( EU_0 \leq EUX_1 \) for each indicator \( U \in \mathbb{L}(X_0) \). Then the r.r.v. \( g(X_0, X_1) \) is integrable, with

\[
0 \leq E g(X_0, X_1) \leq E\lambda(X_1) - E\lambda(X_0).
\]

(8.4.2)

**Proof.** 1. Let \((x_0, x_1) \in \mathbb{R}^2\) be arbitrary. Then

\[
0 \leq g(x_0, x_1) = \theta(|x_0| \vee |x_1|) \int_{y=x(0)}^{x(1)} \int_{u=x(0)}^{u} dudv
\]

Yuen-Kwok Chan 263 Constructive Probability
where the last equality is a direct application of the Fundamental Theorem of Calculus.

2. Let \((\Omega, L(X_0), E)\) denote the probability subspace of \((\Omega, L, E)\) generated by the r.r.v. \(X_0\). Let \(V \in L(X_0)\) be an arbitrary indicator such that \(\lambda'(X_0)\) is bounded. Suppose Condition (i) in the hypothesis holds, i.e. \(E(X_1|X_0) = X_0\). Then, by the properties of conditional expectations and the boundlessness of the r.r.v. \(\lambda'(X_0)\) \(V \in L(X_0)\), we obtain

\[
E(X_1 - X_0)\lambda'(X_0)V = E(X_0 - X_0)\lambda'(X_0)V = 0.
\]

Suppose Condition (ii) holds. Then \(EUX_0 \leq EUX_1\) for each indicator \(U \in L(X_0)\), and the function \(\lambda : R \to R\) is nondecreasing. Hence the bounded r.r.v. \(\lambda'(X_0)\) \(V \in L(X_0)\) is nonnegative. Therefore, by Proposition 5.6.7 we have

\[
E\lambda'(X_0)VX_0 \leq E\lambda'(X_0)VX_1.
\]

Summing up, in either case, we have

\[
E(X_1 - X_0)\lambda'(X_0)V \geq 0,
\]

for each indicator \(V \in L(X_0)\) such that \(\lambda'(X_0)\) is bounded.

Now the r.r.v.'s \(\lambda(X_0), \lambda(X_1), X_0, X_1\) are integrable by hypothesis. Let \(b > a > 0\) be arbitrary. Since the function \(\lambda'\) is continuous, it is bounded on \([-b, b]\). Hence the r.r.v. \(\lambda'(X_0)1_{[a,|X(0)|]}\) is bounded. Therefore inequality [8.4.3] implies that \(g(X_0, X_1)1_{[a,|X(0)|]}\) is integrable. At the same time, inequality [8.4.4] holds with \(V \equiv 1_{[b,|X(0)|]}\). Consequently,

\[
0 \leq Eg(X_0, X_1)1_{[b,|X(0)|]} - Eg(X_0, X_1)1_{[a,|X(0)|]} = E(\lambda(X_1) - \lambda(X_0) - \lambda'(X_0)(X_1 - X_0))V \\
\leq E(\lambda(X_1) - \lambda(X_0))V = E(\lambda(X_1) - \lambda(X_0))1_{[b,|X(0)|]} \to 0
\]

as \(b > a \to \infty\), where the second inequality is due to inequality [8.4.3]. Hence the integral \(g(X_0, X_1)1_{[a,|X(0)|]}\) converges as \(a \to \infty\). It follows from the Monotone Convergence Theorem that the r.r.v.

\[
g(X_0, X_1) = \lim_{a \to \infty} g(X_0, X_1)1_{[a,|X(0)|]}
\]

is integrable, with

\[
Eg(X_0, X_1) = \lim_{a \to \infty} Eg(X_0, X_1)1_{[a,|X(0)|]} \\
\leq \lim_{a \to \infty} E(\lambda(X_1) - \lambda(X_0) - \lambda'(X_0)(X_1 - X_0))1_{[a,|X(0)|]} \\
\leq \lim_{a \to \infty} E(\lambda(X_1) - \lambda(X_0))1_{[a,|X(0)|]} = E\lambda(X_1) - E\lambda(X_0),
\]

where the first inequality follows from inequality [8.4.3] and the second inequality follows from inequality [8.4.4]. The theorem is proved.
8.4. CONVEXITY AND MARTINGALE CONVERGENCE

In the following, keep in mind the convention in Definition 5.1.3 regarding regular points of r.r.v.’s. Now we are ready to prove the advertised maximal inequality.

**Definition 8.4.3. (The special convex function).** Define the continuous function \( \lambda : \mathbb{R} \to \mathbb{R} \) by

\[
\lambda(x) \equiv 2x + (e^{-|x|} - 1 + |x|)
\]

for each \( x \in \mathbb{R} \). We will call \( \lambda \) the special convex function.

**Theorem 8.4.4. (A maximal inequality for wide-sense submartingales).** Then the following holds.

1. The special convex function \( \lambda \) is increasing and strictly convex, with

\[
|x| \leq |\lambda(x)| \leq 3|x|
\]

for each \( x \in \mathbb{R} \).

2. Let \( Q \equiv \{t_0, t_1, \cdots, t_n\} \) be an arbitrary finite subset of \( \mathbb{R} \), with \( t_0 < t_1 < \cdots < t_n \). Let \( X : Q \times \Omega \to \mathbb{R} \) be an arbitrary wide-sense submartingale relative to the filtration \( \mathcal{L} \equiv \{L_t(i) : i = 1, \cdots, n\} \). Let \( \epsilon > 0 \) be arbitrary. Suppose

\[
E\lambda(X_{t(n)}) - E\lambda(X_{t(0)}) < \frac{1}{6}\epsilon^3 \exp(-3(E|X_{t(0)}| \lor E|X_{t(n)}|) \epsilon^{-1}).
\]

Then

\[
P(\bigvee_{k=0}^n |X_{t(k)} - X_{t(0)}| > \epsilon) < \epsilon.
\]

We emphasize that the last two displayed inequalities are regardless of how large \( n \geq 0 \) is. We also note that, in view of inequality 8.4.4, the r.r.v. \( \lambda(Y) \) is integrable for each integrable r.r.v. \( Y \). Thus inequality 8.4.7 is in contrast to the classical counterpart which requires either \( X_{t(n)}^p \) is integrable for some \( p > 1 \) or \( |X_{t(n)}| \log |X_{t(n)}| \) is integrable.

**Proof.** 1. First note that \( \lambda(0) = 0 \). Elementary calculus yields a continuous first derivative \( \lambda' \) on \( \mathbb{R} \) such that

\[
\lambda'(x) = 2 + (-e^{-x} + 1) \geq 2
\]

for each \( x \geq 0 \), and such that

\[
\lambda'(x) = 2 + (e^x - 1) \geq 1
\]

for each \( x \leq 0 \). Thus the function \( \lambda \) is increasing. Moreover \( \lambda \) has a positive and continuous second derivative

\[
\lambda''(x) = e^{-|x|}
\]

for each \( x \in \mathbb{R} \). Hence

\[
\theta(x) \equiv \inf_{y \in [-x,x]} \lambda''(y) = e^{-x} > 0
\]

for each \( x > 0 \). Thus the function \( \lambda \) is strictly convex. Furthermore, since \( 0 \leq e^{-r} - 1 + r \leq r \) for each \( r \geq 0 \), the triangle inequality yields

\[
|x| = 2|x| - |x| \leq 2|x| - (e^{-|x|} - 1 + |x|)
\]

Yuen-Kwok Chan 265 Constructive Probability
for each \( i \) and by the strictly convex function \( \overline{\lambda} \) in the hypothesis can be rewritten as

\[
g(x_0, x_1) = \frac{1}{2} (x_1 - x_0)^2 \theta(|x_0| \lor |x_1|) \leq \frac{1}{2} (x_1 - x_0)^2 \exp(-(|x_0| \lor |x_1|))
\] (8.4.11)

for each \((x_0, x_1) \in \mathbb{R}^2\).

2. By relabeling if necessary, we assume, without loss of generality, that

\[
(t_0, t_1, \ldots, t_n) = (0, 1, \ldots, n).
\]

Let \( \varepsilon > 0 \) be as given. Write \( K = E|X_0| \lor E|X_n|, b = 3K\varepsilon^{-1} \), and

\[
\gamma \equiv \frac{1}{2} \varepsilon^2 \theta(b) = \frac{1}{2} \varepsilon^2 e^{-b} = \frac{1}{2} \varepsilon^2 \exp(-3K\varepsilon^{-1}).
\]

Then inequality (8.4.7) in the hypothesis can be rewritten as

\[
E \overline{\lambda}(X_n) - E \overline{\lambda}(X_0) < \frac{1}{3} \varepsilon \gamma.
\] (8.4.12)

Let \( \tau = t_0 \in \mathcal{Q} \) be the simple first exit time of the process \( X \) from \( 0 \) to \( \varepsilon \)-neighborhood of \( X_0 \), in the sense of Definition (8.2.4). Define the probability subspace \( L^{(\tau)} \) relative to the simple stopping time \( \tau \), as in Definition (8.2.3). Define the r.r.v.

\[
X_\tau \equiv \sum_{i \in \mathcal{Q}} X_i 1_{(\tau=1)} \in L^{(\tau)}.
\]

As in Corollary (8.3.6) define the process \( X' = \{0, 1, 2\} \times \Omega \rightarrow \mathbb{R} \) by

\[
(X'_0, X'_1, X'_2) = (X_0, X_\tau, X_n),
\]

and define the filtration \( \mathcal{F}' \equiv \{L^{(i)} : i = 0, 1, 2\} \) by

\[
(L^{(0)}, L^{(1)}, L^{(2)}) \equiv (L^{(0)}, L^{(\tau)}, L^{(n)}).
\]

Then, by Corollary (8.3.6) the process \( X' \) is a wide-sense submartingale relative to the filtration \( \mathcal{F}' \). In other words, \( E UX'_i \leq E UX'_j \) for each indicator \( U \in L(X'_i) \subset L^{(i-1)} \), for each \( i = 1, 2 \).

Thus the conditions in Theorem (8.4.2) are satisfied by the pair \( X'_0, X'_1 \) of r.r.v.’s and by the strictly convex function \( \overline{\lambda} \), for each \( i = 1, 2 \). Accordingly, for each \( i = 1, 2 \), Theorem (8.4.2) implies that the nonnegative r.r.v. \( Y_i \equiv g(X'_{i-1}, X'_i) \) is integrable, with

\[
0 \leq EY_i \leq E \overline{\lambda}(X'_i) - E \overline{\lambda}(X'_{i-1}).
\] (8.4.13)

Consequently,

\[
0 \leq EY_1 \leq E \overline{\lambda}(X'_1) - E \overline{\lambda}(X'_0) \leq E \overline{\lambda}(X'_2) - E \overline{\lambda}(X'_0).
\]

Yuen-Kwok Chan 266 Constructive Probability
8.4. CONVEXITY AND MARTINGALE CONVERGENCE

\[ \equiv \bar{\lambda}(X_n) - \bar{\lambda}(X_0) < \frac{1}{3}\varepsilon\gamma, \]

where the last inequality is inequality 8.4.12. Chebychev’s inequality therefore yields a measurable set \( A \) with \( P(A^c) < \frac{1}{4}\varepsilon \) such that

\[ A \subset (Y_1 \leq \gamma). \]

Next, consider each \( i = 0, 1 \). Then, by equality 8.4.5 and equality 8.4.13 we obtain

\[ E|X'_i| \leq \bar{\lambda}(X'_i) \leq \bar{\lambda}(X'_1) \equiv \bar{\lambda}(X_n) \leq K \equiv \frac{1}{3}\varepsilon b, \]

Chebychev’s inequality therefore yields \( P(B_i^c) < \frac{1}{4}\varepsilon \) where \( B_i \equiv (|X_i'| \leq b) \).

Now consider each \( \omega \in AB_0B_1 \). Then \( |X'_0(\omega)| \leq |X'_1(\omega)| \leq b \). Hence

\[ \frac{1}{2}(X'_i(\omega) - X_0(\omega))^2 \theta(b) \equiv \frac{1}{2}(X'_i(\omega) - X'_0(\omega))^2 \theta(b) \]

\[ \leq \frac{1}{2}(X'_1(\omega) - X'_0(\omega))^2 \theta(|X'_0(\omega)| \vee |X'_1(\omega)|) \equiv g(X'_0(\omega), X'_1(\omega)) \]

\[ \equiv Y_i(\omega) \leq \gamma \equiv \frac{1}{2}\varepsilon^2 \theta(b), \]

where the first inequality is because \( \theta \) is a decreasing function, and where the last inequality is because \( \omega \in A \subset (Y_1 \leq \gamma) \). Dividing by \( \frac{1}{2}\theta(b) \) and taking square roots, we obtain

\[ |X''(0,\varepsilon,\omega)(\omega) - X_0(\omega)| \equiv |X''(\omega) - X_0(\omega)| \leq \varepsilon \]

for each \( \omega \in AB_0B_1 \). It follows from the basic properties of simple first exit time that, on \( AB_0B_1 \), we have

\[ \bigvee_{\omega \in \Omega} |X'_i - X_0| \leq \varepsilon. \]

Summing up,

\[ P\left( \bigvee_{k=0}^n |X''(k) - X''(0)| > \varepsilon \right) \leq P(AB_1B_2)^c < \frac{1}{3}\varepsilon + \frac{1}{3}\varepsilon + \frac{1}{3}\varepsilon = \varepsilon, \]

as alleged. \( \Box \)

Theorem 8.4.4 easily leads to the following a.u. convergence theorem for wide-sense submartingales. We emphasize that, while constructive proofs of a.u. convergence for a martingale \( X : \{1, 2, \cdots \} \times \Omega \to R \) are well known if \( \lim_{k \to \infty} E|X_k|^p \) exists for some \( p > 1 \), the following theorem requires no \( L_p \)-integrability for \( p > 1 \).

**Theorem 8.4.5. (a.u. Convergence of wide-sense submartingales).** Let \( X : Q \times \Omega \to R \) be an arbitrary wide-sense submartingale relative to its natural filtration \( \mathcal{F} \), where the parameter set \( Q \) is either \( Q \equiv \{1, 2, \cdots \} \) or \( Q \equiv \{-\varepsilon, -2, -1\} \). Suppose (i) there exists \( b_0 > 0 \) such that \( b_0 \geq E|X_i| \) for each \( i \in Q \). As in the previous theorem, define the increasing strictly convex function \( \bar{\lambda} : R \to R \) by

\[ \bar{\lambda}(x) \equiv 2x + (e^{-|x|} - 1 + |x|) \]

(8.4.14)

Yuen-Kwok Chan 267 Constructive Probability
for each $x \in R$. Then, for each $t \in Q$, we have $|X_t| \leq |X_t| \leq 3|X_t|$, whence the r.r.v. $X_t$ is integrable, with $|\mathbb{E}X_t| \leq 3b_0$.

Suppose, in addition, (ii) $\lim_{t \to \infty} E\lambda(X_t)$ exists. Then the following holds.

1. If $X_t \to Y$ a.u. as $|t| \to \infty$ in $Q$, for some r.r.v. $Y$.

2. A rate of the above a.u. convergence can be obtained as follows. Let $(b_h)_{h=1,2,\ldots}$ be an arbitrary sequence of positive real numbers such that $b_h \leq b_0$ and such that $b_h \geq E|X_t|$ for each $t \in Q$ with $|t| \geq h$, for each $h \geq 1$. Let $k_0 \equiv 0$, and let $(k_m)_{m=1,2,\ldots}$ be a nondecreasing sequence of nonnegative integers such that

$$|E\lambda(X_t) - E\lambda(X_s)| < \frac{1}{6}2^{-3m}\exp(-2^{-m}3b_{k(m-1)})$$  \hspace{1cm} (8.4.15)

for each $t,s \in Q$ with $s \leq t$ and $|t|, |s| \geq k_m$, for each $m \geq 1$. Then, for each $m \geq 1$, there exists a measurable set $A_m$ with $P(A_m) < 2^{-m+2}$ such that

$$A_m \subset \bigcap_{p=m+1}^{\infty} \bigcap_{q=p}^{\infty} \{ |X_t - Y| \leq 2^{-p+3} \}.$$  \hspace{1cm} (8.4.16)

Note that, if $X$ is a martingale with $Q \equiv \{1,2,\ldots\}$, and if both $\lim_{t \to \infty} E|X_t|$ and $\lim_{t \to \infty} Ee^{-|X_t|}$ exist, then both Conditions (i) and (ii) hold because $E\lambda$ is a constant. In general, note also that if Condition (i) holds, then, since $E\lambda(X_t)$ is a nondecreasing function of $t \in Q$ according to Theorem [8.4.2], and since $E\lambda(X_t) \leq 3|X_t| \leq 3b_0$ for each $t \in Q$, Condition (ii) is, classically, automatically satisfied.

**Proof.** 1. First note that Assertion 1 of Theorem [8.4.4] implies that $|X_t| \leq |X_t| \leq 3|X_t|$ whence the r.r.v. $X_t$ is integrable, with $|E\lambda(X_t)| \leq E|\lambda(X_t)| \leq 3|X_t| \leq 3b_0$, for each $t \in Q$.

2. Let $h \geq 1$ be arbitrary. Condition (i) in the hypothesis guarantees that there exists $b_h \in (0,b_0)$ such that $b_h \geq E|X_t|$ for each $t \in Q$ with $|t| \geq h$. If necessary, we can always take $b_h \equiv b_0$.

3. Let $m \geq 1$ be arbitrary. Take any $\epsilon_m \in (2^{-m},2^{-m+1})$. Then inequality (8.4.15) implies that

$$E\lambda(X_t) - E\lambda(X_s) < \frac{1}{6}2^{-3m}\exp(-3b_{k(m-1)}2^m) < \frac{1}{6}\epsilon_m^3\exp(-3b_{k(m-1)}\epsilon_m^{-1})$$  \hspace{1cm} (8.4.17)

for each $t,s \in Q$ with $s \leq t$ and $|t|, |s| \geq k_m$.

4. We will first prove the theorem for the case where $Q \equiv \{1,2,\ldots\}$. Let $m \geq 1$ be arbitrary. Then $E|X_t| \leq b_{k(m-1)}$ for each $t \in Q$ with $t \geq k_{m-1}$. In particular, $E|X_{k(m)}| \vee E|X_{k(m+1)}| \leq b_{k(m-1)}$. Hence, since $e^{-r}$ is a decreasing function of $r \in R$, inequality (8.4.17) yields

$$E\lambda(X_{k(m+1)}) - E\lambda(X_{k(m)}) < \frac{1}{6}\epsilon_m^3\exp(-3E|X_{k(m)}| \vee E|X_{k(m+1)}|\epsilon_m^{-1}).$$  \hspace{1cm} (8.4.18)

Therefore Theorem [8.4.4] implies that $P(B_m) < \epsilon_m$, where we define

$$B_m \equiv \bigcup_{k=m}^{k(m+1)} \{ X_k - X_{k(m)} | > \epsilon_m \}.$$  \hspace{1cm} (8.4.19)

Yuen-Kwok Chan 268 Constructive Probability
Now define \( A_m \equiv \bigcap_{h=m}^\infty B_h^c \). Then

\[
P(A_m^c) \leq \sum_{h=m}^\infty P(B_h) = \sum_{h=m}^\infty \mathcal{E}_h < \sum_{h=m}^\infty 2^{-h+1} = 2^{-m+2}.
\]

Consider each \( \omega \in A_m \). Let \( p \geq m \) and \( j \geq k_p \) be arbitrary. Then \( k_h \leq i \leq k_{h+1} \) and \( k_n \leq j \leq k_{n+1} \) for some \( n \geq h \geq p \). Consequently,

\[
|X_i(\omega) - Y(\omega)| \leq |X_i(\omega) - X_{k(h)}(\omega)| + |X_{k(h)}(\omega) - X_{k(h+1)}(\omega)| + \cdots + |X_{k(n)}(\omega) - X_j(\omega)|
\]

\[
< 2^{-h+1} + \sum_{k=h}^\infty 2^{-k+1} = 2^{-h+1} + 2^{-h+2} < 2^{-p+3}, \tag{8.4.20}
\]

where the second inequality is because \( \omega \in A_m \subset B_m^c B_{h+1}^c \cdots B_n^c \). Since \( 2^{-p+3} \) is arbitrarily small for sufficiently large \( p \geq m \), we see that the sequence \( (X_k(\omega))_{k=1,2,\ldots} \) of real numbers is Cauchy, and so \( Y(\omega) \equiv \lim_{k \to \infty} X_k(\omega) \) exists. Fixing \( i \) and letting \( j \to \infty \) in inequality (8.4.20), we obtain

\[
|X_i(\omega) - Y(\omega)| \leq 2^{-p+3}
\]

for each \( i \geq k_p \), where \( p \geq m \) is arbitrary, for each \( \omega \in A_m \). Hence

\[
A_m \subset \bigcap_{p=m}^\infty \bigcap_{i=k(p)}^\infty (|X_i - Y| \leq 2^{-p+3}) = \bigcap_{p=m}^\infty \bigcap_{i=k(p)}^\infty (|X_i - Y| \leq 2^{-p+3}).
\]

Thus \( X_i \to Y \) uniformly on the measurable set \( A_m \), where \( P(A_m^c) < 2^{-m+2} \) is arbitrarily small when \( m \geq 1 \) is sufficiently large. In other words, \( X_i \to Y \) a.u. By Proposition 5.1.9 the function \( Y \) is a r.v. The theorem has been proved for the case where \( Q = \{1,2,\ldots\} \).

5. The proof for the case where \( Q = \{-1,-2,\cdots\} \) is almost a mirror image of the preceding paragraph. Let \( m \geq 1 \) be arbitrary. Then \( E|X_t| \leq b_{k(m-1)} \) for each \( t \in Q \) with \( t \leq -k_{m-1} \). In particular, \( E|X_{-k(m+1)}| \vee E|X_{-k(m)}| \leq b_{k(m-1)} \). Hence, since \( e^{-r} \) is a decreasing function of \( r \in R \), inequality 8.4.17 yields

\[
E\overline{X}_{-k(m+1)} - E\overline{X}_{-k(m+1)} < \frac{1}{3} \varepsilon_m^3 \exp(-3(E|X_{-k(m+1)}| \vee E|X_{-k(m)}|)\varepsilon_m^{-1}). \tag{8.4.21}
\]

Therefore Theorem 8.4.4 implies that \( P(B_m) < \varepsilon_m \), where we define

\[
B_m \equiv (\bigvee_{k=m}^{k(m+1)} |X_{-k} - X_{-k(m+1)}| > \varepsilon_m). \tag{8.4.22}
\]

Now define \( A_m \equiv \bigcap_{h=m}^\infty B_h^c \). Then

\[
P(A_m^c) \leq \sum_{h=m}^\infty P(B_h) = \sum_{h=m}^\infty \varepsilon_h < \sum_{h=m}^\infty \varepsilon_h < \sum_{h=m}^\infty 2^{-h+1} = 2^{-m+2}.
\]
CHAPTER 8. MARTINGALES

Consider each \( \omega \in A_m \). Let \( p \geq m \) and \( j \geq i \geq k_p \) be arbitrary. Then \( k_h \leq i \leq k_{h+1} \) and \( k_n \leq j \leq k_{n+1} \) for some \( n \geq h \geq p \). Consequently,

\[
|X_{-j}(\omega) - X_{-i}(\omega)| \\
\leq |X_{-j}(\omega) - X_{-k_{n+1}}(\omega)| + |X_{-k_{n+1}}(\omega) - X_{-k_{n}}(\omega)| + \cdots + |X_{-k_{h+1}}(\omega) - X_{i}(\omega)| \\
\leq \varepsilon_n + (\varepsilon_n + \cdots + \varepsilon_h) \\
< 2^{-n+1} + \sum_{k=h}^\infty 2^{-k+1} = 2^{-n+1} + 2^{-h+2} < 2^{-p+3}, \tag{8.4.23}
\]

where the second inequality is because \( \omega \in A_m \subset B_p^mB_{p+1}^m \cdots B_h^m \). Since \( 2^{-p+3} \) is arbitrarily small for sufficiently large \( p \geq m \), we see that the sequence \( \{X_{-k}(\omega)\}_{k=1,2,\ldots} \) of real numbers is Cauchy, and so \( Y(\omega) \equiv \lim_{k \to \infty} X_{-k}(\omega) \) exists. Fixing \( i \) and letting \( f \to \infty \) in inequality \( 8.4.23 \) we obtain

\[
|X_{-j}(\omega) - Y(\omega)| \leq 2^{-p+3}
\]

for each \( i \geq k_p \), where \( p \geq m \) is arbitrary, for each \( \omega \in A_m \). Hence

\[
A_m \subset \bigcap_{p=m}^\infty \bigcap_{i=k(p)}^\infty (|X_{-i} - Y| \leq 2^{-p+3}) = \bigcap_{p=m}^\infty \bigcap_{t|m \in Q: |t| \geq k(p)} (|X_t| \leq 2^{-p+3}).
\]

Thus \( X_{-i} \to Y \) uniformly on the measurable set \( A_m \), with \( P(A_m) < 2^{-m+2} \) arbitrarily small when \( m \geq 1 \) is sufficiently large. In other words, \( X_t \to Y \) a.u. as \( |t| \to \infty \) with \( t \in Q \equiv \{\ldots, -2, -1\} \). By Proposition 5.1.9 the function \( Y \) is a r.r.v. The theorem has been proved also for the case where \( Q \equiv \{\ldots, -2, -1\} \). \( \square \)

8.5 The Law of Large Numbers

Applications of martingales are numerous. One application is to prove the Strong Law of Large numbers (SLLN). This theorem says that if \( Z_1, Z_2, \cdots \) is a sequence of integrable independent and identically distributed r.r.v’s, with mean 0, then \( n^{-1}(Z_1 + \cdots + Z_n) \to 0 \) a.u. Historically the first proof of this theorem in its generality, due to Kolmogorov, is constructive, complete with rates of convergence. See, for example, Theorem 5.4.2 of [Chung 1968]. Subsequently, remarkable proofs are also given in terms of a.u. martingale convergence via Doob’s upcrossing inequality. See, for example, Theorem 9.4.1 of [Chung 1968]. As observed earlier, the theorem that deduces a.u. convergence from upcrossing inequalities actually implies the principle of infinite search, and cannot be made constructive. For that reason, we present below a constructive proof by a simple application of Theorem 8.4.3 in the previous section. A similar constructive proof is most likely known in the literature.

First the weak law, with a well known proof by characteristic functions.

Theorem 8.5.1. (Weak Law of Large Numbers). Suppose \( Z_1, Z_2, \cdots \) is a sequence of integrable, independent, and identically distributed r.r.v’s with mean 0, on some
probability space \((\Omega, \mathcal{L}, E)\). Let \(\eta_{\text{int}}\) be a simple modulus of integrability of \(Z_1\), in the sense of Definition 4.7.3. For each \(m \geq 1\), let \(S_m = m^{-1}(Z_1 + \cdots + Z_m)\). Then

\[ E|S_m| \to 0 \]

as \(m \to \infty\). More precisely, for each \(m \geq 1\), there exists an integer \(q_m \equiv q_{m, \eta_{\text{int}}} \geq 1\) such that \(E|S_k| \leq 2^{-m}\) for each \(k \geq q_m\).

**Proof.**

1. By hypothesis, the independent r.r.v.'s \(Z_1, Z_2, \ldots\) have a common distribution \(J\) on \(R\). Hence they share a common characteristic function \(\psi\). Therefore, for each \(n \geq 1\), the characteristic function of the r.r.v. \(S_n\) is given by \(\psi_n \equiv \psi^n(\frac{z}{n})\). Let \(J_0\) denote the distribution of \(S_n\). Let \(J_0\) denote the distribution on \(R\) which assigns probability 1 to the point \(0 \in R\). Then the characteristic function of \(J_0\) is the constant function \(\psi_0 \equiv 1\) on \(R\). Define the remainder function \(r_1\) of the first degree Taylor expansion of the characteristic function \(\psi\) by

\[ \psi(u) = 1 + iuEZ_1 + r_1(u) = 1 + r_1(u) \]

for each \(u \in R\), where the mean \(EZ_1\) vanishes by hypothesis.

2. Separately, take an arbitrary \(a > \eta_{\text{int}}(1)\). Then \(E|Z_1| \leq E|Z_1|1_{\{|Z_1| > a\}} + a \leq 1 + a\), by the Definition 4.7.3 of a simple modulus of integrability. Letting \(a \downarrow \eta_{\text{int}}(1)\) then yields

\[ E|Z_k| = E|Z_1| \leq b \equiv 1 + \eta_{\text{int}}(1) \]

for each \(k \geq 1\).

3. Let \(n \geq 1\) be arbitrary. Define the positive real number

\[ c \equiv \pi^{-1}2^{2n+4}, \]

and integer

\[ p_n \equiv p_{n, \eta_{\text{int}}} \equiv \frac{8bc^{3}}{\pi} \eta_{\text{int}}(\frac{\pi}{8c})]1. \]

Consider each \(k \geq p_n\) and each \(u \in [-c, c]\). Write \(\alpha \equiv \frac{\pi}{4c}\) for short. Then

\[ |\frac{u}{k}| \leq \frac{c}{k} \leq \frac{c}{p_n} < \frac{\pi c}{8bc}(\eta_{\text{int}}(\frac{\pi}{8c}))^{-1} = \frac{\alpha}{2b}(\eta_{\text{int}}(\frac{\alpha}{2}))^{-1}. \]

Hence, by Assertion 2 of Proposition 8.7.2, where the dimension is set to 1, and where \(X, \lambda, \epsilon, b\) are replaced by \(Z, \frac{u}{k}, \alpha, b\) respectively, we obtain

\[ |r_1(\frac{u}{k})| < \alpha |\frac{u}{k}| \leq \alpha \frac{c}{k} = \frac{\pi}{4kc}. \]

For abbreviation, write \(z \equiv r_1(\frac{u}{k})\). Then \(|z| < \frac{\pi}{4kc}\). Therefore the binomial expansion yields

\[ |(1 + r_1(\frac{u}{k}))^k - 1| \equiv |(1 + z)^k - 1| \]

\[ = |(1 + C_k^1z + C_k^2z^2 + \cdots + C_k^kz^k) - 1| \]

Yuen-Kwok Chan

Constructive Probability
\[
\leq C_1^k \frac{\pi}{4c} \cdot \frac{\pi}{4c}^2 + \cdots + C_k^k \left( \frac{\pi}{4c} \right)^k \\
\leq \left( \frac{\pi}{4c} \right)^k + \left( \frac{\pi}{4c} \right)^2 \cdots + \left( \frac{\pi}{4c} \right)^k < \frac{\pi}{4c} \left( 1 - \frac{\pi}{4c} \right)^{-1} \\
\equiv \frac{\pi}{4c} \left( 1 - \frac{\pi}{2} \cdot 2^{-2n+4} \right)^{-1} = \frac{\pi}{4c} \left( 1 - \pi^2 \cdot 2^{-2n+6} \right)^{-1} < \frac{\pi}{4c} \cdot 2 = \frac{\pi}{2c},
\]

where

\[
C_j^k = \frac{k(k-1) \cdots (k-j+1)}{j!} \leq k^j
\]

for each \( j = 1, \ldots, k \). Consequently,

\[
|\psi_k(u) - \psi_0(u)| = |\psi_k(\frac{u}{k}) - 1|
\]

\[
= |(1 + r_1(\frac{u}{k}))^k - 1| < \frac{\pi}{2c}.
\]

(8.5.4)

where \( u \in [-c, c] \), \( k \geq p_n \), and \( n \geq 1 \) are arbitrary.

4. Now let \( a \in (2^{-n}, 2^{-n+1}) \) be arbitrary. Define the function \( f \in C(R) \) by

\[
f(x) \equiv a^{-1} (1 - a^{-1}|x|)_+
\]

(8.5.5)

for each \( x \in R \). Then the Fourier Transform \( \hat{f} \) of the function \( f \) satisfies

\[
|\hat{f}(u)| \equiv \left| \int_{x \in R} e^{iux} f(x) dx \right| = \frac{2}{a} \int_0^a (\cos ux)(1 - \frac{x}{a}) dx
\]

\[
= \frac{2}{a} \int_0^a \sin ux \frac{1}{u} \frac{1}{a} dx = \frac{2}{a} \frac{(1 - \cos au)}{a^2 u^2} \leq 1 \wedge \frac{4}{a^2 u^2}
\]

for each \( u \in R \), where the third equality is by integration by parts in Calculus. Therefore \( \hat{f} \) is Lebesgue integrable on \( R \). Hence Assertion 3 of Theorem 5.8.9 implies that

\[
J_k f = (2\pi)^{-1} \int \hat{f}(-u) \psi_k(u) du,
\]

with a similar equality when \( k \) is replaced by 0. Consequently,

\[
2\pi |J_k f - J_0 f| = |\int \hat{f}(-u) (\psi_k(u) - \psi_0(u)) du|
\]

\[
= |\int_{|u| \leq c} \hat{f}(-u)((1 + r_1(\frac{u}{k}))^k - 1) du + \int_{|u| > c} \hat{f}(-u)(\psi_k(u) - \psi_0(u)) du|
\]

\[
\leq \int_{|u| \leq c} |(1 + r_1(\frac{u}{k}))^k - 1| du + \int_{|u| > c} \frac{4}{a^2 u^2} \cdot 2 du
\]

\[
< \int_{|u| \leq c} \frac{\pi}{2c} du + \frac{16}{a^2 c} \leq \pi + \frac{16}{2 \cdot 2^{2n-6}} = \pi + \pi = 2\pi,
\]

whence

\[
|J_k f - J_0 f| \leq 1.
\]
8.5. THE LAW OF LARGE NUMBERS

At the same time, from the defining formula (8.5.5) we see that \(1_{[-a,a]} \geq af\). Hence

\[ P(|S_k| > a) = J_k(1 - 1_{[-a,a]}) \]

\[ \leq 1 - a J_k f \leq 1 - a(J_0 f - 1) = 1 - a(f(0) - 1) = 1 - a(a^{-1} - 1) = a, \]

where \(a \in (2^{-n}, 2^{-n+1})\), \(k \geq p_n\), and \(n \geq 1\) are arbitrary. Since \(a\) is arbitrarily small for sufficiently large \(n \geq 1\), we conclude that \(S_k \to 0\) in probability.

5. To prove \(E|S_k| \to 0\), first note that, by Proposition 4.7.2 for each \(k \geq 1\), the r.r.v. \(Z_k\) has a modulus of integrability \(\delta\) defined by

\[ \delta(\epsilon) = \frac{\epsilon}{2} / \eta_{\text{intg}}(\frac{\epsilon}{2}) \]

for each \(\epsilon > 0\). Let \(m \geq 1\) be arbitrary. Let \(n \equiv (m + 2) \vee \lfloor 1 - \log_2(\delta(2^{-m-1})) \rfloor\). Take an arbitrary \(a \in (2^{-n}, 2^{-n+1})\). Define

\[ q_{m,n}(\eta_{\text{intg}}) \equiv p_{n,\eta}(\eta_{\text{intg}}). \quad (8.5.6) \]

Consider each \(k \geq q_{m,n}(\eta_{\text{intg}}) \equiv p_{n,\eta}(\eta_{\text{intg}})\). Then, by Step 4, we have

\[ P(|S_k| > a) < a < 2^{-n+1} < \delta(2^{-m-1}). \]

Hence, since \(\delta\) is a modulus of integrability of \(Z_k\) for each \(\kappa = 1, \ldots, k\), it follows that

\[ E|S_k|1_{(|S(k)| > a)} \leq k^{-1} \sum_{\kappa=1}^{k} E|Z_k|1_{(|S(k)| > a)} \leq k^{-1} \sum_{\kappa=1}^{k} 2^{-m-1} = 2^{-m-1}. \]

Consequently,

\[ E|S_k| \leq E|S_k|1_{(|S(k)| \leq a)} + E|S_k|1_{(|S(k)| > a)} \leq a + 2^{-m-1} \]

\[ < 2^{-n+1} + 2^{-m-1} \leq 2^{-m-1} + 2^{-m-1} = 2^{-m}, \]

where \(m \geq 1\) and \(k \geq q_{m,n}(\eta_{\text{intg}})\) are arbitrary. We conclude that \(E|S_k| \to 0\) as \(k \to \infty\). \(\Box\)

Theorem 8.5.2. (Strong Law of Large Numbers). Suppose \(Z_1, Z_2, \ldots\) is a sequence of integrable, independent, and identically distributed r.r.v’s with mean 0, on some probability space \((\Omega,L,E)\). Let \(\eta_{\text{intg}}\) be a simple modulus of integrability of \(Z_1\), in the sense of Definition 4.7.3 Then

\[ S_k \equiv k^{-1}(Z_1 + \cdots + Z_k) \to 0 \quad a.u. \]

as \(k \to \infty\). More precisely, for each \(m \geq 1\) there exists an integer \(k_m \equiv k_{m,\eta}(\eta_{\text{intg}})\) and a measurable set \(A_m\), with \(P(A_m^c) < 2^{-m+2}\) and with

\[ A_m \subset \bigcap_{p=m}^{\infty} \bigcap_{k=k(p)}^{\infty} \{|S_k| \leq 2^{-p+3}\}. \quad (8.5.7) \]
Chapter 8. Martingales

Proof. 1. Let \( m \geq j \geq 1 \) be arbitrary, and let \( I_j \) denote the distribution of \( Z_j \) on \( R \). Then, in view of the the hypothesis of independence and identical distribution, the r.v. \((Z_1, \ldots, Z_j, \ldots, Z_m)\) with values in \( R^m \) has the same distribution as the r.v. \((Z_{j+1}, \ldots, Z_1, \ldots, Z_m)\), where, for brevity, the latter stands for the sequence obtained from \((Z_1, \ldots, Z_j, \ldots, Z_m)\) by swapping the first- and the \( j \)-th members. Now let \( h \) be an arbitrary. Thus

\[
E h(Z_1, \ldots, Z_j, \ldots, Z_m) = Eh(Z_j, \ldots, Z_1, \ldots, Z_m)
\]  

for each integrable function \( h \) on \( R^m \) relative to the joint distribution \( E_{Z(1), \ldots, Z(m)} \).

2. Let \( Q = \{ \ldots, -2, -1 \} \). For each \( k \geq 1 \), define \( X_{-k} \equiv S_k \). Let \( \mathcal{L} \equiv \mathcal{L}_X \equiv \{ L(X) : t \in Q \} \) be the natural filtration of the process \( X : Q \times \Omega \to R \). Let \( t \in Q \) be arbitrary. Then \( t = -n \) for some \( n \geq 1 \). Hence \((\Omega, L^{(X)}, E)\) is the probability subspace of \((\Omega, L, E)\) generated by the family

\[
G^{(X)} \equiv \{ X_r : r \in Q; r \leq t \} = \{ S_m : m \geq n \}.
\]

In other words, \((\Omega, L^{(X)}, E)\) is the completion of the integration space

\[
(\Omega, L_{(ab)}(G^{(X)}), E),
\]

where

\[
L_C(G^{(X)}) = \{ f(S_n, \ldots, S_m) : m \geq n; f \in C(R^{m-n+1}) \}. \tag{8.5.9}
\]

By Lemma 8.1.3 the process \( X \) is adapted to its natural filtration \( \mathcal{L} \).

3. We will prove that the process \( X \) is a martingale relative to the filtration \( \mathcal{L} \). To that end, let \( s, t \in Q \) be arbitrary with \( t \leq s \). Then \( t = -n \) and \( s = -k \) for some \( n \geq k \geq 1 \). Let \( Y \in L_C(G^{(X)}) \) be arbitrary. Then, in view of equality 8.5.9, we have

\[
Y = f(S_n, \ldots, S_m)
\]

for some \( f \in C_{ab}(R^{m-n+1}) \), for some \( m \geq n \). Let \( j = 1, \ldots, n \) be arbitrary. Then, since the r.r.v. \( Y \) is bounded, the r.r.v. \( YZ_j \) is integrable. Hence, by equality 8.5.8 we have

\[
Ef((Z_1 + \cdots + Z_j + \cdots + Z_n)n^{-1}, \ldots, (Z_1 + \cdots + Z_j + \cdots + Z_m)m^{-1})Z_j
\]

\[
= Ef((Z_j + \cdots + Z_j + \cdots + Z_n)n^{-1}, \ldots, (Z_j + \cdots + Z_j + \cdots + Z_m)m^{-1})Z_1
\]

\[
= Ef((Z_1 + \cdots + Z_j + \cdots + Z_n)n^{-1}, \ldots, (Z_1 + \cdots + Z_j + \cdots + Z_m)m^{-1})Z_1.
\]

In short,

\[
E YZ_j = EYZ_1
\]

for each \( j = 1, \ldots, n \). Therefore, since \( k \leq n \), we have

\[
EYS_k = k^{-1}E(YZ_1 + \cdots + YZ_k) = EYZ_1.
\]

In particular, \( EYS_n = EYZ_1 = EYS_1 \). In other words, \( EYX_t = EYX_t \), where \( X_t \in L^{(X)} \), and where \( Y \in L_C(G^{(X)}) \) is arbitrary. Hence

\[
E(X_t|L^{(X)}) = X_t,
\]

Yuen-Kwok Chan 274 Constructive Probability
8.5. THE LAW OF LARGE NUMBERS

according to Assertion 5 of Proposition 5.6.6. Since \( s, t \in Q \) are arbitrary with \( t \leq s \), the process \( X \) is a martingale relative to its natural filtration \( \mathcal{F} = \{ L^{(X,t)} : t \in Q \} \).

4. Let \( m \geq 1 \) be arbitrary and write \( h \equiv 3m + 8 \). By Theorem 8.5.1, there exists an integer \( q_{h,\eta(\text{intg})} \geq 1 \) so large that \( E[S_h] \leq 2^{-h} \) for each \( k \geq q_{h,\eta(\text{intg})} \). Define

\[
  k_m \equiv k_{m,\eta(\text{intg})} \equiv q_{h,\eta(\text{intg})} \equiv q_{3m+8,\eta(\text{intg})} \geq 1.
\]

Thus

\[
  E[X_{-k}] \equiv E[S_k] \leq b_m \equiv 2^{-3m+8} \tag{8.5.10}
\]

for each \( k \geq k_m \). Since \( 2^{-3m-8} \) is arbitrarily small for sufficiently large \( m \geq 1 \), we see that \( E[X_t] \to 0 \) as \( k \equiv |t| \to \infty \), with \( t \in Q \). Consequently \( X_t \to 0 \) in probability. Hence \( e^{-|X(t)|} \to 1 \) in probability. The Dominated Convergence Theorem then implies that \( Ee^{-|X(t)|} \to 1 \) as \( |t| \to \infty \) with \( t \in Q \).

5. With arbitrary \( m \geq 1 \), consider each \( t, s \in Q \) with \( |t|, |s| \geq k_m \). Recall the increasing and strictly convex function \( \lambda : R \to R \) defined in Theorem 8.4.5 by

\[
  \lambda(x) \equiv 2x + (e^{-|x|} - 1 + |x|) \tag{8.5.11}
\]

for each \( x \in R \). Then

\[
  |E\lambda(X_t) - E\lambda(X_s)| = |E(2X_t + (e^{-|X(t)|} - 1 + |X_t|)) - E(2X_s + (e^{-|X(s)|} - 1 + |X_s|))| \leq E(|X_t| + |X_s|) + E((|X_t| + |X_s|)|) < 2^2 2^{-3m-8} = 2^{-3m-6}
\]

\[
  = 2^{-3m-1} \lambda^2(2^{-3m-2}) < 2^{-3m-1} 2^{-1} \equiv \lambda^2(e^{-1}), \tag{8.5.12}
\]

where the second equality is because \( X \) is a martingale, where the first inequality is thanks to the elementary inequality \( e^{-r} - 1 \leq r \) for each \( r \geq 0 \), and where the second inequality is from inequality 8.5.10. Thus \( \lim_{|t| \to \infty} E\lambda(X_t) \) exists.

6. Continuing with arbitrary \( m \geq 1 \), take any \( \varepsilon_m \in (2^{-m}, 2^{-m+1}) \). Since

\n
inequality 8.5.12 implies

\[
  |E\lambda(X_t) - E\lambda(X_s)| < 2^{-3m-1} 2^{-1} e^{-1} \tag{8.5.13}
\]

for each \( t, s \in Q \) with \( |t|, |s| \geq k_m \). In view of inequalities 8.5.10 and 8.5.13, all the conditions in the hypothesis of Theorem 8.4.5 are satisfied. Accordingly, \( X_t \to Y \) a.s. as \( |t| \to \infty \), for some r.f.v \( Y \). At the same time, since \( E[X_t] \to 0 \) as \( |t| \to \infty \), some subsequence of \( (X_t) \) converges to 0 a.s. as \( |t| \to \infty \). Hence \( Y = 0 \) a.s. Summing up, \( S_k \equiv X_{-k} \to 0 \) a.s. as \( k \to \infty \). Moreover, in view of inequality 8.5.13, Theorem 8.4.5 implies that, for each \( m \geq 1 \), there exists a measurable set \( A_m \) with \( P(A_m') < 2^{-m+2} \) such that

\[
  A_m \subset \bigcap_{p=1}^{\infty} \bigcap_{|t| \geq k(p)} \{|X_t - Y| \leq 2^{-p+3} \} \equiv \bigcap_{p=1}^{\infty} \bigcap_{k \geq k(p)} \{|S_k| \leq 2^{-p+3} \}, \tag{8.5.14}
\]

as desired. \( \square \)

Yuen-Kwok Chan 275 Constructive Probability
Chapter 9

a.u. Continuous Processes on 

\([0, 1]\)

In this chapter, let \((S, d)\) be a locally compact metric space. Unless otherwise specified, this will serve as the state space for the processes in this chapter. We consider an arbitrary consistent family \(F\) of f.j.d.’s which is continuous in probability, with state space \(S\) and parameter set \([0, 1]\). We will find conditions on the f.j.d.’s in \(F\) under which an a.u. continuous process \(X\) can be constructed with marginal distributions given by the family \(F\).

The classical approach to the existence of such processes \(X\), as elaborated in [Billingsley 1974], uses the following theorem.

**Theorem 9.0.1. (Prokhorov’s Relative Compactness Theorem).** Each tight family \(\mathcal{J}\) of distributions on a locally compact metric space \((H, d_H)\) is relative compact, in the sense that each sequence in \(\mathcal{J}\) contains a subsequence which converges weakly to some distribution on \((H, d_H)\).

Prokhorov’s theorem however implies the principle of infinite search, and is therefore not constructive. This can be seen as follows. Let \((r_n)_{n=1,2,\ldots}\) be an arbitrary nondecreasing sequence in \(\{0, 1\}\). Let the doubleton \(H\) be endowed with the Euclidean metric \(d_H\) defined by \(d_H(x, y) = |x - y|\) for each \(x, y \in H\). For each \(n \geq 1\), let \(J_n\) be the distribution on \((H, d_H)\) which assigns unit mass to \(r_n\); in other words, \(J_n(f) \equiv f(r_n)\) for each \(f \in C(H, d_H)\). Then the family \(\mathcal{J} \equiv \{J_1, J_2, \ldots\}\) is tight, and Prokhorov’s theorem implies that \(J_n\) converges weakly to some distribution \(J\) on \((H, d_H)\). It follows that \(J_n g\) converges as \(n \to 0\), where \(g \in C(H, d_H)\) is defined by \(g(x) = x\) for each \(x \in H\). Thus \(r_n = g(r_n) = J_n g\) converges as \(n \to 0\). Since \((r_n)_{n=1,2,\ldots}\) is an arbitrary nondecreasing sequence in \(\{0, 1\}\), the principle of infinite search follows from Prokhorov’s theorem.

In our constructions, we will bypass any use of Prokhorov’s theorem or to any unjustified supremums, in favor of direct proofs using Borel-Cantelli estimates. We will give a necessary and sufficient condition on the f.j.d.’s in the family \(F\), for \(F\) to be extendable to an a.u. continuous process \(X\). We will call this condition \(C\)-regularity.
We will derive a modulus of a.u. continuity of the process $X$ from a given modulus of continuity in probability and a given modulus of $C$-regularity of the consistent family $F$, to be defined presently. We will also prove that the extension is uniformly metrically continuous on an arbitrary set $\hat{F}_0$ of such consistent families $F$ which share a common modulus of $C$-regularity.

In essence, the material presented in Sections 1 and 2 of the present work is a constructive and more general version of, materials from Section 7 of Chapter 2 of [Billingsley 1974], the latter treating only the special case where $S = R$. We remark that the generalization to the arbitrary locally compact state space $(S,d)$ is not entirely trivial, because we forego the convenience of linear interpolation in $R$.

A subsequent chapter in the present work will introduce a condition, analogous to $C$-regularity, for the treatment of processes which are, almost uniformly, right continuous with left limits, again with a general locally compact metric space as state space.

In Section 3, we will prove a generalization of Kolmogorov’s theorem for a.u. locally Hoelder continuity, in a sense to be made precise in Section 3, with state space $(S,d)$.

Separately, in Section 4, in the case of Gaussian processes, we will present the sufficient condition and the proof in [Garsia, Rodemich, and Rumsey 1970] for the construction of an a.u. continuous process given the modulus of continuity of the covariance function. A minor modification of their proof makes it strictly constructive.

We note that, for a more general parameter space which is a subset of $R^m$ for some $m \geq 0$, with some restriction on its local $\varepsilon$-entropy, [Potthoff 2009-2] gives sufficient conditions on the pair distributions $F_{ts}$ to guarantee the construction of an a.u. continuous or an a.u. locally Hoelder, real-valued, random field.

In this and later chapters we will use the following notations for the dyadic rationals.

**Definition 9.0.2. (Notations for dyadic rationals).** For each $m \geq 0$, define $p_m = 2^m$, $\Delta_m = 2^{-m}$, and define the enumerated set of dyadic rationals

$$Q_m \equiv \{t_0, t_1, \ldots, t_{p(m)}\} = \{q_{m,0}, \ldots, q_{m,p(m)}\}$$

$$\equiv \{0, \Delta_m, 2\Delta_m, \ldots, 1\} \subset [0,1],$$

and

$$Q_\infty \equiv \bigcup_{m=0}^{\infty} Q_m \equiv \{t_0, t_1, \ldots\},$$

where the second equality is equality of sets without the enumeration. Let $m \geq 0$ be arbitrary. Then the enumerated set $Q_m$ is a $2^{-m}$-approximation of $[0,1]$, with $Q_m \subset Q_{m+1}$. Conditions in Definition 3.1.1 can easily be verified for the sequence

$$\xi_{[0,1]} \equiv (Q_m)_{m=1,2,\ldots}$$

to be a binary approximation of $[0,1]$ relative to the reference point $q_0 \equiv 0$.

In addition, for each $m \geq 0$, define the enumerated set of dyadic rationals

$$Q_m \equiv \{u_0, u_1, \ldots, u_{p(2m)}\} = \{0, 2^{-m}, 2 \cdot 2^{-m}, \ldots, 2^m\} \subset [0,2^m].$$
9.1. Extension of a.u. Continuous Processes with Dyadic Rational Parameters to Parameters in [0, 1]

and

\[ \overline{Q}_m = \bigcup_{m=0}^{\infty} \overline{Q}_m = \{u_0, u_1, \ldots\}, \]

where the second equality is equality of sets without the enumeration.

\[ \square \]

**Definition 9.0.3.** (Miscellaneous Notations and conventions). As usual, to lighten notational burden, we will write an arbitrary subscripted symbol \( a(b) \) interchangeably with \( a(b) \). We will write \( TU \) for a composite function \( T \circ U \). If \( f : A \to B \) is a function from a set \( A \) to a set \( B \), and if \( A' \) is a nonempty subset \( A \), then the restricted function \( f|A' : A' \to B \) will also be denoted simply by \( f \) when there is little risk of confusion. If \( A \) is a measurable subset on a probability space \( (\Omega, \mathcal{L}, E) \), then we will write \( PA \), \( P(A) \), \( E(A) \), \( EA \), or \( E1_A \), interchangeably. For arbitrary r.r.v. \( Y \in L \) and measurable subsets \( A, B \), we will write \( (A; B) \equiv AB \), \( E(Y; A) \equiv E(Y1_A) \), and \( A \in L \). For further abbreviations, we drop parentheses when there is little risks of confusion. For example, we write \( 1_{Y \leq \beta; Z > \alpha} \equiv 1_{(Y \leq \beta)(Z > \alpha)} \). For an arbitrary integrable function \( X \in L \), will sometimes use the more suggestive notation \( \int E(d\omega)X(\omega) \) for \( EX \), where \( \omega \) is a dummy variable.

Let \( Y \) be an arbitrary r.r.v. Recall from Definition 5.1.3 the convention that if measurability of the set \( (Y < \beta) \) or \( (Y \leq \beta) \) is required in a discussion, for some \( \beta \in R \), then it is understood that the real number \( \beta \) has been chosen from the regular points of the r.r.v. \( Y \).

Recall that \( \lfloor \cdot \rfloor_1 \) is an operation which assigns to each \( a \in R \) an integer \( [a]_1 \in (a, a + 2) \).

9.1 Extension of a.u. Continuous processes with dyadic rational parameters to parameters in [0, 1]

Our approach to extend a given family \( F \) of f.j.d.’s which is continuous in probability on the parameter set [0, 1] is as follows. First note that \( F \) carries no more useful information than its restriction \( F|Q_\infty \), where \( Q_\infty \) is the dense subset of dyadic rationals in [0, 1], because the family can be recovered from the \( F|Q_\infty \), thanks to continuity in probability. Hence we can first extend the family \( F|Q_\infty \) to a process \( Z : Q_\infty \times \Omega \to S \), by the Daniell-Kolmogorov Theorem or the Daniell-Kolmogorov-Skorokhod Theorem. Then any condition of the family \( F \) is equivalent to a condition of \( Z \).

In particular, in the current context, any condition on f.j.d.’s to make \( F \) extendable to an a.u. continuous process \( X : [0, 1] \times \Omega \to S \) can be discussed in the more general terms of a process \( Z : Q_\infty \times \Omega \to S \), the latter to be extended by limit to a process \( X \). It is intuitively obvious that any a.u. continuous process \( Z : Q_\infty \times \Omega \to S \) is extendable to an a.u. continuous process \( X : [0, 1] \times \Omega \to S \), because \( Q_\infty \) is dense \([0, 1]\). In this section, we will make this precise, and prove that the extension construction is itself a metrically continuous construction.
Definition 9.1.1. (Metric Space of a.u. Continuous Processes). Let $C[0,1]$ be the space of continuous functions $x : [0, 1] \to S$, endowed with the uniform metric defined by

$$d_{C[0,1]}(x, y) \equiv \sup_{t \in [0,1]} d(x(t), y(t)) \quad (9.1.1)$$

for each $x, y \in C[0,1]$. Write $\hat{d}_{C[0,1]} \equiv 1 \land d_{C[0,1]}$. Let $\hat{C}[0,1]$ denote the set of stochastic processes $X : [0, 1] \times \Omega \to S$ which are a.u. continuous on $[0, 1]$. Define a metric $\rho_{\hat{C}[0,1]}$ on $\hat{C}[0,1]$ by

$$\rho_{\hat{C}[0,1]}(X, Y) \equiv E \sup_{t \in [0,1]} \hat{d}(X_t, Y_t) \equiv E\hat{d}_{C[0,1]}(X, Y) \quad (9.1.2)$$

for each $X, Y \in \hat{C}[0,1]$. The next lemma says that $(\hat{C}[0,1], \rho_{\hat{C}[0,1]})$ is a well-defined metric space. □

Lemma 9.1.2. ($\rho_{\hat{C}[0,1]}$ is a metric). The function $\sup_{t \in [0,1]} \hat{d}(X_t, Y_t)$ is a r.r.v. The function $\rho_{\hat{C}[0,1]}$ is well-defined and is a metric.

Proof. Let $X, Y \in \hat{C}[0,1]$ be arbitrary, with moduli of a.u. continuity $\delta_{auc}^X, \delta_{auc}^Y$, respectively. First note that the function $\sup_{t \in [0,1]} \hat{d}(X_t, Y_t)$ is defined a.s., on account of continuity on $[0, 1]$ of $X, Y$ on a full subset of $\Omega$. We need to prove that it is measurable, so that the expectation in the defining formula (9.1.2) makes sense.

To that end, let $\varepsilon > 0$ be arbitrary. Then there exist measurable sets $D_X, D_Y$ with $P(D_X^c) \lor P(D_Y^c) < \varepsilon$ such that

$$d(X_t, X_s) \lor d(Y_t, Y_s) \leq \varepsilon$$

for each $t, s \in [0, 1]$ with $|t - s| < \delta$ $\equiv \delta_{auc}^X(\varepsilon) \land \delta_{auc}^Y(\varepsilon)$. Now let the sequence $s_0, \ldots, s_n$ be an arbitrary $\delta$-approximation of $[0, 1]$, for some $n \geq 1$. Then, for each $t \in [0, 1]$, we have $|t - s_k| < \delta$ for some $k = 0, \ldots, n$, whence

$$d(X_t, X_{s(k)}) \lor d(Y_t, Y_{s(k)}) \leq \varepsilon \quad (9.1.3)$$

on $D \equiv D_X \lor D_Y$, which in turn implies

$$|d(X_t, Y_t) - d(X_{s(k)}, Y_{s(k)})| \leq 2\varepsilon$$

on $D$. It follows that

$$|\sup_{t \in [0,1]} \hat{d}(X_t, Y_t) - \sqrt[n]{\hat{d}(X_{s(k)}, Y_{s(k)})}| \leq 2\varepsilon$$

on $D$, where $Z \equiv \bigvee_{k=1}^{n} \hat{d}(X_{s(k)}, Y_{s(k)})$ is a r.r.v., and where $P(D^c) < 2\varepsilon$. For each $p \geq 1$, we can repeat this argument with $\varepsilon \equiv \frac{1}{p}$. Thus we obtain a sequence $Z_p$ of r.r.v.’s with $Z_p \to \sup_{t \in [0,1]} \hat{d}(X_t, Y_t)$ in probability as $p \to \infty$. The function $\sup_{t \in [0,1]} \hat{d}(X_t, Y_t)$ is accordingly a r.r.v., and, being bounded by 1, integrable. Summing up, the expectation in equality (9.1.2) exists, and $\rho_{\hat{C}[0,1]}$ is well-defined.

Verification of the conditions for the function $\rho_{\hat{C}[0,1]}$ to be a metric is straightforward and omitted. □
9.1. EXTENSION OF A.U. CONTINUOUS PROCESSES WITH DYADIC RATIONAL PARAMETERS TO PARAMETERS IN $[0,1]$

Definition 9.1.3. (Extension by limit of a process with parameter set $Q_\infty$). Let $Z : Q_\infty \times \Omega \rightarrow S$ be an arbitrary process. Define a function by

$$\text{domain}(X) \equiv \Phi_{\text{Lim}}(Z) \equiv \{(r, \omega) \in [0,1] \times \Omega : \lim_{s \rightarrow r, t \in Q(\infty)} Z(s, \omega) \text{ exists}\}$$

and

$$X(r, \omega) \equiv \lim_{s \rightarrow r, t \in Q(\infty)} Z(s, \omega)$$

for each $(r, \omega) \in \text{domain}(X)$. We will call $X$ the extension-by-limit of the process $Z$ to the parameter set $[0,1]$. A similar definition is made where the interval $[0,1]$ is replaced by the interval $[0,\infty)$, and where the set $Q_\infty$ of dyadic rationals in $[0,1]$ is replaced by the set $Q_\infty$ of dyadic rationals in $[0,\infty)$.

We emphasize that, absent any additional conditions on the process $Z$, the function $X$ need not be a process; it need not even be a well-defined function.

\[ \square \]

Theorem 9.1.4. (Extension by limit of a.u. continuous process on $Q_\infty$ to a.u. continuous process on $[0,1]$; and metrical continuity of said extension). Let $R_0$ be a subset of $\hat{R}(Q_\infty \times \Omega, S)$ whose members are a.u. continuous with a common modulus of a.u. continuity $\delta_{\text{auc}}$. Then the following holds.

1. Let $Z \in R_0$ be arbitrary. Then its extension-by-limit $X \equiv \Phi_{\text{Lim}}(Z)$ is an a.u. continuous process such that $X_t = Z_t$ on $\text{domain}(X_t)$ for each $t \in Q_\infty$. Moreover, the process $X$ has the same modulus of a.u. continuity $\delta_{\text{auc}}$ as $Z$.

2. Recall that $(\hat{R}(Q_\infty \times \Omega, S), \rho_{\text{Prob}})$ is the metric space of processes $Z : Q_\infty \times \Omega \rightarrow S$. The extension-by-limit

$$\Phi_{\text{Lim}} : (R_0, \rho_{\text{Prob}}) \rightarrow (\hat{C}[0,1], \rho_{\hat{C}[0,1]})$$

is uniformly continuous, with a modulus of continuity $\delta_{\text{Lim}}(\cdot, \delta_{\text{auc}})$.

Proof. 1. Let $Z \in R_0$ be arbitrary. Let $\epsilon > 0$ be arbitrary. Then, by hypothesis, there exists $\delta_{\text{auc}}(\epsilon) > 0$ and a measurable set $D \subseteq \Omega$ with $P(D^c) < \epsilon$ such that, for each $\omega \in D$ and for each $s, s' \in Q_\infty$ with $|s - s'| < \delta_{\text{auc}}(\epsilon)$, we have

$$d(Z(s, \omega), Z(s', \omega)) \leq \epsilon. \quad (9.1.4)$$

Next let $\omega \in D$ and $r, r' \in [0,1]$ be arbitrary with $|r - r'| < \delta_{\text{auc}}(\epsilon)$. Letting $s, s' \rightarrow r$ with $s, s' \in Q_\infty$, we have $|s - s'| \rightarrow 0$, and so $d(Z(s, \omega), Z(s', \omega)) \rightarrow 0$ as $s, s' \rightarrow r$. Since $(S, d)$ is complete, we conclude that the limit

$$X(r, \omega) \equiv \lim_{s \rightarrow r, t \in Q(\infty)} Z(s, \omega)$$

exists. Moreover, letting $s' \rightarrow r$ with $s, s' \in Q_\infty$, inequality $9.1.4$ yields

$$d(Z(s, \omega), X(r, \omega)) \leq \epsilon. \quad (9.1.5)$$

Yuen-Kwok Chan 281 Constructive Probability
Since $\varepsilon > 0$ is arbitrary, we see that $Z_{r} \to X_{r}$ a.u. as $s \to r$. Hence $X_{r}$ is a r.v. Thus $X : [0,1] \times \Omega_{0} \to S$ is a stochastic process.

Now let $s \to r$ and $s' \to r'$ with $s, s' \in Q_{m}$ in inequality 9.1.4 Then we obtain

$$d(X(r, \omega), X(r', \omega)) \leq \varepsilon,$$

where $\omega \in D$ and $r, r' \in [0,1]$ are arbitrary with $|r - r'| < \delta_{\text{auc}}(\varepsilon)$. Thus $X$ has the same modulus of a.u. continuity $\delta_{\text{auc}}$ as $Z$.

2. It remains to verify that the mapping $\Phi_{\lim}$ is a continuous function. To that end, let $\varepsilon > 0$ be arbitrary. Write $\alpha = \frac{1}{2}\varepsilon$. Let $m \equiv m(\varepsilon, \delta_{\text{auc}}) \geq 1$ be so large that $2^{-m} < \delta_{\text{auc}}(\alpha)$. Define

$$\delta_{\text{lim}}(\varepsilon, \delta_{\text{auc}}) \equiv 2^{-p(m)-1}\alpha^{2}.$$

Let $Z, Z' \in \hat{R}_{0}$ be arbitrary such that

$$\rho_{\text{prob}}(Z, Z') < \delta_{\text{lim}}(\varepsilon, \delta_{\text{auc}}).$$

Equivalently,

$$E \sum_{n=0}^{\infty} 2^{-n-1}d(Z_{(n)}, Z'_{(n)}) < 2^{-p(m)-1}\alpha^{2}. \quad (9.1.7)$$

Then, by Chebychev’s inequality, there exists a measurable set $A$ with $P(A^{c}) < \alpha$ such that, for each $\omega \in A$, we have

$$\sum_{n=0}^{\infty} 2^{-n-1}d(Z(t_{n}, \omega), Z'(t_{n}, \omega)) < 2^{-p(m)-1}\alpha,$$

whence

$$d(Z(t_{n}, \omega), Z'(t_{n}, \omega)) < \alpha \quad (9.1.8)$$

for each $n = 0, \ldots, p_{m}$.

Now let $X \equiv \Phi_{\lim}(Z)$ and $X' \equiv \Phi_{\lim}(Z')$. By Assertion 1, the processes $X$ and $X'$ have the same modulus of a.u. continuity $\delta_{\text{auc}}$ as $Z$ and $Z'$. Hence, there exists measurable sets $D, D'$ with $P(D^{c}) \vee P(D'^{c}) < \alpha$ such that, for each $\omega \in D \cap D'$, we have

$$d(X(r, \omega), X(s, \omega)) \vee d(X'(r, \omega), X'(s, \omega)) \leq \alpha \quad (9.1.9)$$

for each $r, s \in [0,1]$ with $|r - s| < \delta_{\text{auc}}(\alpha)$.

Now consider each $\omega \in ADD'$. Let $r \in [0,1]$ be arbitrary. Since $t_{0}, \ldots, t_{p(m)}$ is a $2^{-m}$-approximation of $[0,1]$, there exists $n = 0, \ldots, p_{m}$ such that $|r - t_{n}| < 2^{-m} < \delta_{\text{auc}}(\alpha)$. Then inequality 9.1.9 holds with $s \equiv t_{n}$. Combining inequalities 9.1.8 and 9.1.9 we obtain

$$d(X(r, \omega), X'(r, \omega))$$

$$\leq d(X(r, \omega), X(s, \omega)) + d(X(s, \omega), X'(s, \omega)) + d(X'(r, \omega), X'(s, \omega))$$

$$= d(X(r, \omega), X(s, \omega)) + d(Z(s, \omega), Z'(s, \omega)) + d(X'(r, \omega), X'(s, \omega)) < 3\alpha,$$

where $\omega \in ADD'$ and $r \in [0,1]$ are arbitrary. It follows that

$$\rho_{\text{auc}}(X, X') \equiv E \sup_{r \in [0,1]} d(X_{r}, X'_{r})$$

Yuen-Kwok Chan 282 Constructive Probability
\[ \leq E \sup_{r \in [0,1]} \hat{d}(X_r, X'_r)1_{ADD'} + P(ADD') < 3\alpha + 3\alpha = 6\alpha \equiv \varepsilon. \]

We conclude that \( \delta_{\text{lim}}(\cdot, \delta_{\text{auc}}) \) is a modulus of continuity of \( \Phi_{\text{lim}} \).

\[ \square \]

9.2 \textit{C-regular families of f.j.d.'s and C-regular processes}

**Definition 9.2.1.** (C-regularity). Let \((\Omega, L, E)\) be an arbitrary sample space. Let \(Z : Q_\infty \times \Omega \to S\) be an arbitrary process. We will say that \(Z\) is a C-regular process if there exists an increasing sequence \(m = (m_n)_{n=0,1,...}\) of positive integers, called the \textit{modulus of C-regularity of the process Z}, such that, for each \(n \geq 0\) and for each \(\beta_n > 2^{-n}\) such that the set

\[ A^{(n)}_{t,s} \equiv (d(Z_t, Z_s) > \beta_n) \]

is measurable for each \(s, t \in Q_m\), we have

\[ P(C_n) < 2^{-n} \]  

(9.2.1)

where

\[ C_n \equiv \bigcup_{t \in Q(m(n))} \bigcup_{s \in [t]^{[Q(m(n+1))}} A^{(n)}_{t,s} \cup A^{(n)}_{s,t}, \]  

(9.2.2)

where, for each \(t \in Q_m\), we abuse notations and write \(t' \equiv 1 \wedge (t + 2^{-m(n)}) \in Q_m\).

Let \(F\) be a consistent family of f.j.d.'s which is continuous in probability on \([0,1]\).

Then the family \(F\) of consistent f.j.d.'s is said to be C-regular, with the sequence \(m = (m_n)_{n=0,1,...}\) as a modulus of C-regularity if \(F|Q_m\) is family of marginal distributions of some C-regular process \(Z\).

\[ \square \]

We will prove that a process on \([0,1]\) is a.u. continuous iff it is C-regular. Note that C-regularity is a condition on the f.j.d.'s while a.u. continuity is a condition on sample paths.

**Theorem 9.2.2.** (a.u. Continuity implies C-regularity). Let \((\Omega, L, E)\) be an arbitrary sample space. Let \(X : [0,1] \times \Omega \to S\) be an a.u. continuous process, with a modulus of a.u. continuity \(\delta_{\text{auc}}\). Then the process \(X\) is C-regular, with a modulus of C-regularity given by \(m \equiv (m_n)_{n=0,1,...}\), where \(m_0 \equiv 1\) and

\[ m_n \equiv [m_{n-1} \vee (-\log_2 \delta_{\text{auc}}(2^{-n-1}))]_1 \]

for each \(n \geq 1\).

**Proof.** First note that \(X\) is continuous in probability. Separately, let \(n \geq 0\) be arbitrary. By Definition 6.1 of a.u. continuity, there exists a measurable set \(D_n\) with \(P(D_n') < 2^{-n}\) such that, for each \(\omega \in D_n\) and for each \(s, t \in Q_m\) with \(|t - s| < \delta_{\text{auc}}(2^{-n})\), we have

\[ d(X(t, \omega), X(s, \omega)) \leq 2^{-n}. \]  

(9.2.3)

Let \(\beta_n > 2^{-n}\) be arbitrary and let

\[ A^{(n)}_{t,s} \equiv (d(X_t, X_s) > \beta_n) \]

Yuen-Kwok Chan 283 Constructive Probability
for each \(s, t \in Q_m\). Define
\[
C_n \equiv \bigcup_{t \in Q(m(n))} \bigcup_{s \in [t, t']} A_{t, s}^{(n)} \cup A_{s, t}^{(n)},
\]
(9.2.4)
where, as before, for each \(t \in Q_{m(n)}\) we abuse notations and write \(t' \equiv 1 \wedge (t + 2^{-m(n)}) \in Q_m\). Suppose, for the sake of a contradiction, that \(P(D_n C_n) > 0\). Then there exists some \(\omega \in D_n C_n\). Hence, by equality \(9.2.4\) there exists \(t \in Q_{m(n)}\) and \(s \in [t, t'] Q_{m(n+1)}\) with
\[
d(X(t, \omega), X(s, \omega)) \vee d(X(s, \omega), X(t', \omega)) > \beta_n.
\]
(9.2.5)
It follows that
\[
|s - t| \vee |s - t'| \leq 2^{-m(n)} < \delta_{\text{auc}}(2^{-n})
\]
(9.2.6)
Inequalities \(9.2.6\) and \(9.2.3\) together imply that
\[
d(X(t, \omega), X(s, \omega)) \vee d(X(s, \omega), X(t', \omega)) \leq 2^{-n} < \beta_n,
\]
contradicting inequality \(9.2.5\). We conclude that \(P(D_n C_n) = 0\). Consequently,
\[
P(C_n) = P(D_n \cup D_n') C_n = P(D_n' C_n) \leq P(D_n') < 2^{-n}.
\]
Thus the conditions in Definition 9.2.1 are satisfied for the family \(F\) of marginal distributions of \(X\) to be \(C\)-regular, with modulus of \(C\)-regularity given by \(\overline{m}\).

The next theorem is the converse of Theorem 9.2.2 and is the main theorem in this section.

**Theorem 9.2.3.** \((C\text{-}regularity\ implies\ a.u.\ continuity)\). Let \((\Omega, L, E)\) be an arbitrary sample space. Let \(F\) be a \(C\)-regular family of consistent f.d.d.'s. Then there exists an a.u. continuous process \(X : [0, 1] \times \Omega \rightarrow S\) with marginal distributions given by \(F\).

Specifically, let \(\overline{m} \equiv (m_n)_{n=0, 1, ...}\) be a modulus of \(C\)-regularity of \(F\). Let \(Z : Q_m \times \Omega \rightarrow S\) be an arbitrary process with marginal distributions given by \(F|Q_m\). Let \(\varepsilon > 0\) be arbitrary. Define \(h \equiv [0 \vee (4 - \log_2 \varepsilon)]\) and \(\delta_{\text{auc}}(\cdot, \overline{m}) \equiv 2^{-h}\). Then \(\delta_{\text{auc}}(\cdot, \overline{m})\) is a modulus of a.u. continuity of \(Z\).

Moreover, the extension-by-limit \(X \equiv \Phi_{\text{Lim}}(Z) : [0, 1] \times \Omega \rightarrow S\) of the process \(Z\) to the full parameter set \([0, 1]\) is a.u. continuous, with the same modulus of a.u. continuity \(\delta_{\text{auc}}(\cdot, \overline{m})\), and with marginal distributions given by \(F\).

**Proof.** 1. First let \(n \geq 0\) be arbitrary. Take any \(\beta_n \in (2^{-n}, 2^{-n+1})\). Then, by Definition 9.2.1
\[
P(C_n) < 2^{-n}
\]
(9.2.7)
where
\[
C_n \equiv \bigcup_{t \in Q(m(n))} \bigcup_{s \in [t, t']} (d(Z_t, Z_s) > \beta_n) \cup (d(Z_s, Z_{t'}) > \beta_n),
\]
(9.2.8)
where, as before, for each \(t \in Q_{m(n)}\) we abuse notations and write \(t' \equiv 1 \wedge (t + 2^{-m(n)}) \in Q_{m(n)}\).
9.2. C-REGULAR FAMILIES OF F.J.D.'S AND C-REGULAR PROCESSES

2. Now define \( D_n = (\bigcup_{j=n}^{\infty} C_j)^c \). Then
\[
P(D_n^c) \leq \sum_{j=n}^{\infty} P(C_j) < \sum_{j=n}^{\infty} 2^{-j} = 2^{-n+1}.
\]

Consider each \( \omega \in D_n \). Consider each \( t \in Q_{m(n)} \). For each \( s \in [t, t'] Q_{m(n+1)} \), since \( \omega \in C_n^c \), we have
\[
d(Z(t, \omega), Z(s, \omega)) \leq \beta_n < 2^{-n+1}.
\]

In short
\[
[t, t'] Q_{m(n+1)} \subset (d(Z(\cdot, \omega), Z(t, \omega)) < 2^{-n+1}),
\]
where \( t \in Q_{m(n)} \) is arbitrary. Repeating the above argument with \( n \) replaced by \( n + 1 \) and with \( t \) replaced by each \( s \in [t, t'] Q_{m(n+1)} \), we obtain
\[
[s, s'] Q_{m(n+2)} \subset (d(Z(\cdot, \omega), Z(s, \omega)) < 2^{-n}),
\]
where \( s' \equiv 1 \wedge (s + 2^{-m(n+1)}) \in Q_{m(n+1)} \). Since
\[
[t, t'] Q_{m(n+2)} = [t, t'] Q_{m(n+1)} \cap \bigcup_{s \in [t, t'] Q_{m(n+1)}} [s, s'] Q_{m(n+2)},
\]
relations 9.2.9 and 9.2.10 together yield
\[
[t, t'] Q_{m(n+2)} \subset (d(Z(\cdot, \omega), Z(t, \omega)) < 2^{-n+1} + 2^{-n}).
\]

Inductively with \( k = n + 1, n + 2, \ldots \), we obtain
\[
[t, t'] Q_{m(k)} \subset (d(Z(\cdot, \omega), Z(t, \omega)) < 2^{-n+1} + 2^{-n} + \cdots 2^{-k+2}) \subset (d(Z(\cdot, \omega), Z(t, \omega)) < 2^{-n+2})
\]
for each \( k \geq n + 1 \). Therefore
\[
[t, t'] Q_{\infty} = [t, t'] \bigcup_{k=n+1}^{\infty} Q_{m(k)} \subset (d(Z(\cdot, \omega), Z(t, \omega)) < 2^{-n+2}).
\]

In particular \( d(Z(t', \omega), Z(t, \omega)) < 2^{-n+2} \), and so the last displayed condition implies
\[
[t, t'] Q_{\infty} \subset (d(Z(\cdot, \omega), Z(t, \omega)) \lor d(Z(\cdot, \omega), Z(t', \omega)) < 2^{-n+3}),
\]
where \( n \geq 1, \omega \in D_n \), and \( t \in Q_{m(n)} \) are arbitrary.

3. Continuing with arbitrary \( n \geq 1 \), suppose \( r, s \in Q_{\infty} \) are arbitrary such that \( 0 < s - r < 2^{-m(n)} \). Then there exist \( t, u \in Q_{m(n)} \) with \( t \leq u \) such that \( r \in [t, t'] \) and \( s \in [u, u'] \), where \( u' \equiv 1 \wedge (u + 2^{-m(n)}) \in Q_{m(n)} \). If \( t' < u \) then \( s \geq u \geq t' + 2^{-m(n)} \geq r + 2^{-m(n)} \), a contradiction. Hence \( u \leq t' \). On the other hand, \( t \leq u \) by the choice of \( t, u \). Consequently, \( u = t \) or \( u = t' \). At the same time, according to relation 9.2.11, we have
\[
d(Z(r, \omega), Z(t, \omega)) \lor d(Z(r, \omega), Z(t', \omega)) < 2^{-n+3}.
\]

Yuen-Kwok Chan 285 Constructive Probability
CHAPTER 9. A.U. CONTINUOUS PROCESSES ON [0, 1]

Similarly,
\[ d(Z(s, \omega), Z(u, \omega)) \vee d(Z(s, \omega), Z(u', \omega)) < 2^{-n+3}. \]

If \( u = t \), then it follows that
\[ d(Z(r, \omega), Z(s, \omega)) \leq d(Z(r, \omega), Z(t, \omega)) + d(Z(u, \omega), Z(s, \omega)) < 2^{-n+4}. \]

If \( u = t' \), then similarly
\[ d(Z(r, \omega), Z(s, \omega)) \leq d(Z(r, \omega), Z(t', \omega)) + d(Z(u, \omega), Z(s, \omega)) < 2^{-n+4}. \]

Summing up, for each \( \omega \in D_n \), for each \( n \geq 1 \), and for each \( r, s \in \mathcal{Q}_\omega \) with \( 0 < s - r < 2^{-m(n)} \), we have
\[ d(Z(r, \omega), Z(s, \omega)) < 2^{-n+4}. \] \[ (9.2.12) \]

By symmetry, the last inequality therefore holds for each \( \omega \in D_n \), for each \( n \geq 1 \), and for each \( r, s \in \mathcal{Q}_\omega \) with \( |s - r| < 2^{-m(n)} \).

4. Now let \( \varepsilon > 0 \) be arbitrary. Let \( n \equiv \lfloor 0 \lor (4 - \log_2 \varepsilon) \rfloor \) and \( \delta_{\text{auc}}(\varepsilon, \mathcal{M}) \equiv 2^{-m(n)} \), as in the hypothesis. By the previous paragraphs, we see that the measurable set \( D_n \equiv (\bigcup_{j=n}^\infty C_j)^c \) is such that \( P(D_n) \leq 2^{-n+1} < \varepsilon \) and such that \( d(Z(r, \omega), Z(s, \omega)) < 2^{-n+4} < \varepsilon \) for each \( r, s \in \mathcal{Q}_\omega \) with \( |s - r| < \delta_{\text{auc}}(\varepsilon, \mathcal{M}) \equiv 2^{-m(n)} \). Thus the process \( Z \) is a.u. continuous, with \( \delta_{\text{auc}}(\cdot, \mathcal{M}) \) as a modulus of a.u. continuity of \( Z \).

5. By Proposition 9.1.4, the complete extension \( X \equiv \Phi_{\text{Lim}}(Z) \) of the process \( Z \) to the full parameter set \([0, 1] \) is a.u. continuous with the same modulus of a.u. continuity \( \delta_{\text{auc}}(\cdot, \mathcal{M}) \).

The theorem is proved. \( \Box \)

**Theorem 9.2.4. (Continuity of extension-by-limit of C-regular processes)**. Recall the metric space \((\tilde{R}(\mathcal{Q}_\omega \times \Omega, S), \rho_{\text{Prrob}})\) of stochastic processes with parameter set \( \mathcal{Q}_\omega \equiv \{0, 1, \cdots \} \), sample space \((\Omega, L, E)\), and state space \((S, d)\). Let \( R_0 \) be a C-equiregular subset of \( \tilde{R}(\mathcal{Q}_\omega \times \Omega, S) \) with a modulus of C-regularity \( \mathcal{M} \equiv (m_n)_{n=0,1,\cdots} \). Let \((\tilde{C}[0, 1], \rho_{\tilde{C}[0, 1]})\) be the metric space of a.u. continuous processes on \([0, 1] \), as in Definition 9.1.1.

Then the extension-by-limit
\[ \Phi_{\text{Lim}} : (\tilde{R}_0, \rho_{\text{Prrob}}) \to (\tilde{C}[0, 1], \rho_{\tilde{C}[0, 1]}) \]
as in Definition 9.1.3 is uniformly continuous, with a modulus of continuity \( \delta_{\text{reg, auc}}(\cdot, \mathcal{M}) \)

**Proof.** Let \( \varepsilon > 0 \) be arbitrary. Define
\[ j \equiv \lfloor 0 \lor (4 - \log_2 \frac{\varepsilon}{4}) \rfloor, \]
\[ h_j \equiv 2^{m(j)}, \]
and
\[ \delta_{\text{reg, auc}}(\varepsilon, \mathcal{M}) \equiv 2^{-h(j) - 2j - j}. \]

We will prove that \( \delta_{\text{reg, auc}}(\cdot, \mathcal{M}) \) is a modulus of continuity of \( \Phi_{\text{Lim}} \) on \( \tilde{R}_0 \).

Yuen-Kwok Chan 286 Constructive Probability
9.2. C-REGULAR FAMILIES OF F.J.D.'S AND C-REGULAR PROCESSES

1. Let \( Z, Z' \in \mathcal{R}_0 \) be arbitrary and let \( X \equiv \Phi_{\text{Lim}}(Z), X' \equiv \Phi_{\text{Lim}}(Z') \). Suppose

\[
\rho_{\text{prob}, Q(\omega)}(Z, Z') \equiv E \sum_{n=0}^{\infty} 2^{-n-1} \delta_{\tilde{d}(Z_{(n)}, Z'_{(n)})} < \delta_{\text{reg, auc}}(\varepsilon, \mathcal{M}). \tag{9.2.13}
\]

We need to prove that \( \rho_{C_{0.1}}(X, X') < \varepsilon \).

To that end, first note that, by Step 4 in the proof of Theorem 9.2.3, there exist measurable sets \( D_j, D'_j \) with \( P(D'_j) \lor P(D'_j) < 2^{-j+1} \) such that

\[
d(X_r, X_s) \lor d(X'_r, X'_s) = d(Z_r, Z_s) \lor d(Z'_r, Z'_s) \leq 2^{-j+4} \tag{9.2.14}
\]
on \( D_jD'_j \), for each \( r, s \in Q_m \) with \(|r-s| < 2^{-m(j)}\). Consider each \( \omega \in D_jD'_j \) and \( t \in [0, 1] \).

Then there exists \( s \in Q_m(j) \) such that \(|r-s| < 2^{-m(j)}\). Letting \( r \to t \) with \( r \in Q_m \) and \(|r-s| < 2^{-m(j)}\), inequality 9.2.14 yields

\[
d(X_t(\omega), X_s(\omega)) \lor d(X'_t(\omega), X'_s(\omega)) \leq 2^{-j+4}.
\]

Consequently,

\[
|d(X_t(\omega), X'_t(\omega)) - d(X_s(\omega), X'_s(\omega))| < 2^{-j+5},
\]

where \( \omega \in D_jD'_j \) and \( t \in [0, 1] \) are arbitrary. Therefore

\[
| \sup_{t \in [0, 1]} d(X_t, X'_t) - \bigvee_{s \in Q(m(j))} d(X_s, X'_s) | \leq 2^{-j+5} \tag{9.2.15}
\]
on \( D_jD'_j \). Note here that Lemma 9.1.2 earlier proved that the supremum is a r.r.v.

2. Separately, take any \( \alpha \in (2^{-j}, 2^{-j+1}) \) and define

\[
A_j \equiv \bigvee_{s \in Q(m(j))} d(X_s, X'_s) \leq \alpha. \tag{9.2.16}
\]

Then inequality 9.2.15 and equality 9.2.16 together yield

\[
G_j \equiv D_jD'_jA_j \subset \big( \sup_{t \in [0, 1]} d(X_t, X'_t) \leq 2^{-j+5} + 2^{-j+1} \big). \tag{9.2.17}
\]

3. By inequality 9.2.13 we have

\[
\rho_{\text{prob}, Q(\omega)}(Z, Z') < \delta_{\text{reg, auc}}(\varepsilon, \mathcal{M}) \equiv 2^{-h(j) - 2j - 1}, \tag{9.2.18}
\]

where \( h_j \equiv 2^{m(j)} \). Hence

\[
E \bigvee_{s \in Q(m(j))} \tilde{d}(X_s, X'_s) = E \bigvee_{k=0}^{h(j)} \tilde{d}(X_{(k)}, X'_{(k)}) \leq 2^{h(j)+1} E \sum_{k=0}^{h(j)} 2^{-k-1} \tilde{d}(X_{(k)}, X'_{(k)})
\]

\[
\leq 2^{h(j)+1} E \sum_{k=0}^{h(j)} 2^{-k-1} \tilde{d}(Z_{(k)}, Z'_{(k)}) \leq 2^{h(j)+1} \rho_{\text{prob}, Q(\omega)}(Z, Z') < 2^{-2j} < \alpha^2. \tag{9.2.19}
\]
CHAPTER 9. A.U. CONTINUOUS PROCESSES ON [0, 1]

Chebychev’s inequality therefore implies that

\[ P(A'_j) < \alpha < 2^{-j+1}. \]

Hence

\[ \rho_{C[0,1]}(X, X') \equiv E \sup_{t \in [0,1]} d(X_t, X'_t) \leq E 1_{G(j)} \sup_{t \in [0,1]} d(X_t, X'_t) + P(G'_j) \]

\[ \leq (2^{-j+5} + 2^{-j+1}) + P(A'_j) + P(D'_j) \]

\[ < (2^{-j+5} + 2^{-j+1}) + 2^{-j+1} + 2^{-j+1} + 2^{-j+1} < 2^{-j+6} < \varepsilon. \]

Since \( \varepsilon > 0 \) is arbitrary, we see that \( \delta_{\text{reg}, \text{auc}}(\cdot, \mathfrak{m}) \) is a modulus of continuity of \( \Phi_{\text{Lim}} \). \( \square \)

Theorems 9.2.3 and 9.2.4 can now be restated in terms of \( C \)-regular consistent families of \( f.j.d.s \).

Corollary 9.2.5. (Construction of a.u. continuous processes from \( C \)-regular families of \( f.j.d.s \) to ) Let

\[ (\Theta_0, L_0, I_0) \equiv ([0,1], L_0, \int \cdot dx) \]

denote the Lebesgue integration space based on the interval \( \Theta_0 \equiv [0,1] \). Let \( \xi \) be a fixed binary approximation of \( (S, d) \) relative to a reference point \( x_0 \in S \). As usual, write \( \hat{d} \equiv 1 \land d \). Recall from Definition 6.2.11 the metric space \( F_{C\rho}([0,1], S), \rho_{C\rho} \equiv \rho_{C\rho}(x_0) \). \( \xi \equiv 0 \). Define the restriction function \( \Phi_{[0,1], Q(\infty)} \equiv \hat{F}_0 \to \hat{F}_0 \to Q_\infty \) by \( \Phi_{[0,1], Q(\infty)}(F) \equiv F|Q_\infty \) for each \( F \in \hat{F}_0 \).

Then the following holds.

1. The function

\[ \Phi_{f.j.d., \text{auc}, \xi} \equiv \Phi_{\text{Lim}} \circ \Phi_{D\rho_{C\rho}, \xi} \circ \Phi_{[0,1], Q(\infty)} : (\hat{F}_0, \rho_{C\rho}, \xi) \to (\hat{C}(0,1), \rho_{C(0,1)}) \]

(9.2.20)

is well defined, where \( \Phi_{D\rho_{C\rho}, \xi} \) is the Daniell-Kolmogorov-Skorokhod extension constructed in Theorem 9.4.2, and where \( \Phi_{\text{Lim}} \) is the extension-by-limit constructed in Theorem 9.2.3.

2. For each consistent family \( F \in \hat{F}_0 \), the a.u. continuous process \( X \equiv \Phi_{f.j.d., \text{auc}, \xi}(F) \) has marginal distributions given by \( F \).

3. The construction \( \Phi_{f.j.d., \text{auc}, \xi} \) is uniformly continuous.

Proof. 1. Let \( F \in \hat{F}_0 \) be arbitrary. By hypothesis, \( F \) is \( C \)-regular, with \( \mathfrak{m} \) as a modulus of \( C \)-regularity. Since the process \( Z \equiv \Phi_{D\rho_{C\rho}, \xi}(F|Q_\infty) : Q_\infty \times \Theta_0 \to S \) extends \( F|Q_\infty \), so is \( Z \). In other words, \( Z \in \hat{R}_0 \), where \( \hat{R}_0 \) is the set of \( C \)-regular processes on \( Q_\infty \), with sample space \( (\Theta_0, L_0, I_0) \), and with \( \mathfrak{m} \) as a modulus of \( C \)-regularity. In other words, the set of processes \( \hat{R}_0 \) is \( C \)-equiregular. Hence the a.u. continuous process \( X \equiv \Phi_{\text{Lim}}(Z) \) is well defined by Theorem 9.2.3 with \( X|Q_\infty = Z \). Thus the composite mapping in equality (9.2.20) is well defined. Assertion 1 is verified.
2. Being $C$-regular, the family $F \in \hat{F}_0$ is continuous in probability. Hence, for each $r_1, \cdots, r_n \in [0, 1]$, and $f \in C_{ub}(\mathbb{S}^n)$ we have

$$F_{r_1, \cdots, r(n)} = \lim_{s(i) \to r(i); s(i) \in \mathbb{Q}; i = 1, \cdots, n} F_{s(1), \cdots, s(n)} f$$

$$= \lim_{s(i) \to r(i); s(i) \in \mathbb{Q}; i = 1, \cdots, n} \mathbb{I}_0 f(Z_{s(1)}, \cdots, Z_{s(n)})$$

$$= \lim_{s(i) \to r(i); s(i) \in \mathbb{Q}; i = 1, \cdots, n} \mathbb{I}_0 f(X_{s(1)}, \cdots, X_{s(n)})$$

$$= \mathbb{I}_0 f(X_{r(1)}, \cdots, X_{r(n)})$$,

where the last equality follows from the a.u. continuity of $X$. We conclude that $F$ is the family of marginal distributions of $X$. Then the uniform continuity of $f$ and $\mathbb{I}_0$ will prove a sufficient condition, on pairwise joint distributions, for a.u. continuity of $\mathbb{I}_0 f(X_{r(1)}, \cdots, X_{r(n)})$.

3. Recall the metric space $(\hat{R}(\mathcal{Q}_\omega \times \Theta_0, S), \rho_{prob, \mathcal{Q}_\omega})$ of processes $Z : \mathcal{Q}_\omega \times \Theta_0 \to S$. Then the uniform continuity of

$$\Phi_{[0,1],\mathcal{Q}_\omega} : (\hat{F}_0, \hat{\rho}_{CP, \xi}, [0,1]) \to (\hat{F}_0, \hat{\rho}_{Marg, \xi}, \mathcal{Q}_\omega)$$

is trivial from Definition 6.2.11. The Daniel-Kolmogorv-Skorokhod Extension

$$\Phi_{DKS, \xi} : (\hat{F}_0, \hat{\rho}_{Marg, \xi}, \mathcal{Q}_\omega) \to (\hat{R}(\mathcal{Q}_\omega \times \Theta_0, S), \rho_{prob, \mathcal{Q}_\omega})$$

is uniformly continuous by Theorem 6.4.4. Moreover, by Step 1, we have

$$\Phi_{DKS, \xi}(\hat{F}_0) \subset \hat{R}_0 \subset \hat{R}(\mathcal{Q}_\omega \times \Omega, S),$$

where the set of processes $\hat{R}_0$ is $C$-equiregular. Therefore, finally, Theorem 9.2.4 says that

$$\Phi_{Lim} : (\hat{R}_0, \rho_{prob, \mathcal{Q}_\omega}) \to (\hat{C}[0,1], \rho_{\mathcal{C}[0,1]})$$

is uniformly continuous. Combining the composite function

$$\Phi_{fjd, auc, \xi} \equiv \Phi_{Lim} \circ \Phi_{DKS, \xi} \circ \Phi_{[0,1],\mathcal{Q}_\omega}$$

is uniformly continuous. Assertion 3 is proved.

### 9.3 Sufficient Condition for a.u. locally Hölder Continuity

Let $(S, d)$ be a locally compact metric space. In Theorems 9.2.2 and 9.2.3 we saw that the $C$-regularity of a process $Z : \mathcal{Q}_\omega \times \Omega \to (S, d)$ is necessary and sufficient for the a.u. continuity of its extension-by-limit $X \equiv \Phi_{Lim}(Z) : [0,1] \times \Omega \to S$. In this section, we will prove a sufficient condition, on pairwise joint distributions, for a.u. continuity of $\Phi_{Lim}(Z)$.

Refer to the last two sections for notations. For a measurable set $A$ relative to an arbitrary probability subspace $(\Omega, L, E)$, we will write $A \in L$ and $1_A \in A$ interchangeably, and write $P(A), E(A)$, and $E1_A$ interchangeably. As usual, we will write the symbols...
Let \( a, b \) and \( a(b) \) interchangeably. Recall also the convention that, for an arbitrary r.v. \( U \) and for any \( a \in R \), we write \( P(U \leq a) \) or \( P(U < a) \) only with the explicit or implicit condition that the real number \( a \) has been so chosen that the sets \( (U \leq a) \) or \( (U < a) \) are measurable.

**Theorem 9.3.1. (A sufficient condition on pair distributions for a.u. continuous extension).** Let \( \kappa \geq 1 \) be arbitrary. Let \( \gamma \equiv (\gamma_k)_{k=\kappa,\kappa+1,\ldots} \) and \( \varepsilon \equiv (\varepsilon_k)_{k=\kappa,\kappa+1,\ldots} \) be two sequences of positive real numbers with \( \sum_{k=\kappa}^{\infty} \gamma_k < \infty \) and \( \sum_{k=1}^{\infty} \varepsilon_k < \infty \).

Let \( \Omega \subset \mathbb{R} \times (\Omega, L, E) \rightarrow (S, d) \) be an arbitrary process such that, for each \( k \geq \kappa \) and for each \( \alpha_k \geq \gamma_k \), we have

\[
\sum_{n \in \{0,1\}^Q(k)} P(d(Z_{\omega}, Z_{\omega + \Delta(k+1)}) > \alpha_k) + \sum_{n \in \{0,1\}^Q(k)} P(d(Z_{\omega + \Delta(k+1)}, Z_{\omega + \Delta(k)}) > \alpha_k) \leq 2\varepsilon_k.
\]

(9.3.1)

Then the extension-by-limit \( X \equiv \Phi_{\text{Lim}}(\gamma) : [0, 1] \times \Omega \rightarrow (S, d) \) is an a.u. continuous process. Specifically, there exists a sequence \( (D_n)_{n=\kappa,\kappa+1,\ldots} \) of measurable sets such that (i) \( D_{\kappa} \subset D_{\kappa+1} \subset \cdots \), (ii) for each \( n \geq \kappa \), we have

\[
P(D^c_n) \leq 2 \sum_{k=n}^{\infty} \varepsilon_k,
\]

(9.3.2)

and (iii) for each \( n \geq \kappa \), and for each \( \omega \in D_n \), we have

\[
d(X_r(\omega), X_s(\omega)) < 8 \sum_{k=n}^{\infty} \gamma_k
\]

for each \( r, s \in [0, 1] \) with \(|r - s| \leq 2^{-n}\).

Consequently, the process \( X \) has a modulus of a.u. continuity defined as follows. Let \( \varepsilon > 0 \) be arbitrary. Take \( n \geq \kappa \) so large that \( 8 \sum_{k=n}^{\infty} \gamma_k \geq 2 \sum_{k=1}^{\infty} \varepsilon_k < \varepsilon \). Define \( \delta_{\text{a.u.}}(\cdot, \gamma, \varepsilon) \equiv 2^{-n} \). Then the operation \( \delta_{\text{a.u.}}(\cdot, \gamma, \varepsilon) \) is a modulus of a.u. continuity for the process \( X \).

**Proof.** 1. Let \( Z : Q_{\infty} \times \Omega \rightarrow S \) be as given in the hypothesis. Let \( k \geq \kappa \) be arbitrary, and take any \( \alpha_k \in [\gamma_k, 2\gamma_k) \). Define

\[
C_k \equiv \bigcup_{r \in \{0,1\}^Q(k)} (d(Z_r, Z_{r + \Delta(k+1)}) > \alpha_k) \cup (d(Z_{r + \Delta(k+1)}, Z_{r + \Delta(k)}) > \alpha_k).
\]

(9.3.4)

Then \( P(C_k) \leq 2\varepsilon_k \), thanks to inequality (9.3.1) in the hypothesis. Moreover, for each \( \omega \in C_k \), and for each \( r \in Q_k \) and \( s \in Q_{k+1} \) with \(|r - s| \leq \Delta_{k+1} \), we have

\[
d(Z_r, Z_s) \leq \alpha_k.
\]

(9.3.5)

2. Let \( n \geq \kappa \) be arbitrary, but fixed till further notice. Define the measurable set

\[
D_n \equiv \bigcup_{k=n}^{\infty} C_k.
\]
9.3. SUFFICIENT CONDITION FOR A.U. LOCALLY HOEDEL CONTINUITY

Then

\[ PD_{\varepsilon} \leq \sum_{k=n}^{\infty} 2\varepsilon_k. \]  

Moreover, \( D_n \subset D_m \) for each \( m \geq n \).

Now let \( r, s \in \mathcal{Q}_\omega \) be arbitrary with \( |s - r| < 2^{-n} \). First assume that \( 0 < s - r < 2^{-n} \). Then there exists \( r_n, s_n \in \mathcal{Q}_n \) such that \( r \in [r_n, (r_n + 2^{-n}) \wedge 1] \) and \( s \in [s_n, (s_n + 2^{-n}) \wedge 1] \). It follows that

\[ r_n \leq r < s \leq (s_n + 2^{-n}), \]

which implies \( r_n \leq s_n \), and that

\[ s_n \leq s < r + 2^{-n} \leq (r_n + 2^{-n}) + 2^{-n}, \]

which implies \( s_n \leq (r_n + 2^{-n}) \). Combining, we obtain

\[ s_n = r_n \quad \text{or} \quad s_n = (r_n + 2^{-n}). \]  

Separately, we have \( r \in [r_n, r_n + 2^{-n}] \mathcal{Q}_\omega \). Inductively, consider each \( k = n, n + 1, \ldots \). Then we have either (i) \( r \in [r_k, r_k + 2^{-k-1}] \mathcal{Q}_\omega \), or (ii) \( r \in [r_k + 2^{-k-1}, r_k + 2^{-k}] \mathcal{Q}_\omega \). In Case (i) let \( r_{k+1} = r_k \). In Case (ii) let \( r_{k+1} = r_k + 2^{-k-1} \). Then we have \( r_{k+1} \in \mathcal{Q}_{k+1} \), and, in either case, \( r \in [r_{k+1}, (r_{k+1} + 2^{-k-1}) \mathcal{Q}_\omega \). Moreover,

\[ |r_k - r_{k+1}| \leq 2^{-k-1} = \Delta_{k+1} \]  

for each \( k \geq n \), and so \( r_k \to r \). We can construct a similar sequence \( (s_k)_{k=n, n+1, \ldots} \) relative to \( s \) such that

\[ |s_k - s_{k+1}| \leq 2^{-k-1} = \Delta_{k+1} \]  

for each \( k \geq n \).

4. Now consider each \( \omega \in D_n \), and consider each \( k \geq n \). Then \( \omega \in D_n \subset C_{n \omega} \). Hence equalities \[ 9.3.7 \] and inequality \[ 9.3.5 \] imply that

\[ d(Z_{r(n)}(\omega), Z_{s(n)}(\omega)) \leq 2\alpha_n. \]  

Similarly, inequalities \[ 9.3.8 \] and \[ 9.3.5 \] imply that

\[ d(Z_{r(k)}(\omega), Z_{r(k+1)}(\omega)) \leq \alpha_k. \]

Since \( r_k \to r \), it follows that

\[ d(Z_{r(n)}(\omega), Z_{r}(\omega)) \leq \sum_{k=n}^{\infty} d(Z_{r(k)}(\omega), Z_{r(k+1)}(\omega)) \leq \sum_{k=n}^{\infty} \alpha_k. \]  

Similarly

\[ d(Z_{s(n)}(\omega), Z_{s}(\omega)) \leq \sum_{k=n}^{\infty} \alpha_k. \]

Combining inequalities \[ 9.3.10 \] \[ 9.3.11 \] and \[ 9.3.12 \] we obtain

\[ d(Z_{r}(\omega), Z_{s}(\omega)) \leq d(Z_{r(n)}(\omega), Z_{s(n)}(\omega)) + d(Z_{r}(\omega), Z_{r(n)}(\omega)) + d(Z_{s}(\omega), Z_{s(n)}(\omega)) \]

Yuen-Kwok Chan 291 Constructive Probability
where \( r, s \in Q_\infty \) are arbitrary with \( 0 < s - r < 2^{-n} \). The same inequality \( \ref{9.3.13} \) holds, by symmetry, for arbitrary \( r, s \in Q_\infty \) with \( 0 < r - s < 2^{-n} \). It holds trivially in the case where \( r = s \). Summing up, we have

\[
d(Z_r(\omega), Z_s(\omega)) < 8 \sum_{k=n}^{\infty} \gamma_k, \tag{9.3.14}
\]

for arbitrary \( r, s \in Q_\infty \) with \(|r - s| < 2^{-n}\), for arbitrary \( \omega \in D_n \), where \( P(D_n^c) \leq \sum_{k=n}^{\infty} 2 \gamma_k \).

It follows that the process \( Z \) is a.u. continuous, with a modulus of a.u. continuity \( \delta_{a.u.c} \) defined as follows. Let \( \epsilon > 0 \) be arbitrary. Let \( n \geq \kappa \) be so large that \( \sum_{k=n}^{\infty} \gamma_k \leq \epsilon \). Define \( \delta_{loc,Hldr}(\epsilon) \equiv \delta_{a.u.c}(\epsilon, \Omega, \gamma_k) \equiv 2^{-n} \). Proposition \( \ref{9.1.4} \) then says that the extension-by-limit \( X = \Phi_{Lim}(Z) \) is an a.u. continuous process, with the same modulus of a.u. continuity \( \delta_{loc,Hldr} \). By continuity, inequality \( \ref{9.3.14} \) immediately extends to the process \( X \) for arbitrary \( r, s \in [0, 1] \) with \(|r - s| \leq 2^{-n}\), yielding the desired inequality \( \ref{9.3.3} \).

As a corollary, we will prove a theorem due to Kolmogorov, which gives a sufficient condition for the construction of an a.u. locally Hoelder process, in the following sense.

**Definition 9.3.2. (a.u. locally Hoelder process).** Let \( a > 0 \) be arbitrary. A process \( X : [0, a] \times \Omega \to (S, d) \) is said to be a.u. locally Hoelder continuous, or a.u. locally Hoelder for short, if there exist constants \( c, \theta > 0 \) such that, for each \( \epsilon > 0 \) there exists some \( \delta_{loc,Hldr}(\epsilon) > 0 \) and some measurable set \( D \) with \( P(D^c) < \epsilon \) such that, for each \( \omega \in D \), we have

\[
d(X_r(\omega), X_s(\omega)) < c|r - s|^\theta \tag{9.3.15}
\]

for each \( r, s \in [0, a] \) with \(|r - s| < \delta_{loc,Hldr}(\epsilon) \). The process is then said to have a.u. locally Hoelder exponent \( \theta \), a.u. locally Hoelder coefficient \( c \), and modulus of a.u. locally Hoelder continuity.

**Theorem 9.3.3. (A sufficient condition on pair distributions for a.u. locally Hoelder continuity).** Let \( (S, d) \) be a locally compact metric space. Let \( c_0, a, w > 0 \) be arbitrary. Let \( \theta \) be arbitrary such that \( \theta < a^{-1}w \).

Suppose \( Z : Q_\infty \times (\Omega, L, E) \to (S, d) \) is an arbitrary process such that

\[
P(d(Z_r, Z_s) > b) \leq c_0 b^{-w}|r - s|^{1+w} \tag{9.3.16}
\]

for each \( b > 0 \), for each \( r, s \in Q_\infty \). Then the extension-by-limit \( X = \Phi_{Lim}(Z) : [0, 1] \times \Omega \to (S, d) \) is a.u. locally Hoelder with exponent \( \theta \).

Note that inequality \( \ref{9.3.16} \) is satisfied if

\[
Ed(Z_r, Z_s)^w \leq c_0 |r - s|^{1+w} \tag{9.3.17}
\]

**Proof.** Let \( Z : Q_\infty \times (\Omega, L, E) \to (S, d) \) be an arbitrary process such that inequality \( \ref{9.3.16} \) holds.
9.3. SUFFICIENT CONDITION FOR A.U. LOCALLY HOELDER CONTINUITY

1. For abbreviation, define the constants $a \equiv (w - \theta u) > 0$, $c_1 \equiv 8(1 - 2^{-\theta})^{-1}$, and $c \equiv c_1^{2\theta}$. Let $\kappa \geq 2$ be so large that $2^{-ka\kappa^2} \leq 1$ for each $k \geq \kappa$. Let $k \geq \kappa$ be arbitrary. Define

$$\epsilon_k \equiv c_0 2^{-w-1}k^{-2} \tag{9.3.18}$$

and

$$\gamma_k \equiv 2^{-kw/2}k^2/u. \tag{9.3.19}$$

Take any $\alpha_k \geq \gamma_k$ such that the set $(d(Z_t, Z_s) > \alpha_k)$ is measurable for each $t, s \in Q_\infty$. Let $t \in [0, 1] \|Q_k$ be arbitrary. We estimate

$$P(d(Z_t, Z_{t+\Delta(k+1)}) > \alpha_k) \leq c_0 \alpha_k^{-\Delta^1_{w}} \Delta_{k+1}$$

$$\leq c_0 \gamma_k^{-2}\Delta_{k+1} - \Delta_{k+1}$$

$$= c_0 \alpha_k^{-2}\Delta_{k+1} - \Delta_{k+1}$$

$$= c_0 2^{-w-1}k^{-2} - \Delta_{k+1}$$

where the first inequality is thanks to inequality 9.3.16. Similarly

$$P(d(Z_t, Z_{t+\Delta(k+1)}) > \alpha_k) \leq c_0 2^{-w-1}k^{-2} - \Delta_{k+1}.$$

Combining, we obtain

$$\sum_{t \in [0, 1] \|Q(k)} P(d(Z_t, Z_{t+\Delta(k+1)}) > \alpha_k) + \sum_{t \in [0, 1] \|Q(k)} P(d(Z_t, Z_{t+\Delta(k+1)}) > \alpha_k)$$

$$\leq 2 \cdot 2^k (c_0 2^{-w-1}k^{-2} - \Delta_{k+1}) = 2c_0 2^{-w-1}k^{-2} = 2\epsilon_k,$$

where $k \geq \kappa$ is arbitrary. Since $\sum_{k=\infty} \gamma_k < \infty$ and $\sum_{k=\infty} \epsilon_k < \infty$, the conditions in the hypothesis of Theorem 9.3.1 are satisfied by the objects $Z_t, \gamma_k = \kappa, \kappa+1, \ldots, (\epsilon_k)_{k=\kappa, \kappa+1, \ldots}$. Accordingly, the extension-by-limit $X \equiv \Phi_{\lim}(Z) : [0, 1] \times \Omega \rightarrow (S, d)$ is a.u. continuous, such that there exists a sequence $(D_k)_{n=\kappa, \kappa+1, \ldots}$ of measurable sets such that (i) $D_k \subset D_{k+1} \subset \cdots$, (ii) for each $n \geq \kappa$, we have

$$P(D_k) \leq 2 \sum_{k=n}^{\infty} \epsilon_k, \tag{9.3.20}$$

and (iii) for each $n \geq \kappa$, and for each $\omega \in D_n$, we have

$$d(X_r(\omega), X_s(\omega)) < 8 \sum_{k=n}^{\infty} \gamma_k \tag{9.3.21}$$

for each $r, s \in [0, 1]$ with $|r - s| \leq 2^{-n}$.

2. We will now estimate bounds for the partial sum on the right-hand side of each of the inequalities 9.3.20 and 9.3.21. To that end, consider each $n \geq \kappa$. Then

$$2 \sum_{k=n}^{\infty} \epsilon_k \equiv 2 \sum_{k=n}^{\infty} c_0 2^{-w-1}k^{-2} \leq 2c_0 2^{-w-1} \int_{y=n-1}^{\infty} y^{-2} dy \leq 2c_0 2^{-w-1}(n-1)^{-1}. \tag{9.3.22}$$

Yuen-Kwok Chan 293 Constructive Probability
At the same time,

\[
8 \sum_{k=n}^{\infty} \gamma_k \equiv 8 \sum_{k=n}^{\infty} 2^{-kw_0/u} k^{2/u} \equiv 8 \sum_{k=n}^{\infty} 2^{-k\theta w_0/u} 2^{-ka/u} k^{2/u} \\
= 8 \sum_{k=n}^{\infty} 2^{-k\theta} 2^{-ka/u} k^{2/u} \leq 8 \sum_{k=n}^{\infty} 2^{-k\theta} \\
= 8 \cdot 2^{-\theta} (1 - 2^{-\theta})^{-1} \equiv c_1 2^{-\theta}
\]

\[ (9.3.23) \]

3. Let \( \varepsilon > 0 \) be arbitrary. Take \( m \geq 0 \) so large that \( 2c_0 2^{w_0 - 1}(m - 1)^{-1} < \varepsilon \). Inequality \( (9.3.22) \) then implies that \( P(D_m) \leq \varepsilon \). Define \( \delta_{\text{LocHldr}}(\varepsilon) \equiv 2^{-m} \). Consider each \( \omega \in D_m \subset D_{m+1} \subset \cdots \). Then, for each \( n \geq m \), we have \( \omega \in D_n \), whence inequalities \( (9.3.21) \) and \( (9.3.23) \) together imply that

\[
d(X_r(\omega), X_s(\omega)) < c_1 2^{-n\theta}
\]

\[ (9.3.24) \]

for each \( (r, s) \in G_n \equiv \{(r, s) \in [0, 1]^2 : 2^{-n-1} \leq |r - s| \leq 2^{-n}\} \). Hence

\[
d(X_r(\omega), X_s(\omega)) < c_1 2^{\theta} 2^{-(n+1)\theta} \leq c_1 2^{\theta} |r - s| \theta \equiv c|r - s|^{\theta}
\]

\[ (9.3.25) \]

for each \( (r, s) \in G_n \). Therefore

\[
d(X_r(\omega), X_s(\omega)) \leq c|r - s|^{\theta}
\]

\[ (9.3.26) \]

for each \( (r, s) \in \bigcup_{n=m}^{\infty} G_n \). Since \( \bigcup_{n=m}^{\infty} G_n \) is dense in \( G \equiv \{(r, s) \in [0, 1]^2 : |r - s| \leq 2^{-m}\} \), and since \( X(\cdot, \omega) \) is a continuous function, it follows that inequality \( (9.3.26) \) holds for each \( (r, s) \in G \). In other words, it holds for each \( r, s \in [0, 1] \) with \( |r - s| \leq 2^{-m} \equiv \delta_{\text{LocHldr}}(\varepsilon) \). Thus the process \( X \) is a.u. locally Hölder with exponent \( \theta \), as alleged. \( \square \)

The next corollary implies Theorem 12.4 of [Billingsley 1968]. The latter asserts only a.u. continuity and is only for real-valued processes.

**Corollary 9.3.4. (A sufficient condition on pair distributions for time-scaled a.u. locally Hölder continuity).** Let \((S, d)\) be a locally compact metric space. Let \(c_0, u, w > 0\) be arbitrary. Let \( \theta \) be arbitrary such that \( \theta < u^{-1}w \). Let \( K : [0, 1] \to [0, 1] \) be an arbitrary continuous and nondecreasing function, with \( K(0) = 0 \) and \( K(1) = 1 \).

Suppose \( Z : Q_\infty \times (\Omega, L, E) \to (S, d) \) is an arbitrary process such that

\[
P(d(Z_r, Z_s) > b) \leq c_0 b^{-w} |K(r) - K(s)|^{1+w}
\]

\[ (9.3.27) \]

for each \( b > 0 \), for each \( r, s \in Q_\infty \). Then the extension-by-limit \( X \equiv \Phi_{\text{LIM}}(Z) : [0, 1] \times \Omega \to (S, d) \), subject to a deterministic time scaling, is a.u. locally Hölder. More precisely, there exists a continuous and strictly increasing function, with \( G(0) = 0 \) and \( G(1) = 1 \), such that the process \( X_G : [0, 1] \times \Omega \to (S, d) \), defined by \( X_G(t) \equiv X_{G(t)} \) for each \( t \in [0, 1] \), is a.u. locally Hölder with exponent \( \theta \).
9.3. SUFFICIENT CONDITION FOR A.U. LOCALLY HOELDER CONTINUITY

Proof. 1. Fix any \( \alpha \geq 0 \) such that the continuous function \( H : [0, 1] \to [0, 1] \), defined by
\[
H(t) \equiv (K(t) + \alpha t)(1 + \alpha)^{-1}
\] (9.3.28)
for each \( t \in [0, 1] \), is strictly increasing. Clearly \( H(0) = 0 \) and \( H(1) = 1 \). Let \( G \equiv H^{-1} \) be the inverse function of \( H \), which is also a continuous increasing function, with \( G(0) = 0 \) and \( G(1) = 1 \). Write \( a \equiv 1 + \alpha \). Then, equality (9.3.28) implies that, for each \( t \leq s \in [0, 1] \), we have
\[
(s - t) \equiv H \circ G(s) - H \circ G(t) \geq a^{-1}\alpha(G(s) - G(t)),
\]
whence
\[
G(s) - G(t) \leq \alpha^{-1}a(s - t).
\]
2. For each \( k \geq 1 \), define
\[
\zeta_k \equiv \bigvee_{r \in Q(k)} (K(t + \Delta_k) - K(t)),
\] (9.3.29)
\[
\varepsilon_k \equiv 2^{-u}c_0 \zeta_k^{w/2},
\] (9.3.30)
and
\[
\gamma_k \equiv \zeta_k^{w/2u}.
\] (9.3.31)
Then \((\zeta_k)_{k=1,2,\ldots}\) is a non increasing sequence in \([0,1]\). Let \( \varepsilon > 0 \) be arbitrary. Let \( k \geq 1 \) be so large that \( \Delta_k \equiv 2^{-k} < \delta_k(\varepsilon) \). Then \( 0 \leq K(t + \Delta_k) - K(t) < \varepsilon \) for each \( t \in Q_k \). Hence \( \zeta_k \to 0 \). Therefore, for each \( \lambda > 0 \), we have \( \sum_{k=1}^{\infty} \varepsilon_k^\lambda < \infty \). Consequently, \( \sum_{k=1}^{\infty} \gamma_k < \infty \) and \( \sum_{k=1}^{\infty} \varepsilon_k < \infty \).

3. Now let \( Z : Q_\infty \times (\Omega, L, \mathcal{E}) \to (S,d) \) be an arbitrary process such that inequality (9.3.27) holds. Let \( k \geq 1 \) be arbitrary, and take any \( \alpha_k \geq \gamma_k \). We estimate
\[
P(d(Z_t, Z_{t+\Delta(k+1)}) > \alpha_k) \leq c_0 \zeta_k^{-w}[(t + \Delta_{k+1}) - K(t)]^{1+w}
\]
\[
= c_0 \zeta_k^{-w}[K(t + \Delta_{k+1}) - K(t)]^{w}(K(t + \Delta_{k+1}) - K(t))
\leq c_0 \zeta_k^{-w} \gamma_k^w(K(t + \Delta_k) - K(t))
\leq c_0 \zeta_k^{-w} \gamma_k^w(K(t + \Delta_k) - K(t))
\equiv c_0 \zeta_k^{-w/2} \gamma_k^w(K(t + \Delta_k) - K(t))
= c_0 \zeta_k^{-w/2} \gamma_k (K(t + \Delta_k) - K(t))
\]
where the first inequality is thanks to inequality (9.3.27) and where the second inequality is by the defining formula (9.3.29) for \( \zeta_k \). Similarly
\[
P(d(Z_t+\Delta(k+1), Z_{t+\Delta(k)}) > \alpha_k) \leq c_0 \zeta_k^{-w/2}(K(t + \Delta_k) - K(t))
\]

Combining, we obtain
\[
\sum_{t \in [0,1)Q(k)} P(d(Z_t, Z_{t+\Delta(k+1)}) > \alpha_k) + \sum_{t \in [0,1)Q(k)} P(d(Z_t+\Delta(k+1), Z_{t+\Delta(k)}) > \alpha_k)
\]

Yuen-Kwok Chan 295 Constructive Probability
is due to the defining equality 9.3.28. Thus the process where the first inequality is thanks to inequality 9.3.32, and where the second inequality the hypothesis of Theorem 9.3.3 Accordingly, the extension-by-limit process. Inequality 9.3.27 extends, by continuity, to

\[ P(d(X_r, X_s) > b) \leq c_0 b^{-u} |K(r) - K(s)|^{1+w} \]  

(9.3.32)

for each \( b > 0 \), for each \( r, s \in [0, 1] \).

4. Define the process \( Y : Q_\omega \times (\Omega, L, E) \rightarrow (S, d) \) by \( Y_t \equiv X_{G(t)} \) for each \( t \in Q_\omega \). Let \( b > 0 \) and \( r, s \in Q_\omega \) be arbitrary. Then

\[ P(d(Y_r, Y_s) > b) \equiv P(d(X_{G(r)}, X_{G(s)}) > b) \]

\[ \leq c_0 b^{-u} |K(G(r)) - K(G(s))|^{1+w} \leq c_0 b^{-u} |H(G(r)) - H(G(s))|^{1+w} \]

\[ = c_0 b^{-u} |r - s|^{1+w}, \]  

(9.3.33)

where the first inequality is thanks to inequality 9.3.32 and where the second inequality is due to the defining equality 9.3.28. Thus the process \( Y \) satisfies the conditions in the hypothesis of Theorem 9.3.3. Accordingly, the extension-by-limit \( Y_t \equiv \Phi_{Lim}(Y) : [0, 1] \times \Omega \rightarrow (S, d) \) is a u. locally Hölder process with exponent \( \theta \), hence u. continuous. Therefore, a.s., we have, for each \( t \in [0, 1] \), the equality

\[ Y_t \equiv \lim_{r \rightarrow t, r \in Q_\omega} Y_r \equiv \lim_{r \rightarrow t, r \in Q_\omega} X_{G(r)} \]

\[ = \lim_{G(r) \rightarrow G(t), G(r) \in G(Q_\omega)} X_{G(r)} = \lim_{s \rightarrow G(t), s \in G(Q_\omega)} X_s = X_{G(t)}. \]

It follows that the process \( X_G : [0, 1] \times \Omega \rightarrow (S, d) \) is a.u. locally Hölder, as asserted.

\[ \square \]

### 9.4 The Brownian Motion

An application of Theorem 9.3.3 is in the construction of the all important Brownian motion.

**Definition 9.4.1. (Brownian Motion in \( R \)).** An a.u. continuous process \( B : [0, \infty) \times (\Omega, L, E) \rightarrow R \) is called a Brownian Motion if (i) \( B_0 = 0 \), (ii) for each sequence \( 0 \equiv t_0 \leq t_1 \leq \cdots \leq t_n \leq t_\infty \) in \([0, \infty)\), the r.r.v.’s \( B_{t_1} - B_{t_0}, \ldots, B_{t_n} - B_{t_{n-1}} \) are independent, and (iii) for each \( s, t \in [0, \infty) \), the r.r.v. \( B_t - B_s \) is normal with mean 0 and variance \( t - s \).

Recall here Definition 6.1.4 of an a.u. continuous process with a metric parameter space. \( \square \)

In the following, let \( Q_\omega \) stand for the set of dyadic rationals in \([0, \infty)\).
Theorem 9.4.2. (Construction of Brownian motion in \( \mathbb{R} \)). Brownian Motions in \( \mathbb{R} \) exist. Specifically, the following holds.

1. Let \( Z : \Omega_{\omega} \times (\Omega, L, E) \rightarrow R \) be an arbitrary process such that (i) \( Z_0 = 0 \), (ii) for each sequence \( 0 \equiv t_0 \leq t_1 \leq \cdots \leq t_n = t \) in \( \Omega_{\omega} \), the r.r.v.'s \( Z(t_1) - Z(t_0), \ldots, Z(t_n) - Z(t_{n-1}) \) are independent, and (iii) for each \( s, t \in \Omega_{\omega} \), the r.r.v. \( Z_t - Z_s \) is normal with mean 0 and variance \( |t - s| \). Then the extension-by-limit

\[
B \equiv \Phi_{\lim}(Z) : [0, \infty) \times \Omega \rightarrow \mathbb{R}
\]

is a Brownian motion.

2. For each \( n \geq 1 \) and for each \( t_1, \ldots, t_n \in \Omega_{\omega} \) define the f.j.d.

\[
F_{t_1, \ldots, t_n} = \Phi_{0, \Sigma}
\]

where

\[
\Sigma = [\Sigma(t_k, t_j)]_{k=1, \ldots, n; j=1, \ldots, n} \equiv [t_k \wedge t_j]_{k=1, \ldots, n; j=1, \ldots, n}.
\]

Then the family \( F = \{F_{t_1, \ldots, t_n} : m \geq 1; t_1, \ldots, t_m \in [0, \infty)\} \) of f.j.d.'s is consistent and is continuous in probability.

3. Let \( Z : \Omega_{\omega} \times (\Omega, L, E) \rightarrow R \) be an arbitrary process with marginal distributions given by the family \( F|\Omega_{\omega} \) where \( F \) is defined in Assertion 2 above. Then the extension-by-limit

\[
B \equiv \Phi_{\lim}(Z) : [0, \infty) \times \Omega \rightarrow \mathbb{R}
\]

is a Brownian motion.

Proof. For convenience, let \( U, U_1, U_2, \ldots \) be an independent sequence of standard normal r.r.v.'s. on some probability space \( (\Omega, L, E) \).

1. Let \( Z : \Omega_{\omega} \times (\Omega, L, E) \rightarrow R \) be an arbitrary process such that Conditions (i-iii) hold. Let \( b > 0 \), and \( s_1, s_2 \in \Omega_{\omega} \) be arbitrary. Then, by Condition (iii), the r.r.v. \( Z_{s_1} - Z_{s_2} \) is normal with mean 0 and variance \( |s_1 - s_2| \). Consequently, by the formulas in Proposition 5.7.5 for moments of standard normal r.r.v.'s, we obtain

\[
E(Z_{s_1} - Z_{s_2})^4 = 3|s_1 - s_2|^2.
\]

Chebychev’s inequality then implies that, for each \( b > 0 \), we have

\[
P(|Z_{s_1} - Z_{s_2}| > b) \equiv P(|Z_{s_1} - Z_{s_2})^4 > b^4)
\]

\[
\leq b^{-4}E(Z_{s_1} - Z_{s_2})^4 = 3b^{-4}|s_1 - s_2|^2,
\]

where \( s_1, s_2 \in \Omega_{\omega} \) are arbitrary.

2. Let \( N \geq 0 \) be arbitrary and consider the shifted process \( Z_N : \Omega_{\omega} \times (\Omega, L, E) \rightarrow R \) defined by \( Z_{N,t} \equiv Z_{N+s} \) for each \( s \in \Omega_{\omega} \). Then, for each \( b > 0 \), and \( s_1, s_2 \in \Omega_{\omega} \), we have

\[
P(|Z_{N,t} - Z_{N,s}| > b) \equiv P(|Z_{N+s_1} - Z_{N+s_2}| > b)
\]

\[
\leq 3b^{-4}((N + s_1) - (N + s_2))^2 = 3b^{-4}|s_1 - s_2|^2,
\]

where the inequality follows from inequality \( \Phi_{\lim} \) Thus the process Y satisfies the hypothesis of Theorem \( \Phi_{\lim} \) with \( c_0 = 3, u = 4, \) and \( w = 1 \). Accordingly, the extension-by-limit \( W = \Phi_{\lim}(Y) : [0, 1] \times \Omega \rightarrow R \) is a.u. locally Hoelder, hence a.u. continuous. In particular, for each \( t \in [N, N+1] \), the limit

\[
B_t \equiv \lim_{r \to t, t \in \Omega_{\omega} \cap [N, N+1]} Z_r \equiv \lim_{N+s, t \in \Omega_{\omega}} Z_{N+s} \equiv \lim_{s \to t, s \in \Omega_{\omega}} Z_N \equiv W_{t-N}.
\]

Yuen-Kwok Chan 297 Constructive Probability
exist and are equal as r.v.'s. In other words, \( B[[N,N+1] : [N,N+1] \times \Omega \rightarrow R \) is a well defined process. Moreover, since the process \( W \equiv \Phi_{t_{im}}(Y) : [0,1] \times \Omega \rightarrow R \) is a.u. continuous, we see that \( B[[N,N+1] \) is a.u. continuous, where \( N \geq 0 \) is arbitrary. Combining, it follows that the process \( B : [0,\infty) \times \Omega \rightarrow R \) is an a.u. continuous process, in the sense of Definition 6.1.4. Note that \( B_0 = Z_0 = 0 \), in view of Condition (i).

3. Let the sequence \( 0 \equiv t_0 \leq t_1 \leq \cdots \leq t_n \leq t_\infty \) in \( [0,\infty) \) and the sequence \( 0 \equiv s_0 \leq s_1 \leq \cdots \leq s_{n-1} \leq s_n \) in \( \mathbb{Q}_\infty \) be arbitrary. Let \( f_i \in C_{ab}(R) \) be arbitrary for each \( i = 1,\cdots,n \). Then, using Conditions (ii) and (iii) in the hypothesis, we obtain

\[
E \prod_{i=1}^{n} f_i(B_{s(i)} - B_{s(i-1)}) = E \prod_{i=1}^{n} f_i(Z_{s(i)} - Z_{s(i-1)})
\]

\[
= \prod_{i=1}^{n} E f_i(Z_{s(i)} - Z_{s(i-1)}) = \prod_{i=1}^{n} \int_{\mathbb{R}} \Phi_{0,s(i)-s(i-1)}(du) f_i(u).
\]

(9.4.2)

Now let \( s_i \rightarrow t_i \) for each \( i = 1,\cdots,n \). Since the process \( B \) is a.u. continuous, the left-hand side of equality (9.4.2) converges to \( E \prod_{i=1}^{n} f_i(B_{t(i)} - B_{t(i-1)}) \). At the same time, since

\[
\int_{\mathbb{R}} \Phi_{0,t}(du) f_i(u) = \tilde{E} f(\sqrt{t}U)
\]

is a continuous function of \( t \), the right-hand side of equality (9.4.2) converges to

\[
\prod_{i=1}^{n} \int_{\mathbb{R}} \Phi_{0,t(i)-t(i-1)}(du) f_i(u).
\]

Combining, we see that

\[
E \prod_{i=1}^{n} f_i(B_{t(i)} - B_{t(i-1)}) = \prod_{i=1}^{n} \int_{\mathbb{R}} \Phi_{0,t(i)-t(i-1)}(du) f_i(u).
\]

Consequently, the r.v.'s \( B_{t(1)} - B_{t(0)},\cdots,B_{t(n)} - B_{t(n-1)} \) are independent, with normal distributions with mean 0 and variances given by \( t_1 - t_0,\cdots,t_n - t_{n-1} \) respectively.

All the conditions in Definition 9.4.1 have been verified for the process \( B \) to be a Brownian motion. Assertion 1 is proved.

4. To prove Assertion 2, define the function \( \sigma : [0,\infty)^2 \rightarrow [0,\infty) \) by \( \sigma(s,t) \equiv s \wedge t \) for each \( (s,t) \in [0,\infty)^2 \). The function \( \sigma \) is clearly symmetric and continuous. We will verify that it is nonnegative definite in the sense of Definition 7.2.2. To that end, let \( n \geq 1 \) and \( t_1,\cdots,t_n \in [0,\infty) \) be arbitrary. We need only show that the square matrix

\[
\Sigma \equiv [\sigma(t_k,t_j)]_{k=1,\cdots,n,j=1,\cdots,n} = [t_k \wedge t_j]_{k=1,\cdots,n,j=1,\cdots,n}
\]

is nonnegative definite. Let \( (\lambda_k,\cdots,\lambda_k) \in \mathbb{R}^n \) be arbitrary. We wish to prove that

\[
\sum_{k=1}^{n} \sum_{j=1}^{n} \lambda_k (t_k \wedge t_j) \lambda_j \geq 0.
\]

(9.4.3)
First assume that $|t_k - t_j| > 0$ if $k \neq j$. Then there exists a permutation $\pi$ of the indices $1, \ldots, n$ such that $t_{\pi(k)} \leq t_{\pi(j)}$ if $k \leq j$. It follows that

$$
\sum_{k=1}^{n} \sum_{j=1}^{n} \lambda_k (t_k \wedge t_j) \lambda_j = \sum_{k=1}^{n} \sum_{j=1}^{n} \lambda_{\pi(k)} (t_{\pi(k)} \wedge t_{\pi(j)}) \lambda_{\pi(j)} \equiv \sum_{k=1}^{n} \sum_{j=1}^{n} \theta_k (s_k \wedge s_j) \theta_j, \tag{9.4.4}
$$

where we write $s_k \equiv t_{\pi(k)}$ and $\theta_k \equiv \lambda_{\pi(k)}$ for each $k = 1, \ldots, n$. Recall the independent standard normal r.v.’s $U_0, \ldots, U_n$ non the probability space $(\tilde{\Omega}, \mathcal{F}, \mathbb{P})$. Thus $EU_k U_j = 1$ for each $k = j$ or not. Define $V_k \equiv \sum_{i=1}^{k} \sqrt{s_i - s_{i-1}} U_i$ for each $k = 1, \ldots, n$, where $s_0 \equiv 0$. Then $\tilde{E} V_k = 0$ and

$$
\tilde{E} V_k V_j = \sum_{i=1}^{k \wedge j} (s_i - s_{i-1}) \tilde{E} U_i^2 = \sum_{i=1}^{k \wedge j} (s_i - s_{i-1}) = s_{k \wedge j} = s_k \wedge s_j \tag{9.4.5}
$$

for each $k, j = 1, \ldots, n$. Consequently,

$$
\sum_{k=1}^{n} \sum_{j=1}^{n} \theta_k (s_k \wedge s_j) \theta_j = \tilde{E} \sum_{k=1}^{n} \sum_{j=1}^{n} \theta_k V_k V_j \theta_j = \tilde{E} (\sum_{k=1}^{n} \theta_k V_k)^2 \geq 0.
$$

Hence the sum on the left-hand side of equality $\text{9.4.4}$ is non-negative. In other words, inequality $\text{9.4.3}$ is valid if the point $(t_1, \ldots, t_n) \in [0, \infty)^n$ is such that $|t_k - t_j| > 0$ if $k \neq j$. Since the set of such points is dense in $[0, \infty)^n$, inequality $\text{9.4.3}$ holds, by continuity, for each $(t_1, \ldots, t_n) \in [0, \infty)^n$. In other words, the function $\sigma : [0, \infty)^2 \to [0, \infty)$ is nonnegative definite according to Definition 7.2.2.

5. For each $m \geq 1$ and each sequence $t_1, \ldots, t_m \in [0, \infty)$, write the nonnegative definite matrix

$$
\Sigma \equiv [\sigma(t_k, t_{\theta})]_{k=1, \ldots, m; \theta=1, \ldots, m}, \tag{9.4.6}
$$

and define

$$
F_{t_1, \ldots, t_m} \equiv \Phi_0, \Sigma, \tag{9.4.7}
$$

where $\Phi_0, \Sigma$ is the normal distribution with mean 0 and covariance matrix $\Sigma$. Take any $M \geq 1$ so large that $t_1, \ldots, t_m \in [0, M]$. Proposition 7.2.3 says that the family

$$
F^{(M)} \equiv \{ F_{t_1, \ldots, t_m} : m \geq 1; r_1, \ldots, r_m \in [0, M] \}
$$

is consistent and is continuous in probability. Hence, for each $f \in C(\mathbb{R}^n)$, and for each sequence mapping $i : \{1, \ldots, n\} \to \{1, \ldots, m\}$, we have

$$
F_{t_1, \ldots, t_m} (f \circ \check{i}^\prime) = F_{i(t_1), \ldots, i(t_m)} f, \tag{9.4.8}
$$

where the dual function $\check{i}^\prime : \mathbb{R}^m \to \mathbb{R}^n$ is defined by

$$
\check{i}^\prime (x_1, \ldots, x_m) \equiv (x_{i(1)}, \ldots, x_{i(n)}) \tag{9.4.9}
$$

for each $(x_1, \ldots, x_m) \in \mathbb{R}^m$. Thus the family

$$
F \equiv \{ F_{t_1, \ldots, t_m} : m \geq 1; t_1, \ldots, t_m \in [0, \infty) \} \tag{9.4.10}
$$

is consistent and is continuous in probability.
of f.j.d.’s is consistent and is continuous in probability. Assertion 2 is proved.

6. To prove the remaining Assertion 3, let \( Z : \mathcal{Q}_a \times (\Omega, L, E) \rightarrow R \) be an arbitrary process with marginal distributions given by the family \( F_{\mathcal{Q}_a} \), where \( F \) is defined in Assertion 2 above. Such a process \( Z \) exists by the Daniel-Kolmogorv- or the Daniel-Kolmogorv-Skorokhod Extension Theorem.

7. Let \( t_1, t_2 \in \mathcal{Q}_a \) be arbitrary. Then, according to Steps 5 and 6 above, the r.r.v.’s \( Z_{t(1)}, Z_{t(2)} \) have a jointly normal distribution given by \( F_{t(1), t(2)} \equiv \Phi_{0, 0} \) where \( \Phi_{0, 0} \equiv [t_r \wedge t_h]_{k=1,2; h=1,2} \). Hence

\[
EZ_{t(1)}Z_{t(2)} = t_1 \wedge t_2.
\]

It follows that \( Z_{t(1)} - Z_{t(2)} \) is a normal r.r.v. with mean 0, and with variance given by

\[
E(Z_{t(1)} - Z_{t(2)})^2 = EZ_{t(1)}^2 + ZB_{t(2)} - 2EZ_{t(1)}Z_{t(2)} = t_1 + t_2 - 2t_1 \wedge t_2 = |t_1 - t_2|.
\]

8. Now let 0 \( \equiv t_0 \leq t_1 \leq \cdots \leq t_{n-1} \leq t_n \) be arbitrary in \( \mathcal{Q}_a \). Then the r.r.v.’s \( Z_{t(1)}, \cdots, Z_{t(n)} \) have joint distribution \( F_{t(1), \cdots, t(n)} \) according to Steps 5 and 6. Hence \( Z_{t(1)}, \cdots, Z_{t(n)} \) are jointly normal. Therefore the r.r.v.’s \( Z_{t(1)} - Z_{t(0)}, \cdots, Z_{t(n)} - Z_{t(n-1)} \) are jointly normal. Moreover, for each \( i, k = 1, \cdots, n \) with \( i < k \), we have

\[
E(Z_{t(i)} - Z_{t(i-1)})(Z_{t(k)} - Z_{t(k-1)})
\]

\[
= EZ_{t(i)}Z_{t(k)} - EZ_{t(i)}Z_{t(k-1)} - EZ_{t(i-1)}Z_{t(k)} + EZ_{t(i-1)}Z_{t(k-1)}
\]

\[
= t_i - t_{i-1} + t_{k-1} - t_{k} = 0. \quad (9.4.11)
\]

Thus the jointly normal r.r.v.’s \( Z_{t(1)} - Z_{t(0)}, \cdots, Z_{t(n)} - Z_{t(n-1)} \) are pairwise uncorrelated. Hence, by Assertion 3 of Proposition 5.7.3 they are mutually independent. Summing up Steps 7 and 8, all of Conditions (i-iii) of Assertion 1 have been verified for the process \( Z \). Accordingly, the extension-by-limit

\[
B \equiv \Phi_{\text{Lim}}(Z) : [0, \infty) \times \Omega \rightarrow R
\]

is a Brownian motion. Assertion 3 and the theorem is proved.

The following corollary is Levy’s well known result on the a.u. Hoelder continuity of a Brownian motion. A stronger theorem by Levy gives the best modulus of a.u. continuity of a Brownian motion, and shows that the \( \theta \in (0, \frac{1}{2}) \) is the best Hoelder exponent that can be hoped for; a.u. local Hoelder continuity for Brownian motion with exponent \( \frac{1}{2} \) fails.

**Corollary 9.4.3.** (Brownian Motion on a finite interval is a.u. locally Hoelder with exponent less than \( \frac{1}{2} \)). Let \( B : [0, \infty) \times (\Omega, L, E) \rightarrow R \) be a Brownian motion. Let \( \theta \in (0, \frac{1}{2}) \) and \( a > 0 \) be arbitrary. Then \( B|_{[0,a]} \) is a.u. locally Hoelder with exponent \( \theta \).

**Proof.** Since \( \theta < \frac{1}{2} \), there exists \( m \geq 0 \) so large that \( \theta < (2 + 2m)^{-1}m \). Consider the process \( X : [0, 1] \times (\Omega, L, E) \rightarrow R \) defined by \( X_t \equiv B_{at} \) for each \( t \in [0, 1] \). Consider each \( b > 0 \) and each \( r, s \in [0, 1] \). Then the r.r.v. \( X_r - X_s \equiv B_{at} - B_{at} \) is normally distributed with mean 0 and variance \( a|r - s| \). Therefore

\[
E|X_r - X_s|^2 = 2E|X_r - X_s|^2 \sim \text{a}^{1+m}m |r - s|^{1+m},
\]

Yuen-Kwok Chan 300 Constructive Probability
where $c_0 \equiv EU^2 + 2m$ is the $(2+m)$-th moment of a standard normal r.r.v. $U$. Thus the process $X|Q_\infty$ satisfies inequality 9.3.17 of Theorem 9.3.3 with $u = 2 + 2m$, $c_0 \equiv \tau_0 a^{1+m}$, and $w \equiv m$. Note that $\theta < u^{-1}w$ by the choice of $m$. Hence, accordingly to Theorem 9.3.3 the process $X$ is a.u. locally Hoelder with exponent $\theta$, with some a.u. locally Hoelder coefficient $c$, and with some modulus of a.u. locally Hoelder continuity $\delta_{\text{LocHldr}}$.

Let $\epsilon > 0$ be arbitrary. Then, according to Definition 9.3.2 there exists measurable set $D$ with $P(D) < \epsilon$ such that, for each $\omega \in D$, we have

$$|X_r(\omega) - X_s(\omega)| < c|r - s|^{\theta}$$

(9.4.12)

for each $r, s \in [0, 1]$ with $|r - s| < \delta_{\text{LocHldr}}(\epsilon)$. Now consider each $\omega \in D$ and each $t, u \in [0, a]$ with $|t - u| < a\delta_{\text{LocHldr}}(\epsilon)$. Then inequality 9.4.12 yields

$$|B_t(\omega) - B_u(\omega)| \equiv |X_{t/a}(\omega) - X_{u/a}(\omega)| < c|a^{1-1}t - a^{-1}s|^{\theta} = ca^{-1}|t - s|^{\theta}.$$  

(9.4.13)

Thus we see that the process $B|[0,a]$ is a.u. locally Hoelder with exponent $\theta$, according to Definition 9.3.2 as alleged.

### 9.5 The Garsia-Rodemich-Rumsey Theorem

In this section, we will restrict our attention to real-valued Gaussian processes with parameter set $[0, 1]$. We will let $\sigma : [0, 1] \times [0, 1] \to R$ be an arbitrary continuous symmetric positive definite function.

[Garsia, Rodemich, and Rumsey 1970] gives a condition on the modulus of continuity of $\sigma$ under which there exists an a.u. continuous Gaussian process $X$ with $\sigma$ as covariance functions. The Garsia-Rodemich-Rumsey proof is by showing that the partial sums of the Karhunen-Loeve expansion relative to $\sigma$ are, under said condition, a.u. convergent to an a.u. continuous process. We will quote the key real-variable lemma in [Garsia, Rodemich, and Rumsey 1970]. We will then present a proof of the main theorem which is, in essence, the proof in the cited paper except that we dispense with an unnecessary appeal to a version of the submartingale convergence theorem which states that every submartingale with bounded expectations converges a.u. to some r.r.v. This version implies the principle of infinite search. The constructive version, Theorem 8.4.5 requires additional information on the convergence of some sequences of expectations, in order to yield the a.u. convergence and the measurability of the limiting r.r.v.

Instead of supplying a proof of the convergence of the submartingale derived from the Karhunen-Loeve expansion, we bypass both the Karhunen-Loeve expansion and the use of submartingales. We will derive Borel-Cantelli styled estimates on conditional expectations, thus sticking to elementary time-domain analysis and obviating the need, for the present purpose, of more ground work of spectral analysis of the covariance function. We note that the use of conditional expectations in relation to the Karhunen-Loeve expansion is mentioned in [Garsia, Rodemich, and Rumsey 1970] for a related result.
First some notations. Define

\[ \Delta \sigma(s, t) \equiv \sigma(s, s) + \sigma(t, t) - 2\sigma(s, t) \] (9.5.1)

for each \( t, s \in [0, 1] \). It follows from the continuity of \( \sigma \) that \( \Delta \sigma(s, t) \to 0 \) as \( |s-t| \to 0 \).

In the following, recall that \( \int_0^1 d\mathcal{P} \) denotes the Riemann-Stieltjes integration relative to an arbitrary distribution function \( \mathcal{P} \) on \([0,1]\).

**Definition 9.5.1. (Two auxiliary functions).** Introduce the auxiliary function

\[ \Psi(v) \equiv \exp\left(\frac{1}{4}v^2\right) \] (9.5.2)

for each \( v \in [0, \infty) \), with its inverse

\[ \Psi^{-1}(u) \equiv 2\sqrt{\log u} \] (9.5.3)

for each \( u \in [1, \infty) \).

Next we cite, without the proof from [Garsia, Rodemich, and Rumsey 1970], a remarkable real variable lemma. It derives the global modulus of continuity, inequality 9.5.5 below, of a function from a condition on its local properties, inequality 9.5.4 below. It is key to the main theorem.

**Lemma 9.5.2. (Garsia-Rodemich-Rumsey Real Variable Lemma).** Let the function \( \Psi \) and its inverse \( \Psi^{-1} \) be as in Definition 9.5.1. Let \( \mathcal{P} : [0,1] \to [0,\infty) \) be an arbitrary continuous nondecreasing function with \( \mathcal{P}(0) = 0 \). Let \( f \) be an arbitrary continuous function on \([0,1]\), and let \( B > 0 \) be such that the function

\[ \Psi\left(\frac{|f(t) - f(s)|}{\mathcal{P}(|t-s|)}\right) \]

doing \((t,s)\in [0,1]^2\) is integrable, with

\[ \int_0^1 \int_0^1 \Psi\left(\frac{|f(t) - f(s)|}{\mathcal{P}(|t-s|)}\right) dtds \leq B, \] (9.5.4)

Then

\[ |f(t) - f(s)| \leq 8 \int_0^{|t-s|} \Psi^{-1}\left(\frac{4B}{u^2}\right) d\mathcal{P}(u) \] (9.5.5)

for each \((t,s)\in [0,1]^2\).

**Proof.** See [Garsia, Rodemich, and Rumsey 1970].
where the second equality is equality of sets without the enumeration, and

\[ Q_\infty = \bigcup_{N=0}^{\infty} Q_N = \{ t_0, t_1, \cdots \}. \]

Recall that \([\cdot]\) is the operation which assigns to each \(a \in R\) an integer \([a]\) \in \((a, a + 2)\). Recall also the matrix notations in Definition 5.7.1, and the basic properties of conditional distributions established in Propositions 5.6.6 and 5.8.17. As usual, to lessen the burden on subscripts, we write the symbols \(x_y\) and \(x(y)\) interchangeably for any expressions \(x\) and \(y\).

**Lemma 9.5.3. (Interpolation of Gaussian process with conditional expectations).**

Let \(Y : Q_\infty \times \Omega \rightarrow R\) be an arbitrary centered Gaussian process with a continuous positive definite covariance function \(\sigma\). Thus \(E(Y_t - Y_s)^2 = \Delta \sigma(t, s)\) for each \(t, s \in Q_\infty\). Let \(\overline{\mathcal{P}} : [0, 1] \rightarrow [0, \infty)\) be an arbitrary continuous nondecreasing function such that

\[ \int_{s \leq t \leq t + 1} \sigma(s, t)^{1/2} \leq \overline{\mathcal{P}}(u) \]

for each \(u \in [0, 1]\). Then there exists \(Y^{(n)} : [0, 1] \times \Omega \rightarrow R\) such that the following holds.

1. Let \(n \geq 0\) and \(t \in [0, 1]\) be arbitrary. Define the r.v.

\[ Y^{(n)}_t = Y_t^{(n)} \equiv E(Y_t | Y_{t_0}, \cdots, Y_{t_n}). \]

Then, for each fixed \(n \geq 0\), the process \(Y^{(n)} : [0, 1] \times \Omega \rightarrow R\) is an a.u. continuous centered Gaussian process. Moreover, \(Y^{(n)}_t = Y_t\) for each \(r \in \{t_0, \cdots, t_n\}\). We will call the process \(Y^{(n)}\) the interpolated approximation of \(Y\) by conditional expectations on \(\{t_0, \cdots, t_n\}\).

2. For each fixed \(t \in [0, 1]\), the process \(Y_t : \{0, 1, \cdots\} \times \Omega \rightarrow R\) is a martingale relative to the filtration \(\mathcal{F} = \{L(Y_{t_0}, \cdots, Y_{t_n}) : n = 0, 1, \cdots\}\).

3. If \(m > n \geq 1\), define

\[ Z^{(m,n)}_t = Y^{(m)}_t - Y^{(n)}_t \in L(Y_{t_0}, \cdots, Y_{t_m}) \]

for each \(t \in [0, 1]\). Let \(\Delta > 0\) be arbitrary. Suppose \(n\) is so large that the subset \(\{t_0, \cdots, t_n\}\) is a \(\Delta\)-approximation of \([0, 1]\). Define the continuous nondecreasing function \(\overline{\mathcal{T}} : [0, 1] \rightarrow [0, \infty)\) by

\[ \overline{\mathcal{T}}(u) = \overline{\mathcal{P}}(u) + 2\overline{\mathcal{P}}(\Delta) \]

for each \(u \in [0, 1]\). Then

\[ E(Z^{(m,n)}_t - Z^{(m,n)}_s)^2 \leq \overline{\mathcal{T}}(t - s). \]

**Proof.** First note that since \(Y : Q_\infty \times \Omega \rightarrow R\) is centered Gaussian with covariance function \(\sigma\), we have

\[ E(Y_t - Y_s)^2 = EY_t^2 - 2EY_t Y_s + EY_s^2 = \sigma(t, s) - 2\sigma(t, s) + \sigma(t, s) \equiv \Delta \sigma(t, s) \]
for each \( t, s \in Q_n \).

1. Let \( n \geq 0 \) be arbitrary. Then the r.v. \( U_n \equiv (Y_{t(0)}, \cdots, Y_{t(n)}) \) with values in \( R^{n+1} \) is normal, with mean 0 and has the positive definite covariance matrix
\[
\sigma_n \equiv EU_n U_n^T = [\sigma(t_h, t_j)]_{h=0,\ldots,n; j=0,\ldots,n}.
\]

For each \( t \in [0,1] \), define
\[
c_{n,t} = (\sigma(t, t_0), \cdots, \sigma(t, t_n)) \in R^{n+1}
\]
and define the Gaussian process \( Y^{(n)} : [0,1] \times \Omega \rightarrow R \) by
\[
Y^{(n)}_t \equiv c_{n,t} \sigma_n^{-1} U_n.
\]

Then, since \( c_{n,t} \) is continuous in \( t \), the process \( Y^{(n)} \) is a.u. continuous.

Moreover, for each \( t \in Q_n \), the conditional expectation of \( Y_t \) given \( U_n \) is, according to Proposition \[5.8.17\] given by
\[
E(Y_t|Y_{t(0)}, \cdots, Y_{t(n)}) = E(Y_t|U_n) = c_{n,t} \sigma_n^{-1} U_n \equiv Y^{(n)}_t.
\]
Thus \( Y^{(n)}_t \equiv Y_t(n) = Y^{(n)}_t \). Hence, since \( Y^{(n)} \) is an a.u. continuous and centered Gaussian process, so is \( Y^{(n)} \). Assertion 1 is proved. Note that, for each \( r \in \{t_0, \cdots, t_n\} \) and for each \( m \geq n \), we have \( r \in \{t_0, \cdots, t_m\} \), whence \( Y_r \in L(U_m) \)
\[
Y^{(m)}_r = E(Y_r|U_m) = Y_r,
\]
where the second equality is a trivial consequence of the conditional expectation.

2. Let \( m > n \geq 1 \) be arbitrary. Then, for each \( t \in Q_n \), we have
\[
E(Y^{(m)}_t|U_n) = E(E(Y^{(m)}_t|U_m)|U_n) = E(Y^{(n)}_t|U_n) = Y^{(n)}_t,
\]
where the first and third equality are by equality \[9.5.6\] and where the second equality is because \( L(U_n) \subset L(U_m) \). Hence, for each \( V \in L(U_n) \), we have
\[
EY^{(m)}_t V = EY^{(n)}_t V
\]
for each \( t \in Q_n \), and, by continuity, also for each \( t \in [0,1] \). Thus \( E(Y^{(m)}_t|U_n) = Y^{(n)}_t \) for each \( t \in [0,1] \). We conclude that, for each fixed \( t \in [0,1] \), the process \( Y_t : \{0,1,\cdots\} \times \Omega \rightarrow R \) a martingale relative to the filtration \( \{L(U_n) : n = 0,1,\cdots\} \). Assertion 2 is proved.

3. Let \( m > n \geq 1 \) and \( t, s \in [0,1] \) be arbitrary. Then
\[
Z^{(m,n)}_t - Z^{(m,n)}_s \equiv Y^{(m)}_t - Y^{(m)}_s - Y^{(m)}_s = Y^{(m)}_t - Y^{(m)}_s - E(Y^{(m)}_t - Y^{(m)}_s|U_n).
\]
Hence, by Proposition \[5.6.6\]
\[
E(Z^{(m,n)}_t - Z^{(m,n)}_s)^2 \leq E(Y^{(m)}_t - Y^{(m)}_s)^2
\]
Yuen-Kwok Chan 304 Constructive Probability
Suppose \( t, s \in Q_m \). Then equality \( 9.5.6 \) implies that
\[
Y_t^{(m)} - Y_s^{(m)} = E(Y_t - Y_s | U_m).
\] (9.5.8)

Hence,
\[
E(Z_t^{(m,n)} - Z_s^{(m,n)})^2 \leq E(Y_t^{(m)} - Y_s^{(m)})^2 \leq E(Y_t - Y_s)^2 = \Delta \sigma(t, s),
\]
where \( t, s \in Q_m \) are arbitrary, and where the second inequality is by equality \( 9.5.8 \) and by Proposition \( 5.6.6 \). By continuity, we therefore have
\[
E(Z_t^{(m,n)} - Z_s^{(m,n)})^2 \leq E(Y_t^{(m)} - Y_s^{(m)})^2 \leq \Delta \sigma(t, s) \leq 2\tau(|t - s|)
\] (9.5.9)
where \( t, s \in [0, 1] \) are arbitrary.

Now let \( \Delta > 0 \) be arbitrary. Suppose \( n \geq 1 \) is so large that the subset \( \{t_0, \cdots, t_n\} \) is a \( \Delta \)-approximation of \( [0, 1] \). Let \( t', s' \in \{t_0, \cdots, t_n\} \) be such that \( |t - t'| \lor |s - s'| < \Delta \). Then equality \( 9.5.7 \) implies that
\[
Z_t^{(m,n)} \equiv Y_t^{(m)} - Y_t^{(n)} = Y_t - Y_t = 0,
\] (9.5.10)
with a similar inequality for \( s' \). Applying inequality \( 9.5.9 \) to \( t, t' \) in place of \( t, s \), we obtain
\[
E(Z_t^{(m,n)} - Z_{t'}^{(m,n)})^2 \leq 2\tau(|t - t'|) \leq 2\tau(\Delta),
\]
and a similar inequality for the pair \( s, s' \) in place of \( t, t' \). In addition, equality \( 9.5.10 \) implies
\[
Z_t^{(m,n)} - Z_s^{(m,n)} = (Z_t^{(m,n)} - Z_{t'}^{(m,n)}) - (Z_s^{(m,n)} - Z_{s'}^{(m,n)}).
\]
Hence Minkowski’s inequality yields
\[
\sqrt{E(Z_t^{(m,n)} - Z_s^{(m,n)})^2} \leq \sqrt{E(Z_t^{(m,n)} - Z_{t'}^{(m,n)})^2} + \sqrt{E(Z_s^{(m,n)} - Z_{s'}^{(m,n)})^2} \leq 2\tau(\Delta).
\] (9.5.11)
Combining inequalities \( 9.5.9 \) and \( 9.5.11 \) we obtain
\[
E(Z_t^{(m,n)} - Z_s^{(m,n)})^2 \leq (\tau(|t - s|) \lor 2\tau(\Delta))^2 \leq \frac{\tau(\Delta)}{\Delta}(|t - s|).
\]
Assertion 3 is proved.

The next lemma prepares for the proof of the main theorem. It contains a redundant assumption of a.u. continuity, which will be stripped off in the main theorem.

**Lemma 9.5.4.** (Modulus of a.u. continuity with the redundant assumption of a.u. continuity). Let \( V : [0, 1] \times \Omega \to R \) be an arbitrary a.u. continuous and centered Gaussian process, with a continuous positive definite covariance function \( \sigma \). Thus
\[
\xi_{t,s} \equiv E(V_t - V_s)^2 = \Delta \sigma(t, s)
\]
Yuen-Kwok Chan 305 Constructive Probability
for each \( t, s \in [0, 1] \), where the operator \( \Delta \) is defined in equality (9.5.1). Let \( \mathcal{P} : [0, 1] \to [0, \infty) \) be a continuous increasing function, with \( \mathcal{P}(0) = 0 \), such that \( \sqrt{-\log u} \) is integrable relative to the distribution function \( \mathcal{P} \) on \([0, 1] \). Thus
\[
\int_0^1 \sqrt{-\log u} \mathcal{P}(u) < \infty. \tag{9.5.12}
\]

Suppose
\[
\bigvee_{0 \leq s, t \leq 1; |s-t| \leq u} \xi_{s,t} \leq \mathcal{P}(u)^2 \tag{9.5.13}
\]
for each \( u \in [0, 1] \). Then there exists an integrable r.v. \( B \) with \( EB \leq \sqrt{2} \) such that
\[
|V(t, \omega) - V(s, \omega)| \leq 16 \int_0^{\sqrt{|s-t|}} \sqrt{\log \left( \frac{4B(\omega)}{u^2} \right)} d\mathcal{P}(u) \tag{9.5.14}
\]
for each \( t, s \in [0, 1] \), for each \( \omega \in \text{domain}(B) \).

Proof. With positive definiteness of the function \( \sigma \), the defining equality (9.5.1) implies that \( \Delta \sigma(s, t) > 0 \) for each \( s, t \in [0, 1] \) with \( |s-t| > 0 \). Hence, in view of inequality (9.5.21) we have \( \mathcal{P}(u) > 0 \) for each \( u \in (0, 1] \).

Define the full subset
\[
D \equiv \{(t, s) \in [0, 1]^2 : |t-s| > 0\}
\]
of \([0, 1]^2\). Because the process \( V \) is a.u. continuous, there exists a full set \( A \subset \Omega \) such that \( V(\cdot, \omega) \) is continuous on \([0, 1] \). Moreover, \( V \) is a measurable function on \([0, 1] \times \Omega \). Define the function \( U : [0, 1]^2 \times \Omega \to \mathbb{R} \) by
\[
\text{domain}(U) \equiv D \times A
\]
and
\[
U(t, s, \omega) \equiv \Psi\left(\frac{|V(t, \omega) - V(s, \omega)|}{\mathcal{P}(|t-s|)}\right)
\equiv \exp\left(\frac{1}{4} \frac{(V(t, \omega) - V(s, \omega))^2}{\mathcal{P}(|t-s|)^2}\right) \tag{9.5.15}
\]
for each \((t, s, \omega) \in \text{domain}(U)\). Then \( U \) is a measurable on \([0, 1]^2 \times \Omega \).

Let \( t, s \in [0, 1] \) be arbitrary. Then \( \xi_{s,t} \leq \mathcal{P}(|t-s|)^2 \) Hence
\[
\frac{1}{\sqrt{2\pi \mathcal{P}}(s,t)} \exp\left(\frac{u^2}{4 \mathcal{P}(|t-s|)^2}\right) \exp\left(-\frac{u^2}{2 \mathcal{P}(s,t)}\right) \leq \frac{1}{\sqrt{2\pi \mathcal{P}}(s,t)} \exp\left(-\frac{u^2}{4 \mathcal{P}(s,t)}\right). \tag{9.5.16}
\]

The measurable function of \( (t, s, u) \) on the right-hand side is integrable on \([0, 1]^2 \times \mathbb{R} \) relative to the product Lebesgue integration, with
\[
\int_0^1 \int_0^1 \int_{-\infty}^\infty \frac{1}{\sqrt{2\pi \mathcal{P}}} \exp\left(-\frac{u^2}{4 \mathcal{P}(s,t)}\right) du \, dt \, ds = \int_0^1 \int_0^1 \sqrt{2} \, dt \, ds = \sqrt{2}.
\]

Yuen-Kwok Chan 306 Constructive Probability
9.5. THE GARSIA-RODEMICH-RUMSEY THEOREM

Hence the measurable function of \((t, s, u)\) on the left-hand side of (9.5.16) is integrable on \([0, 1]^2 \times R\), with integral bounded by \(\sqrt{2}\).

Now let \(b > 0\) be arbitrary. Note that the r.r.v. \(V(t, \cdot) - V(s, \cdot)\) is Gaussian, with mean 0 and variance \(\xi_{2, 5}^2\). Hence

\[
E \int_0^1 \int_0^1 b \wedge U \, dt \, ds
= \int_0^1 \int_0^1 \int_0^\infty b \wedge \int \frac{e^{-u^2/4}}{\sqrt{2\pi \xi_{2, 5}}} \exp(-1/2 \xi_{2, 5}^2) \, du \, dt \, ds
\]

\[
= \int_0^1 \int_0^\infty \frac{1}{\sqrt{2\pi \xi_{2, 5}}} \exp(-1/2 \xi_{2, 5}^2) \, du \, \left( \int dt \right) \left( \int ds \right)
\]

\[
\to \int_0^1 \int_0^\infty \frac{1}{\sqrt{2\pi \xi_{2, 5}}} \exp(-1/2 \xi_{2, 5}^2) \, du \, \left( \int dt \right) \left( \int ds \right) \leq \sqrt{2}, \tag{9.5.17}
\]
as \(b \to \infty\). Therefore The Monotone Convergence Theorem [4.4.8] implies that the r.r.v. \(U\) is integrable on \([0, 1]^2 \times \Omega\). Hence, by Fubini’s Theorem, the function

\[
B \equiv \int_0^1 \int_0^1 U \, dt \, ds \equiv \int_0^1 \int_0^1 \sqrt{\frac{|V(t, \cdot) - V(s, \cdot)|}{\sqrt{t - s}}} \, dt \, ds
\]
is an integrable r.r.v, with expectation given by

\[
E(B) = E \int_0^1 \int_0^1 U \, dt \, ds \leq \sqrt{2}.
\]

Consider each \(\omega \in \text{domain}(B)\). Then

\[
B(\omega) = \int_0^1 \int_0^1 \sqrt{\frac{|V(t, \omega) - V(s, \omega)|}{\sqrt{t - s}}} \, dt \, ds. \tag{9.5.18}
\]

In view of equality (9.5.18) Lemma 9.5.2 implies that

\[
|V(t, \omega) - V(s, \omega)| \leq 8 \int_0^{[t-s]} \Psi^{-1} \left( \frac{4B(\omega)}{u^2} \right) d\bar{\Psi}(u) \equiv 16 \int_0^{[t-s]} \sqrt{-\log \left( \frac{4B(\omega)}{u^2} \right)} d\bar{\Psi}(u). \tag{9.5.19}
\]
The lemma is proved.

\[\Box\]

**Theorem 9.5.5. (Garsia-Rodemich-Rumsey Theorem).** Let \(\bar{\Psi} : [0, 1] \to [0, \infty)\) be a continuous increasing function, with \(\bar{\Psi}(0) = 0\), such that \(-\log u\) is integrable relative to the distribution function \(\bar{\Psi}\) on \([0, 1]\). Thus

\[
\int_0^1 \sqrt{-\log u} d\bar{\Psi}(u) < \infty. \tag{9.5.20}
\]

Let \(\sigma : [0, 1] \times [0, 1] \to R\) be an arbitrary symmetric positive definite function such that

\[
\sqrt{\int_{0 \leq s, t \leq 1; |s - t| \leq u} (\Delta \sigma(s, t))^{1/2} d\bar{\Psi}(u). \tag{9.5.21}
\]

Yuen-Kwok Chan 307 Constructive Probability
CHAPTER 9. A.U. CONTINUOUS PROCESSES ON \([0,1]\)

Then there exists an a.u. continuous centered Gaussian process \(X: [0,1] \times \Omega \to \mathbb{R}\) with \(\sigma\) as covariance function. Moreover, there exists an integrable r.r.v \(B\) with \(EB \leq \sqrt{2}\) such that

\[
|X(t, \omega) - X(s, \omega)| \leq 16 \int_0^{\sqrt{|t-s|}} \log(\frac{4B(\omega)}{u^2})d\mathcal{P}(u)
\]

for each \(t,s \in [0,1]\), for each \(\omega \in \text{domain}(B)\).

Proof. 1. As observed in the beginning of the proof of Lemma 9.5.4, the positive definiteness of the function \(\sigma\) implies that \(\mathcal{P}(u) > 0\) for each \(u \in (0,1]\).

2. Let

\[
F^\sigma = \Phi_{\text{covar.fjd}}(\sigma)
\]

be the consistent family of normal f.j.d.’s on the parameter set \([0,1]\) associated with mean function 0 and the given covariance function \(\sigma\), as defined in equalities 7.2.4 and 7.2.3 of Theorem 7.2.5. Let \(Y: Q_{n} \times \Omega \to \mathbb{R}\) be an arbitrary process with marginal distributions given by \(F^\sigma|Q_{n}\), the restriction of the family \(F^\sigma\) of the normal f.j.d.’s to the countable parameter subset \(Q_{n}\).

3. By hypothesis, the function \(\mathcal{P}\) is continuous at 0, with \(\mathcal{P}(0) = 0\). Hence there is a modulus of continuity \(\delta_{\mathcal{P}}: (0, \infty) \to (0, \infty)\) such that \(\mathcal{P}(u) < \varepsilon\) for each \(u\) with \(0 \leq u < \delta_{\mathcal{P}}(\varepsilon)\), for each \(\varepsilon > 0\).

4. Also by hypothesis, the function \(\sqrt{-\log u}\) is integrable relative to \(\int_0^1 d\mathcal{P}\). Hence there exists a modulus of integrability \(\delta_{\mathcal{P},1}: (0, \infty) \to (0, \infty)\) such that

\[
\int_{0,c[\varepsilon]} \sqrt{-\log ud\mathcal{P}(u)} < \varepsilon
\]

for each \(c \in [0,1]\) with \(\int_{0,c} d\mathcal{P} = \mathcal{P}(c) < \delta_{\mathcal{P},1}(\varepsilon)\).

5. Let \(b > 0\) be arbitrary. Then

\[
\Psi^{-1}(\frac{4b}{u^2}) \equiv 2\sqrt{2\log b - 2\log u} \leq 2\sqrt{2} (\sqrt{\log b} + \sqrt{-\log u})
\]

(9.5.23)

where the functions of \(u\) on both ends have domain \((0,1]\) and are continuous on \((0,1]\). Hence these functions are measurable relative to \(\int_0^1 d\mathcal{P}\). Since the right-hand side of inequality (9.5.23) is an integrable function of \(u\) relative to the integration \(\int_0^1 d\mathcal{P}\), so is the function on the left-hand side.

6. Define \(m_0 \equiv 0\). Let \(k \geq 1\) be arbitrary, but fixed till further notice. In view of Steps 3-5, there exists \(m_k \equiv m_k(\delta_{\mathcal{P},0}, \delta_{\mathcal{P},1}) \geq m_{k-1}\) so large that

\[
16 \int_0^{\Delta(m(k))} \Psi^{-1}(\frac{k^2}{u^2})d\mathcal{P}(u) < k^{-2},
\]

(9.5.24)

where \(\Delta(m(k)) \equiv 2^{-m(k)}\). Write \(p_0 = p_{m(0)} = 1\) and \(p_{m(k)} \equiv 2^{m(k)}\).

7. Let \(n \geq 0\) be arbitrary. Define, as in Lemma 9.5.3 the interpolated process \(Y^{(n)}: [0,1] \times \Omega \to \mathbb{R}\) of \(Y: Q_{n} \times \Omega \to \mathbb{R}\) by conditional expectations on \(\{t_0, \cdots, t_n\}\). Then Lemma 9.5.3 implies that (i) \(Y^{(n)}\) is a centered Gaussian process, (ii) \(Y^{(n)}\) is a.u.
continuous, and (iii) \( Y_r^{(n)} = Y_r \) for each \( r \in \{ t_0, \ldots, t_n \} \). Consequently the difference process
\[
Z^{(k)} = Z^{(m(k),m(k-1))} = Y^{(m(k))} - Y^{(m(k-1))}
\]
is a.u. continuous. Note that from Condition (iii), we have
\[
Z_0^{(k)} = Y_0^{(m(k))} - Y_0^{(m(k-1))} = Y_0 - Y_0 = 0.
\]

For convenience define the trivial process \( Z^{(0)} = 0 \).

8. Let \( t, s \in [0, 1] \) be arbitrary with \( |t - s| > 0 \). Then, since \( \{t_0, t_1, \ldots, t_{j(m(k-1))}\} \) is a \( \Delta_{m(k-1)} \)-approximation of \([0, 1]\), we have, by Lemma 9.5.3,
\[
\xi_{k,t,s} = E (Z_t^{(k)} - Z_s^{(k)})^2 = E (Z_t^{(m(k),m(k-1))} - Z_s^{(m(k),m(k-1))})^2 \leq \overline{p}_k^2 (|t - s|) \quad (9.5.25)
\]
where
\[
\overline{p}_k (u) \equiv 2 (\overline{p} (u) \wedge \overline{p} (\Delta_{m(k-1)}))
\]
for each \( u \geq 0 \). Note that \( \overline{p}_k (u) \) is constant for \( u > \Delta_{m(k-1)} \). Hence the definition of Riemann-Stieljes integrals implies that, for each nonnegative function \( f \) on \([0, 1]\) which is integrable relative to the distribution function \( \overline{p} \), we have
\[
\int_0^1 f(u) d\overline{p}_k (u) = \int_0^{\Delta_{m(k-1)}} f(u) d\overline{p}_k (u)
\]
\[
= 2 \int_0^{\Delta_{m(k-1)}} f(u) d\overline{p}(u) < \infty. \quad (9.5.26)
\]
In particular
\[
\int_0^1 \sqrt{-\log u} d\overline{p}_k (u) = 2 \int_0^{\Delta_{m(k-1)}} \sqrt{-\log u} d\overline{p}(u) < \infty \quad (9.5.27)
\]

9. Inequalities [9.5.25] and [9.5.27] show that the a.u. continuous process \( Z^{(k)} \) and the function \( \overline{p}_k \) satisfy the conditions in the hypothesis of Lemma 9.5.4. Accordingly, there exists an integrable r.r.v. \( B_k \) with \( EB_k \leq \sqrt{2} \) such that
\[
|Z^{(k)}(t, \omega) - Z^{(k)}(s, \omega)| \leq 16 \int_0^{t-s} \sqrt{\log \left( \frac{4B_k (\omega)}{u^2} \right)} d\overline{p}_k (u)
\]
\[
= 16 \int_0^{t-s \wedge \Delta_{m(k-1)}} \sqrt{\log \left( \frac{4B_k (\omega)}{u^2} \right)} d\overline{p}(u) \quad (9.5.28)
\]
for each \( t, s \in [0, 1] \), for each \( \omega \in \text{domain}(B_k) \).

10. Let \( \alpha_k \in (2^{-3}k^2, 2^{-2}k^2) \) be arbitrary, and define \( A_k \equiv (B_k \leq \alpha_k) \). Chebychev’s inequality then implies that
\[
P(A_k^c) \equiv P(B_k > \alpha_k) \leq \alpha_k^{-1} \sqrt{2} < 2^3 \sqrt{2}k^{-2}.
\]
Consider each \( \omega \in A_k \). Then inequality [9.5.28] implies that, for each \( t, s \in [0, 1] \), we have
\[
|Z_t^{(k)} (\omega) - Z_s^{(k)} (\omega)| \leq 16 \int_0^{\Delta_{m(k-1)}} \sqrt{\log \left( \frac{4\alpha_k}{u^2} \right)} d\overline{p}(u)
\]

Yuen-Kwok Chan 309 Constructive Probability
where the last inequality is by inequality 9.5.24. In particular, if we set $s = 0$ and recall that $Z_0^{(k)} = 0$, we obtain

$$|Y_t^{(m(k))}(\omega) - Y_t^{(m(k-1))}(\omega)| = |Z_t^{(k)}(\omega)| < (k - 1)^{-2},$$

(9.5.29)

where $\omega \in A_k$ is arbitrary, if $k > 1$. Since $P(A_k^c) < 2^3 \sqrt{2} k^{-2}$, we conclude that $Y_t^{(m(k))}$ converges a.u. to the limit r.v. $X_t = \lim_{k \to \infty} Y_t^{(m(k))}$. Thus we obtain the limiting process $X : [0, 1] \times \Omega \to R$.

11. We will next prove that the process $X$ is a.u. continuous. To that end, note that, since $Y_t^{(m(k))}$ is an a.u. continuous process according to Condition (ii) in Step 7, there exist a measurable set $D_k$ with $P(D_k^c) < k^{-1}$ and some $c_k > 0$, such that, for each $\omega \in D_k$, we have

$$|Y_t^{(m(k))}(\omega) - Y_s^{(m(k))}(\omega)| < k^{-1}$$

for each $t, s \in [0, 1]$ with $|s - t| < c_k$. Separately, define the measurable set $C_k \equiv \bigcap_{h=k+1}^{\infty} A_h$. Then $P(C_k^c) \leq \sum_{h=k+1}^{\infty} 2^3 \sqrt{2} k^{-2} < 2^3 \sqrt{2} k^{-1}$.

Now consider each $\omega \in D_k C_k$, and each $t, s \in [0, 1]$ with $|s - t| < c_k$. Then

$$X_t(\omega) = Y_t^{(m(k))}(\omega) + \sum_{h=k+1}^{\infty} (Y_t^{(m(h))}(\omega) - Y_t^{(m(k-1))}(\omega)) \equiv Y_t^{(m(k))}(\omega) + \sum_{h=k+1}^{\infty} Z_t^{(h)}(\omega),$$

with a similar equality when $t$ is replaced by $s$. Hence

$$|X_t(\omega) - X_s(\omega)| \leq |Y_t^{(m(k))}(\omega) - Y_s^{(m(k))}(\omega)| + \left| \sum_{h=k+1}^{\infty} (Z_t^{(h)}(\omega) - Z_s^{(h)}(\omega)) \right|$$

$$\leq |Y_t^{(m(k))}(\omega) - Y_s^{(m(k))}(\omega)| + \sum_{h=k+1}^{\infty} h^{-2}$$

$$\leq k^{-1} + k^{-1} = 2k^{-1},$$

where $\omega \in D_k C_k$ and $t, s \in [0, 1]$ with $|s - t| < c_k$ are arbitrary. Since $P(D_k C_k)^c < k^{-1} + 2^3 \sqrt{2} k^{-1}$ and $2k^{-1}$ are arbitrarily small if $k \geq 1$ is sufficiently large, we see that $X : [0, 1] \times \Omega \to R$ is an a.u. continuous process. Consequently, the process $X$ is continuous in probability.

12. Now we will verify that the process $X$ is Gaussian, centered, and has covariance function $\sigma$. Note that $X|Q_\infty = Y$. Hence $X|Q_\infty$ has marginal distributions given by the family $F^\sigma|Q_\infty$ of f.j.d.’s. Since the process $X$ and the family $F^\sigma$ are continuous in probability, and since the subset $Q_\infty$ is dense in the parameter set $[0, 1]$, it follows that $X$ has marginal distributions given by the family $F^\sigma$. Thus $X$ is Gaussian, centered, and has covariance function $\sigma$.

13. Therefore

$$\xi_{t,s} \equiv E(X_t - X_s)^2 = \Delta \sigma(t, s) \leq \bar{\rho}^2(|t - s|).$$
In view of inequalities (9.5.20) and (9.5.21) in the hypothesis, the conditions in Lemma 9.5.4 are satisfied by the process $X$ and the function $p$. Hence Lemma 9.5.4 implies the existence of an integrable r.v. $B$ with $EB \leq \sqrt{2}$ such that

$$
|X(t, \omega) - X(s, \omega)| \leq 16 \int_0^{|t-s|} \sqrt{\log(\frac{4B(\omega)}{u^2})} d\mathcal{P}(u)
$$

(9.5.30)

for each $t,s \in [0,1]$, for each $\omega \in \text{domain}(B)$, as desired. \qed
Chapter 10

a.u. Càdlàg Processes

In this chapter, let \((S, d)\) be a locally compact metric space, with a fixed reference point \(x_0\). As usual, write \(\hat{d} = 1 \wedge d\). We will study processes \(X : [0, \infty) \times \Omega \to S\) whose sample paths are right continuous with left limits, or càdlàg (the commonly used French acronym "continue à droite, limite à gauche").

Classically, the proof of existence of such processes relies on Prokhorov’s Relative Compactness Theorem. As discussed in the beginning of Chapter 9 of the present book, this theorem implies the principle of infinite search. We will therefore bypass Prokhorov’s theorem, in favor of direct proofs using Borel-Cantelli estimates.

In Section 1 a version of Skorokhod’s definition of càdlàg functions from \([0, \infty)\) to \(S\). Each càdlàg function will come with a modulus of càdlàg, much as a continuous function comes with a modulus of continuity. In Section 2 we study a Skorokhod metric \(d_D\) on the space \(D\) of càdlàg functions.

In Section 3 we define an a.u. càdlàg process \(X : [0, 1] \times \Omega \to S\) as a process which is continuous in probability and which has, almost uniformly, càdlàg sample functions. In Section 4, we introduce a \(D\)-regular process \(Z : Q_\infty \times \Omega \to S\), in terms of the marginal distributions of \(Z\), where \(Q_\infty\) is the set of dyadic rationals in \([0, 1]\). We then prove, in Sections 4 and 5, that a process \(X : [0, 1] \times \Omega \to S\) is a.u. càdlàg iff its restriction \(X|Q_\infty\) is \(D\)-regular, or equivalently, iff \(X\) is the extension, by right limit, of a \(D\)-regular process \(Z\). Thus we obtain a characterization of an a.u. càdlàg processes in terms of conditions on its marginal distributions. Equivalently, we have a procedure to construct an a.u. càdlàg process \(X\) from a consistent family \(F\) of f.j.d.’s which is \(D\)-regular. We will derive the modulus of a.u. càdlàg of \(X\) from the given modulus of \(D\)-regularity of \(F\).

In Section 6, we will prove that this construction is metrically continuous, in epsilon-delta terms. Such continuity of construction also seems to be hitherto unknown. In Sections 7 we apply the construction to obtain a.u. càdlàg processes with strongly right continuous marginal distributions; in Section 8, to a.u. càdlàg Martingales; in Section 9, to processes which are right Hölder in a sense to be made precise there. In Section 10, we state the generalization of definitions and results in Sections 1-9, to the parameter interval \([0, \infty)\), without giving the straightforward proofs.

Before proceeding, we remark that our constructive method for a.u. càdlàg processes is by using certain accordion functions, defined in Definition 10.5.3 as time-
varying boundaries for hitting times. This will be clarified as we go along. This method was first used in [Chan 1974] to construct an a.u. càdlàg Markov process from a given strongly continuous semigroup.

Definition 10.0.1. (Notations for dyadic rationals). For ease of reference, we restate he following notations in Definition 9.0.2 related to dyadic rationals. For each $m \geq 0$, define $p_m \equiv 2^m$, $\Delta_m \equiv 2^{-m}$, and recall the enumerated set of dyadic rationals

$$Q_m \equiv \{0, q_0, \cdots, q_m, p(m)\} \equiv \{0, \Delta_m, 2\Delta_m, \cdots, 1\} \subset [0,1],$$

where the second equality is equality of sets without the enumeration. Thus

$$Q_\infty \equiv \bigcup_{m=0}^\infty Q_m \equiv \{0, 1\},$$

where the second equality is equality of sets without the enumeration. Thust

$$Q_m \equiv \{q_0, q_1, \cdots, q_m, p(m)\} \equiv \{0, 2^{-m}, 2 \cdot 2^{-m}, \cdots, 1\}$$

is a $2^{-m}$-approximation of $[0,1]$, with $Q_m \subset Q_{m+1}$, for each $m \geq 0$.

Moreover, for each $m \geq 0$, recall the enumerated set of dyadic rationals

$$\overline{Q}_m \equiv \{0, u_0, u_1, \cdots, u_{p(2m)}\} \equiv \{0, 2^{-m}, 2 \cdot 2^{-m}, \cdots, 2^m\} \subset [0,2^m],$$

and

$$\overline{Q}_m \equiv \bigcup_{m=0}^\infty \overline{Q}_m \equiv \{0, u_0, u_1, \cdots\},$$

where the second equality is equality of sets without the enumeration. □

## 10.1 Càdlàg Functions

Recall some notations and conventions. To minimize clutter, a subscripted expression $a \_b$ will be written interchangeably with $a(b)$. For an arbitrary function $x$, we write $x(t)$ only with the explicit or implicit condition that $t \in \text{domain}(x)$. If $X : A \times \Omega \to S$ is a random field, and if $B$ is a subset of $A$, then $X|B \equiv X|(B \times \Omega)$ denotes the random field obtained by restricting the parameter set to $B$.

Definition 10.1.1. (Pointwise left- and right limits). Let $Q$ be an arbitrary subset of $[0, \infty)$. Let the function $x : Q \to S$ be arbitrary such that domain$(x)$ is dense in $Q$. Let the point $t \in Q$ be arbitrary.

The function $x$ is said to be right continuous at a point $t \in \text{domain}(x)$ if $\lim_{r \searrow t, r \geq t} x(r) = x(t)$. The function $x$ is said to have a left limit at a point $t \in Q$ if $\lim_{r \nearrow t, r < t} x(r)$ exists.

Suppose, for each $t \in Q$ such that $\lim_{r \searrow t, r \geq t} x(r)$ exists, we have $t \in \text{domain}(x)$. Then we say that the function $x$ is right complete.

□

Recall that the function $x$ is said to be continuous at $t$ if $t \in \text{domain}(x)$ and if $\lim_{r \to t} x(r) = x(t)$. Trivially, if $x$ is continuous at $t$, then it is right continuous and has left limit at $t$.

The next definition is essentially Skorokhod’s characterization of càdlàg functions.
10.1. CÀDLÀG FUNCTIONS

**Definition 10.1.2. (Càdlàg function on [0, 1]).** Let \((S, d)\) be a locally compact metric space. Let \(x : [0, 1] \to S\) be a function such that \(domain(x)\) contains the enumerated set \(Q_\infty\) of dyadic rationals in \([0, 1]\). Suppose the following conditions are satisfied.

1. (Right continuity). The function \(x\) is right continuous at each \(t \in domain(x)\), and is continuous at \(t = 1\).
2. (Right completeness). Let \(t \in [0, 1]\) be arbitrary. If \(\lim_{r \to t^+} x(r)\) exists, then \(t \in domain(x)\).
3. (Approximation by step functions). For each \(\varepsilon > 0\), there exist \(\delta_{\text{cdlg}}(\varepsilon) > 0\), \(p \geq 1\), and a sequence

\[0 = \tau_0 < \tau_1 < \cdots < \tau_{p-1} < \tau_p = 1\]  

(10.1.1)

in \(domain(x)\), such that (i) for each \(i = 1, \ldots, p\), we have

\(\tau_i - \tau_{i-1} \geq \delta_{\text{cdlg}}(\varepsilon)\)

and (ii) for each \(i = 0, \ldots, p - 1\), we have

\[d(x, x(\tau_i)) \leq \varepsilon,\]  

(10.1.2)

on the interval \(\theta_i \equiv [\tau_i, \tau_{i+1}]\) or \(\theta_i \equiv [\tau_i, \tau_{i+1}]\) according as \(i \leq p - 2\) or \(i = p - 1\).
We will call \((\tau_i)_{i=0,\ldots,p}\) a sequence of \(\varepsilon\)-division points of \(x\) with separation at least \(\delta_{\text{cdlg}}(\varepsilon)\).

Then \(x\) said to be a càdlàg function on \([0, 1]\) with values in \(S\), with the operation \(\delta_{\text{cdlg}}\) as a modulus of càdlàg. Here we let brevity supersede grammar.

We will let \(D[0,1]\) denote the set of càdlàg functions. Two members of \(D[0,1]\) are considered equal if they are equal as functions, i.e. if they have the same domain and have equal values in the common domain.

\[\square\]

Note that Condition 3 implies that the end points 0, 1 are in \(domain(x)\). Condition 3 implies also that \(p \leq \delta_{\text{cdlg}}(\varepsilon)^{-1}\). Let \(x, y \in D[0,1]\) be arbitrary, with moduli of càdlàg \(\delta_{\text{cdlg}}, \delta_{\text{cdlg}}'\) respectively. Then the operation \(\delta_{\text{cdlg}} \wedge \delta_{\text{cdlg}}'\) is obviously a common modulus of càdlàg of \(x, y\). The next lemma is a simple consequence of right continuity, and generalizes its counterpart for \(C[0,1]\).

**Lemma 10.1.3. (A càdlàg function is uniquely determined by its values on a dense subset of its domain).** Let \(x, y \in D[0,1]\) be arbitrary. Suppose \(B \equiv domain(x) \cap domain(y)\) contains a dense subset \(A\) of \([0,1]\). Then the following holds.

1. Let \(t \in B\) and \(\alpha > 0\) be arbitrary. Then there exists \(r \in [t,t + \alpha) \cap A\) such that

\[d(x(t), x(r)) \vee d(y(t), y(r)) \leq \alpha.\]  

(10.1.3)

2. Let \(f : S^2 \to R\) be a uniformly continuous function. Let \(c \in R\) be arbitrary such that \(f(x(r), y(r)) \leq c\) for each \(r \in A\). Then \(f(x, y) \leq c\). In other words \(f(x(t), y(t)) \leq c\) for each \(t \in domain(x) \cap domain(y)\). The same assertion holds when “\(\leq\)" is replaced by “\(\geq\)" or by “\(=\)”. In particular, if \(d(x(r), y(r)) \leq \varepsilon\) for each \(r \in A\), for some \(\varepsilon > 0\), then \(f(x, y) \leq \varepsilon\) on \(domain(x) \cap domain(y)\).
3. Suppose \( x(r) = y(r) \) for each \( r \in A \). Then \( x = y \). In other words, \( \text{domain}(x) = \text{domain}(y) \) and \( x(t) = y(t) \) for each \( t \in \text{domain}(x) \).

4. Let \( \lambda : [0, 1] \rightarrow [0, 1] \) be an arbitrary continuous and increasing function with \( \lambda(0) = 0 \) and \( \lambda(1) = 1 \). Then \( x \circ \lambda \in D[0, 1] \).

**Proof.** Let \( \delta_{\text{cdlg}} \) be a common modulus of càdlàg of \( x \) and \( y \).

1. Let \( t \in B \) and \( \alpha > 0 \) be arbitrary. Let \((\tau_i)_{i=0}^0\) and \((\tau'_i)_{i=0}^0\) be sequences of \( \mathbb{Q} \)-division points of \( x \) and \( y \) respectively, with separation at least \( \delta_{\text{cdlg}}(\frac{1}{\alpha}) \). Then \( \tau_{p-1} \vee \tau'_{p-1} < 1 \). Hence either (i) \( t < 1 \), or (ii) \( \tau_{p-1} \vee \tau'_{p-1} \leq t \). Consider Case (i).

Since \( x, y \) are right continuous at \( t \), according to Definition \( \text{[10.1.2]} \) and since \( A \) is dense in \([0, 1]\), there exists \( r \in A \cap [t, 1 \wedge (t + \alpha)] \) such that

\[
d(x(t), x(r)) \vee d(y(t), y(r)) \leq \alpha,
\]

as desired. Consider Case (ii). Take \( r \in (\tau_{p-1} \vee \tau'_{p-1}, t) \cap A \). Then \( t, r \in [\tau_{p-1}, 1] \cap [\tau'_{p-1}, 1] \). Hence Condition 3 in Definition \( \text{[10.1.2]} \) implies that

\[
d(x(t), x(r)) \leq d(x(\tau_{p-1}), x(t)) \vee d(x(\tau'_{p-1}), x(r)) \leq \frac{\alpha}{2} + \frac{\alpha}{2} = \alpha.
\]

Similarly, \( d(y(t), y(r)) \leq \alpha \). Assertion 1 is proved.

2. Let \( t \in B \) be arbitrary. By Assertion 1, for each \( k \geq 1 \), there exists \( r_k \in [t, t+\frac{1}{k}) \cap A \) such that inequality

\[
d(x(t), x(r_k)) \vee d(y(t), y(r_k)) \leq \frac{1}{k}
\]

holds. Hence, by right continuity of \( x, y \) and continuity of \( f \), we have

\[
f(x(t), y(t)) = \lim_{k \to \infty} f(x(r_k), y(r_k)) \leq c.
\]

3. By hypothesis, \( d(x(r), y(r)) = 0 \) for each \( r \in A \). Let \( t \in \text{domain}(x) \) and \( \varepsilon > 0 \) be arbitrary. Since \( x \) is right continuous at \( t \), there exists \( c > 0 \) such that

\[
d(x(r), x(t)) < \varepsilon \tag{10.1.4}
\]

for each \( r \in [t, t+c) \cap \text{domain}(x) \). Consider each \( s \in [t, t+c) \cap \text{domain}(y) \). Let \( \alpha = (t + c - s) \wedge \varepsilon \). By Assertion 1 applied to the pair \( y, y \) in \( D[0, 1] \), there exists \( r \in [s, s + \alpha) \cap A \) such that \( d(y(s), y(r)) \leq \alpha \leq \varepsilon \). Then \( r \in [t, t+c) \cap A \), whence inequality \( \text{[10.1.4]} \) holds. Combining,

\[
d(y(s), x(t)) \leq d(y(s), y(r)) + d(y(r), x(r)) + d(x(r), x(t)) < \varepsilon + 0 + \varepsilon = 2\varepsilon.
\]

Since \( \varepsilon > 0 \) is arbitrary, we see that \( \lim_{r \to t \geq 0} y(s) \) exists and is equal to \( x(t) \). Hence the right completeness Condition 2 in Definition \( \text{[10.1.2]} \) implies that \( t \in \text{domain}(y) \). Condition 1 in Definition \( \text{[10.1.2]} \) then implies that \( y(t) = \lim_{r \to t < 0} y(s) = x(t) \). Since \( t \in \text{domain}(x) \) is arbitrary, we conclude that \( \text{domain}(x) \subset \text{domain}(y) \) and \( x = y \) on \( \text{domain}(x) \). By symmetry, \( \text{domain}(x) = \text{domain}(y) \).

4. Since \( \lambda \) is continuous and increasing, it has an inverse \( \lambda^{-1} \) which is also continuous and increasing, with some modulus of continuity \( \delta \). Let \( \delta_{\text{cdlg}} \) be a modulus.
of càdlàg of \( x \). We will prove that \( x \circ \lambda \) is càdlàg, with \( \delta_1 \equiv \tilde{\delta} \circ \delta_{\text{cdlg}} \) as a modulus of càdlàg. To that end, let \( \varepsilon > 0 \) be arbitrary. Let

\[
0 \equiv \tau_0 < \tau_1 < \cdots < \tau_{p-1} < \tau_p = 1
\]  

(10.1.5)

be a sequence of \( \varepsilon \)-division points of \( x \) with separation at least \( \delta_{\text{cdlg}}(\varepsilon) \). Thus, for each \( i = 1, \ldots, p \), we have \( \tau_i - \tau_{i-1} \geq \delta_{\text{cdlg}}(\varepsilon) \). Suppose \( \lambda \tau_i - \lambda \tau_{i-1} < \tilde{\delta}(\delta_{\text{cdlg}}(\varepsilon)) \) for some \( i = 1, \ldots, p \). Then, since \( \tilde{\delta} \) is a modulus of continuity of the inverse function \( \lambda^{-1} \), it follows that

\[
\lambda \tau_i - \lambda \tau_{i-1} = \lambda^{-1} \lambda \tau_i - \lambda^{-1} \lambda \tau_{i-1} < \delta_{\text{cdlg}}(\varepsilon),
\]

a contradiction. Hence

\[
\lambda \tau_i - \lambda \tau_{i-1} \geq \tilde{\delta}(\delta_{\text{cdlg}}(\varepsilon)) \equiv \delta_1(\varepsilon)
\]

for each \( i = 1, \ldots, p \). Moreover, for each \( i = 0, \ldots, p-1 \), we have

\[
d(x, x(\tau_i)) \leq \varepsilon
\]

(10.1.6)

on the interval \( \theta_i \equiv [\tau_i, \tau_{i+1}] \) or \( \theta_i \equiv [\tau_i, \tau_{i+1}] \) according as \( i \leq p - 2 \) or \( i = p - 1 \). Since the function \( \lambda \) is increasing, it follows that

\[
d(x \circ \lambda, x \circ \lambda(\tau_i)) \leq \varepsilon
\]

(10.1.7)

on the interval \( \theta'_i \equiv [\lambda^{-1} \tau_i, \lambda^{-1} \tau_{i+1}] \) or \( \theta'_i \equiv [\lambda^{-1} \tau_i, \lambda^{-1} \tau_{i+1}] \) according as \( i \leq p - 2 \) or \( i = p - 1 \). Thus the sequence

\[
0 = \lambda^{-1} \tau_0 < \lambda^{-1} \tau_1 < \cdots < \lambda^{-1} \tau_{p-1} < \lambda^{-1} \tau_p = 1
\]

is a sequence of \( \varepsilon \)-division points of \( x \) with separation at least \( \delta_1(\varepsilon) \). Condition 3 in Definition 10.1.2 has been proved for the function \( x \circ \lambda \). In view of the monotonicity and continuity of the function \( \lambda \), the other conditions can also be easily verified. Accordingly, the function \( x \circ \lambda \) is càdlàg, with a modulus of càdlàg \( \delta_1 \).

Proposition 10.1.4. (Points of continuity of càdlàg function). Let \( x \in D[0, 1] \) be arbitrary with a modulus of càdlàg \( \delta_{\text{cdlg}} \). Then the function \( x \) on \([0, 1]\) is continuous at the end points 0 and 1. Moreover, domain(\( x \)) contains all but countably many points in \([0, 1]\).

More precisely, for each \( k \geq 1 \), let \( (\tau_{k,i})_{i=0,\ldots,p(k)} \) be a sequence of \( \frac{1}{k} \)-division points of \( x \) with separation at least \( \delta_{\text{cdlg}}\left(\frac{1}{k}\right) \). Then the following holds.

1. Define the set \( A \equiv \bigcap_{k=1}^{\infty} \bigcup_{i=0}^{p(k)-1} \theta_{k,i} \), where \( \theta_{k,i} \equiv [\tau_{k,i}, \tau_{k,i+1}] \) or \( \theta_{k,i} \equiv [\tau_{k,i}, \tau_{k,i+1}] \) according as \( i = 0, \ldots, p_k - 2 \) or \( i = p_k - 1 \). Then the set \( A \) contains all but countably many points in \([0, 1]\), and is a subset of domain(\( x \)).

2. Define the set \( A' \equiv \bigcap_{k=1}^{\infty} \bigcup_{i=0}^{p(k)-1} \theta'_{k,i} \), where \( \theta'_{k,i} \equiv [0, \tau_{k,i}] \) or \( \theta'_{k,i} \equiv [\tau_{k,i}, \tau_{k,i+1}] \) according as \( i = 0 \) or \( i = 1, \ldots, p_k - 1 \). Then the set \( A' \) contains all but countably many points in \([0, 1]\), and the function \( x \) has a left limit at each \( t \in A' \).

3. Define the set \( A'' \equiv \bigcap_{k=1}^{\infty} \bigcup_{i=0}^{p(k)-1} (\tau_{k,i}, \tau_{k,i+1}) \). Then the set \( A'' \) contains all but countably many points in \([0, 1]\), and the function \( x \) is continuous at each \( t \in A'' \).

Yuen-Kwok Chan 317 Constructive Probability
4. The function \( x \) is bounded on domain \((x)\). Specifically,

\[
d(x_0, x(t)) \leq b \equiv \sum_{i=0}^{p(1)-1} d(x_0, x(v_{1,i}))) + 1
\]

for each \( t \in \text{domain}(x) \), where \( x_0 \) is an arbitrary, but fixed, reference point in \( S \).

**Proof.** By Definition [10.1.2] we have \( 1 \in \text{domain}(x) \). Condition 3 in Definition [10.1.2] implies that \( 0 = \tau_{1,0} \in \text{domain}(x) \) and that \( x \) is continuous at \( 0 \) and \( 1 \).

1. Let \( t \in A \) be arbitrary. Let \( k \geq 1 \) be arbitrary. Then \( t \in \theta_{k,i} \) for some \( i = 0, \ldots, p_k - 1 \). Let \( \delta_0 = \tau_{k,i+1} - t \) or \( \delta_0 = 2 \) according as \( i = 0, \ldots, p_k - 2 \) or \( i = p_k - 1 \). Then \( \text{domain}(x) \cap [t, t + \delta_0] \) is a nonempty subset of \( \theta_{k,i} \). Moreover, by Condition 3 of Definition [10.1.2] we have \( d(x(r), x(\tau_{k,i})) \leq \frac{1}{k} \) for each \( r \in \text{domain}(x) \cap [t, t + \delta_0] \). Hence \( d(x(r), x(t)) \leq \frac{1}{k} \delta_0 \) for each \( r, s \in \text{domain}(x) \cap [t, t + \delta_0] \). Since \( \frac{1}{k} \delta_0 \) is arbitrarily small, and since the metric space \((S, d)\) is complete, we see that \( \lim_{r \to r_0} x(r) \) exists. The right completeness Condition 2 of Definition [10.1.2] therefore implies that \( t \in \text{domain}(x) \). We conclude that \( A \subseteq \text{domain}(x) \).

2. Let \( t \in \mathcal{A}' \) be arbitrary. Let \( k \geq 1 \) be arbitrary. Then \( t \in \theta_{k,i} \) for some \( i = 0, \ldots, p_k - 1 \). Let \( \delta_0 = 2 \) or \( \delta_0 = t - \tau_{k,i} \) according as \( i = 0 \) or \( i = 1, \ldots, p_k - 1 \). Then \( \text{domain}(x) \cap (t - \delta_0, t) \) is a nonempty subset of \( \theta_{k,i} \). Moreover, by Condition 3 of Definition [10.1.2] we have \( d(x(r), x(\tau_{k,i})) \leq \frac{1}{k} \) for each \( r \in \text{domain}(x) \cap (t - \delta_0, t) \). Argument similar to the previous paragraph then shows that \( \lim_{r \to r_0} x(r) \) exists.

3. Since \( \mathcal{A}' \subseteq A \), we have \( \mathcal{A}' \subseteq \text{domain}(x) \), thanks to Assertion 2 above. Let \( t \in \mathcal{A}' \) be arbitrary. Let \( k \geq 1 \) be arbitrary. Then \( t \in (\tau_{k,i}, \tau_{k,i+1}) \) for some \( i = 0, \ldots, p_k - 1 \). Hence, by Condition 3 of Definition [10.1.2] we have \( d(x(r), x(t)) \leq \frac{1}{k} \) for each \( r \in \text{domain}(x) \cap (\tau_{k,i}, \tau_{k,i+1}) \). We conclude that the function \( x \) is continuous at \( t \).

4. Finally, observe that each of the sets \( A, \mathcal{A}', \mathcal{A}'' \) contains the metric complement of the countable subset \( \{ \tau_{k,i} \} \). Thus each contains all but countably many points in \([0, 1]\), and is dense in \([0, 1]\). Now let \( t \in A \subseteq \text{domain}(x) \) be arbitrary. Then \( t \in \theta_{1,i} \) for some \( i = 0, \ldots, p_1 - 1 \). Hence

\[
d(x_0, x(t)) \leq d(x_0, x(\tau_{1,i}))) + d(x(\tau_{1,i}), x(t)) \leq \sum_{j=0}^{p(1)-1} d(x_0, x(v_{1,j}))) + 1.
\]

Since \( A \) is dense in \([0, 1]\) and since the function \( d : S^2 \to \mathbb{R} \) is uniformly continuous, Lemma [10.1.3] implies that \( d(x_0, x(r)) \leq b \) for each \( r \in \text{domain}(x) \). \( \square \)

**Proposition 10.1.5. (a.u. right continuity of càdlàg function).** Let \( x \in D[0, 1] \) be arbitrary, with a modulus of càdlàg \( \delta_{cdlg} \). For each \( \alpha > 0 \), let

\[
h \equiv [2 + \sqrt{2} - \log_2 \alpha]_1,
\]

and define

\[
\delta_{h, \alpha} = 2^{-h} \delta_{cdlg}(2^{-h}) > 0.
\]

Let \( \varepsilon > 0 \) be arbitrary. Then there exist a Lebesgue measurable subset \( A \) of \( \text{domain}(x) \) with Lebesgue measure \( \mu(A) < \varepsilon \), such that for each \( \alpha \in (0, \varepsilon) \), we have

\[
d(x(r), x(s)) < \alpha
\]

for each \( t \in A \cap \text{domain}(x) \) and \( s \in [t, t + \delta_h(\alpha, \delta_{cdlg})) \cap \text{domain}(x) \).
10.1. CÀDLÀG FUNCTIONS

Proof. 1. Let \( h \geq 0 \) be arbitrary. Write \( \alpha_h = 2^{-h} \). Then there exist an integer \( p_h \geq 1 \) and a sequence
\[
\tau_0 < \tau_1 < \cdots < \tau_{p_h-1} < \tau_{p(h)} = 1
\] (10.1.8)
in \( \text{domain}(x) \), such that (i) for each \( i = 1, \ldots, p_h \), we have
\[
\tau_{h,i} - \tau_{h,i-1} \geq \delta_{\text{d}lg}(\alpha_h) \tag{10.1.9}
\]
and (ii) for each \( i = 0, \ldots, p_h - 1 \), we have
\[
d(x, x(\tau_{h,i})) \leq \alpha_h, \tag{10.1.10}
\]
on the interval \( \text{th, i} = [\tau_{h,i}, \tau_{h,i+1}] \) or \( \text{th, i} = [\tau_{h,i}, \tau_{h,i+1}] \) according as \( i \leq p_h - 2 \) or \( i = p_h - 1 \).

2. Let \( i = 0, \ldots, p_h - 1 \) be arbitrary. Define
\[
\overline{\text{th, i}} = [\tau_{h,i}, \tau_{h,i+1} - \alpha_h(\tau_{h,i+1} - \tau_{h,i})] \subset \text{th, i}. \tag{10.1.11}
\]
Define \( \overline{\text{th}} = \bigcup_{i=0}^{p(h)-1} \overline{\text{th, i}}. \) Then
\[
\mu(\overline{\text{th}}) = \sum_{i=0}^{p(h)-1} \mu(\overline{\text{th, i}}) = \sum_{i=0}^{p(h)-1} (\tau_{h,i+1} - \tau_{h,i})(1 - \alpha_h) = 1 - \alpha_h,
\]
whence \( \mu(\overline{\text{th}}) = \alpha_h = 2^{-h} \), where \( h \geq 0 \) is arbitrary.

3. Now let \( \varepsilon > 0 \) be arbitrary, and let \( k = \lceil 1 + 0 \vee -\log_2 \varepsilon \rceil \). Define \( A = \bigcup_{h=k}^{\infty} \overline{\text{th}}. \) Then
\[
\mu(A) \leq \sum_{h=k+1}^{\infty} 2^{-h} = 2^{-k} < \varepsilon.
\]
Consider each \( t \in A \cap \text{domain}(x) \). Let \( \alpha \in (0, \varepsilon) \) be arbitrary, and let \( h = \lceil 2 + 0 \vee -\log_2 \alpha \rceil \). Then
\[
h > 2 + 0 \vee -\log_2 \alpha > 2 + (1 + 0 \vee -\log_2 \varepsilon) > k,
\]
Hence \( h \geq k + 1 \) and so \( t \in A \subset \overline{\text{th}}. \) Therefore \( t \in \overline{\text{th, i}} = [\tau_{h,i}, \tau_{h,i+1} - \alpha_h(\tau_{h,i+1} - \tau_{h,i})] \) for some \( i = 0, \ldots, p_h - 1 \). Moreover,
\[
c
\]
Now let \( s \in [t, t + \delta_{\text{d}lg}(\alpha, \delta_{\text{d}lg})) \cap \text{domain}(x) \) be arbitrary. Then
\[
\tau_{h,i} \leq s \leq t + \delta_{\text{d}lg}(\alpha, \delta_{\text{d}lg}) < \tau_{h,i+1} - \alpha_h(\tau_{h,i+1} - \tau_{h,i}) < \tau_{h,i+1} - \alpha_h - \delta_{\text{d}lg}(2^{-h}) + 2^{-h} \delta_{\text{d}lg}(2^{-h}) = \tau_{h,i+1}
\]
Hence \( s \in [\tau_{h,i}, \tau_{h,i+1}) \). It follows that
\[
d(x(s), x(\tau_{h,i})) \vee d(x(t), x(\tau_{h,i})) \leq \alpha_h
\]
and therefore that
\[
d(x(s), x(t)) \leq 2\alpha_h = 2^{-h+1} < \alpha.
\]
CHAPTER 10. A.U. CÅDLÅG PROCESSES

The next proposition shows that if a function satisfies all the conditions in Definition 10.1.2 except perhaps the right completeness Condition 2, then it can be right completed and extended to a càdlàg function. This is analogous to the completion of a uniformly continuous function on a dense subset of $[0,1]$.

**Proposition 10.1.6. (Right-limit extension and càdlàg completion).** Let $(S,d)$ be a locally compact metric space. Suppose $Q = [0,1]$ or $Q = [0,\infty)$. Let $x : Q \to S$ be a function whose domain is dense in $Q$ and which is right continuous at each $t \in \text{domain}(x)$. Define its right-limit extension $\overline{x} : Q \to S$ by

$$\text{domain}(\overline{x}) = \{ t \in Q : \lim_{r \to t^+} x(r) \text{ exists} \},$$

and by

$$\overline{x}(t) = \lim_{r \to t^+} x(r)$$

for each $t \in \text{domain}(\overline{x})$. Then the following holds.

1. The function $\overline{x}$ is right continuous at each $t \in \text{domain}(\overline{x})$.
2. Suppose $t \in Q$ is such that $\lim_{r \to t^+} \overline{x}(r)$ exists. Then $t \in \text{domain}(\overline{x})$.
3. Suppose $Q = [0,1]$. Suppose, in addition, that $\delta_{cdlg} : (0,\infty) \to (0,\infty)$ is an operation such that $x$ and $\delta_{cdlg}$ satisfy Conditions 3 in Definition 10.1.2. Then $\overline{x} \in D[0,1]$. Moreover, $\overline{x}$ has $\delta_{cdlg}$ as a modulus of càdlàg. Furthermore, $x = \overline{x}|\text{domain}(x)$.

We will then call $\overline{x}$ the càdlàg completion of $x$.

**Proof.** 1. Since, by hypothesis, $x$ is right continuous at each $t \in \text{domain}(x)$, it follows from the definition of $\overline{x}$ that $\text{domain}(x) \subset \text{domain}(\overline{x})$ and that $\overline{x} = x$ on $\text{domain}(x)$. In other words, $x = \overline{x}|\text{domain}(x)$. Since $\text{domain}(x)$ is, by hypothesis, dense in $Q$, so is $\text{domain}(\overline{x})$. Now let $t \in \text{domain}(\overline{x})$ and $\varepsilon > 0$ be arbitrary. Then, by the defining equality $10.1.13$

$$\overline{x}(t) = \lim_{r \to t^+} x(r).$$

Hence there exists $\delta_0 > 0$ such that

$$d(\overline{x}(t), x(r)) \leq \varepsilon$$

(10.1.14)

for each $r \in \text{domain}(x) \cap [t,t+\delta_0]$. Let $s \in \text{domain}(\overline{x}) \cap [t,t+\delta_0]$ be arbitrary. Then, again by the defining equalities $10.1.12$ and $10.1.13$ there exists a sequence $(r_j)_{j=1,2,\ldots}$ in $\text{domain}(x) \cap [s,t+\delta_0]$ such that $r_j \to s$ and $\overline{x}(s) = \lim_{j \to \infty} x(r_j)$. For each $j \geq 1$, we then have $r_j \in \text{domain}(x) \cap [t,t+\delta_0]$. Hence inequality $10.1.14$ holds for $r = r_j$, for each $j \geq 1$. Letting $j \to \infty$, we therefore obtain $d(\overline{x}(t), \overline{x}(s)) \leq \varepsilon$. Since $\varepsilon > 0$ is arbitrary, we conclude that $\overline{x}$ is right continuous at $t$. Assertion 1 has thus been verified.

2. Next suppose $\lim_{r \to t^+} \overline{x}(r)$ exists. Then, since $x = \overline{x}|\text{domain}(x)$, the right limit

$$\lim_{r \to t^+} x(r) = \lim_{r \to t^+} \overline{x}(r)$$

exists. Hence $t \in \text{domain}(\overline{x})$ by the defining equality $10.1.12$ Condition 2 of Definition 10.1.2 has been proved for $\overline{x}$.
3. Now let \( \varepsilon > 0 \) be arbitrary. Because \( x = \mathfrak{x} \text{domain}(x) \), each sequence \( (\tau_i)_{i=0,\ldots,p} \) of \( \varepsilon \)-division points of \( x \), with separation at least \( \delta_{\text{cdlg}}(\varepsilon) \), is also a sequence of \( \varepsilon \)-division points of \( \mathfrak{x} \) with separation at least \( \delta_{\text{cdlg}}(\varepsilon) \). Therefore Condition 3 in Definition 10.1.2 holds for \( \mathfrak{x} \) and the operation \( \delta_{\text{cdlg}} \). Summing up, the function \( \mathfrak{x} \) is càdlàg, with \( \delta_{\text{cdlg}} \) as a modulus of càdlàg.

The next definition introduces simple càdlàg functions as càdlàg completion of step functions.

**Definition 10.1.7. (Simple càdlàg function).** Let \( 0 = \tau_0 < \cdots < \tau_{p-1} < \tau_p = 1 \) be an arbitrary sequence in \([0, 1]\) such that

\[
\bigwedge_{i=1}^{p'} (\tau_i - \tau_{i-1}) \geq \delta_0
\]

for some \( \delta_0 > 0 \). Let \( x_0, \ldots, x_{p-1} \) be an arbitrary sequence in \( S \).

Define a function \( z : [0, 1] \to S \) by

\[
domain(z) \equiv \bigcup_{i=0}^{p-1} \theta_i, \tag{10.1.15}
\]

where \( \theta_i = [\tau_i, \tau_{i+1}] \) or \( \theta_i = [\tau_i, \tau_{i+1}] \) according as \( i = 0, \ldots, p-2 \) or \( i = p-1 \), and by

\[ z(r) \equiv x_i \]

for each \( r \in \theta_i \), for each \( i = 0, \ldots, p-1 \). Let \( x \equiv \mathfrak{Z} \in D[0, 1] \) be the càdlàg completion of \( z \). Then \( x \) is called the simple càdlàg function determined by the pair of sequences \( (\tau_i)_{i=0,\ldots,p-1}, (x_i)_{i=0,\ldots,p-1} \). In symbols, we then write

\[ x \equiv \Phi_{\text{smpl}}((\tau_i)_{i=0,\ldots,p-1}, (x_i)_{i=0,\ldots,p-1}), \]

or simply \( x \equiv \Phi_{\text{smpl}}((\tau_i), (x_i)) \) when the range of subscripts is understood. The sequence \( (\tau_i)_{i=0,\ldots,p} \) is then called the sequence of division points of the simple càdlàg function \( x \). The next lemma verifies that \( x \) is a well-defined càdlàg function, with the constant operation \( \delta_{\text{cdlg}}(\cdot) \equiv \delta_0 \) as a modulus of càdlàg.

**Lemma 10.1.8. (Simple càdlàg functions are well defined).** Use the notations and assumptions in Definition [10.1.7]. Then \( z \) and \( \delta_{\text{cdlg}} \) satisfy the conditions in Proposition [10.1.6]. Accordingly, the càdlàg completion \( \mathfrak{Z} \in D[0, 1] \) of \( z \) is well-defined.

**Proof.** First note that \( \domain(z) \) contains the metric complement of \( \{\tau_1, \ldots, \tau_p\} \) in \([0, 1]\). Hence \( \domain(z) \) is dense in \([0, 1]\). Let \( t \in \domain(z) \) be arbitrary. Then \( t \in \theta_i \) for some \( i = 0, \ldots, p-1 \). Hence, for each \( r \in \theta_i \), we have \( z(r) \equiv x_i \equiv z(t) \). Therefore \( z \) is right continuous at \( t \). Conditions 1 in Definition [10.1.2] has been verified for \( z \). The proof of Condition 3 in Definition [10.1.2] for \( z \) and \( \delta_{\text{cdlg}} \) being trivial, the conditions in Proposition [10.1.6] are satisfied.

Yuen-Kwok Chan 321 Constructive Probability
Lemma 10.1.9. (Insertion of division points leave a simple càdlàg function unchanged). Let \( p \geq 1 \) be arbitrary. Let \( 0 \equiv q_0 < q_1 < \cdots < q_p \equiv 1 \) be an arbitrary sequence in \([0, 1]\), with an arbitrary subsequence \( 0 \equiv q_{i(0)} < q_{i(1)} < \cdots < q_{i(k)} \equiv 1 \). Let \( (w_0, \ldots, w_{k-1}) \) be an arbitrary sequence in \( S \). Let

\[
x = \Phi_{\text{ampl}}((q_{i(k)})_{k=0,\ldots,k-1}, (w_k)_{k=0,\ldots,k-1}).
\]

Let

\[
y = \Phi_{\text{ampl}}((q_j)_{j=0,\ldots,p-1}, (x(q_j))_{j=0,\ldots,p-1}).
\]

Then \( x = y \).

Proof. Let \( j = 0, \ldots, p-1 \) and \( t \in [q_j, q_{j+1}) \) be arbitrary. Then \( t \in [q_j, q_{j+1}) \subset [q_{i(k)}, q_{i(k-1)}) \) for some unique \( k = 0, \ldots, k-1 \). Hence \( y(t) = x(q_j) = w_k = x(t) \). Thus \( y = x \) on the dense subset \( \bigcup_{j=0}^{p-1} [q_j, q_{j+1}) \) of \( \text{domain}(y \cap \text{domain}(x)) \). Hence, by Lemma [10.1.3] we have \( y = x \).

\[ \square \]

### 10.2 Skorokhod Space \( D[0, 1] \) of Càdlàg Functions

Following Skorokhod, via [Billingsley 1968], we proceed to define a metric on the space \( D[0, 1] \) of càdlàg functions. This metric is similar to the supremum metric in \( C[0, 1] \), except that it allows a small distortion of the time scale in \([0, 1]\) by some continuous and increasing function \( \lambda : [0, 1] \to [0, 1] \) with \( \lambda(0) = 0 \) and \( \lambda(1) = 1 \).

Let \( \lambda, \lambda' \) be any such continuous and increasing functions. We will write, for abbreviation, \( \lambda t \) for \( \lambda(t) \), for each \( t \in [0, 1] \). We will write \( \lambda^{-1} \) for the inverse of \( \lambda \), and write \( \lambda' \lambda \equiv \lambda' \circ \lambda \) for the composite function.

**Definition 10.2.1. (Skorokhod metric).** Let \( A \) denote the set of continuous and increasing functions \( \lambda : [0, 1] \to [0, 1] \) with \( \lambda(0) = 0 \) and \( \lambda(1) = 1 \), such that there exists \( c > 0 \) with

\[
|\log \frac{\lambda t - \lambda s}{t - s}| \leq c,
\]

or, equivalently,

\[
e^{-c}(t - s) \leq \lambda t - \lambda s \leq e^c(t - s),
\]

for each \( 0 \leq s < t \leq 1 \). We will call \( A \) the set of admissible functions on \([0, 1]\).

Let \( x, y \in D[0, 1] \) be arbitrary. Let \( A_{x,y} \) denote the set consisting of all pairs \((c, \lambda) \in [0, \infty) \times A \) such that inequality [10.2.1] holds for each \( 0 \leq s < t \leq 1 \), and such that

\[
d(x, y \circ \lambda) \leq c.
\]

Recall that the last inequality means \( d(x(t), y(\lambda t)) \leq c \) for each \( t \in \text{domain}(t) \cap \lambda^{-1} \text{domain}(y) \).

Let

\[
B_{x,y} \equiv \{ c \in [0, \infty) : (c, \lambda) \in A_{x,y} \text{ for some } \lambda \}
\]

Define the metric \( d_{D[0, 1]} \) on \( D[0, 1] \) by

\[
d_{D[0, 1]}(x, y) \equiv \inf B_{x,y}.
\]
We will presently prove that \( d_{D[0,1]} \) is well-defined and is indeed a metric, called the Skorokhod metric on \( D[0,1] \). When the interval \([0, 1]\) is understood, we write \( d_D \) for \( d_{D[0,1]} \).

\[ \square \]

Intuitively, the number \( c \) bounds both the (i) error in the time measurement, represented by the distortion \( \lambda \), and (ii) the supremum distance between the functions \( x \) and \( y \) when allowance is made for said error. Existence of the infimum in equality \[10.2.3\] would follow easily from the principle of infinite search. We will supply such a constructive proof, in the following Lemmas \[10.2.4\] through \[10.2.7\] and Proposition \[10.2.8\] Proposition \[10.2.9\] will complete the proof that \( d_{D[0,1]} \) is a metric. Then we will prove that the Skorokhod metric space \((D[0,1], d_D)\) is complete.

First two elementary lemmas.

**Lemma 10.2.2. (A condition for existence of infimum or supremum).** Let \( B \) be an arbitrary nonempty subset of \( R \).

1. Suppose, for each \( k \geq 0 \), there exists \( \alpha_k \in \mathbb{R} \) such that (i) \( \alpha_k \leq c + 2^{-k} \) for each \( c \in B \), and (ii) \( c \leq \alpha_k + 2^{-k} \) for some \( c \in B \). Then \( \inf B \) exists, and \( \inf B = \lim_{k \to \infty} \alpha_k \), with \( \alpha_k - 2^{-k} \leq \inf \mathbb{B} \leq \alpha_k + 2^{-k} \) for each \( k \geq 0 \).

2. Suppose, for each \( k \geq 0 \), there exists \( \alpha_k \in \mathbb{R} \) such that (iii) \( \alpha_k \geq c - 2^{-k} \) for each \( c \in B \), and (iv) \( c \geq \alpha_k - 2^{-k} \) for some \( c \in B \). Then \( \sup B \) exists, and \( \sup B = \lim_{k \to \infty} \alpha_k \), with \( \alpha_k - 2^{-k} \leq \sup \mathbb{B} \leq \alpha_k + 2^{-k} \) for each \( k \geq 0 \).

**Proof.** Let \( h, k \geq 0 \) be arbitrary. Then, by Condition (ii), there exists \( c \in B \) such that \( c \leq \alpha_k + 2^{-k} \). At the same time, by Condition (i), we have \( \alpha_k \leq c + 2^{-h} \leq \alpha_k + 2^{-k} + 2^{-h} \). Similarly, \( \alpha_k \leq \alpha_k + 2^{-h} + 2^{-k} \). Thus \( |\alpha_h - \alpha_k| \leq 2^{-h} + 2^{-k} \). We conclude that the limit \( \alpha = \lim_{k \to \infty} \alpha_k \) exists. Let \( c \in B \) be arbitrary. Letting \( k \to \infty \) in Condition (i), we see that \( \alpha \leq c \). Thus \( \alpha \) is a lower bound for the set \( B \). Suppose \( \beta \) is a second lower bound for \( B \). By condition (ii) there exists \( c \in B \) be such that \( c \leq \alpha_k + 2^{-k} \). Then \( \beta \leq c \leq \alpha_k + 2^{-k} \). Letting \( k \to \infty \), we obtain \( \beta \leq \alpha \). Thus \( \alpha \) is the greatest lower bound of the set \( B \). In other words, \( \inf B \) exists and is equal to \( \alpha \), as alleged. Assertion 1 is proved. The proof of Assertion 2 is similar. \( \square \)

**Lemma 10.2.3. (Logarithm of certain difference quotients).** Let

\[ 0 = \tau_0 < \cdots < \tau_{p-1} < \tau_p = 1 \]

be an arbitrary sequence in \([0, 1]\). Suppose the function \( \lambda \in \Lambda \) is linear on \([\tau_i, \tau_{i+1}]\) for each \( i = 0, \cdots, p - 1 \). Then

\[ \sup_{0 \leq s < t \leq 1} \left| \log \frac{\lambda t - \lambda s}{t - s} \right| = \alpha \equiv \sqrt[p-1]{\sum_{i=0}^{p-1} \left| \log \frac{\lambda \tau_{i+1} - \lambda \tau_i}{\tau_{i+1} - \tau_i} \right|}. \]  

\[ (10.2.4) \]

**Proof.** Let \( s, t \in \Lambda \equiv \bigcup_{i=0}^{p-1} (\tau_i, \tau_{i+1}] \) be arbitrary, with \( s < t \). Then \( \tau_i < s < \tau_{i+1} \) and \( \tau_j < t < \tau_{j+1} \) for some \( i, j = 0, \cdots, p - 1 \) with \( i \leq j \). Hence, in view of the linearity of \( \lambda \) on each of the intervals \([\tau_i, \tau_{i+1}]\) and \([\tau_j, \tau_{j+1}]\), we obtain

\[ \lambda t - \lambda s = (\lambda t - \lambda \tau_j) + (\lambda \tau_j - \lambda \tau_{j-1}) + \cdots + (\lambda \tau_{i+2} - \lambda \tau_{i+1}) + (\lambda \tau_{i+1} - \lambda s) \]

Yuen-Kwok Chan 323 Constructive Probability
\[ le e^a(t - \tau_j) + e^a(\tau_j - \tau_{j-1}) + \cdots + e^a(\tau_j - \tau_{j-1}) + e^a(\tau_{j+1} - s) \]
\[ = e^a(t - s). \]

Similarly \( \lambda t - \lambda s \geq e^{-a}(t - s) \). Thus
\[ e^{-a}(t - s) \leq \lambda t - \lambda s \leq e^a(t - s), \]
where \( s, t \in A \) with \( s < t \) are arbitrary. Since \( A \) is dense in \([0, 1]\), the last displayed inequality holds, by continuity, for each \( s, t \in [0, 1] \) with \( s < t \). Equivalently,
\[ |\log \frac{\lambda(t - \lambda s)}{t - s}| \leq \alpha \quad (10.2.5) \]
for each \( s, t \in [0, 1] \) with \( s < t \). At the same time, for each \( \varepsilon > 0 \), there exists \( j = 0, \cdots, m \) such that
\[ |\log \frac{\lambda\tau_{j+1} - \lambda\tau_j}{\tau_{j+1} - \tau_j}| > \alpha - \varepsilon. \]
Thus
\[ \alpha < |\log \frac{\lambda u - \lambda v}{u - v}| + \varepsilon \quad (10.2.6) \]
where \( u \equiv \tau_{j+1} \) and \( v \equiv \lambda \tau_j \). Since \( \varepsilon > 0 \) is arbitrary, inequalities \([10.2.5]\) and \([10.2.6]\) together imply the desired equality \([10.2.4]\) thanks to Lemma \([10.2.2]\). \( \square \)

Now some metric-like properties of the sets \( B_{x,y} \) introduced in Definition \([10.2.1]\).

**Lemma 10.2.4. (Metric-like properties of the sets \( B_{x,y} \)).** Let \( x, y, z \in D[0, 1] \) be arbitrary. Then \( B_{x,y} \) is nonempty. Moreover, the following holds.
1. \( 0 \in B_{x,y} \). More generally, if \( d(x, y) \leq b \) for some \( b \geq 0 \), then \( b \in B_{x,y} \).
2. \( B_{x,y} = B_{y,x} \).
3. Let \( c \in B_{x,y} \) and \( c' \in B_{x,z} \) be arbitrary. Then \( c + c' \in B_{x,z} \). Specifically, suppose \((c, \lambda) \in A_{x,y} \) and \((c', \lambda') \in A_{x,z} \) for some \( \lambda, \lambda' \in \Lambda \). Then \((c + c', \lambda, \lambda') \in A_{x,z} \).

**Proof.**
1. Let \( \lambda_0 : [0, 1] \rightarrow [0, 1] \) be the identity function. Then, trivially, \( \lambda_0 \) is admissible and \( d(x, x \circ \lambda_0) = 0 \). Hence \((0, \lambda_0) \in A_{x,z} \). Consequently, \( 0 \in B_{x,z} \). More generally, if \( d(x, y) \leq b \) then for some \( b \geq 0 \), then \( d(x, y \circ \lambda_0) = d(x, y) \leq b \), whence \( b \in B_{x,y} \).
2. Next consider each \( c \in B_{x,y} \). Then there exists \((c, \lambda) \in A_{x,y} \), satisfying inequalities \([10.2.1]\) and \([10.2.2]\). For each \( 0 \leq s < t \leq 1 \), if we write \( u \equiv \lambda^{-1}t \) and \( v \equiv \lambda^{-1}s \), then
\[ |\log \frac{\lambda^{-1}t - \lambda^{-1}s}{t - s}| = |\log \frac{u - v}{\lambda u - \lambda v}| = |\log \frac{\lambda u - \lambda v}{u - v}| \leq c. \quad (10.2.7) \]
Consider each \( t \in \text{domain}(y) \cap (\lambda^{-1})^{-1}\text{domain}(x) \). Then \( u \equiv \lambda^{-1}t \in \text{domain}(x) \cap \lambda^{-1}\text{domain}(y) \). Hence
\[ d(y(t), x(\lambda^{-1}t)) = d(y(\lambda u), x(u)) \leq c. \quad (10.2.8) \]
Thus \((c, \lambda^{-1}) \in A_{y,x} \). Consequently \( c \in B_{y,x} \). Since \( c \in B_{x,y} \) is arbitrary, we conclude that \( B_{x,y} \subset B_{y,x} \), and, by symmetry, that \( B_{x,y} = B_{y,x} \).
3. Consider arbitrary \( c \in B_{x,y} \) and \( c' \in B_{y,z} \). Then \((c, \lambda) \in A_{x,y} \) and \((c', \lambda') \in A_{y,z}\) for some \( \lambda, \lambda' \in \Lambda \). The composite function \( \lambda' \lambda \) on \([0, 1]\) then satisfies
\[
\left| \log \frac{\lambda' \lambda t - \lambda' \lambda s}{t - s} \right| = \left| \log \frac{\lambda' \lambda t - \lambda' \lambda s}{\lambda t - \lambda s} + \log \frac{\lambda t - \lambda s}{t - s} \right| \leq c + c'.
\]

Let \( r \in A \equiv \text{domain}(x) \cap \lambda^{-1} \text{domain}(y) \cap (\lambda' \lambda)^{-1} \text{domain}(z) \) be arbitrary. Then
\[
d(x(r), z(\lambda' \lambda r)) \leq d(x(r), y(\lambda r)) + d(y(\lambda r), z(\lambda' \lambda r)) \leq c + c'.
\]

By Proposition [10.1.4] the set \( A \) is dense in \([0, 1]\). It therefore follows from Lemma [10.1.3] that
\[
d(x, z \circ (\lambda' \lambda)) \leq c + c'.
\]

Combining, we see that \((c + c', \lambda' \lambda) \in B_{x,z}\). \(\square\)

**Definition 10.2.5. (Notations).** We will use the following notations.

1. Recall, from Definition 10.2.1, the set \( \Lambda \) of admissible functions on \([0, 1]\). Let \( \lambda_0 \in \Lambda \) be the identity function, i.e. \( \lambda_0 t = t \) for each \( t \in [0, 1] \). Let \( m' \geq m \) be arbitrary. Then \( \Lambda_{m,m'} \) will denote the finite subset of \( \Lambda \) consisting of functions \( \lambda \) such that (i) \( \lambda Q_m \subseteq Q_{m'} \), and (ii) \( \lambda \) is linear on \([q_{m,i}, q_{m,i+1}]\) for each \( i = 0, \cdots, p_m - 1 \).

2. Let \( B \) be an arbitrary compact subset of \((S,d)\), and let \( \delta : (0,\infty) \to (0,\infty) \) be an arbitrary operation. Then \( D_B \) will denote the subset of \( D[0,1] \) consisting of càdlàg functions \( x \) with values in the compact set \( B \) and with \( \delta \) as a modulus of càdlàg.

3. Let \( U \equiv \{u_1, \cdots, u_M\} \) be an arbitrary finite subset of \((S,d)\). Then \( D_{\text{simple}, m,U}[0, 1] \) will denote the finite subset of \( D[0, 1] \) consisting of simple càdlàg functions with values in \( U \) and with \( q_m \) as a sequence of division points.

4. Let \( \delta_{\log @ \cdot} \) be a modulus of continuity at 1 of the natural logarithm function \( \log \). Specifically, let \( \delta_{\log @ \cdot}(\epsilon) \equiv 1 - e^{-\epsilon} \) for each \( \epsilon > 0 \). Note that \( 0 < \delta_{\log @ \cdot} < 1 \). \( \square \)

The next lemma proves that \( \inf B_{x,y} \) exists for arbitrary simple càdlàg functions \( x,y \). With only finite searches, we need to give a constructive proof, along with a method of approximating the alleged infimum to arbitrary precision.

**Lemma 10.2.6.** \((d_D[0,1]) \) is well defined on \( D_{\text{simple}, m,U}[0, 1] \). Let \( M, m \geq 1 \) be arbitrary. Let \( U \equiv \{u_1, \cdots, u_M\} \) be an arbitrary finite subset of \((S,d)\). Let \( x,y \in D_{\text{simple}, m,U}[0, 1] \) be arbitrary. Then \( d_D(x,y) \equiv \inf B_{x,y} \) exists.

Specifically, take any \( b \geq \sqrt{m_{i-1}|d(u_i, u_j)|} \). Let \( (x_i)_{i=0, \cdots, p(m)-1} \) be an arbitrary sequence in \( U \), and consider the simple càdlàg function
\[
x \equiv \Phi_{\text{simple}}((q_{m,i})_{i=0,\cdots,p(m)-1}, (x_i)_{i=0,\cdots,p(m)-1}).
\]

Let \( k \geq 0 \) be arbitrary. Take \( m' \geq m \) so large that
\[
2^{-m'} \leq 2^{-m-2} e^{-b} \delta_{\log @ \cdot}(2^{-k}) < 2^{-m-2} e^{-b}.
\]

For each \( \nu \in \Lambda_{m,m'} \), define

Yuen-Kwok Chan 325 Constructive Probability
CHAPTER 10. A.U. CÀDLÀG PROCESSES

\[
\beta_v \equiv \bigvee_{i=0}^{p(m)-1} \left( \log \frac{v q_{m,i+1} - v q_{m,i}}{q_{m,i+1} - q_{m,i}} \right) \vee d(y(v q_{m,i}), x(q_{m,i})) \vee d(y(q_{m,i}), x(v^{-1} q_{m,i})).
\]

(10.2.10)

Then there exists \( v \in \Lambda_{m,m'} \) with \( (\beta_v, v) \in A_{x,y} \) such that \( d_P(x,y) \in [\beta_v - 2^{-k+1}, \beta_v] \).

Thus \( \beta_v \) is a \( 2^{-k+1} \)-approximation of \( d_P(x,y) \), and \( (d_P(x,y) + 2^{-k+1}, v) \in A_{x,y} \).

Proof. 1. Let \( m, k, m' \) be as given. For abbreviation, write \( \varepsilon \equiv 2^{-k} \), \( p \equiv p_m \equiv 2^m \), and

\[
\tau_i \equiv \xi_i \equiv q_{m,i} \equiv i2^{-m} \in Q_m
\]

for each \( i = 0, \cdots, p \). Similarly, write \( n \equiv p_{m'} \equiv 2^m', \Delta \equiv 2^{-m'} \), and

\[
\eta_j \equiv q_{m',j} \equiv j2^{-m'} \in Q_{m'}
\]

for each \( j = 0, \cdots, n \). Then, by hypothesis, \( x \equiv \Phi_{\text{simple}}((\tau_i)_{i=0,\cdots,p}, (x_i)_{i=0,\cdots,p-1}) \). Similarly,

\[
y \equiv \Phi_{\text{simple}}((\xi_j)_{j=0,\cdots,p}, (y_i)_{i=0,\cdots,p-1})
\]

for some sequence \( (y_i) \in U \). By the definition of simple càdlàg functions, we have \( x = x_i \) and \( y = y_i \) on \( [\tau_i, \tau_{i+1}] \equiv [\xi_j, \xi_{j+1}] \), for each \( i = 0, \cdots, p - 1 \). By hypothesis,

\[
b \geq \bigvee_{i,j=0}^{M} d(u_i, u_j) \geq \bigvee_{i,j=0}^{p-1} d(x_i, y_j) \geq d(x(t), y(t))
\]

for each \( t \in \text{domain}(x) \cap \text{domain}(y) \). Hence \( b \in B_{x,y} \) by Lemma[10.2.4]

Define

\[
\alpha_v \equiv \bigwedge_{v \in \Lambda(m,m')} \beta_v.
\]

We will prove that (i) \( \alpha_v \leq \varepsilon + 2^{-k} \) for each \( c \in B_{x,y} \), and (ii) \( c \leq \alpha_v + 2^{-k} \) for some \( c \in B_{x,y} \). It will then follow from Lemma[10.2.2] that \( \inf B_{x,y} \) exists, and that \( \inf B_{x,y} = \lim_{k \to \infty} \alpha_v \).

2. We will first prove Condition (i). To that end, let \( c \in B_{x,y} \) be arbitrary. Since \( b \in B_{x,y} \), there is no loss of generality in assuming that \( c \leq b \). Since \( c \in B_{x,y} \) by assumption, there exists \( \lambda \in \Lambda \) such that \( (c, \lambda) \in A_{x,y} \). In other words,

\[
|\log \frac{\lambda t - \lambda s}{t - s}| \leq c
\]

(10.2.11)

for each \( 0 \leq s < t \leq 1 \), and

\[
d(x, y \circ \lambda) \leq c.
\]

(10.2.12)

Consider each \( i = 1, \cdots, p - 1 \). There exists \( j_i = 1, \cdots, n - 1 \) such that

\[
\eta_{j_i-1} \leq \lambda \tau_i < \eta_{j_i+1}.
\]

(10.2.13)
Either (i')
\[ d(y(\eta_{j(i)}), x(\tau_i)) < d(y(\eta_{j(i)}), x(\tau_i)) + \epsilon, \]

or (ii')
\[ d(y(\eta_{j(i)}), x(\tau_i)) < d(y(\eta_{j(i)}), x(\tau_i)) + \epsilon. \]

In case (i'), define \( \zeta_i \equiv \eta_{j(i)} - 1 \). In case (ii'), define \( \zeta_i \equiv \eta_{j(i)} \). Then, in both Cases (i') and (ii'), we have
\[ \zeta_i - \Delta < \lambda \tau_i < \zeta_i + 2\Delta, \] (10.2.14)

and
\[ d(y(\zeta_i), x(\tau_i)) \leq d(y(\eta_{j(i)}), x(\tau_i)) \wedge d(y(\eta_{j(i)}), x(\tau_i)) + \epsilon. \] (10.2.15)

At the same time, in view of inequality [10.2.13], there exists a point
\[ s \in (\lambda \tau_i, \lambda \tau_i + 1) \cap \left( (\eta_{j(i)} - 1, \eta_{j(i)}) \cup (\eta_{j(i)}, \eta_{j(i)} + 1) \right). \]

Then \( t \equiv \lambda^{-1} s \in (\tau_i, \tau_i + 1) \), whence \( x(\tau_i) = x(t) \). Moreover, either \( s \in (\eta_{j(i)} - 1, \eta_{j(i)}) \), in which case \( y(\eta_{j(i)} - 1) = y(s) \), or \( s \in (\eta_{j(i)}, \eta_{j(i)} + 1) \), in which case \( y(\eta_{j(i)}) = y(s) \). In either case, inequality [10.2.13] yields
\[ d(y(\zeta_i), x(\tau_i)) \leq d(y(s), x(\tau_i)) + \epsilon = d(y(\lambda t), x(t)) + \epsilon \leq c + \epsilon, \] (10.2.16)

where the last inequality is from inequality [10.2.12]. Now let \( \zeta_0 \equiv 0 \) and \( \zeta_p \equiv 1 \). Then, for each \( i = 0, \ldots, p - 1 \), inequality [10.2.14] implies that
\[ \zeta_i - \Delta < \lambda \tau_i < \zeta_i + 2\Delta, \] (10.2.17)

\[ \zeta_{i+1} - \zeta_i > (\lambda \tau_i + 1 - 2\Delta) - (\lambda \tau_i + \Delta) > \lambda \tau_{i+1} - \lambda \tau_i - 4\Delta \]
\[ \geq e^{-c}(\tau_{i+1} - \tau_i) - 4\Delta \geq e^{-b} 2^m - 2^m + 2 \geq 0, \]

where the last inequality is from inequality [10.2.9]. Thus \( (\zeta_i)_{i=0,\ldots,p} \) is an increasing sequence in \( Q_m \). As such, it determines a unique function \( \mu \in \Lambda_{m,m'} \) which is linear on \( [\tau_i, \tau_{i+1}] \) for each \( i = 0, \ldots, p - 1 \), with \( \mu \tau_i \equiv \zeta_i \) for each \( i = 0, \ldots, p \). By Lemma [10.2.3], we then have
\[ \sup_{0 \leq s \leq t \leq 1} |\log \frac{\mu(t) - \mu(s)}{t - s}| \leq \int_{0}^{p-1} |\log \frac{\mu(\tau_{i+1}) - \mu(\tau_i)}{\tau_{i+1} - \tau_i}| \]
\[ = \int_{0}^{p-1} |\log(\lambda \tau_{i+1} - \lambda \tau_i) - \lambda (\tau_{i+1} - \tau_i)| \]
\[ \leq \int_{0}^{p-1} |\log(\lambda \tau_{i+1} - \lambda \tau_i) + \int_{0}^{p-1} |\log(\lambda \tau_{i+1} - \lambda \tau_i)| \]
\[ \leq c + \int_{0}^{p-1} |\log(1 + \frac{(\zeta_{i+1} - \lambda \tau_{i+1}) - (\zeta_i - \lambda \tau_i)}{\lambda \tau_{i+1} - \lambda \tau_i})| \]

Yuen-Kwok Chan 327 Constructive Probability
At the same time, relation (10.2.22) implies that
\[ \eta \text{ where we recall that} \mu \]
Separately, by the definition of \( \mu \), inequality (10.2.9). Hence
\[ \therefore \text{thanks again to inequality (10.2.9). Hence} \]
where the inequality on the right-hand side is from inequality (10.2.14) applied to \( i'' \).

We will proceed to verify also that

\[ \text{Combining the last two displayed inequalities, we see that there exists a point} \]
where we recall that \( \xi \equiv \tau_i \equiv q_{m,i} \equiv t \leq m' \in Q_m \), for each \( i = 0, \cdots, p - 1 \). To that end, consider each \( j = 1, \cdots, p - 1 \). Then, for each \( i = 0, \cdots, p - 1 \), we have \( \xi_j, \mu \tau_i \equiv \xi \in Q_m'. \) Hence
\[ \text{for some} \ i = 0, \cdots, p - 1. \text{ Either} (i'') \ \xi_j = \xi, \text{ or} (ii'') \ \xi_j \geq \xi_i + \Delta. \text{ First consider Case} \]
\[ \therefore \text{by inequality (10.2.16) Now consider Case (iii’). Then, in view of inequality (10.2.14)} \]
we obtain
\[ \lambda \tau_i < \xi_i + 2\Delta \leq \xi_i + \Delta. \]
At the same time, relation (10.2.22) implies that \( \xi_j < \xi_{i+1} \). Hence
\[ \xi_j \leq \xi_{i+1} - \Delta < \lambda \tau_{i+1}, \]
where the inequality on the right-hand side is from inequality (10.2.14) applied to \( i + 1 \).
Combining the last two displayed inequalities, we see that there exists a point
\[ s \in [\lambda \tau_i \vee \xi_j, \lambda \tau_{i+1} \wedge (\xi_j + \Delta)]. \]
It follows that \( s \in [\xi_j, \xi_j + \Delta) \subset [\zeta_i, \zeta_{i+1}) \), and that \( r = \lambda^{-1}s \in [\tau_i, \tau_{i+1}) \). Therefore \( y(s) = y(\xi_j) \) and \( x(r) = x(\tau_i) \) by the definition of the simple càdlàg functions \( x \) and \( y \). Moreover, 
\[
\mu^{-1} \xi_j \in [\mu^{-1} \zeta_i, \mu^{-1} \zeta_{i+1}) \equiv [\tau_i, \tau_{i+1}),
\]
whence \( x(\mu^{-1} \xi_j) = x(\tau_i) \). Combining, we obtain
\[
d(y(\xi_j), x(\mu^{-1} \xi_j)) = d(y(s), x(\tau_i)) = d(y(s), x(r)) = d(y(\lambda r), x(r)) \leq c + \varepsilon,
\]
where \( j = 1, \cdots, p - 1 \) is arbitrary. Thus we have verified inequality \ref{eq:inequality10.2.21}

Inequalities \ref{eq:inequality10.2.19} \ref{eq:inequality10.2.20} and \ref{eq:inequality10.2.21} together imply that
\[
\beta_\mu = \frac{1}{p} \sum_{i=0}^{p-1} \left| \log \frac{\mu \tau_{i+1} - \mu \tau_i}{\tau_{i+1} - \tau_i} \right| \leq \beta_v \leq \frac{1}{p} \sum_{i=0}^{p-1} \left| \log \frac{\nu \tau_{i+1} - \nu \tau_i}{\tau_{i+1} - \tau_i} \right| \equiv \beta_v \leq \frac{1}{p} \sum_{i=0}^{p-1} \left| \log \frac{\nu \tau_{i+1} - \nu \tau_i}{\tau_{i+1} - \tau_i} \right| = \beta_v < \alpha_k + \varepsilon.
\]

Hence \( \alpha_k \equiv \bigwedge_{v \in \Lambda_{m,m'}} \beta_v \leq c + \varepsilon \), where \( c \in B_{x,y} \) is arbitrary. The desired Condition (i) is established.

3. Since \( \Lambda_{m,m'} \) is a finite set, there exists \( v \in \Lambda_{m,m'} \) such that \( \beta_v < \alpha_k + \varepsilon \). Thus
\[
\beta_v = \left\{ \frac{1}{p} \sum_{i=0}^{p-1} \left| \log \frac{\nu \tau_{i+1} - \nu \tau_i}{\tau_{i+1} - \tau_i} \right| \right\} \equiv \beta_v < \alpha_k + \varepsilon.
\]

Then, by Lemma \ref{lemma:lemma10.2.3} we have
\[
\sup_{0 \leq s < t \leq 1} \left| \log \frac{vt - vs}{t - s} \right| = \frac{1}{p} \sum_{i=0}^{p-1} \left| \log \frac{\nu \tau_{i+1} - \nu \tau_i}{\tau_{i+1} - \tau_i} \right| \leq \beta_v.
\]

We will show that \( d(y \circ v, x) \leq \beta_v \). To that end, consider each point \( t \) in the dense subset \( A \equiv Q_m^r \cup v^{-1}Q_m^r \) of \([0,1]\). Then
\[
t \in [\tau_i, \tau_{i+1}) \cap v^{-1}([\xi_j, \xi_{j+1})]
\]
for some \( i, j = 0, \cdots, p - 1 \). It follows that either (i"") \( v^{-1} \xi_j \leq \tau_i \), or (ii"") \( \tau_i < v^{-1} \xi_j \). In Case (i"") we have \( \xi_j \leq v \tau_i \leq vt < \xi_{j+1} \), whence
\[
d(y(vt), x(t)) = d(y(v \tau_i), x(\tau_i)) \leq \beta_v,
\]
where we used the definition of simple càdlàg functions. In Case (ii"") \ref{eq:inequality10.2.22} implies that \( \tau_i < v^{-1} \xi_j \leq t < \tau_{i+1} \), whence
\[
d(y(vt), x(t)) = d(y(\xi_j), x(v^{-1} \xi_j)) \leq \beta_v,
\]
where we used, once more, the definition of simple càdlàg functions. Since \( t \) is an arbitrary member of the dense subset \( A \) of \([0,1]\), we conclude that
\[
d(y \circ v, x) \leq \beta_v
\]
Combining with inequality \ref{eq:inequality10.2.22} we conclude that \( (\beta_v, v) \in A_{x,y} \). Since \( \beta_v < \alpha_k + 2^{-k} \), it follows that \( c \equiv \alpha_k + 2^{-k} \in B_{x,y} \), thus proving Condition (ii).
4. Since $k \geq 0$ is arbitrary, it follows from Lemma 10.2.2 that both $\lim_{k \to \infty} \alpha_k$ and $d_D(x,y) = \inf_{B \in \mathcal{B}}$ exist, and are equal to each other.

5. Finally, let $c \in B_{x,y}$ be arbitrary. Then, by Step 2, there exists $\mu \in \Lambda_{m,m'}$ such that $\beta_\mu \leq c + \varepsilon \equiv c + 2^{-k}$. By Step 3, there exists $\nu \in \Lambda_{m,m'}$ with $\beta_\nu < \alpha_k + 2^{-k} - \beta_\mu + 2^{-k}$ such that $(\beta_\nu, \nu) \in A_{x,y}$. Combining, $\beta_\nu < c + 2^{-k+1}$. Since $c \in B_{x,y}$ is arbitrary, it follows that $d_D(x,y) = 2^{-k+1}$. In other words, $\beta_\nu \leq d_D(x,y) + 2^{-k+1}$. Summing up, we have $\nu \in \Lambda_{m,m'}$ with $(\beta_\nu, \nu) \in A_{x,y}$, such that $d_D(x,y) \leq \beta_\nu - 2^{-k+1}, \beta_\nu$. The Lemma is proved. \hfill \Box

The next lemma prepares for a subsequent generalization of Arzela-Ascoli Theorem to càdlàg functions.

**Lemma 10.2.7. (Preparatory lemma for Arzela-Ascoli Theorem for $D[0,1]$).** Let $B$ be an arbitrary compact subset of $(S,d)$. Let $k \geq 0$ be arbitrary. Let $U \equiv \{ v_1, \ldots, v_M \}$ be a $2^{-k-1}$-approximation of of $B$. Let $x \in D[0,1]$ be arbitrary with values in the compact set $B$ and with a modulus of càdlàg $\delta_{cdlg}$. Let $m \geq 1$ be so large that

$$m \equiv m(k, \delta_{cdlg}) \equiv \lfloor 1 - \log_2 (\delta_{cdlg}(2^{-k}) \delta_{cdlg}(2^{-k-1})) \rfloor_+.$$

Then there exist an increasing sequence $(\eta_i)_{i=0,\ldots,n-1}$ in $Q_m$, and a sequence $(u_i)_{i=0,\ldots,n-1}$ in $U$, such that

$$2^{-k} \in B_{x,\tau},$$

where

$$\tau \equiv \Phi_{\text{simple}}((\eta_i)_{i=0,\ldots,n-1},(u_i)_{i=0,\ldots,n-1}) \in D_{\text{simple},m,U}[0,1].$$

**Proof.** Let $k,m$ be as given. Then

$$2^{-m} < 2^{-1} \delta_{\text{log@1}}(2^{-k}) \delta_{\text{cdlg}}(2^{-k-1}). \tag{10.2.26}$$

For abbreviation, write $\varepsilon \equiv 2^{-k}, p \equiv p_m \equiv 2^m$, and $(q_0, \ldots, q_p) \equiv (0, 2^{-m}, 2^{-m-1}, \ldots, 1)$. By Definition 10.1.2, there exists a sequence of $\xi$-division points $(\tau_i)_{i=0,\ldots,n}$ of the càdlàg function $x$, with separation at least $\delta_{\text{cdlg}}(\xi)$. Thus

$$\bigwedge_{i=0}^{n-1} (\tau_{i+1} - \tau_i) \geq \delta_{\text{cdlg}}(\xi), \tag{10.2.27}$$

Define $\eta_0 \equiv 0$ and $\eta_n \equiv 1$. Consider each $i = 1, \ldots, n-1$. Then there exists $j_i = 1, \ldots, p - 1$ such that $\tau_i \in (q_{j(i)-1}, q_{j(i)+1})$. Define $\eta_i \equiv q_{j(i)} \in Q_m$. Then

$$|\eta_i - \tau_i| < 2^{-m} < 2^{-1} \delta_{\text{log@1}}(2^{-k}) \delta_{\text{cdlg}}(2^{-k-1}) < 2^{-1} \delta_{\text{cdlg}}(2^{-k-1}) \equiv \frac{1}{2} \delta_{\text{cdlg}}(\xi).$$

In view of inequality 10.2.27 it follows that

$$\bigwedge_{i=0}^{n-1} (\eta_{i+1} - \eta_i) > \bigwedge_{i=0}^{n-1} (\tau_{i+1} - \tau_i) - \delta_{\text{cdlg}}(\xi) \geq 0.$$
Thus \((\eta_i)_{i=0, \ldots, n}\) is an increasing sequence in \([0, 1]\). Therefore we can define the increasing function \(\nu \in \Lambda\) by (i) \(\nu \tau_i = \eta_i\) for each \(i = 0, \ldots, n\), and (ii) \(\nu\) is linear on 
\([\tau_i, \tau_{i+1}]\) for each \(i = 1, \ldots, n-1\).

By Lemma 10.2.3,

\[
\sup_{0 \leq s < t \leq 1} \left| \log \frac{\nu t - \nu s}{t - s} \right| = \sum_{j=0}^{n-1} \left| \log \frac{\nu \tau_{i+1} - \nu \tau_i}{\tau_{i+1} - \tau_i} \right|
\]

\(= \sum_{i=0}^{n-1} \left| \log \frac{\eta_{i+1} - \eta_i}{\tau_{i+1} - \tau_i} \right| = \sum_{i=0}^{n-1} \left| \log (1 + a_i) \right|\) \quad (10.2.28)

where, for each \(i = 0, \ldots, n-1\),

\[a_i \equiv \frac{(\eta_{i+1} - \tau_{i+1}) - (\eta_i - \tau_i)}{\tau_{i+1} - \tau_i},\]

with

\[|a_i| \leq \frac{2^{-m+1}}{\tau_{i+1} - \tau_i} < 2^{-m+1} \cdot \delta \cdot \log \left( \frac{\frac{\varepsilon}{2}}{\tau_{i+1} - \tau_i} \right) \leq \delta \cdot \log(1 + \varepsilon),\]

where the inequality is from the hypothesis. Hence \(|\log(1 + a_i)| \leq \varepsilon\) for each \(i = 0, \ldots, n-1\) by the definition of the definition of the modulus of continuity \(\delta \cdot \log(1 + \varepsilon)\) in Definition 10.2.5. Inequality (10.2.28) therefore yields

\[
\sup_{0 \leq s < t \leq 1} \left| \log \frac{\nu t - \nu s}{t - s} \right| \leq \varepsilon. \quad (10.2.29)
\]

Next, by hypothesis, the càdlàg function \(x\) has values in the compact set \(B\), and that \(U \equiv \{v_1, \ldots, v_M\}\) is an \(2^{-k-1}\)-approximation of \(B\). Hence, for each \(i = 0, \ldots, n-1\), there exists \(u_i \in U\) such that \(d(u_i, x(\tau_i)) < 2^{-k-1} \equiv \frac{\varepsilon}{2}\). Also by hypothesis, we have

\[x \equiv \Phi_{\text{simple}}((\eta_i)_{i=0, \ldots, n-1}, (u_i)_{i=0, \ldots, n-1}) \in D_{\text{simple, m}, U}[0, 1].\]

We will prove that \((\varepsilon, v) \in A_{x, \pi}\) and therefore that \(\varepsilon \in B_{x, \pi}\). To that end, consider each \(i = 0, \ldots, n-1\) and each \(\tau \in [\tau_i, \tau_{i+1}]\). Then \(\nu \tau \in [\eta_i, \eta_{i+1}]\). Hence

\[d(x(\tau), \pi(\nu)) \leq d(x(\tau), x(\tau_i)) + d(x(\tau_i), u_i) + d(u_i, \pi(\eta_i)) + d(\pi(\eta_i), \pi(\nu)) < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} + 0 + 0 = \varepsilon.\]

Since the set \(A \equiv \bigcup_{i=0}^{m} [\tau_i, \tau_{i+1}]\) is dense in \([0, 1]\), Lemma 10.1.3 implies that

\[d(x, \pi \circ v) \leq \varepsilon.\]

Combining with inequality (10.2.29) we see that \((\varepsilon, v) \in A_{x, \pi}\). It follows that \(\varepsilon \in B_{x, \pi}\). The lemma is proved. \(\square\)

The next lemma proves the existence of \(\inf B_{x, y}\) for each \(x, y \in D[0, 1]\). The next proposition then verifies that the Skorokhod metric is indeed a metric.
Lemma 10.2.8. (Skorokhod metric is well defined). Let \( x, y \in D[0, 1] \) be arbitrary. Then the infimum \( d_D[0,1](x,y) \equiv \inf B_{\bar{x},y} \) in Definition 10.2.4 exists.

Proof. Let \( \delta \equiv \delta_{dlg} \) be a common modulus of càdlàg of \( x \) and \( y \). Let \( k > 0 \) be arbitrary and write \( \varepsilon \equiv 2^{-k} \). Take \( m \geq 1 \) large enough to satisfy inequality \( 10.2.26 \) in Lemma 10.2.4. By Lemma 10.2.7 there exists \( b \geq 0 \) such that \( d(x,x_c) \vee d(y,y_c) \leq b \). Since \((S,d)\) is locally compact, the bounded set \((d(\cdot,x_c) \leq b)\) is contained in some compact subset \( B \) of \( S \). Hence \( x, y \in D_{B,\delta}[0,1] \). Let \( U \equiv \{n_1, \cdots, n_M \} \) be an \( \mathcal{F}_\varepsilon \)-approximation of \( B \). Then, according to Lemma 10.2.5 there exists \( \bar{s}, \bar{y} \in D_{\text{simple},m,U}[0,1] \) such that \( \varepsilon \in B_{\bar{s},\bar{y}} \) and \( \varepsilon \in B_{\bar{s},\bar{y}} \). At the same time, by Lemma 10.2.6 the infimum \( \alpha \equiv \inf B_{\bar{s},\bar{y}} \) exists.

Now let \( c \in B_{x,y} \) be arbitrary. Then \( c + \varepsilon + \varepsilon \in B_{\bar{s},\bar{y}} \) by Lemma 10.2.4. Hence \( \alpha \leq c + 2\varepsilon \). Conversely, take any \( \bar{x} \in B_{\bar{s},\bar{y}} \) such that \( \bar{x} < \inf B_{\bar{s},\bar{y}} + \varepsilon \equiv \alpha + \varepsilon \). Then \( c \equiv \bar{x} + \varepsilon + \varepsilon \in B_{x,y} \) by Lemma 10.2.4. Hence \( c \equiv \bar{x} + 2\varepsilon < \alpha + 3\varepsilon \). Since \( \varepsilon \equiv 2^{-k} > 0 \) is arbitrarily small, \( 10.2.26 \) implies that \( \inf B_{x,y} \) exists.

Proposition 10.2.9. (Skorokhod metric is indeed a metric). \( (D[0,1],d_D) \) is a metric space. Moreover, if \( x, y \in D[0,1] \) are such that \( d_D(x,y) \leq c \) on a dense subset of \( \text{domain}(x) \cap \text{domain}(y) \), then \( d_D(x,y) \leq c \).

Proof. Let \( x, y, z \in D[0,1] \) be arbitrary. Let \( \delta_{dlg} \) be a common modulus of càdlàg of \( x, y \) and \( z \). By Lemma 10.2.8 \( d_D(x,y) \equiv \inf B_{\bar{x},y} \) exists. By Lemma 10.2.4 we have \( 0 \in B_{x,y} \equiv B_{\bar{x},y} \). It follows immediately that \( d_D(x,x) = 0 \) and \( d_D(x,y) = d_D(y,x) \). Now let \( \varepsilon > 0 \) be arbitrary. By the definition of infimums, there exist \( c \in B_{x,y} \) and \( c' \in B_{y,z} \) such that \( c < \inf B_{x,y} + \varepsilon \equiv d_D(x,y) + \varepsilon \) and \( c' < \inf B_{y,z} + \varepsilon \equiv d_D(y,z) + \varepsilon \). Hence, again by Lemma 10.2.4 we have

\[
d_D(x,z) \equiv \inf B_{x,z} \leq c + c' < d_D(x,y) + \varepsilon + d_D(y,z) + \varepsilon.
\]

Since \( \varepsilon > 0 \) is arbitrary, it follows that \( d_D(x,z) \leq d_D(x,y) + d_D(y,z) \).

It remains to prove that if \( d_D(x,y) = 0 \) then \( x = y \). To that end, suppose \( d_D(x,y) = 0 \). Let \( \varepsilon > 0 \) be arbitrary. Let \( (\tau_i)_{i=1,\cdots,p} \) and \( (\eta_j)_{j=1,\cdots,n} \) be sequences of \( \varepsilon \)-division points of \( x,y \) respectively. Let \( m \geq \varepsilon^{-1/2} \) be arbitrary. Consider each \( k \geq m \vee 2 \). Then \( \varepsilon_k \equiv k^{-2} \leq m^{-2} \leq \varepsilon \). Moreover, since \( d_D(x,y) = 0 < \varepsilon_k \), we have \( \varepsilon_k \in B_{x,y} \). Therefore there exists, by Definition 10.2.4 some \( \lambda_k \in \Lambda \) such that

\[
\left| \log \frac{\lambda_k r - \lambda_k s}{r-s} \right| \leq \varepsilon_k \quad \text{(10.2.30)}
\]

for each \( r, s \in [0,1] \) with \( s \leq r \), and such that

\[
d(x(t), y(\lambda_k t)) \leq \varepsilon_k \quad \text{(10.2.31)}
\]

for each \( t \in \text{domain}(x) \cap \lambda_k^{-1}\text{domain}(y) \). Then inequality \( 10.2.30 \) implies that

\[
e^{-\varepsilon(k)} r \leq \lambda_k r \leq e^{\varepsilon(k)} r, \quad \text{(10.2.32)}
\]

for each \( r \in [0,1] \). Define

\[
C_k \equiv \left\{ \bigcup_{j=0}^{n} [e^{-\varepsilon(k)} \eta_j, e^{\varepsilon(k)} \eta_j] \right\}.
\]

Yuen-Kwok Chan 332 Constructive Probability
where the superscript \( c \) signifies the measure-theoretic complement of a Lebesgue measurable set in \([0,1]\). Let \( \mu \) denote the Lebesgue measure on \([0,1]\). Then

\[
\mu(C_k) \geq 1 - \sum_{i=0}^{n} (e^{\epsilon(k)} \eta_j - e^{-\epsilon(k)} \eta_j)
\]

\[
\geq 1 - \sum_{j=0}^{n} (e^{\epsilon(k)} - e^{-\epsilon(k)}) \geq 1 - (n+1)(e^{2\epsilon(k)} - 1) \geq 1 - 2(n+1)e\epsilon_k \equiv 1 - 2(n+1)e\epsilon k^{-2},
\]

where \( k \geq m \) is arbitrary, and where we used the elementary inequality \( e^{r} - 1 \leq er \) for each \( r \in (0,1) \).

Define

\[
C \equiv \bigcup_{h=m}^{\infty} \bigcap_{k=h+1}^{\infty} C_k.
\]

Then

\[
\mu(C^c) \leq \sum_{k=h+1}^{\infty} \mu(C_k) \leq \sum_{k=h+1}^{\infty} 2(n+1)e\epsilon k^{-2} = 2(n+1)e\epsilon h^{-1}
\]

for each \( h \geq m \). Hence \( \mu(C^c) = 0 \) and \( C \) is a full subset of \([0,1] \). Consequently

\[
A \equiv C \cap \text{domain}(x) \cap \text{domain}(y) \cap \bigcap_{k=m}^{\infty} \lambda_k^{-1} \text{domain}(y)
\]

is a full subset of \([0,1] \) and, as such, is dense in \([0,1] \). Now let \( t \in A \) be arbitrary. Let \( h \geq m \) be arbitrary. Then there exists \( k \geq h \) such that \( t \in C_k \). Hence there exists \( j = 0, \ldots, n-1 \) such that \( t \in (e^{\epsilon(k)} \eta_j, e^{-\epsilon(k)} \eta_{j+1}) \). It then follows from inequality \( \text{[10.2.32]} \) that

\[
\eta_j < e^{-\epsilon(k)} t \leq \lambda_k t \leq e^{\epsilon(k)} t < \eta_{j+1},
\]

whence

\[
\lambda_k t, t \in (\eta_j, \eta_{j+1}).
\]

Therefore

\[
d(x(t), y(t)) = d(x(t), y(\lambda_k t)) + d(y(\lambda_k t), y(t)) \leq \epsilon_k + 2\epsilon \leq 3\epsilon,
\]

where \( t \in A \) is arbitrary. Since \( \epsilon > 0 \) is arbitrary, we see that \( x = y \) on the dense subset \( A \). It follows from Lemma \( \text{[10.1.3]} \) that \( x = y \). Summing up, we conclude that \( d_D \) is a metric.

Finally, suppose \( x, y \in D[0,1] \) are such that \( d(x(t), y(t)) \leq c \) for each \( t \) in a dense subset of \( \text{domain}(x) \cap \text{domain}(y) \). Then \( c \in B_{x, y} \) by Lemma \( \text{[10.2.4]} \). Hence \( d_D(x,y) \equiv \inf B_{x,y} \leq c \). The Proposition is proved.
Then there exist an increasing sequence \((\eta_i)_{i=0,\ldots,n-1}\) in \(Q_m\), and a sequence \((u_i)_{i=0,\ldots,n-1}\) in \(U\), such that
\[
d_{D[0,1]}(x,\tau) < 2^{-k},
\]
where
\[
\tau \equiv \Phi_{\text{simple}}((\eta_i)_{i=0,\ldots,n-1},(u_i)_{i=0,\ldots,n-1}) \in D_{\text{simple},m,U}[0,1].
\]

Proof. By Lemma \([10.2.7]\) there exist an increasing sequence \((\eta_i)_{i=0,\ldots,n-1}\) in \(Q_m\), and a sequence \((u_i)_{i=0,\ldots,n-1}\) in \(U\), such that \(2^{-k} \in B_{\eta,\tau}\). At the same time \(d_{D[0,1]}(x,\tau) \equiv \inf B_{x,\tau}\) according to Definition \([10.2.1]\). Hence \(d_{D[0,1]}(x,\tau) < 2^{-k}\), as desired. \(\square\)

**Theorem 10.2.11. (Skorokhod space is Complete).** The Skorokhod space \((D[0,1],d_D)\) is complete.

Proof. 1. Let \((y_k)_{k=1,2,\ldots}\) be an arbitrary Cauchy sequence in \((D[0,1],d_D)\). We need to prove that \(d_D(y_k,y) \to 0\) for some \(y \in D[0,1]\). Since \((y_k)_{k=1,2,\ldots}\) is Cauchy, it suffices to show that some subsequence converges. Hence, by passing to a subsequence if necessary, there is no loss in generality in assuming that
\[
d_D(y_k,y_{k+1}) < 2^{-k} \tag{10.2.33}
\]
for each \(k \geq 1\). Let \(\delta_k \equiv \delta_{d_D,k}\) be a modulus of càdlàg of \(y_k\), for each \(k \geq 1\). We may assume, again without loss of generality, that \(\delta_k \leq 1\) for each \(k \geq 1\). For convenience, let \(y_0 \equiv x_0\) denote the constant càdlàg function on \([0,1]\).

2. Let \(k \geq 1\) be arbitrary. Then
\[
d_D(y_0,y_k) \leq d_D(y_0,y_1) + 2^{-1} + \cdots + 2^{-k+1} < b_0 \equiv d_D(y_0,y_1) + 1.
\]
Hence \(d(x_0,y_k(t)) \leq b_0\) for each \(t \in \text{domain}(y_k)\). Thus the values of \(y_k\) are contained in some compact subset \(B\) of \((S,d)\) which contains \((d(x_0,\cdot) \leq b_0)\). Define \(b \equiv 2b_0\). Then \(d(y_k(t),y_k(s)) \leq 2b_0 \equiv b\), for each \(t \in \text{domain}(y_k), s \in \text{domain}(y_k)\), for each \(h,k \geq 0\).

3. Next, refer to Definition \([9.0.2]\) for notations related to dyadic rationals, and refer to Definition \([10.2.1]\) for the notations related to the Skorokhod metric. In particular, for each \(x,y \in D[0,1]\), recall the sets \(A_{x,y}\) and \(B_{x,y}\). Thus \(d_D(x,y) \equiv \inf B_{x,y}\). Let \(\lambda_0 \in \Lambda\) denote the identity function on \([0,1]\).

4. The next two steps will replace the sequence \((y_k)_{k=0,1,\ldots}\) with a sequence \((x_k)_{k=0,1,\ldots}\) of simple càdlàg functions with division points which are dyadic rationals in \([0,1]\). To that end, take an arbitrary \(m_0 \geq 0\), and, inductively for each \(k \geq 1\), take \(m_k \geq 1\) so large that
\[
2^{-m(k)} < 2^{-m(k-1)} - e^{-h} \delta_{d_D,k}(2^{-k-1}) \tag{10.2.34}
\]
5. Define \(x_0 \equiv y_0 \equiv x_0\). Let \(k \geq 1\) be arbitrary, and write \(n_k \equiv p_{m(k)}\). Then
\[
2^{-m(k)} < 2^{-1} \delta_{d_D,k}(2^{-k-1}).
\]
Hence Theorem \([10.2.10]\) the Arzela-Ascoli Theorem for the Skorokhod space, applies to the càdlàg function \(y_k\), to yield a simple càdlàg function \(x_k\) with the sequence
\[
\tau_k \equiv (\tau_k,0,\tau_k,1,\cdots,\tau_k,n(k)-1) \equiv q_{m(k)}(0,0,\cdots,q_{m(k)},n(k)-1)
\]
of dyadic rationals as division points, such that
\[ d_D(y_k, x_k) \leq 2^{-k}. \quad (10.2.35) \]

It follows that
\[ d_D(x_k, x_{k+1}) \leq d_D(x_k, y_k) + d_D(y_k, x_{k+1}) + d_D(x_{k+1}, s_k+1) \]
\[ < 2^{-k} + 2^{-k} + 2^{-k-1} < 2^{-k+2}. \quad (10.2.36) \]

Moreover, since \( x_0 \equiv x_o \equiv y_0 \), we have
\[ d_D(x_0, x_k) \leq d_D(y_0, y_k) + 2^{-k} \]
\[ < d_D(y_0, y_1) + d_D(y_1, y_2) + \cdots + d_D(y_{k-1}, y_k) + 2^{-k} \]
\[ < d_D(y_0, y_1) + 2^{-1} + \cdots + 2^{-k+1} + 2^{-k} < b_0 \equiv d_D(y_0, y_1) + 1. \]

Thus \( d(x_0, x_k(t)) \leq b_0 \) for each \( t \in \text{domain}(x_k) \). Consequently,
\[ d(x_k(t), x_h(s)) \leq b \equiv 2b_0 \quad (10.2.37) \]
for each \( t \in \text{domain}(x_k), s \in \text{domain}(x_h) \), for each \( h, k \geq 0 \).

6. Now let \( k \geq 0 \) be arbitrary. We will construct \( \lambda_{k+1} \in \Lambda_{m(k+1),m(k+2)} \) such that
\[ (2^{-k+2}, \lambda_{k+1}) \in A_{s(k),x(k+1)} \quad (10.2.38) \]

To that end, note that \( x_k, x_{k+1} \in D_{\text{simple},m(k+1),U}[0,1] \), where \( U \) is the finite subset of \( S \) consisting of the values of the two simple càdlàg functions \( x_k, x_{k+1} \). Then \( \bigvee_{u, v \in U} d(u, v) \leq b_0 \) in view of inequality \( 10.2.37 \). At the same time, applying inequality \( 10.2.34 \) to \( k+2 \) in place of \( k \), we obtain
\[ 2^{-m(k+2)} \leq 2^{-m(k+1)} - e^{-b} \delta_{\log@1}(2^{-k+2}). \quad (10.2.39) \]

Hence we can apply Lemma \( 10.2.6 \) to the quintuple \( (m_{k+1}, m_{k+2}, k+2, x_k, x_{k+1}) \) in place of the quintuple \( (m, m', k, x, y) \) there, to construct some \( \lambda_{k+1} \in \Lambda_{m(k+1),m(k+2)} \) such that
\[ (d_D(x_k, x_{k+1}) + 2^{-k-1}, \lambda_{k+1}) \in A_{s(k),x(k+1)}. \quad (10.2.40) \]

Since, from inequality \( 10.2.36 \) we have
\[ d_D(x_k, x_{k+1}) + 2^{-k-1} < (2^{-k} + 2^{-k} + 2^{-k-1}) + 2^{-k-1} < 2^{-k+2}, \]
relation \( 10.2.40 \) trivially implies the desired relation \( 10.2.38 \). Consequently,
\[ |\log \frac{\lambda_{k+1} t - \lambda_{k+1} s}{t - s}| \leq 2^{-k+2} \quad (10.2.41) \]
for each \( s, t \in [0,1] \) with \( s < t \), and
\[ d(x_k(t), x_{k+1}(t)) \leq 2^{-k+2} \quad (10.2.42) \]

Yuen-Kwok Chan 335 Constructive Probability
for each \( t \in \text{domain}(x_k) \cap \lambda_{k+1}^{-1} \text{domain}(x_{k+1}). \)

7. For each \( k \geq 0 \), define the composite admissible function

\[
\mu_k \equiv \lambda_k \lambda_{k-1} \cdots \lambda_0 \in \Lambda.
\]

We will prove that \( \mu_k \to \mu \) uniformly on \([0, 1]\) for some \( \mu \in \Lambda \). To that end, let \( h > k \geq 0 \) be arbitrary. By Lemma 10.2.4, relation 10.2.38 implies that

\[
(2^{-k+2} + 2^{-k+1} + \cdots + 2^{-h+3}, \lambda_h \lambda_{h-1} \cdots \lambda_{k+1}) \in A_{\xi(k), \eta(h)}.
\]

Hence, since \( 2^{-k+2} + 2^{-k+1} + \cdots + 2^{-h+3} < 2^{-k+3} \), we also have

\[
(2^{-k+3}, \lambda_h \lambda_{h-1} \cdots \lambda_{k+1}) \in A_{\xi(k), \eta(h)}. \tag{10.2.43}
\]

Let \( t, s \in [0, 1] \) be arbitrary with \( s < t \). Write \( t' \equiv \mu_k t \) and \( s' \equiv \mu_k s \). Then

\[
\left| \log \frac{\mu_k t - \mu_k s}{\mu_k t - \mu_k s'} \right| = \left| \log \frac{\lambda_h \lambda_{h-1} \cdots \lambda_{k+1} t' - \lambda_h \lambda_{h-1} \cdots \lambda_{k+1} s'}{t' - s'} \right| < 2^{-k+3}. \tag{10.2.44}
\]

Equivalently,

\[
\exp(-2^{-k+3})(t' - s') < \lambda_h \lambda_{h-1} \cdots \lambda_{k+1} t' - \lambda_h \lambda_{h-1} \cdots \lambda_{k+1} s' < \exp(2^{-k+3})(t' - s') \tag{10.2.45}
\]

for each \( t', s' \in [0, 1] \) with \( s' < t' \). In the special case where \( s = 0 \), inequality 10.2.44 reduces to

\[
\left| \log \mu_k t - \log \mu_k s \right| = \left| \log \frac{\mu_k t}{\mu_k s} \right| < 2^{-k+3}. \tag{10.2.46}
\]

Hence the limit

\[
\mu t \equiv \lim_{h \to \infty} \mu_k t
\]

exists, where \( t \in (0, 1] \) is arbitrary. Moreover, letting \( k = 0 \) and \( h \to \infty \) in inequality 10.2.44, we obtain

\[
\left| \log \frac{\mu t - \mu s}{t - s} \right| \leq 3 = 8. \tag{10.2.47}
\]

Therefore \( \mu \) is an increasing function which is uniformly continuous on \((0, 1]\). Furthermore,

\[
te^{-8} \leq \mu t \leq te^8
\]

where \( t \in (0, 1] \) is arbitrary. Hence \( \mu \) can be extended to a continuous increasing function on \([0, 1]\), with \( \mu 0 = 0 \). Since \( \mu_k 1 = 1 \) for each \( k \geq 0 \), we have \( \mu 1 = 1 \). In view of inequality 10.2.47, we conclude that \( \mu \in \Lambda \).

8. By letting \( h \to \infty \) in inequality 10.2.44, we obtain

\[
\left| \log \frac{\mu t - \mu s}{\mu_k t - \mu_k s} \right| \leq 2^{-2+3} \tag{10.2.48}
\]
where \( t, s \in [0, 1] \) are arbitrary with \( s < t \). Replacing \( t, s \) by \( \mu^{-1}_k t, \mu^{-1}_k s \) respectively, we obtain

\[
|\log \frac{\mu_k \mu^{-1}_k t - \mu_k \mu^{-1}_k s}{t - s}| = |\log \frac{t - s}{\mu_k \mu^{-1}_k t - \mu_k \mu^{-1}_k s}| \leq 2^{-k+3},
\]

(10.2.49)

where \( t, s \in [0, 1] \) are arbitrary with \( s < t \), and where \( k \geq 0 \) is arbitrary.

9. Let \( k \geq 0 \) be arbitrary. Recall from Step 5 that \( n_k \equiv p_{m(k)} \equiv 2^{m(k)} \), and that

\[
\tau_k \equiv (\tau_{h,0}, \tau_{h,1}, \cdots, \tau_{h,n(k)-1}) \equiv q_{m(k)} \equiv (q_{m(k),0}, q_{m(k),1}, \cdots, q_{m(k),n(k)-1})
\]

is a sequence of division points of the simple càdlàg function \( x_k \). Define the set

\[
A \equiv \bigcap_{h=0}^{\infty} \mu_k^{-1}(\{\tau_{h,0}, \tau_{h,1}\} \cup \{\tau_{h,1}, \tau_{h,2}\} \cup \cdots \cup \{\tau_{h,m(k)-1}, \tau_{h,m(k)}\})
\]

(10.2.50)

Then \( A \) contains all but countably many points in \([0, 1]\), and is therefore dense in \([0, 1]\).

Define

\[
u_k \equiv x_k \circ \mu_k^{-1}.
\]

(10.2.51)

Then \( \nu_k \in D[0, 1] \) by Lemma 10.1.3 Moreover,

\[
u_{k+1} = x_{k+1} \circ \lambda_{k+1} \mu_k^{-1}.
\]

(10.2.52)

Now let \( r \in A \) and \( h \geq k \) be arbitrary. Then, by the defining equality (10.2.50) of the set \( A \), there exists \( i = 0, \cdots, n_h - 1 \) such that

\[
\mu_h \mu^{-1}_h r \in [\tau_{h,i}, \tau_{h,i+1}) \subset \text{domain}(x_h).
\]

(10.2.53)

Hence,

\[
\lambda_{h+1} \mu_h \mu^{-1}_h r \in \lambda_{h+1}[\tau_{h,i}, \tau_{h,i+1})
\]

Moreover,

\[
r \in \text{domain}(x_h \circ \mu_h \mu^{-1}) \equiv \text{domain}(\nu_k).
\]

(10.2.54)

From equalities (10.2.52) and (10.2.51) and inequality (10.2.42) we obtain

\[
d(u_{k+1}(r), u_k(r)) \equiv d(x_{k+1}(\lambda_{k+1} \mu_k^{-1} r), x_k(\mu_k^{-1} r)) \leq 2^{-k+2}.
\]

(10.2.55)

Hence, since \( r \in A \) and \( k \geq 0 \) are arbitrary, we conclude that \( \lim_{k \to \infty} \nu_k \) exists on \( A \).

Define the function \( u : [0, 1] \to S \) by \( \text{domain}(u) \equiv A \) and by \( u(t) \equiv \lim_{k \to \infty} \nu_k(t) \) for each \( t \in \text{domain}(u) \). Inequality (10.2.55) then implies that

\[
d(u(r), u_k(r)) \leq 2^{-k+3}
\]

(10.2.56)

where \( r \in A \) and \( k \geq 0 \) are arbitrary. We proceed to verify the conditions in Proposition 10.1.6 for the function \( u \) to have a càdlàg completion.

10. For that purpose, let \( r \in A \) and \( h \geq k \) be arbitrary. Then, as observed in Step 9, we have \( r \in \text{domain}(u_k) \). Hence, since \( u_k \) is càdlàg, it is right continuous at \( r \). Therefore there exists \( c_h > 0 \) such that

\[
d(u_h(t), u_h(r)) < 2^{-h+3}
\]
for each \( t \in [r, r + c_h] \cap A \). In view of inequality 10.2.56, it follows that
\[
d(u(t), u(r)) \leq d(u(t), u_h(t)) + d(u_h(t), u_h(r)) + d(u_h(r), u(r)) < 3 \cdot 2^{-h+3}
\]
for each \( t \in [r, r + c_h] \cap A \). Thus \( u \) is right continuous at each point \( r \in A = \text{domain}(u) \).

Condition 1 in Definition 10.1.2 has been verified for the function \( u \).

11. We will now verify Conditions 3 in Definition 10.1.2. To that end, let \( \varepsilon > 0 \) be arbitrary. Take \( k \geq 0 \) so large that \( 2^{-k+4} < \varepsilon \), and define \( \delta(\varepsilon) \equiv \exp(-2^{-k+3})2^{-m(k)}. \)

Let \( j = 0, \cdots, n_k \) be arbitrary. For brevity, define \( \tau'_j \equiv \mu \mu_k^{-1} \tau_{k,j} \). By inequality 10.2.41, we have
\[
\lambda_{h+1,t} - \lambda_{h+1,s} \geq (t-s)\exp(-2^{-h+2})
\]
for each \( s, t \in [0,1] \) with \( s < t \), for each \( h \geq 0 \). Hence, for each \( j = 0, \cdots, n_k - 1 \), we have
\[
\tau'_{j+1} - \tau'_j = \mu \mu_k^{-1} \tau_{k,j+1} - \mu \mu_k^{-1} \tau_{k,j} = \lim_{h \to \infty} (\mu \mu_k^{-1} \tau_{k,j+1} - \mu \mu_k^{-1} \tau_{k,j}) = \lim_{h \to \infty} (\lambda_h \cdots \lambda_{k+1} \tau_{k,j+1} - \lambda_h \cdots \lambda_{k+1} \tau_{k,j}) \geq \exp(-2^{-k+3})(\tau_{k,j+1} - \tau_{k,j}) = \exp(-2^{-k+3})2^{-m(k)} \equiv \delta(\varepsilon)
\]
(10.2.57)
where the inequality is by inequality 10.2.45. Now consider each \( j = 0, \cdots, n_k - 1 \) and each
\( t' \in \text{domain}(u) \cap [\tau'_j, \tau'_{j+1}] \equiv A \cap [\mu \mu_k^{-1} \tau_{k,j}, \mu \mu_k^{-1} \tau_{k,j+1}] \).

We will show that
\[
d(u(t'), u(\tau'_j)) \leq \varepsilon.
\]
(10.2.58)
To that end, write \( t \equiv \mu^{-1}t' \), and write \( s \equiv \mu_{h}t' \equiv \mu_{h}^{-1}t' \in [\tau_{k,j}, \tau_{k,j+1}] \). Then
\[
x_h(s) = x_h(\tau_{k,j})
\]
(10.2.59)
since \( x_h \) is a simple càdlàg function with \( (\tau_0, \tau_1, \cdots, \tau_{h(n(k)-1)}) \) as a sequence of division points. Let \( h > k \) be arbitrary, and define
\[
r \equiv \mu_{h}^{-1}t' = \mu_{h}t \equiv \lambda_h \lambda_{h-1} \cdots \lambda_{k+1}s.
\]
Then
\[
u_h(t') \equiv x_h(\mu_{h}^{-1}t') \equiv x_h(r) \equiv x_h(\lambda_h \lambda_{h-1} \cdots \lambda_{k+1}s).
\]
Combining with equality 10.2.59, we obtain
\[
d(u_h(t'), x_h(\tau_{k,j})) = d(x_h(\lambda_h \lambda_{h-1} \cdots \lambda_{k+1}s), x_h(s)) \leq 2^{-k+3},
\]
where the last inequality is a consequence of relation 10.2.43 and Consequently
\[
d(u_h(t'), u_h(\tau'_j)) \leq d(u_h(t'), x_h(\tau_{k,j})) + d(u_h(\tau'_j), x_h(\tau_{k,j})) \leq 2^{-k+4} < \varepsilon.
\]
(10.2.60)
where \( t' \in \text{domain}(u) \cap [\tau'_j, \tau'_{j+1}] \) is arbitrary. Letting \( h \to \infty \), we obtain the desired inequality 10.2.58. Inequalities 10.2.58 and 10.2.57 together say that \( (\tau'_j)_{j=0, \cdots, n(k)+1} \) is a sequence of \( \varepsilon \)-division points with separation at least \( \delta(\varepsilon) \).
Thus Conditions 1 and 3 in Definition 10.1.2 have been verified for the objects $u$, $\tau'$, and $\delta_{\text{cdlg}} \equiv \delta$. Therefore Proposition 10.1.6 implies that (i') the completion $y \in D[0, 1]$ of $u$ is well-defined, (ii') $y/\text{domain}(u) = u$, and (iii') $\delta_{\text{cdlg}}$ is a modulus of càdlàg of $y$.

12. Finally, we will prove that $d_D(y_h, y) \to 0$ as $h \to \infty$. To that end, let $h \geq 0$ and $r \in A \subset \text{domain}(u) \subset \text{domain}(y)$ be arbitrary. By the above Condition (ii') we have $u(r) = y(r)$. Hence
\[
d(y(r), x_h \circ \mu_h \mu^{-1}(r)) = d(y(r), u_h(r)) = d(u(r), u_h(r)) \leq 2^{-h+3}
\]
by inequality 10.2.56. Consequently, since $A$ is a dense subset of $[0, 1]$, Lemma 10.1.3 applied to $h$ in the place of $k$, yields
\[
d(y(r), x_h \circ \mu_h \mu^{-1}(r)) \leq 2^{-h+3} \quad (10.2.61)
\]
for each $r \in \text{domain}(y) \cap \mu \mu_h^{-1} \text{domain}(x_h)$. Inequalities 10.2.61 and 10.2.49 together imply that $(2^{-h+3}, \mu_h \mu^{-1}) \in A_{y, x(h)}$, whence $2^{-h+3} \in B_{y, x(h)}$. Accordingly,
\[
d_D(y, x_h) = \inf_{y, x(h)} \leq 2^{-h+3}.
\]
Thus $d_D(y_h, y) \to 0$ as $h \to \infty$. In view of inequality 10.2.35 we conclude that $d_D(y_h, y) \to 0$ as $h \to \infty$.

13. Summing up, for each Cauchy sequence $(y_h)_{h=0,1,\ldots}$, there exists $y \in D[0, 1]$ such that $d_D(y_h, y) \to 0$ as $h \to \infty$. In other words, $(D[0, 1], d_D)$ is complete, as alleged.

\[\Box\]

\section{10.3 a.u. Càdlàg Processes}

Let $(\Omega, L, E)$ be a probability space, and let $(S, d)$ be a locally compact metric space. Let $(D[0, 1], d_D)$ be the Skorokhod space of càdlàg functions on the unit interval $[0, 1]$ with values in $(S, d)$, as introduced in the previous section.

Recall Definition 9.0.2 for notations related to the enumerated set of dyadic rationals $Q_\infty$ in $[0, 1]$.

\begin{definition}[a.u. random càdlàg function] A r.v. $Y : \Omega \rightarrow (D[0, 1], d_D)$ with values in the Skorokhod space is called an almost uniform (a.u.) random càdlàg function, if, for each $\varepsilon > 0$, there exists a measurable set $A$ with $P(A) < \varepsilon$ such that members of the family $\{Y(\omega) : \omega \in A\}$ are càdlàg and share a common modulus of càdlàg.

Of special interest is the subclass of the a.u. random càdlàg functions corresponding to a.u. càdlàg processes on $[0, 1]$, defined next.
\end{definition}

\begin{definition}[a.u. càdlàg process] Let $X : [0, 1] \times \Omega \rightarrow S$ be a stochastic process which is continuous in probability on $[0, 1]$, with a modulus of continuity in probability $\delta_{\text{p}}$. Suppose there exists a full set $B \subset \bigcap_{\ell \in Q(\infty)} \text{domain}(X_\ell)$ with the following properties.
\end{definition}
CHAPTER 10. A.U. CÀDLÀG PROCESSES

1 (Right continuity). For each \( \omega \in B \), the function \( X(\cdot, \omega) \) is right continuous at each \( t \in \text{domain}(X(\cdot, \omega)) \).

2 (Right completeness). Let \( \omega \in B \) and \( t \in [0, 1] \) be arbitrary. If \( \lim_{r \to \infty, r > t} X(r, \omega) \) exists, then \( t \in \text{domain}(X(\cdot, \omega)) \).

3 (Approximation by step functions). Let \( \varepsilon > 0 \) be arbitrary. Then there exist (i) \( \delta_{\text{nuc}}(\varepsilon) > 0 \), (ii) a measurable set \( A \subset B \) with \( P(A^c) < \varepsilon \), (iii) an integer \( h \geq 1 \), and (iv) a sequence of r.v.'s

\[
0 = \tau_0 < \tau_1 < \cdots < \tau_{h-1} < \tau_h = 1,
\]

such that, for each \( i = 0, \cdots, h - 1 \), the function \( X_{\tau(i)} \) is a r.v., and such that, (v) for each \( \omega \in A \), we have

\[
\bigwedge_{i=0}^{h-1} (\tau_{i+1}(\omega) - \tau_i(\omega)) \geq \delta_{\text{nuc}}(\varepsilon),
\]

with

\[
d(X(\tau_i(\omega), \omega), X(\cdot, \omega)) \leq \varepsilon,
\]

on the interval \( \theta_i(\omega) \equiv [\tau_i(\omega), \tau_{i+1}(\omega)) \) or \( \theta_i(\omega) \equiv [\tau_i(\omega), \tau_{i+1}(\omega)] \) according as \( 0 \leq i \leq h - 2 \) or \( i = h - 1 \).

Then the process \( X : [0, 1] \times \Omega \to S \) is called an a.u. càdlàg process, with \( \delta_{\text{cp}} \) as a modulus of continuity in probability and with \( \delta_{\text{nuc}} \) as a modulus of a.u. càdlàg. We will let \( \hat{D}_{\delta_{\text{nuc}}, \delta_{\text{cp}}}[0, 1] \) denote the set of all such processes.

We will let \( \hat{D}[0, 1] \) denote the set of all a.u. càdlàg processes. Two members \( X, Y \) of \( \hat{D}[0, 1] \) are considered equal if there exists a full set \( B' \) such that for each \( \omega \in B' \) we have \( X(\cdot, \omega) = Y(\cdot, \omega) \) as functions on \( [0, 1] \).

\[ \square \]

Definition 10.3.3. (a.u. Random càdlàg function by extension of an a.u. càdlàg process). Let \( X \in \hat{D}[0, 1] \) be arbitrary. Define a function

\[
X^* : \Omega \to D[0, 1]
\]

by

\[
\text{domain}(X^*) \equiv \{ \omega \in \Omega : X(\cdot, \omega) \in D[0, 1] \}
\]

and

\[
X^*(\omega) \equiv X(\cdot, \omega)
\]

for each \( \omega \in \text{domain}(X^*) \). We call \( X^* \) the a.u. random càdlàg function associated with the a.u. càdlàg process \( X \). \( \square \)

Proposition 10.3.4. (Each a.u. càdlàg process extends to a random càdlàg function). Let \( X \in \hat{D}[0, 1] \) be an arbitrary a.u. càdlàg process. Let \( \varepsilon > 0 \) be arbitrary. Then there exists a measurable set \( G \) with \( P(G^c) < \varepsilon \), such that members of the set \( \{ X(\cdot, \omega) : \omega \in G \} \) are càdlàg functions which share a common modulus of càdlàg.

Moreover, \( X^* \) is a r.v. with values in the complete metric space \( (D[0, 1], d_D) \).
Proof. As in Definition 10.3.1 define the full subset \( B \equiv \bigcap_{\omega \in Q(h)} \text{domain} (X_\omega) \) of \( \Omega \). By Conditions (1) and (2) in Definition 10.3.1, members of the set \( \{ X(\cdot, \omega) : \omega \in B \} \) of functions satisfy the corresponding Conditions (1) and (2) in Definition 10.1.2.

Let \( n \geq 1 \) be arbitrary. By Condition (3) in Definition 10.3.1 there exist (i) \( \delta_{\text{ucf}}(2^{-n}) > 0 \), (ii) a measurable set \( A_n \subset B \) with \( P(A_n^c) < 2^{-n} \), (iii) an integer \( h_n \geq 0 \), and (iv) a sequence of r.v.'s

\[
0 = \tau_{n,0} < \tau_{n,1} < \cdots < \tau_{n,h(n)} = 1, \quad (10.3.4)
\]

such that, for each \( i = 0, \cdots, h_n - 1 \), the function \( X(\tau_{n,i}, \cdot) \) is a r.v., and such that, for each \( \omega \in A_n \), we have

\[
\bigwedge_{i=0}^{h(n)-1} (\tau_{n,i+1}(\omega) - \tau_{n,i}(\omega)) \geq \delta_{\text{ucf}}(2^{-n}), \quad (10.3.5)
\]

with

\[
d(X(\tau_{n,i}(\omega), \omega), X(\cdot, \omega)) \leq 2^{-n}
\]

on the interval \( \theta_{n,i} \equiv [\tau_{n,i}(\omega), \tau_{n,i+1}(\omega)) \) or \( \theta_{n,i} \equiv [\tau_{n,i}(\omega), \tau_{n,i+1}(\omega)] \) according as \( i \leq h_n - 2 \) or \( i = h_n - 1 \).

Now let \( \varepsilon > 0 \) be arbitrary. Take \( j \geq 1 \) so large that \( 2^{-j} < \varepsilon \). Define \( G \equiv \bigcap_{n=j+1}^{\infty} A_n \subset B \). Then \( P(G^c) < \sum_{n=j+1}^{\infty} 2^{-n} = 2^{-j} < \varepsilon \). Consider each \( \omega \in G \). Let \( \varepsilon' > 0 \) be arbitrary. Consider each \( n \geq j+1 \) so large that \( 2^{-n} < \varepsilon' \). Define \( \delta_{\text{cflg}}(\varepsilon') \equiv \delta_{\text{ucf}}(2^{-n}) \). Then \( \omega \in A_n \). Hence inequalities (10.3.5) and (10.3.6) hold, and imply that the sequence

\[
0 = \tau_{n,0}(\omega) < \tau_{n,1}(\omega) < \cdots < \tau_{n,h(n)}(\omega) = 1
\]

is a sequence of \( \varepsilon' \)-division points of the function \( X(\cdot, \omega) \), with separation at least \( \delta_{\text{cflg}}(\varepsilon') \). Summing up, all the conditions in Definition 10.1.2 have been verified for the function \( X(\cdot, \omega) \) to be càdlàg, with the modulus of càdlàg \( \delta_{\text{cflg}} \), where \( \omega \in G \) is arbitrary. This proves the first part of the proposition.

Let \( H_{h(n), \delta(0)} \) be the subset of the product metric space \( ([0,1]^{h(n)}, d_{\text{cflg}}^{h(n)}) \odot (S^{\delta(h(n)), \delta^{h(n)}) \) consisting of elements \( \alpha \equiv ((a_0, \cdots, a_{h(n)-1}), (x_0, \cdots, x_{h(n)-1})) \) such that

\[
0 \equiv a_0 < a_1 < \cdots < a_{h(n)} \equiv 1
\]

with

\[
\bigwedge_{i=0}^{h(n)-1} (a_{i+1} - a_i) \geq \delta_0.
\]

Then the function

\[
\Phi_{\text{smpl}} : (H_{h(n), \delta(0)}, d_{\text{cflg}}^{h(n)} \odot d^{h(n)}) \to (D[0,1], d_D),
\]

which assigns to each \( ((a_0, \cdots, a_{h(n)-1}), (x_0, \cdots, x_{h(n)-1}) \in H_{h(n), \delta(0)} \) the simple càdlàg function

\[
\Phi_{\text{smpl}}((a_0, \cdots, a_{h(n)-1}), (x_0, \cdots, x_{h(n)-1})),
\]

is uniformly continuous. Hence, the function

\[
X^{(n)} \equiv \Phi_{\text{smpl}}((\tau_{n,0}, \cdots, \tau_{n,h(n)-1}), (X_{\tau_{n,0}}, \cdots, X_{\tau_{n,h(n)-1}}))
\]
Chapter 10. A.U. Càdlàg Processes

is a r.v. with values in \((D[0,1],d_D)\), according to Proposition 10.3.4. At the same time, inequality \([10.3.6]\) implies that

\[
d_D(X^{(n)},X^\ast) \leq 2^{-n},
\]
on \(A_n\), where \(P(A_n^c) < 2^{-n}\). Hence \(X^{(n)} \to X^\ast\) a.u. Consequently \(X^\ast\) is a r.v. with values in \((D[0,1],d_D)\).

**Definition 10.3.5.** (Metric for the space of a.u. càdlàg processes). Define the metric \(\rho_{\tilde{D}[0,1]}\) on \(\tilde{D}[0,1]\) by

\[
\rho_{\tilde{D}[0,1]}(X,Y) \equiv \int E(d\omega)1 \wedge d_D(X(\cdot,\omega),Y(\cdot,\omega)) \equiv E1 \wedge d_D(X^\ast,Y^\ast) \quad (10.3.10)
\]
for each \(X,Y \in \tilde{D}[0,1]\). The next lemma justifies the definition.

**Lemma 10.3.6.** ((\(\tilde{D}[0,1],\rho_{\tilde{D}[0,1]}\)) is a metric space). The function \(\rho_{\tilde{D}[0,1]}\) is well-defined and is a metric.

**Proof.** Let \(X,Y \in \tilde{D}[0,1]\) be arbitrary. Then, according to Proposition 10.3.4 the random càdlàg functions \(X^\ast,Y^\ast\) associated with \(X,Y\) respectively are r.v.'s with values in \((D[0,1],d_D)\). Therefore the function \(1 \wedge d_D(X^\ast,Y^\ast)\) is an integrable r.v., and the defining equality \(10.3.10\) makes sense.

Symmetry and the triangle inequality can be trivially verified for \(\rho_{\tilde{D}[0,1]}\). Now suppose \(X = Y\) in \(\tilde{D}[0,1]\). Then, by the definition of the equality relation for the set \(\tilde{D}[0,1]\), we have \(X(\cdot,\omega) = Y(\cdot,\omega)\) in \(D[0,1]\), for a.e. \(\omega \in \Omega\). Hence

\[
1 \wedge d_D(X^\ast(\cdot,\omega),Y^\ast(\cdot,\omega)) \equiv 1 \wedge d_D(X(\cdot,\omega),Y(\cdot,\omega)) = 0.
\]

Thus \(1 \wedge d_D(X^\ast,Y^\ast) = 0\) a.s. Consequently, \(\rho_{\tilde{D}[0,1]}(X,Y) = 0\) according to the defining equality \(10.3.10\). The converse is proved similarly. Combining, we conclude that \(\rho_{\tilde{D}[0,1]}\) is a metric.

### 10.4 D-regular Families of f.j.d.'s and D-regular Processes

In this and the following two sections, we give a construction of an a.u. process from a consistent family \(F\) of f.j.d.'s with parameter set \([0,1]\) which satisfies a certain \(D\)-regularity condition to be defined presently. The construction is by (i) taking any process \(Z : Q_m \times \Omega \to S\) with marginal distributions given by \(F|Q_m\), (ii) extending the process \(Z\) to an a.u. càdlàg, process \(X : [0,1] \times \Omega \to S\) by taking right limits of sample paths. Step (i) can be done by the Daniell-Kolmogorov Extension or Daniell-Kolmogorov-Skorokhod Extension, for example. As a matter of fact, we can define \(D\)-regularity for \(F\) as \(D\)-regularity of any process \(Z\) with marginal distributions given by \(F\). The key Step (ii) is then by proving that that a process \(X : [0,1] \times \Omega \to S\) is a.u. càdlàg iff it is the right-limit extension of some \(D\)-regular process \(Z : Q_m \times \Omega \to S\). In this section, we prove the “only if” part. In the next section, we will prove the “if” part, which is the useful part for the purpose of the first sentence in this paragraph.
10.4. D-REGULAR FAMILIES OF F.J.D.'S AND D-REGULAR PROCESSES

Definition 10.4.1. (D-regular processes and D-regular families of f.j.d.'s with parameter set $Q_\infty$). Let $Z : Q_\infty \times \Omega \rightarrow S$ be a stochastic process, with marginal distributions given by the family $F$ of f.j.d.'s. Let $m \equiv (m_n)_{n=0,1,\ldots}$ be an increasing sequence of nonnegative integers. Suppose the following conditions are satisfied.

1. Let $n \geq 0$ be arbitrary. Let $\beta > 2^{-n}$ be arbitrary such that the set

$$A^n_{t,s} \equiv (d(Z_t, Z_s) > \beta)$$

is measurable for each $s, t \in Q_\infty$. Then

$$P(D_n) < 2^{-n},$$

where we define the exceptional set

$$D_n \equiv \bigcup_{t \in Q(m(n))} \bigcup_{s \in Q(m(n+1))} (A^n_{t,s} \cup A^n_{t',s}) (A^n_{t',s} \cup A^n_{t,s}),$$

where for each $t \in Q_{m(n)}$ we abuse notations and write $t' \equiv 1 \land (t + 2^{-m(n)})$.

2. The process $Z$ is continuous in probability on $Q_\infty$, with a modulus of continuity in probability $\delta_{C_p}$.

Then the process $Z : Q_\infty \times \Omega \rightarrow S$ and the family $F$ of f.j.d.'s are said to be D-regular, with the sequence $m$ as a modulus of D-regularity and with the operation $\delta_{C_p}$ as a modulus of continuity in probability.

Let

$$\tilde{R}_{\text{Dreg}, \pi, \delta}(Q_\infty \times \Omega, S)$$

denote the set of all such processes. Let $\tilde{R}_{\text{Dreg}}(Q_\infty \times \Omega, S)$ denote the set of all D-regular processes. Thus $\tilde{R}_{\text{Dreg}, \pi, \delta}(Q_\infty \times \Omega, S)$ and $\tilde{R}_{\text{Dreg}}(Q_\infty \times \Omega, S)$ are subsets of the metric space $(\tilde{R}(Q_\infty \times \Omega, S), \tilde{r}_{\text{Prob}, Q(\infty)})$ introduced in Definition [6.4.1] and, as such, inherit the metric $\tilde{r}_{\text{Prob}, Q(\infty)}$. Thus we have the metric space

$$(\tilde{R}_{\text{Dreg}}(Q_\infty \times \Omega, S), \tilde{r}_{\text{Prob}, Q(\infty)}).$$

Let

$$\hat{F}_{\text{Dreg}, \pi, \delta}(Q_\infty, S)$$

denote the set of all such families $F$ of f.j.d.'s. Let $\hat{F}_{\text{Dreg}}(Q_\infty, S)$ denote the set of all D-regular families of f.j.d.'s. Then $\hat{F}_{\text{Dreg}, \pi, \delta}(Q_\infty, S)$ and $\hat{F}_{\text{Dreg}}(Q_\infty, S)$ are subsets of the metric space $(\hat{F}(Q_\infty, S), \hat{r}_{\text{Marg}, Q(\infty)})$ of consistent families of f.j.d.'s introduced in Definition [6.2.7], where the metric $\hat{r}_{\text{Marg}, Q(\infty)}$ is defined relative to an arbitrarily given, but fixed, binary approximation $\xi \equiv (A_q)_{q=1,2,\ldots}$ of $(S, d)$.

\[ \square \]

Condition 1 in Definition [10.4.1] is, in essence, equivalent to Condition (13.10) in the key Theorem 13.3 of [Billingsley 1999]. The crucial difference of our construction and the last cited theorem is that the latter proves only that (i) a sequence of distributions on the path space which satisfies said Condition (13.10) is tight, and (ii) the weak-convergence limit of any such subsequence sequence of distributions, if such limit exists, and (iii) existence of weak-convergence limit is then guaranteed by Prokhorov’s
CHAPTER 10. A.U. CÂDLÀG PROCESSES

Theorem. Theorem 5.1 in [Billingsley 1999], which says that each subsequence of a tight sequence of distributions contains a subsequence which has a weak-convergence limit. As we observed earlier, Prokhorov’s Theorem implies the principle of infinite search. This is in contrast to our simple and direct construction in developed in this and the next section.

First we extend the definition of D-regularity to families of f.j.d.’s with parameter interval [0, 1] which are continuous in probability on the interval.

Definition 10.4.2. (D-regular families of f.j.d.’s with parameter interval [0, 1]). Recall from [6.2.1] the metric space \((\hat{F}_\text{Dreg}([0,1],S),\hat{\rho}_{\text{Dreg}}_{\xi, [0,1]|(\omega)})\) of families of f.j.d.’s which are continuous in probability on [0, 1], where the metric is defined relative to the enumerated, countable, dense subset \(Q_\omega\) of [0, 1]. Define two subsets of \(\hat{F}_\text{Dreg}([0,1],S)\) by

\[
\hat{F}_\text{Dreg}([0,1],S) \equiv \{ F \in \hat{F}_\text{Dreg}([0,1],S) : F|Q_\omega \in \hat{F}_\text{Dreg}(Q_\omega, S) \},
\]

and

\[
\hat{F}_\text{Dreg,}\varpi\delta_{\partial_\text{Dreg}}([0,1],S) \equiv \{ F \in \hat{F}_\text{Dreg}([0,1],S) : F|Q_\omega \in \hat{F}_\text{Dreg,}\varpi\delta_{\partial_\text{Dreg}}(Q_\omega, S) \}.
\]

These subsets inherit the metric \(\hat{\rho}_{\text{Dreg}}_{\xi, [0,1]|(\omega)}\). \(\square\)

We will prove that a process \(X : [0,1] \times \Omega \to S\) is a.u. càdlàg iff it is the extension by right limit of a D-regular process \(Z : Q_\omega \times \Omega \to S\). The next theorem proves the “only if” part.

Theorem 10.4.3. (Restriction of each a.u. Càdlàg process to \(Q_\omega\) is D-regular). Let \(X : [0,1] \times \Omega \to S\) be an a.u. càdlàg process, with a modulus of a.u. càdlàg \(\delta_{\text{aucl}}\) and a modulus of continuity in probability \(\delta_{\partial_\text{Dreg}}\). Let \(\varpi \equiv (\varpi_n)_{n=0,1,2,\ldots}\) be an arbitrary increasing sequence of integers such that

\[
2^{-m(\varpi)} < \delta_{\text{aucl}}(2^{-\varpi - 1}). \tag{10.4.4}
\]

for each \(n \geq 0\).

Then the process \(Z \equiv X|Q_\omega\) is D-regular, with a modulus of D-regularity \(\varpi\), and with the same modulus of continuity in probability \(\delta_{\partial_\text{Dreg}}\).

Proof. First note that, by Definition \[10.3.1\] \(X\) is continuous in probability on \([0,1]\), with some modulus of continuity in probability \(\delta_{\partial_\text{Dreg}}\). Hence so is \(Z\) on \(Q_\omega\), with the same modulus of continuity in probability \(\delta_{\partial_\text{Dreg}}\). Consequently, Condition 2 in Definition \[10.3.1\] is satisfied.

Now let \(n \geq 0\) be arbitrary. Write \(\varepsilon_n \equiv 2^{-\varpi_n}\). By Condition (3) in Definition \[10.3.2\] there exist (i) \(\delta_{\text{aucl}}(\frac{1}{2}\varepsilon_n) > 0\), (ii) a measurable set \(A_n \subset B \equiv \bigcap_{\varpi \in Q_\omega} \text{domain}(X_i)\) with \(P(A_n) < \frac{1}{2}\varepsilon_n\), (iii) an integer \(h_n \geq 0\), and (iv) a sequence of r.v.’s, \(0 = \tau_{n,0} \leq \tau_{n,1} < \cdots < \tau_{n,h_n-1} < \tau_{n,h_n} = 1\), such that, for each \(i = 0, \ldots, h_n - 1\), the function \(X_{\tau_{n,i}}\) is a r.v., and such that, for each \(\omega \in A_n\), we have

\[
\sum_{i=0}^{h_n-1} (\tau_{n,i+1}(\omega) - \tau_{n,i}(\omega)) \geq \delta_{\text{aucl}}(\frac{1}{2}\varepsilon_n) \tag{10.4.5}
\]

(10.4.6)

Yuen-Kwok Chan 344 Constructive Probability
with
\[ d(X(\tau_{n,i}(\omega),\cdot),X(\cdot,\omega)) \leq \frac{1}{2}\varepsilon_n, \]  
(10.4.7)
on the interval \( \theta_{n,i} \equiv [\tau_{n,i}(\omega),\tau_{n,i+1}(\omega)] \) or \( \theta_{n,i} \equiv [\tau_{n,i}(\omega),1] \) according as \( i \leq h_n - 2 \) or \( i = h_n - 1 \).

Take any \( \beta > 2^{-n} \) such that the set
\[ A^\beta \equiv (d(X_t,X_s) > \beta) \]  
(10.4.8)
is measurable for each \( s,t \in Q \). Let \( D_n \) be the exceptional set as in defining equality \[10.4.3\] Suppose, for the sake of a contradiction, that \( P(D_n) > \varepsilon_n \equiv 2^{-n} \). Then \( P(D_n) > \varepsilon_n > P(A^\beta_n) \) by Condition (ii) above. Hence \( P(D_nA^\beta_n) > 0 \). Consequently, there exists \( \omega \in D_nA^\beta_n \). Since \( \omega \in A^\beta_n \), inequalities \[10.4.6\] and \[10.4.7\] hold at \( \omega \). At the same time, since \( \omega \in D_n \), there exist \( t \in Q(n) \) and \( r,s \in Q(m) \), with \( t < r < s < t' \equiv t + 2^{-m(n)} \), such that
\[ \omega \in (A^\beta_{r,i} \cup A^\beta_{r,i})(A^\beta_{s,i} \cup A^\beta_{s,i})(A^\beta_{t',r} \cup A^\beta_{t',r}). \]  
(10.4.9)
At the same time, the interval \( [0,1] \) is contained in the union \( \bigcup_{i=1}^{h_n-1} (\tau_{n,i}(\omega),\tau_{n,i+1}(\omega)) \). Hence \( t \in [\tau_{n,i-1}(\omega),\tau_{n,i+1}(\omega)] \) for some \( i = 1, \ldots, h_n - 1 \). Now consider each
\[ u,v \in G \equiv \text{domain}(X(\cdot,\omega)) \cap (t,t') \cap \{\tau_{n,i}(\omega)\}^C \]  
with \( u \leq v \). Either (i') \( t < \tau_{n,i}(\omega) \), or (ii') \( \tau_{n,i}(\omega) < t' \). Consider Case (i'). Then
\[ t' \equiv t + 2^{-m(n)} < \tau_{n,i}(\omega) + 2^{-m(n)} \]  
\[ < \tau_{n,i}(\omega) + \varepsilon_n < \tau_{n,i}(\omega) + \varepsilon_n \]  
\[ \leq \tau_{n,i+1}(\omega) \]  
where the second inequality is from inequality \[10.4.4\] and where the last inequality is due to inequality \[10.4.6\] Combining, \( \tau_{n,i-1}(\omega) \leq t < t' < \tau_{n,i+1}(\omega) \). Hence there are three subcases regarding the order of \( u,v \) in relation to the points \( \tau_{n,i-1}(\omega),\tau_{n,i}(\omega) \), and \( \tau_{n,i+1}(\omega) \) in the interval \( [0,1] \): (i'a)
\[ \tau_{n,i-1}(\omega) \leq t < u \leq v < \tau_{n,i}(\omega), \] 
(i'b)
\[ \tau_{n,i-1}(\omega) \leq t < u < \tau_{n,i}(\omega), \] 
\[ v < t' < \tau_{n,i+1}(\omega), \] 
and (i'c)
\[ \tau_{n,i}(\omega) < u \leq v < t' < \tau_{n,i+1}(\omega). \] 
In Subcase (i'a) we have, in view of inequality \[10.4.7\]
\[ g_1(u,v) \equiv d(X_t(\omega),X_s(\omega)) \vee d(X_t(\omega),X_r(\omega)) \leq \varepsilon_n < \beta, \]  
where \( u,v \in G \) with \( u \leq v \) are arbitrary. Since \( G \) is dense in \( \text{domain}(X(\cdot,\omega)) \cap (t,t') \), we therefore obtain, by right continuity at \( r \) and at \( s \),
\[ g_1(r,s) \equiv d(X_t(\omega),X_s(\omega)) \vee d(X_t(\omega),X_r(\omega)) \leq \varepsilon_n < \beta, \]  
Yuen-Kwok Chan 345 Constructive Probability
whence \( \omega \in (A^\beta_{r'} \cup A^\beta_{t,s})^c \). Similarly, in Subcase (i’b), we have
\[
g_2(r,s) \equiv d(X_r(\omega), X_r(\omega)) \lor d(X_s(\omega), X_{r'}(\omega)) < \beta,
\]
whence \( \omega \in (A^\beta_{r'} \cup A^\beta_{t,s})^c \). Likewise, in Subcase (i’c), we have
\[
g_3(r,s) \equiv d(X_r(\omega), X_r(\omega)) \lor d(X_r(\omega), X_{r'}(\omega)) < \beta,
\]
whence \( \omega \in (A^\beta_{r'} \cup A^\beta_{t,s})^c \). Combining,
\[
\omega \in (A^\beta_{r'} \cup A^\beta_{t,s})^c \cup (A^\beta_{r'} \cup A^\beta_{t,s})^c \cup (A^\beta_{r'} \cup A^\beta_{t,s})^c,
\]
contradicting relation \( 10.4.9 \). Thus the assumption that \( P(D_n) > 2^{-n} \) leads to a contradiction. We conclude that \( P(D_n) \leq 2^{-n} \), where \( n \geq 0 \) and \( \beta > 2^{-n} \) are arbitrary. Thus the process \( Z \equiv X|Q_\infty \) satisfies the conditions in Definition 10.4.1 to be \( D \)-regular, with the sequence \( (m_n)_{n=0,1,2,\ldots} \) as a modulus of \( D \)-regularity.

The converse to Theorem 10.4.3 will be proved in the next section. From a \( D \)-regular family \( F \) of f.j.d.’s with parameter set \([0,1]\) we will construct an a.u. càdlàg process with marginal distributions given by the family \( F \).

### 10.5 The Right-Limit Extension of \( D \)-regular Processes

area.u. Càdlàg

Refer to Definition 9.0.2 for the notations related to the enumerated set \( Q_\infty \) of dyadic rationals in the interval \([0,1]\). We proved in Theorem 10.4.3 that the restriction to \( Q_\infty \) of each a.u. càdlàg process on \([0,1]\) is \( D \)-regular. In this section, we will prove the more useful converse theorem, which is the key theorem in this chapter, that the extension by right limit of each \( D \)-regular process on \( Q_\infty \) is a.u. càdlàg. Then we will prove the easy corollary that, given an \( D \)-regular family \( F \) of f.j.d.’s with parameter set \([0,1]\), we can construct an a.u. càdlàg process \( X \) with marginal distributions given by \( F \), and with a modulus of a.u. càdlàg in terms of the modulus of \( D \)-regularity of \( F \).

In the remainder of the section, we will use the following assumption and notations.

**Definition 10.5.1. (Assumption of a \( D \)-regular process).** Let \( Z \in \bar{R}_{D_{\text{reg},m}}^{\delta_{\mathcal{C}_P}}(Q_\infty \times \Omega, S) \) be arbitrary, but fixed for the remainder of this section. In other words, \( Z : Q_\infty \times \Omega \to S \) is a fixed \( D \)-regular process. Let \( m \equiv (m_k)_{k=0,1,\ldots} \) be a fixed modulus of \( D \)-regularity, and let \( \delta_{\mathcal{C}_P} \) be a fixed modulus of continuity in probability.

**Definition 10.5.2. (Notation for the range of a sample function).** Let \( Y : Q \times \Omega \to S \) be an arbitrary process, let \( A \subset Q \) and \( \omega \in \Omega \) be arbitrary. Then we write
\[
Y(A, \omega) \equiv \{ x \in S : x = Y(t, \omega) \text{ for some } t \in A \}.
\]
10.5. THE RIGHT-LIMIT EXTENSION OF $D$-REGULAR PROCESSES AREA.U.
CÀDLÀG

**Definition 10.5.3. (Accordion function).** Let $(\beta_h)_{h=0,1,\ldots}$ be an arbitrary sequence of real numbers such that, for each $k, h \geq 0$ with $k \leq h$, and for each $r,s \in Q_{\infty}$, we have

$$\beta_h \in (2^{-h+1}, 2^{-h+2}),$$  \hfill (10.5.1)

and the set

$$(d(Z_r,Z_s) > \beta_k + \cdots + \beta_h)$$  \hfill (10.5.2)

is measurable, and, in particular, the set

$$A^{\beta(h)}_{r,s} \equiv (d(Z_r,Z_s) > \beta_h)$$  \hfill (10.5.3)

is measurable.

Let $h, n \geq 0$ be arbitrary. Define

$$\beta_{n,h} \equiv \sum_{i=n}^{h} \beta_i,$$  \hfill (10.5.4)

where, by convention, $\sum_{i=n}^{h} \beta_i \equiv 0$ if $h < n$. Define

$$\beta_{n,\infty} \equiv \sum_{i=n}^{\infty} \beta_i.$$  \hfill (10.5.5)

Note that $\beta_{n,\infty} < \sum_{i=n}^{\infty} 2^{-i+2} = 2^{-n+3} \to 0$ as $n \to \infty$. For each subset $A$ of $Q_{\infty}$, write

$$A^- \equiv \{ t \in Q_{\infty} : t \neq s \text{ for each } s \in A \},$$

the metric complement of $A$ in $Q_{\infty}$.

Let $s \in Q_{\infty} = \bigcup_{h=0}^{\infty} Q_{m(h)}$ be arbitrary. Define $\hat{h}(s) \equiv h \geq 0$ to be the smallest integer such that $s \in Q_{m(h)}$. Let $n \geq 0$ be arbitrary. Define

$$\hat{\beta}_n(s) \equiv \beta_{n,\hat{h}(s)} \equiv \sum_{i=n}^{\hat{h}(s)} \beta_i,$$  \hfill (10.5.6)

Thus we have the functions

$$\hat{h} : Q_{\infty} \to \{0,1,2,\ldots\}$$

and

$$\hat{\beta}_n : Q_{\infty} \to (0,\beta_{n,\infty})$$

for each $n \geq 0$. These functions are defined relative to the sequences $(\beta_n)_{n=0,1,\ldots}$ and $(m_n)_{n=0,1,\ldots}$.

For want of a better name, we might call the function $\hat{\beta}_n$ an *accordion function*, because its graph resembles a fractal-like accordion. They will furnish time-varying boundaries for some simple first exit times in the proof of the main theorem. Note that, for arbitrary $s \in Q_{m(k)}$ for some $k \geq 0$, we have $\hat{h}(s) \leq k$ and so $\hat{\beta}_n(s) \leq \beta_n,k$.
CHAPTER 10. A.U. ÇÀDLÀÐ PROCESSES

\[ \square \]

**Definition 10.5.4. (Some small exceptional sets).** Let \( k \geq 0 \) be arbitrary. Then \( \beta_{k+1} > 2^{-k} \). Hence, by the conditions in Definition [10.4.1] for \( \mathcal{m} \equiv (m_k)_{k=0,1,...} \) to be a modulus of \( D \)-regularity of the process \( Z \), we have
\[ P(D_k) \leq 2^{-k}, \quad (10.5.7) \]
where
\[ D_k \equiv \bigcup_{u \in Q(m(k))} \bigcup_{r \in (u,u')Q(m(k+1))} \bigcup_{r \leq s} \big( A_u^\beta(k+1) \cup A_u^\beta(k+1) \big) \big( A_u^\beta(k+1) \cup A_u^\beta(k+1) \big), \quad (10.5.8) \]
where, for each \( u \in Q_m(k) \), we abuse notations and write \( u' \equiv u + \Delta_{m(k)} \).

For each \( h \geq 0 \), define the small exceptional set
\[ D_{h+} \equiv \bigcup_{k=h}^\infty D_k, \quad (10.5.9) \]
with
\[ P(D_{h+}) \leq \sum_{k=h}^\infty 2^{-k} = 2^{-h+1}. \quad (10.5.10) \]

\[ \square \]

**Lemma 10.5.5. (Existence of certain suprema as r.r.v.’s).** Let \( Z : Q_\infty \times \Omega \rightarrow S \) be a \( D \)-regular process, with a modulus of \( D \)-regularity \( \mathcal{m} \equiv (m_k)_{k=0,1,...} \). Let \( h \geq 0 \) and \( v,v',v \in Q_m(h) \) be arbitrary, with \( v \leq v' \). Then the following holds.

1. For each \( r \in [v,v']Q_\infty \), we have
\[ d(Z_\tau,Z_s) \leq \bigvee_{u \in [v,v']Q(m(h))} d(Z_\tau,Z_u) + \hat{\beta}_{h+1}(r), \quad (10.5.11) \]
on \( D_{h+}^r \).

2. The supremum
\[ Y_{v,v'} \equiv \sup_{u \in [v,v']Q(\infty)} d(Z_\tau,Z_u) \]
exists as a r.r.v. Moreover
\[ 0 \leq Y_{v,v'} - \bigvee_{u \in [v,v']Q(m(h))} d(Z_\tau,Z_u) \leq \beta_{h+1,\infty} \leq 2^{-h+4} \]
on \( D_{h+}^r \), where \( P(D_{h+}) \leq 2^{-h+1} \).

3. Write \( \hat{\tau} \equiv 1 \wedge d \). Then
\[ 0 \leq E \sup_{u \in [v,v']Q(\infty)} \hat{d}(Z_\tau,Z_u) - E \bigvee_{u \in [v,v']Q(m(h))} \hat{d}(Z_\tau,Z_u) \leq 2^{-h+5}. \]
where \( h \geq 0 \) and \( v,v' \in Q_m(h) \) are arbitrary with \( v \leq v' \).

Yuen-Kwok Chan 348 Constructive Probability
10.5. THE RIGHT-LIMIT EXTENSION OF D-REGULAR PROCESSES AREA.U. CADLÀG

Proof. 1. First let \( k \geq 0 \) be arbitrary. Consider each \( \omega \in D^c_k \). We will prove that

\[
0 \leq \bigvee_{u \in [v,v']Q(m(k+1))} d(Z_{\omega}(\omega), Z_u(\omega)) - \bigvee_{u \in [v,v']Q(m(k))} d(Z_{\omega}(\omega), Z_u(\omega)) \leq \beta_{k+1}. \tag{10.5.12}
\]

Consider each \( r \in [v,v']Q(m(k+1)) \). Then \( r \in [s,s+\Delta_m(k)]Q_m(k+1) \) for some \( s \in Q_m(k) \) such that \( [s,s+\Delta_m(k)] \subset [v,v'] \). Write \( s' \equiv s + \Delta_m(k) \). We need to prove that

\[
d(Z_{\omega}(\omega), Z_r(\omega)) \leq \bigvee_{u \in [v,v']Q(m(k))} d(Z_{\omega}(\omega), Z_u(\omega)) + \beta_{k+1}. \tag{10.5.13}
\]

If \( r = s \) or \( r = s' \), then \( r \in [v,v']Q_m(k) \) and inequality \( 10.5.13 \) holds trivially. Hence we may assume that \( r \in (s,s')Q_m(k+1) \). Since \( \omega \in D^c_k \) by assumption, the defining equality \( 10.5.8 \) implies that

\[
\omega \in (A_{s,r}^\beta(k+1)\backslash c (A_{s,r}^\beta(k+1)\backslash c (A_{s',r}^\beta(k+1)\backslash c (A_{s',r}^\beta(k+1)\backslash c. \]

Consequently, by the defining equality \( 10.5.3 \) for the sets in the last displayed expression, we have

\[
d(Z_{\omega}(\omega), Z_r(\omega)) \leq \bigvee_{u \in [v,v']Q(m(k))} d(Z_{\omega}(\omega), Z_u(\omega)) \leq \beta_{k+1}.
\]

Hence the triangle inequality implies that

\[
d(Z_{\omega}(\omega), Z_r(\omega)) \leq (d(Z_{\omega}(\omega), Z_r(\omega)) + d(Z_{\omega}(\omega), Z_r(\omega))) + \beta_{k+1}
\]

\[
\leq (d(Z_{\omega}(\omega), Z_r(\omega))) + \bigvee_{u \in [v,v']Q(m(k))} d(Z_{\omega}(\omega), Z_u(\omega)) + \beta_{k+1}
\]

\[
\leq (d(Z_{\omega}(\omega), Z_r(\omega))) + \bigvee_{u \in [v,v']Q(m(k))} d(Z_{\omega}(\omega), Z_u(\omega)) + \beta_{k+1}
\]

\[
\leq \beta_{k+1} + \bigvee_{u \in [v,v']Q(m(k))} d(Z_{\omega}(\omega), Z_u(\omega)) + \beta_{k+1}
\]

establishing inequality \( 10.5.13 \) for arbitrary \( r \in [v,v']Q_m(k+1) \). The desired inequality \( 10.5.12 \) follows.

2. Let \( h \geq 0 \) be arbitrary, and consider each \( \omega \in D^c_h \). Then \( \omega \in D^c_k \) for each \( k \geq h \). Hence, inequality \( 10.5.12 \) can be applied to \( h, h+1, \ldots, k+1 \) to yield

\[
0 \leq \bigvee_{u \in [v,v']Q(m(k+1))} d(Z_{\omega}(\omega), Z_u(\omega)) - \bigvee_{u \in [v,v']Q(m(h))} d(Z_{\omega}(\omega), Z_u(\omega)) \leq \beta_{k+1} + \cdots + \beta_{h+1}.
\]

\[
\leq \beta_{k+1} + \cdots + \beta_{h+1} = \beta_{h+1,k+1} < \beta_{h+1,m} < 2^{-h+2}. \tag{10.5.14}
\]
3. Consider each \( r \in [v', v]Q_{\infty} \). We will prove that
\[
d(Z_r(\omega), Z_r(\omega)) \leq \bigvee_{u \in [v', v]Q(m(h))} d(Z_r(\omega), Z_u(\omega)) + \beta_{h+1}(r). \quad (10.5.15)
\]
The desired inequality is trivial if \( r \in Q_{m(h)} \). Hence we may assume that \( r \in Q_{m(k+1)}Q_{m(k)}^{-} \) for some \( k \geq h \). Then \( \beta_{h}(r) = \beta_{h+1,k+1} \). Therefore the first half of inequality \([10.5.14]\) implies that
\[
d(Z_r(\omega), Z_r(\omega)) \leq \bigvee_{u \in [v', v]Q(m(h))} d(Z_r(\omega), Z_u(\omega)) + \beta_{h+1,k+1} = \bigvee_{u \in [v', v]Q(m(h))} d(Z_r(\omega), Z_u(\omega)) + \beta_{h+1}(r).
\]
Inequality \([10.5.15]\) is proved, where \( \omega \in D_{h+1}^{c} \) is arbitrary. Inequality \([10.5.11]\) follows. Assertion 1 is proved.

4. Next consider the special case where \( \mathfrak{T} = v \). Since \( P(D_{h+1}) \leq 2^{-h+1} \), it follows from inequality \([10.5.14]\) that the a.u. limit
\[
\mathfrak{T}_{v,v'} = \lim_{k \to \infty} \bigvee_{u \in [v', v]Q(m(k+1))} d(Z_r, Z_u)
\]
exists and is a r.r.v. Moreover, for each \( \omega \in \text{domain}(\mathfrak{T}_{v,v'}) \), it is easy to verify that \( \mathfrak{T}_{v,v'}(\omega) \) gives the supremum \( \sup_{u \in [v', v]Q(\infty)} d(Z_r(\omega), Z_u(\omega)) \). Thus the supremum \( Y_{v,v'} \equiv \sup_{u \in [v', v]Q(m(h))} d(Z_r, Z_u) \) is defined and equal to the r.r.v. \( Y_{v,v'} \) on a full set, and is therefore itself a r.r.v. Letting \( k \to \infty \) in inequality \([10.5.14]\) we obtain
\[
0 \leq Y_{v,v'} - \bigvee_{u \in [v', v]Q(m(h))} d(Z_r, Z_u) \leq \beta_{h+1,\infty} \leq 2^{-h+4}
\]
on \( D_{h+1}^{c} \cap \text{domain}(\mathfrak{T}_{v,v'}) \). This proves Assertion 2.

3. Write \( \hat{d} \equiv 1 \wedge d \). Then
\[
0 \leq E \sup_{u \in [v', v]Q(\infty)} \hat{d}(Z_r, Z_u) - E \bigvee_{u \in [v', v]Q(m(h))} \hat{d}(Z_r, Z_u)
\]
\[
= E(1 \wedge Y_{v,v'} - 1 \wedge \bigvee_{u \in [v', v]Q(m(h))} d(Z_r, Z_u))
\]
\[
\leq E1_{D_{h+1}^{c}}(1 \wedge Y_{v,v'} - 1 \wedge \bigvee_{u \in [v', v]Q(m(h))} d(Z_r, Z_u)) + E1_{D_{h+1}}.
\]
\[
\leq 2^{-h+5} + P(D_{h+1}) \leq 2^{-h+4} + 2^{-h+1} < 2^{-h+5}.
\]
Assertion 3 and the lemma is proved. 

Yuen-Kwok Chan 350 Constructive Probability
10.5. THE RIGHT-LIMIT EXTENSION OF D-REGULAR PROCESSES AREA.U.

CÀDLÀG

Definition 10.5.6. (Right-limit extension of a process with dyadic rational parameters). Recall the convention that if $f$ is an arbitrary function, we write $f(x)$ only with the implicit or explicit condition that $x \in \text{domain}(f)$.

1. Let $Q_\infty$ stand for the set of dyadic rationals in $[0, 1]$. Let $Y: Q_\infty \times \Omega \to S$ be an arbitrary process. Define a function $X: [0, 1] \times \Omega \to S$ by

$$\text{domain}(X) \equiv \{(r, \omega) \in [0, 1] \times \Omega : \lim_{u \to r, u \geq r} Y(u, \omega) \text{ exists}\},$$

and by

$$X(r, \omega) \equiv \lim_{u \to r, u \geq r} Y(u, \omega) \quad (10.5.16)$$

for each $(r, \omega) \in \text{domain}(X)$. We will call

$$\Phi_{r\text{Lim}}(Y) \equiv X$$

the right-limit extension of the process $Y$ to the parameter set $[0, 1]$.

2. Let $Q_\infty$ stand for the set of dyadic rationals in $[0, \infty)$. Let $Y: Q_\infty \times \Omega \to S$ be an arbitrary process. Define a function $X: [0, \infty) \times \Omega \to S$ by

$$\text{domain}(X) \equiv \{(r, \omega) \in [0, \infty) \times \Omega : \lim_{u \to r, u \geq r} Y(u, \omega) \text{ exists}\},$$

and by

$$X(r, \omega) \equiv \lim_{u \to r, u \geq r} Y(u, \omega) \quad (10.5.17)$$

for each $(r, \omega) \in \text{domain}(X)$. We will call

$$\Phi_{r\text{Lim}}(Y) \equiv X$$

the right-limit extension of the process $Y$ to the parameter set $[0, \infty)$.

In general, the right-limit extension $X$ need not be a well-defined process. □

In the following proposition, recall that, as in Definition 6.1.3, continuity a.u. is a weaker condition than a.u. continuity.

Proposition 10.5.7. (The right-limit extension of a $D$-regular process is a well-defined stochastic process and is continuous a.u.). The right-limit extension $X \equiv \Phi_{r\text{Lim}}(Z): [0, 1] \times \Omega \to S$ of the $D$-regular process $Z$ is a stochastic process which is continuous a.u.

Specifically, the following holds.

1. Let $\varepsilon > 0$ be arbitrary. Take $v \geq 0$ so large that $2^{-v+5} < \varepsilon$. Take an arbitrary $J \geq 0$ so large that

$$\Delta_{m(J)} \equiv 2^{-m(J)} < 2^{-2\delta_{C_p}(2^{-2v+2})}. \quad (10.5.18)$$

Define

$$\delta_{\text{cun}}(\varepsilon) \equiv \delta_{\text{cun}}(\varepsilon, m, \delta_{C_p}) \equiv \Delta_{m(J)} \in Q_m. \quad (10.5.19)$$

Then, for each $t \in [0, 1]$, there exists an exceptional set $G_t$ with $P(G_t) < \varepsilon$ such that

$$d(X(t, \omega), X(t', \omega)) < \varepsilon$$

Yuen-Kwok Chan 351 Constructive Probability
for each $t' \in [t - \delta_{Cp}(t), t + \delta_{Cp}(t)] \cap \text{domain}(X(\cdot, \omega))$, for each $\omega \in G_t^c$.

2. Moreover, $X(\cdot, \omega)|_{Q_m} = Z(\cdot, \omega)$ for a.e. $\omega \in \Omega$.

3. Furthermore, the process $X$ has the same modulus of continuity in probability $\delta_{Cp}$ as the process $Z$.

4. (Right continuity). For a.e. $\omega \in \Omega$, the function $X(\cdot, \omega)$ is right continuous at each $t \in \text{domain}(X(\cdot, \omega))$.

5. (Right completeness). For a.e. $\omega \in \Omega$, we have $t \in \text{domain}(X(\cdot, \omega))$ for each $t \in [0, 1]$ such that $\lim_{t \rightarrow t'} X(r, \omega)$ exists.

Proof. We will first verify that $X_t \equiv X(t, \cdot)$ is a r.v. with values in $S$, for each $t \in [0, 1]$, then prove the continuity a.u. To that end, let $t \in [0, 1]$ and $\varepsilon > 0$ be arbitrary. Write $\Delta \equiv \Delta_m(t)$. For ease of reference to previous theorems, write $n \equiv \nu$.

1. Recall that $\delta_{Cp}$ is the given modulus of continuity in probability of the process $Z$, and recall that $\beta_n \in (2^{-n+1}, 2^{-n+2})$ is as selected in Definition 10.5.3. When there is no risk of confusion, suppress the subscript $m$, write $p \equiv p_m(t) \equiv 2^{-m}$, and write $q_i \equiv q_m(t, i) \equiv i \Delta \equiv i 2^{-m}$. For each $i = 0, \ldots, p$. Then

$$t \in [0, 1] = [q_0, q_2] \cup \{q_1, q_3\} \cup \ldots \cup [q_{p-3}, q_{p-1}] \cup [q_{p-2}, q_p].$$

Hence there exists $i = 0, \ldots, p - 2$ such that $t \in [q_i, q_{i+2}]$. The neighborhood $\Theta_{t, \varepsilon} \equiv [t - \Delta, t + \Delta] \cap [0, 1]$ of $t$ in $[0, 1]$ is a subset of $[q_{i-1}) \cup (q_{i+1}) \cup q_{i+2}$. Write $\nu \equiv q_{i-1} \cup q_{i+2}$ and $\nu' \equiv q_{i+1}$. Then (i) $\nu, \nu' \in Q_m(t)$, (ii) $\nu < \nu'$, and (iii) the set

$$[\nu, \nu']Q_m(t) = \{q_{i-1}, q_{i+1}, q_{i+2}, q_{i+3} \cup p\}$$

contains 4 or 5 distinct and consecutive elements of $Q_m(t)$. Therefore, for each $u \in \nu, \nu'Q_m(t)$, we have $|\nu - u| \leq 4\Delta < \delta_{Cp}(2^{-2n+2})$, whence

$$E 1 \land d(Z_v, Z_u) \leq 2^{-2n+2} < \beta_n^2,$$

and, by Chebychev’s inequality,

$$P(d(Z_v, Z_u) > \beta_n) \leq \beta_n.$$

Hence the measurable set

$$A_n \equiv \bigcup_{u \in [\nu, \nu']Q_m(t)} (d(Z_v, Z_u) > \beta_n)$$

has probability bounded by $P(A_n) \leq 4\beta_n < 2^{-n+4}$. Define $G_{t, \varepsilon} \equiv D_{t+} \cup A_n$. It follows that

$$P(G_{t, \varepsilon}) \leq P(D_{t+}) + P(A_n) < 2^{-n+4} + 2^{-n+4} = 2^{-n+5} < \varepsilon.$$ 

(10.5.20)

2. Next consider each $\omega \in G_{t, \varepsilon} \equiv D_{t+} \cup A_n$. Then, by the definition of the set $A_n$, we have

$$\bigvee_{s \in [\nu, \nu']Q_m(t)} d(Z(v, \omega), Z(s, \omega)) \leq \beta_n.$$
10.5. THE RIGHT-LIMIT EXTENSION OF $D$-REGULAR PROCESSES AREA.U. CADLÄG

At the same time, since $\omega \in D^c_{n+} \subset D^c_{f, +}$, inequality [10.5.11] of Lemma [10.5.5] where $h, \nu$ are replaced by $J, \nu$ respectively, implies that, for each $r \in \theta_{t, Q_{\omega}} \subset [\nu, \nu'] Q_{\omega}$, we have

$$d(Z_r(\omega), Z_\omega(\omega)) \leq \frac{\beta_{J+1}(r)}{\nu} + \sum_{x \in [\nu, \nu'] Q(m(J))} d(Z_r(\omega), Z_x(\omega))$$

$$= \beta_{J+1}(r) + \beta_n \leq \beta_{J+1, \infty} + \beta_n \leq \beta_{n, \infty}.$$  

Then the triangle inequality yields

$$d(Z(r, \omega), Z(r', \omega)) \leq 2\beta_{n, \infty} < 2^{-n+4} < \varepsilon$$  

(10.5.21)

for each $r, r' \in \theta_{t, Q_{\omega}} \equiv [t - \Delta_{m(J)}, t + \Delta_{m(J)}] Q_{\omega}$, where $\omega \in G^c_{t, \varepsilon}$ is arbitrary, where $\varepsilon > 0$ is arbitrarily small.

3. Now write $\varepsilon_k \equiv 2^{-k}$ for each $k \geq 1$. Then $G_k \equiv \bigcup_{k=1}^{\infty} G_{t, \varepsilon(k)}$ has probability bounded by $P(G_k) \leq 2^{-k+1}$. Hence $H_k \equiv \bigcap_{k=1}^{\infty} G_k$ is a null set. Moreover, for each $\omega \in H^c_k$, we have $\omega \in G^c_{\varepsilon_k}$ for some $k \geq 1$. Therefore the $\lim_{u \rightarrow t} Z(u, \omega)$ exists, whence the right limit $X(t, \omega)$ is well defined and

$$X(t, \omega) \equiv \lim_{u \rightarrow t} Z(u, \omega) = \lim_{u \rightarrow t} Z(u, \omega).$$  

(10.5.22)

Applied to the special case of an arbitrary $u \in Q_{\omega}$ in the place of $t$, equality [10.5.22] implies that $X(u, \omega) = Z(u, \omega)$ for each $\omega \in H^c_k$. Hence the same equality [10.5.22] can be rewritten as

$$X(t, \omega) \equiv \lim_{u \rightarrow t} X(u, \omega) = \lim_{u \rightarrow t} X(u, \omega)$$

for each $\omega \in H^c_k$. Define the null set $H \equiv \bigcup_{u \in Q(\omega)} H_u$. Then $X(u, \omega) = Z(u, \omega)$ for each $u \in Q_{\omega}$, for each $\omega \in H^c_k$. In short, $X(\cdot, \omega) | Q_{\omega} = Z(\cdot, \omega)$ for each $\omega \in H^c_k$. This verifies Assertion 2.

4. For each $k \geq 1$, fix an arbitrary $r_k \in \theta_{t, \varepsilon(k)} Q_{\omega}$. Consider each $k \geq 1$, and each $\omega \in G^c_{\varepsilon_k}$. Then, for each $k \geq \kappa$, we have $r_k, r_k \in \theta_{t, \varepsilon(k)} Q_{\omega}$, and so, by inequality [10.5.21] where $\varepsilon$ is replaced by $\varepsilon_k$, we obtain

$$d(Z(r_k, \omega), Z(r_k, \omega)) \leq \varepsilon_k.$$  

(10.5.23)

Letting $k \rightarrow \infty$, this yields

$$d(X(t, \omega), Z(r_k, \omega)) \leq \varepsilon_k,$$  

(10.5.24)

where $\omega \in G^c_{\varepsilon_k}$ is arbitrary. Since $P(G_k) \leq 2^{-k+1}$ is arbitrarily small for sufficiently large $\kappa$, we conclude that $Z(t(\kappa) \rightarrow X(t)$ a.u. Consequently, the function $X_t$ is r.v. Since $t \in [0, 1]$ is arbitrary, the function $X(\cdot, \omega) = \Phi_{t, \lim}(Z) : [0, 1] \times \Omega \rightarrow S$ is a stochastic process.

5. Let $r' \in \{t - \Delta_{m(J)}, t + \Delta_{m(J)} \cap domain(X(\cdot, \omega)) \}$ be arbitrary. Letting $r \downarrow t$ and $r' \downarrow t'$ in inequality [10.5.21] while $r, r' \in \theta_{t, \varepsilon Q_{\omega}}$, we obtain

$$d(X(t, \omega), X(r', \omega)) \leq \varepsilon.$$  

(10.5.25)

where $\omega \in G^c_{\varepsilon_k}$ is arbitrary. Since $t \in [0, 1]$ is arbitrary, and since $P(G_t, \varepsilon) < \varepsilon$ is arbitrarily small, we see that the process $X$ is continuous a.u. according to Definition [6.1.3].

 Assertions 1 has been proved.
6. Next, we will verify that the process \( X \) has the same modulus of continuity in probability \( \delta_{Cp} \) as the process \( Z \). To that end, let \( \varepsilon > 0 \) be arbitrary, and let \( t, s \in [0,1] \) be such that \( |t - s| < \delta_{Cp}(\varepsilon) \). In Step 5 we saw that there exist sequences \( (r_k)_{k=1,2,...} \) and \( (v_k)_{k=1,2,...} \) in \( Q_\infty \) such that \( r_k \to t, v_k \to s, Z_{r(k)} \to X_t \) a.u. and \( Z_{v(k)} \to X_s \) a.u. Then, for sufficiently large \( k \geq 0 \) we have \( |r_k - v_k| < \delta_{Cp}(\varepsilon) \), whence \( E1 \wedge d(Z_{r(k)}, Z_{v(k)}) \leq \varepsilon \). The last cited a.u. convergence therefore implies that

\[ E1 \wedge d(X_t, X_s) \leq \varepsilon. \]

Summing up, \( \delta_{Cp} \) is a modulus of continuity of probability of the process \( X \). Assertion 3 is proved.

7. Consider each \( \omega \) in the full set \( \bigcap_{u \in Q(\infty)} \text{domain}(Z_u) \). Then the function \( Z(\cdot, \omega) : Q_\infty \to S \) has domain \( Q_\infty \) which is dense in \([0,1] \). Hence its right-limit extension \( X(\cdot, \omega) : [0,1] \to S \) satisfies the conditions in Assertions 4 and 5, according to Proposition 10.1.6. The present proposition is proved.

We now prove the main theorem of this chapter. In the proof, refer to Proposition 8.2.8 for basic properties of simple first exit times.

### Theorem 10.5.8. (The right-limit extension of a D-regular process is a.u. càdlàg).

The right-limit extension

\[ X \equiv \Phi_{Lim}(Z) : [0,1] \times \Omega \to S \]

is a.u. càdlàg. Specifically, (i) it has the same modulus of continuity in probability \( \delta_{Cp} \) as the given \( D \)-regular process \( Z \), and (ii) it has a modulus of a.u. càdlàg \( \delta_{aucl}(\cdot, \bar{m}, \delta_{Cp}) \) defined as follows. Let \( \varepsilon > 0 \) be arbitrary. Let \( n \geq 0 \) be so large that \( 2^{n+6} < \varepsilon \). Let \( J \geq n + 1 \) be so large that

\[ \Delta_{m(J)} = 2^{-m(J)} < 2^{-2} \delta_{Cp}(2^{-2m(n) - 2n - 10}). \] (10.5.26)

Define

\[ \delta_{aucl}(\varepsilon, \bar{m}, \delta_{Cp}) \equiv \Delta_{m(J)}. \]

Note that the operation \( \delta_{aucl}(\cdot, \bar{m}, \delta_{Cp}) \) depends only on \( \bar{m} \) and \( \delta_{Cp} \).

**Proof.** We will prove that the operation \( \delta_{aucl}(\cdot, \bar{m}, \delta_{Cp}) \) thus defined is a modulus of a.u. càdlàg of the right-limit extension \( X \).

1. To that end, let \( i = 1, \ldots, p_{m(n)} \) be arbitrary, but fixed until further notice. When there is little risk of confusion, we suppress references to \( n \) and \( i \), and write

\[ p \equiv p_{m(n)} \equiv 2^{m(n)}, \]

\[ \Delta \equiv \Delta_{m(n)} \equiv 2^{-m(n)}, \]

\[ t \equiv q_{i-1} \equiv q_{m(n),i-1} \equiv (i-1)2^{-m(n)}, \]

and

\[ t' \equiv q_i \equiv q_{m(n),i} \equiv i2^{-m(n)}. \]
Hence
\[ \Delta_m(j) = \delta u m(\varepsilon, m, \delta C_p), \]
where \( \delta u m(\cdot, m, \delta C_p) \) is the modulus of continuity a.u. of the process \( X \) defined in Proposition [10.5.7]. Note also that \( \varepsilon_n \leq \beta_n \).

In the next several steps, we will prove that, for each \( \omega \in D_n^c \), the set \( Z([t, t']Q_m, \omega) \) can be divided into two sections \( Z([t, \tau]Q_m, \omega) \) and \( Z([\tau, t']Q_m, \omega) \) each of which is contained in a ball in \((S, d)\) with radius \( 2^{-n+5} \).

2. First introduce some simple first exit times of the process \( Z \). Let \( k \geq n \) be arbitrary. As in Definition [8.2.7] define the simple first exit time
\[ \eta_k = \eta_{k,i} = \eta_{k,\beta(n),[t,t']Q(m(k))} \]
for the process \( Z([t, t']Q_m(k)) \) to exit the time-varying \( \beta_n \)-neighborhood of \( Z_\eta \). In particular, the r.v. \( \eta_k \) has values in \([t + \Delta_m(k), t']Q_m(k)\). Thus
\[ t + \Delta_m(k) \leq \eta_k \leq t'. \] (10.5.28)

In the case where \( k = n \), this yields
\[ \eta_n = \eta_{n,i} = t' = q_m(n,i). \] (10.5.29)
Since \( Q_m(k) \subset Q_m(k+1) \), the more frequently sampled simple first exit time \( \eta_{k+1} \) comes no later than \( \eta_k \), according to Assertion 5 of Proposition [8.2.8]. Thus
\[ \eta_{k+1} \leq \eta_k. \] (10.5.30)

3. Now let \( \kappa \geq k \geq n \) and \( \omega \in D_n^c \) be arbitrary. We will prove that
\[ t \leq \eta_k(\omega) - 2^{-m(k)} \leq \eta_k(\omega) - 2^{-m(\kappa)} \leq \eta_k(\omega) \leq \eta_k(\omega). \] (10.5.31)
The first of these inequalities is from the first part of inequality [10.5.28]. The third is trivial, and the last is by a repeated application of inequality [10.5.30]. It remains only to prove the second.

To that end, write \( v \equiv t, s \equiv \eta_k(\omega) \) and \( v' \equiv s - \Delta_m(k) \). Then \( v, t, s, v' \in [t, t']Q_m(k) \). Since \( v' < s = \eta_k(\omega) \), the sample path \( Z(\cdot, \omega)\big|_{[t, t']Q_m(k)} \) has not exited the time varying \( \beta_n \)-neighborhood of \( Z(\omega) \) at time \( v' \). In other words,
\[ d(Z_t(\omega), Z_s(\omega)) \leq \beta_n(u) \leq \beta_n(k) \] (10.5.32)
for each \( u \in [v, v']Q_m(k) \). At the same time, \( \omega \in D_n^c \subset D_n^c \). Hence inequality [10.5.11] of Lemma [10.5.5] where \( h, v, \tau \) are replaced by \( k, t, t \) respectively, implies that
\[ d(Z_t(\omega), Z_s(\omega)) \leq \hat{\beta}_{k+1}(r) + \max_{u \in [v, v']Q_m(k)} d(Z_t(\omega), Z_u(\omega)) \]

Yuen-Kwok Chan 355 Constructive Probability
for each \( r \in [t, v']Q_{m(k+1)} \). In particular, for each \( r \in [t, v']Q_{m(k+1)} \subset [v, v']Q_{m(k+1)} \), inequality \( 10.5.33 \) holds. Thus the sample path \( Z(t, \omega)[t, t']Q_{m(k+1)} \) has not exited the time-varying \( \hat{\beta}_n \)-neighborhood of \( Z(t, \omega) \) at time \( v' \equiv \eta_k(\omega) - \Delta_{m(k)} \). In other words,

\[
\eta_k(\omega) - \Delta_{m(k)} < \eta_{k+1}(\omega).
\]

Since both sides of this strict inequality are members of \( Q_{m(k+1)} \), it follows that

\[
\eta_k(\omega) - \Delta_{m(k)} \leq \eta_{k+1}(\omega) - \Delta_{m(k+1)}.
\]

Thus inequality \( 10.5.31 \) has been verified.

4. Inequality \( 10.5.31 \) implies that the limit

\[
\tau \equiv \tau_i \equiv \lim_{k \to \infty} \eta_k
\]

exists uniformly on \( D_{k+1} \), with

\[
t \leq \eta_k - 2^{-m(k)} \leq \tau \leq \eta_k \leq t'
\]

on \( D_{k+1} \). Since \( P(D_{k+1}) \leq 2^{-k+3} \) is arbitrarily small, we conclude that

\[
\eta_k \downarrow \tau \quad \text{a.u.,}
\]

with \( t < \tau \leq t' \), or, in fuller notations, with

\[
q_{i-1} < \tau_i \leq q_i
\]

5. Now let \( h \geq n \) be arbitrary, and let \( \omega \in D_{h+1} \) be arbitrary. Consider each \( u \in [t, \tau(\omega)]Q_{m(k)} \). Then \( u \in [t, \eta_k(\omega)]Q_{m(k)} \) for some \( k \geq h \). Hence, by the basic properties of the simple first exit time \( \eta_k \), we have

\[
d(Z(t, \omega), Z(u, \omega)) \leq \hat{\beta}_n(u) < \beta_{n, \infty}.
\]

Thus we obtain the bounding relation

\[
Z([q_{i-1}, \tau_i(\omega)]Q_{m(k)}) \subset (d(\cdot, Z(q_{i-1}, \omega)) < \beta_{n, \infty}) \subset (d(\cdot, Z(q_{i-1}, \omega)) < 2^{-n+3}).
\]

6. To obtain a similar bounding relation for the set \( Z([\tau_i(\omega), q_i], \omega) \), we will first prove that

\[
d(Z(w, \omega), Z(\eta_h(\omega), \omega)) \leq \beta_{h+1, \infty}
\]

for each \( w \in [\eta_{h+1}(\omega), \eta_h(\omega)]Q_{m(k)} \).

To that end, write, for abbreviation, write \( u \equiv \eta_h(\omega) - \Delta_{m(h)} \), \( r \equiv \eta_{h+1}(\omega) \), and \( u' \equiv \eta_h(\omega) \). From inequality \( 10.5.31 \), where \( k, \kappa \) are replaced by \( h, h+1 \) respectively, we obtain \( u < r < u' \). The desired inequality \( 10.5.38 \) holds trivially if \( r = u' \). Hence we may assume that \( u < r < u' \). Consequently, since \( u, u' \) are consecutive points in
In words, the sample path $Z(\cdot, \omega)|[t, t')Q_{m(h+1)}$ successfully exits the time-varying $\hat{\beta}_n$-neighborhood of $Z(t, \omega)$, for the first time at $r$. Therefore
\[ d(Z(t, \omega), Z(r, \omega)) > \hat{\beta}_n(r) = \beta_{n,h+1}. \quad (10.5.39) \]

On the other hand, since $u \in Q_{m(h)} \subset Q_{m(h+1)}$ and $u < r$, exit has not occurred at time $u$. Hence
\[ d(Z(t, \omega), Z(u, \omega)) \leq \hat{\beta}_n(u) \leq \beta_{n,h}. \quad (10.5.40) \]

Inequalities (10.5.39) and (10.5.40) together yield, by the triangle inequality,
\[ d(Z(u, \omega), Z(r, \omega)) > \beta_{n,h+1} - \beta_{n,h} = \beta_{h+1}. \]

It follows that $\omega \in A_u^{\beta_{(h+1)}}$ by the definition of the sets $A_u^{\beta_{(h+1)}}$.

Now consider an arbitrary $s \in [r, u')Q_{m(h+1)}$. Then, trivially,
\[ \omega \in A_u^{\beta_{(h+1)}} \subset (A_u^{\beta_{(h+1)}} \cup A_s^{\beta_{(h+1)}}) (A_u^{\beta_{(h+1)}} \cup A_{u',s}^{\beta_{(h+1)}}). \quad (10.5.41) \]

At the same time, since $\omega \in D_h^c \subset D_h^c$ and since $u, u' \in Q_{m(h)}$ with $u' \equiv u + \Delta_m(h)$, we can apply the defining formula (10.5.5) of the exceptional set $D_h$, to obtain
\[ \omega \in D_h^c \subset (A_{u',s}^{\beta_{(h+1)}} \cup A_{u',s}^{\beta_{(h+1)}}) \subset (A_{u',s}^{\beta_{(h+1)}}). \quad (10.5.42) \]

Relations (10.5.41) and (10.5.42) together then imply that
\[ \omega \in (A_{u',s}^{\beta_{(h+1)}} \cup A_{u',s}^{\beta_{(h+1)}}) \subset (A_{u',s}^{\beta_{(h+1)}}). \]

Consequently, by the definition of the set $A_{u',s}^{\beta_{(h+1)}}$, we have
\[ d(Z(s, \omega), Z(u', \omega)) \leq \beta_{h+1}, \quad (10.5.43) \]

where $s \in [r, u')Q_{m(h+1)}$ is arbitrary. The same inequality trivially holds for $s = u'$. Summing up,
\[ \sum_{s \in [r, u')Q_{m(h+1)}} d(Z_s(\omega), Z_{u'}(\omega)) \leq \beta_{h+1}. \]

Then, for each $w \in [r, u')Q_{m(h)}$, we can apply inequality (10.5.11) of Lemma (10.5.5) where $h, v, v', \bar{r}, r, u$ are replaced by $h + 1, r, u', u', w, s$ respectively, to obtain
\[ d(Z_w(\omega), Z_{u'}(\omega)) \leq \bar{\beta}_{h+2}(w) + \sum_{s \in [r, u')Q_{m(h+1)}} d(Z_{s}(\omega), Z_{u'}(\omega)) \]
CHAPTER 10. A.U. CÀDLÀG PROCESSES

\[
\leq \beta_{h+2,\infty} + \beta_{h+1,\infty} = \beta_{h+1,\infty}.
\] (10.5.44)

In other words, inequality \[10.5.38\] is verified.

7. Now let \( r' \in (\tau(\omega), \eta_h(\omega)) \) be arbitrary. Then \( r' \in [\eta_{k+1}(\omega), \eta_h(\omega)] \) for some \( k \geq h \).

\[
d(Z(r', \omega), Z(\eta_h(\omega), \omega)) \leq d(Z(r', \omega), Z(\eta_\omega(\omega), \omega)) + d(Z(\eta_\omega(\omega), \omega), Z(\eta_{k-1}(\omega), \omega)) + \cdots + d(Z(\eta_{h+1}(\omega), \omega), Z(\eta_h(\omega), \omega))
\]

\[
\leq \beta_{k+1,\infty} + \beta_{h,\infty} + \cdots + \beta_{h+1,\infty} < 2^{-h+5},
\] (10.5.45)

where the second inequality is by repeated applications of inequality \[10.5.38\] Thus

\[
d(Z(r', \omega), Z(\eta_h(\omega), \omega)) < 2^{-h+5}
\] (10.5.46)

for each \( r' \in (\tau(\omega), \eta_h(\omega)) \) for \( h \geq n \) and \( \omega \in D^r_{h+} \) are arbitrary.

8. We will prove that \( X_r \) is a well defined r.v. To that end, let \( h \geq n \) be arbitrary. By Proposition \[10.5.6\] there exists \( \delta_h \equiv \delta_{\text{cau}}(2^{-m(h)^{-1-h}}) > 0 \) with \( \delta_h \in Q_\infty \) such that, for each \( r \in [0,1] \), there exists an exceptional set \( H_r \) with \( P(H_r) < 2^{-m(h)^{-1-h}} \) such that, for each \( \omega \in H_r^c \), we have

\[
d(X(r, \omega), X(r', \omega)) < 2^{-m(h)^{-1-h}} \leq 2^{-h+5}
\] (10.5.47)

for each \( r' \in [r - \delta_h, r + \delta_h] \cap \text{domain}(X(\cdot, \omega)) \). Define the exceptional set

\[
B_h \equiv \bigcup_{r \in Q(m(h))} H_r.
\] (10.5.48)

Then

\[
P(B_h) \leq \sum_{r \in Q(m(h))} 2^{-m(h)^{-1-h}} < 2^{-h}.
\] (10.5.49)

Now let \( \omega \in B^c_{h+} \) be arbitrary, and write \( r \equiv \eta_h(\omega) \geq \tau(\omega) \). Let \( u \in (\tau(\omega), \tau(\omega) + \delta_h) \) be arbitrary. Then either (i) \( u \in (\tau(\omega), r') \) or (ii) \( u \in [r, r + \delta_h] \). Consider Case (i). Then, since \( \omega \in B^c_r \subset D^r_{h+} \), inequality \[10.5.46\] applies and yields

\[
d(Z_u(\omega), Z_{\eta(h)}(\omega)) \equiv d(Z(u, \omega), Z(r, \omega)) < 2^{-h+5}.
\] (10.5.50)

Consider Case (ii). Then, since \( \omega \in B^c_r \subset H_r^c \) and since \( r, u \in Q_\infty \subset \text{domain}(X(\cdot, \omega)) \), inequality \[10.5.47\] holds with \( X \) replaced by \( Z \), to yield

\[
d(Z_{\eta(h)}(\omega), Z_u(\omega)) \equiv d(Z(r, \omega), Z(u, \omega)) < 2^{-h+5}.
\] (10.5.51)

Combining, we see that

\[
d(Z_{\eta(h)}(\omega), Z_u(\omega)) < 2^{-h+5}
\] (10.5.52)

for each \( u \in (\tau(\omega), \tau(\omega) + \delta_h) \) for \( \omega \in B^c_h \).
Now consider each \( u \in [\tau(\omega), \tau(\omega) + \delta_{\omega}] Q_\omega \). Pick an arbitrary sequence \((u_k)_{k=1,2} \ldots \) in \((u, \tau(\omega) + \delta_{\omega}) Q_\omega \subset (\tau(\omega), \tau(\omega) + \delta_{\omega}) Q_\omega \) with \( u_k \to u \). Then, for each \( k \geq 1 \), inequality \((10.5.52)\) holds for \( u_k \) in the place of \( u \). At the same time, since the process \( Z \) is continuous a.u., we have \( Z_{u(k)}(\omega) \to Z_u(\omega) \). Consequently,

\[
d(Z_{\eta(h)}(\omega), Z_\omega(\omega)) \leq 2^{-h+5}  \tag{10.5.53}
\]

where \( u \in [\tau(\omega), \tau(\omega) + \delta_{\omega}] Q_\omega \) is arbitrary. It follows that \( \lim_{u \to \tau(\omega): u \geq \tau(\omega)} Z(u, \omega) \) exists. In other words, \((\tau(\omega), \omega) \in \text{domain}(X)\), or, equivalently, \( \omega \in \text{domain}(X_\tau) \). Moreover, letting \( u \downarrow \tau(\omega) \) in inequality \((10.5.53)\) we obtain

\[
d(X_{\tau(i)}(\omega), Z_{\eta(h)}(\omega)) = d(X_{\tau(\omega)}, Z_{\eta(h)}(\omega)) \leq 2^{-h+5}  \tag{10.5.54}
\]

where \( \omega \in B_h^D \) is arbitrary. Since

\[
P(B_h \cup D_{h+}) \leq P(B_h) + P(D_{h+}) < 2^{-h} + 2^{-h+4} < 2^{-h+5},
\]

where \( h \geq n \) is arbitrary, we see that \( Z_{\eta(h)} \downarrow X_\tau \) a.u. as \( h \to \infty \). Since \( Z_{\eta(h)} \) is a r.v. for each \( h \geq n \), we conclude that the function \( X_\tau \equiv X_{\tau(i)} \) is a r.v., where \( \tau \equiv \tau_i \) and \( i = 1, \ldots, p \) are arbitrary.

9. Consider the special case where \( h = n \). Consider each \( \omega \in B_n^D \). Recall that \( n = t' = q_i \). Therefore

\[
[\tau(\omega), q_i] Q_\omega = [\tau(\omega), n(\omega)] Q_\omega \subset [\tau(\omega), \tau(\omega) + \delta_{\omega}] Q_\omega \cup (\tau(\omega), n(\omega)] Q_\omega.
\]

Hence

\[
Z([\tau(\omega), q_i] Q_\omega, \omega) \subset Z([\tau(\omega), \tau(\omega) + \delta_{\omega}] Q_\omega, \omega) \cup Z((\tau(\omega), n(\omega)] Q_\omega, \omega)
\]

\[
\subset (d(\cdot, Z_{\eta(h)}(\omega)) \leq 2^{-n+5}) = (d(\cdot, Z(q_i, \omega)) \leq 2^{-n+5}),  \tag{10.5.55}
\]

where \( \omega \in B_n^D \) is arbitrary, and where the second containment relation is thanks to inequalities \((10.5.53)\) and \((10.5.56)\).

10. Now consider an arbitrary \( \omega \in B_n^D \). For convenience, define the constant r.v.'s \( \tau_0 \equiv 0 \) and \( \tau_{p+1} \equiv 1 \). It is easy to combine relations \((10.5.57)\) and \((10.5.55)\) for each of the intervals in the disjoint union

\[
\theta_1 \cup \theta_2 \cup \cdots \cup \theta_p \cup \theta_{p+1},  \tag{10.5.56}
\]

where\n
\[
(\theta_1, \theta_2, \cdots, \theta_p, \theta_{p+1})
\]

\[
\equiv ([\tau_0(\omega), \tau_1(\omega)], [\tau_1(\omega), \tau_2(\omega)], \cdots, [\tau_{p-1}(\omega), \tau_p(\omega)], [\tau_p(\omega), \tau_{p+1}(\omega)]).
\]

More precisely,

\[
Z(\theta Q_\omega, \omega) \equiv Z([\tau_{p-1}(\omega), \tau_p(\omega)] Q_\omega, \omega)
\]

\[
= Z([\tau_{p-1}(\omega), q_{i-1}] Q_\omega, \omega) \cup Z([q_{i-1}, \tau_p(\omega)] Q_\omega, \omega)
\]

\[
\subset (d(\cdot, Z(q_{i-1}, \omega)) \leq 2^{-n+5}) \cup (d(\cdot, Z(q_{i-1}, \omega)) \leq 2^{-n+3})
\]

Yuen-Kwok Chan 359 Constructive Probability
CHAPTER 10. A.U. CÀDLÀG PROCESSES

\[ = (d(\cdot, Z(q_{i-1}, \omega))) \leq 2^{-n+5}, \]

where the containment relation \( \subset \) holds by application of condition \[10.5.37\] to \( i - 1 \), and condition \[10.5.37\] to \( i \), where \( i = 1, \ldots, p \) is arbitrary. Similarly

\[ Z(\theta_{p+1}Q_m, \omega) = Z([\tau_p(\omega), q_p]Q_m, \omega) \subset (d(\cdot, Z(q_p, \omega)) < 2^{-n+5}) \]

by condition \[10.5.55\]. Summing up, we have

\[ Z(\theta_1Q_m, \omega) \subset (d(\cdot, Z(q_{k-1}, \omega))) \leq 2^{-n+5}, \quad (10.5.58) \]

for each \( k = 1, \ldots, p + 1 \).

11. We wish to prove that each of the intervals \( \theta_1, \ldots, \theta_p, \theta_{p+1} \) has positive length, provided that we exclude also a third small exceptional set of \( \omega \). To be precise, recall from the beginning of this proof that

\[ \delta_{cu}(e_n) = \delta_{cu}(e_n, \overline{m}, \delta_{cp}) \equiv \Delta_m(j) \equiv 2^{-m(j)} < 4^{-1} \delta_{cp}(2^{-2n}\varepsilon(n)+2). \quad (10.5.59) \]

For abbreviation write

\[ \overline{\Delta} \equiv \Delta_m(j) < 4^{-1} \delta_{cp}(2^{-2n}\varepsilon(n)+2). \]

By Proposition \[10.5.7\] for a.e. \( \omega \in \Omega \), the right-limit extension \( X(\cdot, \omega) \) is defined at each point in \( Q_m \), with \( X(\cdot, \omega)|Q_m = Z(\cdot, \omega) \). Consequently, for a.e. \( \omega \in \Omega \), domain \( X(\cdot, \omega) \) is dense in \([0,1]\). Moreover, by the same Proposition \[10.5.7\] for each \( r \in [0,1] \), there exists an exceptional set \( G_r \) with \( P(G_r) < \varepsilon_n \) such that, for each \( \omega \in G_r \), we have

\[ d(X(r, \omega), X(r', \omega)) < \varepsilon_n \leq \beta_n \quad (10.5.60) \]

for each \( r' \in [r - z, r + z] \cap \text{domain}(X(\cdot, \omega)). \)

Define the exceptional set

\[ C_n \equiv \bigcup_{r \in Q(m(n))} G_r. \quad (10.5.61) \]

Then

\[ P(C_n) \leq \sum_{r \in Q(m(n))} \varepsilon_n < 2^{m(n)} \varepsilon_n = 2^{-n}. \]

12. Let \( \omega \in B_\mu^D \cap C_\nu^* \) be arbitrary, and let \( s \in [t, t + z]Q_m \) be arbitrary. Then \( \omega \in \Omega \) for each \( r \in Q_m(n) \). Hence inequality \[10.5.60\] holds for each \( r' \in [r - z, r + z] \cap \text{domain}(X(\cdot, \omega)) \), for each \( r \in Q_m(n) \). In particular, \( \omega \in \underline{G}_r \), and so inequality \[10.5.60\] with \( t \) in the place of \( r \), holds on

\[ [t, s]Q_m \subset [t, t + z]Q_m \subset [t - z, t + z] \cap \text{domain}(X(\cdot, \omega)), \]

whence

\[ d(X(t, \omega), X(t', \omega)) \leq \beta_n \leq \hat{\beta}_n(r') \quad (10.5.62) \]

for each \( r' \in [t, s]Q_m. \) Consequently, for each \( k \geq n \), the sample path \( Z(\cdot, \omega)|[t, t']Q_m(k) \) stays within the the time varying \( \hat{\beta}_n \)-neighborhood of \( Z(t, \omega) \) up to and including time

Yuen-Kwok Chan

360

Constructive Probability
10.5. THE RIGHT-LIMIT EXTENSION OF \(D\)-REGULAR PROCESSES

... Hence, according to Assertion 4 of Proposition [8.2.8] the simple first exit time \(\eta_k(\omega) \equiv \eta_{i_0,\beta\{n\},t'}[Q(mk)](\omega)\) can come only after time \(s\). In other words \(s < \eta_k(\omega)\). Letting \(k \to \infty\), we therefore obtain \(s \leq \tau(\omega)\). Since \(s \in [t,t+\overline{\Delta}]Q_\omega\) is arbitrary, it follows that \(t+\overline{\Delta} \leq \tau(\omega)\). Therefore,

\[
|\theta_i| \geq \tau_i(\omega) - q_{i-1} \equiv \tau(\omega) - t \geq \overline{\Delta}, \tag{10.5.63}
\]

where \(i = 1, \ldots, p\) is arbitrary.

13. The interval \(\theta_{p+1} \equiv (\tau_p(\omega), 1]\) however remains, with length possibly less than \(\overline{\Delta}\). To deal with this nuisance, we will blatantly replace \(\tau_p\) with the r.r.v. \(\overline{\tau}_p \equiv \tau_p \wedge (1-\overline{\Delta})\), while keeping \(\overline{\tau}_i \equiv \tau_i\) if \(i \neq p\), and prove that the other desirable properties of the intervals in the sequence\([10.5.57]\) are preserved. More precisely, define the sequence

\[
(\overline{\theta}_1, \overline{\theta}_2, \ldots, \overline{\theta}_p, \overline{\theta}_{p+1})
\equiv ([\tau_0(\omega), \tau_1(\omega)], [\tau_1(\omega), \tau_2(\omega)], \ldots, [\tau_{p-1}(\omega), \tau_p(\omega)], [\overline{\tau}_p(\omega), \tau_{p+1}(\omega)]). \tag{10.5.64}
\]

Note that only the last two members of this sequence are affected by the change. Hence \(|\overline{\theta}_i| \equiv |\theta_i| \geq \overline{\Delta}\), if \(1 \leq i \leq p-1\). Moreover, trivially,

\[
|\overline{\theta}_{p+1}| = 1 - \tau_p(\omega) \wedge (1-\overline{\Delta}) \geq \overline{\Delta}. \tag{10.5.65}
\]

Furthermore,

\[
\overline{\tau}_p(\omega) - q_{p-1} \equiv \tau_p(\omega) \wedge (1-\overline{\Delta}) - q_{p-1} = (\tau_p(\omega) - q_{p-1}) \wedge (1-\overline{\Delta} - q_{p-1})
\]

\[
= (\tau_p(\omega) - q_{p-1}) \wedge (\Delta - \overline{\Delta}) \geq \overline{\Delta} \wedge \overline{\Delta} = \overline{\Delta}, \tag{10.5.66}
\]

where the last inequality follows from inequality\([10.5.63]\) and from the inequality

\[
\Delta - \overline{\Delta} \equiv 2^{-m(n)} - 2^{-m(j)} \geq 2^{-m(j)+1} - 2^{-m(j)} = 2^{-m(j)} = \overline{\Delta}.
\]

Hence

\[
|\overline{\tau}_p| = |\tau_p(\omega) - \tau_{p-1}(\omega)| \geq \tau_p(\omega) - q_{p-1} \geq \overline{\Delta}. \tag{10.5.67}
\]

Combining inequalities\([10.5.63], [10.5.65]\) and\([10.5.67]\) we see that

\[
|\overline{\theta}_k| \equiv |\tau_k(\omega) - \tau_{k-1}(\omega)| \geq \overline{\Delta} \equiv \delta_{\text{inj}(\epsilon, \beta, \delta)}(\nu_p) \tag{10.5.68}
\]

for each \(k = 1, \ldots, p+1\), where \(\nu \in B_c^*D_{\mathbb{C}^*} \) is arbitrary.

14. We will now verify that relation\([10.5.58]\) still holds when \(\theta_k\) is replaced by \(\overline{\theta}_k\) for each \(k = 1, \ldots, p+1\). For \(k \leq 1, \ldots, p\) we have \(\overline{\theta}_k \subset \theta_k\), whence relation\([10.5.58]\) is trivially preserved. It remains to verify that

\[
Z([\overline{\tau}_p(\omega), 1]Q_\omega, \omega) \subset (d', Z(1, \omega)) \leq 2^{-n+5}. \tag{10.5.69}
\]

To that end, let \(r' \in [\overline{\tau}_p(\omega), 1]Q_\omega \equiv [\tau_p(\omega) \wedge (1-\overline{\Delta}), 1]Q_\omega\) be arbitrary. Either (i') \(r' < 1-\overline{\Delta}\) or (ii') \(r' \geq 1-\overline{\Delta}\). In Case (i'), the assumption \(r' < \tau_p(\omega)\) would imply \(r' < \tau_p(\omega)\).
CHAPTER 10. A.U. CÀDLÀG PROCESSES

\[ \tau_p(\omega) \land (1 - \Xi), \text{ a contradiction. Therefore, in Case (i') we have } r' \in [\tau_p(\omega), 1]Q_m \equiv \theta_{p+1}Q_m, \text{ whence} \]

\[ d(Z(r', \omega), Z(1, \omega)) \leq 2^{-n+5} \]

by relation 10.5.58. In Case (ii'), because \(1 \in Q_{m(n)}\), inequality 10.5.60 applies to \(r = 1\), to yield

\[ d(Z(r', \omega), Z(1, \omega)) < \varepsilon_a \leq \beta_\varepsilon < 2^{-n+5}. \quad (10.5.70) \]

Thus relation 10.5.69 has been verified in either case. Summing up,

\[ Z(\overline{\theta}_XQ_m, \omega) \subset d(.)Z(q_{k-1}, \omega) \leq 2^{-n+5}, \quad (10.5.71) \]

for each \(k = 1, \cdots , p + 1\), where \(\omega \in B^p_{p} \cap C_n^C\) is arbitrary.

15. We will now prove that \(X_{q_{(i)}}\) is a r.v. If \(i < p\), then \(\tau_{i} = \tau_{i}\) and so \(X_{q_{(i)}} = X_{q_{(i)}}\) is a r.v. Hence it suffices to treat the case where \(i = p\). Then \(\tau_p = \tau_p \land \overline{\theta} \equiv \tau_p \land \overline{\theta}\) where we write \(\overline{\theta} = 1 - \Xi\) for short. Again, let \(h \geq n\), and \(\omega \in B^p_{h} \cap C_n^C\) be arbitrary. Note that \(\omega \in B^p_{h} \cap H_{q}\). Let

\[ u, v \in [\tau_p(\omega), \tau_p(\omega) + \delta_h]Q_m \quad (10.5.72) \]

be arbitrary. There are three possibilities: (i'') \(\tau_p(\omega) < \overline{\theta}\), (ii'') \(\overline{\theta} < \tau_p(\omega)\), or (iii'') \(|\overline{\theta} - \tau_p(\omega)| < 2^{-h} \delta_h\).

Consider Case (i''). We then have \(\tau_p(\omega) = \tau_p(\omega)\), whence \(u, v \in [\tau_p(\omega), \tau_p(\omega) + \delta_h]Q_m\). Therefore inequality 10.5.53 holds for both \(u\) and for \(v\), which implies, by the triangle inequality, that

\[ d(Z_v(\omega), Z_u(\omega)) < 2^{-h+5} + 2^{-h+5} = 2^{-h+6}. \quad (10.5.73) \]

Consider Case (ii''). We then have \(\tau_p(\omega) = \overline{\theta}\), whence \(u, v \in [\tau_p(\omega), \tau_p(\omega) + \delta_h]Q_m\). Therefore inequality 10.5.47 holds with \(X, r, r'\) replaced by \(Z, \overline{\theta}, u\) respectively, to yield

\[ d(Z(\overline{\theta}, \omega), Z(u, \omega)) < 2^{-h+5}. \quad (10.5.74) \]

Similarly, the last inequality holds for \(v\) in the place of \(u\). Hence the triangle inequality establishes inequality 10.5.73 also for Case (ii'').

Now consider Case (iii''), where \(|\overline{\theta} - \tau_p(\omega)| < 2^{-h} \delta_h\). Let \(w \equiv \overline{\theta} + 2^{-1} \delta_h \in Q_m\). Then, by the triangle inequality,

\[ w \in [\tau_p(\omega), \tau_p(\omega) + \delta_h]Q_m \land [\overline{\theta} + \delta_h]Q_m. \]

Since \(u, \overline{\theta} \in Q_m\), we have either \(u < \overline{\theta}\) or \(u \geq \overline{\theta}\). Suppose \(u < \overline{\theta}\). Then relation 10.5.72 implies that \(\tau_p(\omega) \land \overline{\theta} = \tau_p(\omega) < \overline{\theta}\), whence \(\tau_p(\omega) = \tau_p(\omega)\) and relation 10.5.72 reduces to \(u \in [\tau_p(\omega), \tau_p(\omega) + \delta_h]Q_m\). Hence inequality 10.5.52 holds for \(u\), and similarly for \(w\). The triangle inequality then implies that

\[ d(Z_w(\omega), Z_u(\omega)) < 2^{-h+5} + 2^{-h+5} = 2^{-h+6}. \quad (10.5.75) \]

Now suppose \(u \geq \overline{\theta}\). Then relation 10.5.72 implies that \(u \in [\overline{\theta}, \overline{\theta} + \delta_h]Q_m\). Therefore inequality 10.5.47 holds with \(X, r, r'\) replaced by \(Z, \overline{\theta}, u\) respectively, to yield

\[ d(Z(\overline{\theta}, \omega), Z(u, \omega)) < 2^{-h+5}. \quad (10.5.76) \]
Similarly,
\[ d(Z(q, \omega), Z(w, \omega)) < 2^{-h+5}. \]
Combining the last two displayed inequalities, inequality [10.5.75] is proved for \( u \). Repeating this argument with \( v \) in the place of \( u \), we see that inequality [10.5.75] holds also for \( v \). Hence the triangle inequality implies that
\[ d(Z(u, \omega), Z(v, \omega)) < 2^{-h+6} + 2^{-h+6} = 2^{-h+7}. \] (10.5.77)

Summing up, in each of Cases (i''-iii''), we have inequality [10.5.77] where
\[ u, v \in [\mathfrak{T}_p(\omega), \mathfrak{T}_p(\omega) + \delta_n]Q_\infty \]
and \( h \geq n \) are arbitrary. It follows that \( \lim_{u \to \mathfrak{T}_p(\omega); u \geq \mathfrak{T}_p(\omega)} Z(u, \omega) \) exists. In other words, \( (\mathfrak{T}_p(\omega), \omega) \in \text{domain}(X) \), or, equivalently, \( \omega \in \text{domain}(X_{\mathfrak{T}_p}) \), with \( X_{\mathfrak{T}_p}(\omega) \) by definition equal to this limit. Moreover, letting \( u \downarrow \mathfrak{T}_p(\omega) \) in inequality [10.5.77] we obtain
\[ d(Z(u, \omega), X_{\mathfrak{T}_p}(\omega)) \leq 2^{-h+7}, \] (10.5.78)
where \( v \in [\mathfrak{T}_p(\omega), \mathfrak{T}_p(\omega) + \delta_n]Q_\infty \) and \( h \geq n \) are arbitrary. Now define
\[ \overline{T}_{h,p} = \eta_{h,p} \wedge \mathfrak{q}. \]
Since \( \eta_{h,p}(\omega), \mathfrak{q} \in Q_{m(h)} \), we have either \( \mathfrak{q} \leq \eta_{h,p}(\omega) - 2^{-m(h)} \) or \( \eta_{h,p}(\omega) \leq \mathfrak{q} \). In view of inequality [10.5.74] it follows that either (i'') \( \tau_p(\omega) \leq \eta_{h,p}(\omega) \leq \overline{T}_{h,p} \) or (ii'') \( \overline{T}_{h,p} \leq \tau_p(\omega) \leq \eta_{h,p}(\omega) \). In Case (i''), we have \( \tau_p(\omega) = \tau_p(\omega) \) and \( \overline{T}_{h,p}(\omega) = \eta_{h,p}(\omega) \), whence inequality [10.5.74] implies that
\[ d(X_{\mathfrak{T}_p}(\omega), Z_{\overline{T}_{h,p}}(\omega)) \leq 2^{-h+5}. \] (10.5.79)
In Case (ii''), we have \( \tau_p(\omega) = \overline{T}_{h,p}(\omega) = \mathfrak{q} \), whence the same inequality [10.5.79] holds trivially. Since \( \omega \in B_h^{-C_{\mathfrak{c}}}D_h^{-C_{\mathfrak{c}}} \) is arbitrary, and since \( P(B_h \cup D_{h+}) < 2^{-h+5} \), where \( h \geq n \) is arbitrary, we conclude that \( Z_{\overline{T}_{h,p}}(\omega) \in X_{\mathfrak{T}_p}(\omega) \) a.u. as \( h \to \infty \). Note that, for each \( h \geq n \), the function \( \overline{T}_{h,p} \) is a r.v. with values in the finite set \( Q_{m(h)} \). Hence \( Z_{\overline{T}_{h,p}}(\omega) \) is a r.v. for each \( h \geq n \). We conclude that the function \( X_{\mathfrak{T}_p}(\omega) \) is a r.v.

16. Now define \( H = B_n \cup D_{n+} \cup C_n \), with
\[ P(H) = P(B_n \cup D_{n+} \cup C_n) < 2^{-n} + 2^{-n+3} + 2^{-n} < 2^{-n+4} < \varepsilon. \] (10.5.80)
Let \( \omega \in H' = C_n^{-B_h^{-C_{\mathfrak{c}}}D_h^{-C_{\mathfrak{c}}}} \) and \( \kappa = 1, \ldots, p + 1 \) be arbitrary. Relation [10.5.71] implies that
\[ d(Z(u, \omega), Z(q_{\kappa-1}, \omega)) \leq 2^{-n+5} \]
for each \( u \in \overline{Q}_{m(h)} \). Hence, by the definition of \( X(\cdot, \omega) \) as the right limit of \( Z \), it follows that
\[ d(X(\cdot, \omega), Z(q_{\kappa-1}, \omega)) \leq 2^{-n+5} < \varepsilon \] (10.5.81)
for each \( v \in \overline{T}_{\mathfrak{k}} \cap \text{domain}(X(\cdot, \omega)) \). In particular, since \( \mathfrak{T}_k(\omega) \in \overline{T}_{\mathfrak{k}} \cap \text{domain}(X(\cdot, \omega)) \), we have
\[ d(X(\mathfrak{T}_k(\omega), \omega), Z(q_{\kappa-1}, \omega)) \leq 2^{-n+5}. \]
Combining the last two displayed inequality, we obtain
\[ d(X(\tau_k(\omega), \omega), X(\tau_i(\omega))) \leq 2^{-n+5} + 2^{-n+5} = 2^{-n+6} < \varepsilon \] (10.5.82)
for each \( \nu \in \Theta \cap \text{domain}(X(\cdot, \omega)) \), where \( \omega \in H^c \) is arbitrary.

17. Let \( \omega \in H^c \) and \( i = 1, \cdots, p+1 \) be arbitrary. By inequalities (10.5.35) and (10.5.65)
\[ q_{i-1} + \Delta \leq \tau_i(\omega) \equiv \tau_i(\omega) \leq q_i \] (10.5.83)
if \( i \neq p \). At the same time, inequality (10.5.66) says
\[ q_{p-1} + \Delta \leq \tau_p(\omega) \equiv \tau_p(\omega) \leq 1 - \Delta \leq 1 - \Delta. \]

Thus
\[ 0 \equiv q_0 < \tau_1(\omega) \leq q_1 < \tau_2(\omega) \leq \cdots < \tau_{p-1}(\omega) \leq q_{p-1} < \tau_p(\omega) \leq 1 - \Delta < q_p = 1, \] (10.5.84)
with
\[ \bigwedge_{j=1}^{p+1} (\tau_j(\omega) - \tau_{j-1}(\omega)) \geq \bigwedge_{j=1}^{p} (\tau_j(\omega) - q_{j-1}) \wedge (\tau_{p+1}(\omega) - \tau_p(\omega)) \geq \Delta. \] (10.5.85)

Since \( \varepsilon > 0 \) is arbitrary, inequalities (10.5.85), (10.5.82), and (10.5.80) together show that the sequence
\[ 0 \equiv \tau_0 < \tau_1 < \cdots < \tau_p < \tau_{p+1} \equiv 1 \]
of r.r.v.’s, along with the operation \( \delta_{\text{aucl}} \), satisfy Condition 3 in Definition (10.3.2) for the process \( X \). At the same time Assertions 4 and 5 in Proposition (10.5.7) imply Conditions 1 and 2 respectively in Definition (10.3.2) for the process \( X \). The same Proposition (10.5.7) also says that the process \( X \) is continuous in probability, with modulus of continuity in probability \( \delta_{\text{aucl}} \). All the conditions in Definition (10.3.2) having been verified, the process \( X \) is a.u. càdlàg, with \( \delta_{\text{aucl}} \) as modulus of a.u. càdlàg. The theorem is proved.

\[ \square \]

10.6 Continuity of the Right-Limit-Extension Construction

We will prove that the construction of a.u. càdlàg processes by the right-limit extension of \( D \)-regular processes, given in the previous section, is a continuous construction.

Let \( (S, d) \) be a locally compact metric space. As usual, we write \( \tilde{d} \equiv 1 \wedge d \). Refer to Definition (9.0.2) for notations related to the enumerated set \( Q_m \equiv \{ t_0, t_1, \cdots \} \) of dyadic rationals in the interval \( [0,1] \), and its subset \( Q_m \equiv \{ q_{m,0}, q_{m,1}, \cdots, q_{m,p(m)} \} \equiv \{ t_0, \cdots, t_{p(m)} \} \) for each \( m \geq 0 \).

Recall from Definition (6.4.1) that \( \tilde{R}(Q_m \times \Omega, S) \) denotes the space of stochastic processes with parameter set \( Q_m \), sample space \( \Omega \), and state space \( (S, d) \), and that it is equipped with the metric \( \tilde{\rho}_{\text{Prob}, Q(m)} \) defined by
\[ \tilde{\rho}_{\text{Prob}, Q(m)}(Z, Z') \equiv \sum_{j=0}^{\infty} 2^{-j-1} E 1\wedge d(Z_{i(j)}, Z'_{i(j)}) \] (10.6.1)
for each $Z, Z' \in \hat{R}(Q_\infty \times \Omega, S)$.

Recall from Definitions $[10.3.2]$ and $[10.3.3]$ the metric space $(\hat{D}[0,1], \rho_{\hat{D}[0,1]})$ of a.u. càdlàg processes on the interval $[0,1]$, with

$$\rho_{\hat{D}[0,1]}(X,X') \equiv \int E(\omega) \Delta(X(\cdot,\omega),X'(\cdot,\omega))$$

for each $X, X' \in \hat{D}[0,1]$, where $\Delta_D \equiv 1 \land d_D$, where $d_D$ is the Skorokhod metric on the space $D[0,1]$ of càdlàg functions. Recall that $\lceil \cdot \rceil_1$ is an operation which assigns to each $a \in R$ an integer $\lfloor a \rfloor_1 \in (a, a + 2)$.

**Theorem 10.6.1.** (Continuity of the construction of a.u. càdlàg processes by right-limit extension of $D$-regular processes). Let $\hat{R}_{Dreg,\hat{m},\hat{d}(CP)}(Q_\infty \times \Omega, S)$ denote the subspace of $(\hat{R}(Q_\infty \times \Omega, S), \hat{p}_{Prob,Q(\infty)})$ whose members share some common modulus of continuity in probability $\delta_{CP}$ and some common modulus of $D$-regularity $\hat{m} \equiv (m_n)_{n=0,1,\ldots}$. Let

$$\Phi_{rLim} : (\hat{R}_{Dreg,\hat{m},\hat{d}(CP)}(Q_\infty \times \Omega, S), \hat{p}_{Prob,Q(\infty)}) \to (\hat{D}[aucl], \delta_{CP}[0,1], \rho_{\hat{D}[0,1]}) \quad (10.6.2)$$

be the right-limit extension as constructed in Theorem $[10.5.8]$ where

$$(\hat{D}[aucl], \delta_{CP}[0,1], \rho_{\hat{D}[0,1]})$$

is the metric subspace of a.u. càdlàg processes which share the common modulus of continuity $\delta_{CP}$, and which share the common modulus of a.u. càdlàg $\delta_{aucl} \equiv \delta_{aucl}(\cdot, \hat{m}, \delta_{CP})$ that is defined in Theorem $[10.5.8]$.

Then the function $\Phi_{rLim}$ is uniformly continuous, with a modulus of continuity $\delta_{rLim}(\cdot, \hat{m}, \delta_{CP})$ which depends only on $\hat{m}$ and $\delta_{CP}$.

**Proof.** 1. Let $\varepsilon_0 > 0$ be arbitrary. Let $n \geq 0$ be so large that $2^{-n+6} < \varepsilon$. Let $J \geq n + 1$ be so large that

$$\Delta_{m(J)} \equiv 2^{-m(J)} < 2^{-2} \delta_{CP}(2^{2n+10}) . \quad (10.6.3)$$

Then, according to Theorem $[10.5.8]$ we have

$$\bar{\Delta} \equiv \Delta_{m(J)} = \delta_{aucl}(\varepsilon, \hat{m}, \delta_{CP}).$$

Write $\varepsilon \equiv 2^{-4} \varepsilon_0$. Take $k \geq n$ so large that

$$2^{-m(k) + 2} < (1 - e^{-\varepsilon}) \bar{\Delta} .$$

Write $p \equiv p_{m(n)} \equiv 2^{m(n)}$, $\tilde{p} \equiv p_{m(k)} \equiv 2^{m(k)}$ and $\bar{\Delta} \equiv 2^{-m(k)}$. Define

$$\delta_{rLim}(\varepsilon_0, \hat{m}, \delta_{CP}) \equiv 2^{-\tilde{p}-1} \varepsilon^2 .$$

We will prove that the operation $\delta_{rLim}(\cdot, \hat{m}, \delta_{CP})$ is a modulus of continuity for the the function $\Phi_{rLim}$ in expression $[10.6.2]$. 

Yuen-Kwok Chan 365 Constructive Probability
CHAPTER 10. A.U. CÀDLÀG PROCESSES

To that end, let \( Z, Z' \in \hat{R}_{\text{Dreg, } p, \delta(C_p)}(Q_\infty \times \Omega, S) \) be arbitrary such that

\[
\hat{\rho}_{\text{Prob}, Q(\omega)}(Z, Z') \equiv E \sum_{j=0}^{\infty} 2^{-j-1} \hat{\delta}(Z_{\tau(j)}, Z'_{\tau(j)}) < \delta \equiv \delta_{\text{rLim}}(\varepsilon_0, \pi, \delta_{C_p}). \tag{10.6.4}
\]

Let \( X \equiv \Phi_{\text{rLim}}(Z) \) and \( X' \equiv \Phi_{\text{rLim}}(Z') \). We need only verify that

\[
\rho_{\delta_{\text{rLim}}}(X, X') < \varepsilon_0. \tag{10.6.5}
\]

2. According to Steps 16 and 17 in the proof of Theorem [10.5.8] there exists an increasing sequence

\[
0 = \tau_0 < \tau_1 < \cdots < \tau_p < \tau_{p+1} = 1
\]

of r.r.v.’s, and a measurable set \( H \) with \( P(H) < \varepsilon \), such that, for each \( \omega \in H \), we have

\[
0 = \tau_0(\omega) \equiv q_0 < \tau_1(\omega) \leq q_1 < \tau_2(\omega) \leq \cdots
\]

\[
< \tau_{p-1}(\omega) \leq q_{p-1} < \tau_p(\omega) \leq 1 - \Delta < q_p = \tau_{p+1}(\omega) = 1, \tag{10.6.6}
\]

with

\[
\bigwedge_{j=1}^{p+1} (\tau_j(\omega) - \tau_{j-1}(\omega)) \geq \bigwedge_{i=1}^{p} (\tau_i(\omega) - q_{i-1}) \wedge (\tau_{p+1}(\omega) - \tau_p(\omega)) \geq \Delta. \tag{10.6.7}
\]

Moreover, inequality [10.5.8] in the proof of Theorem [10.5.8] says that, for each \( \omega \in H \) and for each \( i = 1, \cdots, p + 1 \), we have

\[
d(X(\cdot, \omega), Z(q_{i-1}, \omega)) \leq \varepsilon \tag{10.6.8}
\]

on the interval \( \overline{\delta}_i \equiv [\tau_{i-1}(\omega), \tau_i(\omega)] \) or \( \overline{\delta}_i \equiv [\tau_{i-1}(\omega), \tau_i(\omega)] \), according as \( 1 \leq i \leq p \) or \( i = p + 1 \).

3. Relative to the process \( X' \), we can similarly construct the increasing sequence

\[
0 = \tau'_0 < \tau'_1 < \cdots < \tau'_p < \tau'_{p+1} = 1
\]

of r.r.v.’s, and measurable set \( H' \) with \( P(H') < \varepsilon \), such that, for each \( \omega \in H' \), we have

\[
0 = \tau'_0(\omega) = q_0 < \tau'_1(\omega) \leq q_1 < \tau'_2(\omega) \leq \cdots
\]

\[
< \tau'_{p-1}(\omega) \leq q_{p-1} < \tau'_p(\omega) \leq 1 - \Delta < q_p = \tau'_{p+1}(\omega) = 1, \tag{10.6.9}
\]

and

\[
\bigwedge_{j=1}^{p+1} (\tau'_j(\omega) - \tau'_{j-1}(\omega)) \geq \bigwedge_{i=1}^{p} (\tau'_i(\omega) - q_{i-1}) \wedge (\tau'_{p+1}(\omega) - \tau'_p(\omega)) \geq \Delta. \tag{10.6.10}
\]

Moreover, for each \( \omega \in H' \) and for each \( i = 1, \cdots, p + 1 \), we have

\[
d(X'(\cdot, \omega), Z'(q_{i-1}, \omega)) \leq \varepsilon \tag{10.6.11}
\]

Yuen-Kwok Chan 366 Constructive Probability
on the interval $\overline{\theta_i} = [\tau_{i-1}(\omega), \tau_i(\omega)]$ or $\overline{\theta_i} = [\tau_{i-1}(\omega), \tau_i(\omega)]$ according as $1 \leq i \leq p$ or $i = p + 1$.

4. Then, in view of the bound $10.6.4$, Chebychev’s inequality implies that there exists a measurable set $G$ with $P(G) < \varepsilon$ such that, for each $\omega \in G^c$, we have

\[
\begin{align*}
&\sum_{j=0}^{p(m(k))} 2^{-j-1} d(\tau_{i-j}(\omega), \tau_{i}(\omega)) \\
&\leq 2^{p(m(k))} \frac{1}{\delta \varepsilon^{-1}} \equiv 2^{p(m(k))} 2^p \delta \varepsilon^{-1} = \varepsilon.
\end{align*}
\] (10.6.12)

5. Now let $\omega \in H^* H^c G^c$ be arbitrary, but fixed. Let $i = 0, \ldots, p + 1$ be arbitrary. To simplify notations, we will henceforth suppress the reference to $\omega$, and suppress the underline, to write $\tau_i$, $\tau'_i, x, z, z'$ for $\tau_i(\omega), \tau'_i(\omega), \mathcal{X}(\cdot, \omega), \mathcal{X}'(\cdot, \omega), \mathcal{Z}(\cdot, \omega), \mathcal{Z}'(\cdot, \omega)$ respectively. Then inequality $10.6.8$ can be rewritten more compactly as

\[
x(\theta_i) \subset (d(\cdot, z(\tau_{i-1}))) \leq \varepsilon.
\] (10.6.13)

Similarly, inequality $10.6.11$ can be rewritten as

\[
x(\theta'_i) \subset (d(\cdot, z'(\tau_{i-1}))) \leq \varepsilon.
\] (10.6.14)

6. Partition the set $\{0, \ldots, p + 1\}$ into two disjoint subsets $A$ and $B$ such that (i) $|\tau_i - \tau'_i| < 2\hat{\Delta}$ if $i \in A$, and (ii) $|\tau_i - \tau'_i| > \hat{\Delta}$ if $i \in B$. Consider each $i \in B$. We will verify that, then, $1 \leq i \leq p$ and

\[
d(z(q_i), z(q_{i-1})) + d(z'(q_i), z(q_{i-1}')) \leq 6\varepsilon.
\] (10.6.15)

In view of Condition (ii), we may assume, without loss of generality, that $\tau'_i - \tau_i > \hat{\Delta} = 2^{-m(k)}$. Then there exists $u \in [\tau_i, \tau'_i \cap \mathcal{Q}(m(k))$. Since $[\tau_0, \tau'_0] = [0, 0] = \emptyset$ and $[\tau_{p+1}, \tau'_{p+1}] = [1, 1] = \emptyset$, it follows that $1 \leq i \leq p$. Moreover, $10.6.6$ and $10.6.9$ imply that

\[
u \in [\tau_i, \tau'_i) \subset [q_{i-1}, q_i) \subset [\tau'_{i-1}, \tau_{i+1}).
\]

Hence $u \in [\tau_i, \tau_{i+1}) \cap [\tau'_{i-1}, \tau'_i) \subset \theta_{i+1} \theta_i$. Therefore, using relations $10.6.3$ and $10.6.4$, and inequality $10.6.12$ we obtain

\[
d(z(q_i), z(q_{i-1})) \\
\leq d(z(q_i), z(u)) + d(z(u), z'(u)) + d(z'(u), z'(q_{i-1})) + d(z'(q_{i-1}), z(q_{i-1})) \\
\leq \varepsilon + \varepsilon + \varepsilon = 3\varepsilon,
\]

and so

\[
d(z'(q_i), z(q_{i-1})) \leq d(z'(q_i), z(q_i)) + d(z(q_i), z(q_{i-1})) + d(z(q_{i-1}), z'(q_{i-1}))
\]
Thus inequality [10.6.15] is verified.

7. Define an increasing function \( \lambda : [0, 1] \to [0, 1] \) by \( \lambda \tau_i \equiv \tau'_i \) or \( \lambda \tau_i \equiv \tau_i \) according as \( i \in A \) or \( i \in B \), for each \( i = 0, \ldots, p + 1 \), and by linearity on \([\tau_i, \tau_{i+1}]\) for each \( i = 0, \ldots, p \). Here we write \( \lambda t \equiv \lambda (t) \) for each \( t \in [0, 1] \) for brevity. Then, in view of the definition of the index sets \( A \) and \( B \), we have \( |\tau_i - \lambda \tau_i| < 2\Delta \) for each \( i = 0, \ldots, p + 1 \). Now consider each \( i = 0, \ldots, p \), and write

\[
u_i \equiv \frac{\lambda \tau_{i+1} - \tau_{i+1} + \tau_i - \lambda \tau_i}{\tau_{i+1} - \tau_i}.
\]

Then, since \( \tau_{i+1} - \tau_i \geq 2\Delta \) according to inequality [10.6.7] we have

\[
|\nu_i| \leq |\lambda \tau_{i+1} - \tau_{i+1}| + |\lambda \tau_i - \tau_i|/|\Delta|
\]

\[
\leq 2\Delta/|\lambda| + 2\Delta = 2|\lambda| + 2\Delta < (1 - e^{-\epsilon}).
\]

Note that the function \( \log(1 + u) \) of \( u \in [1 - e^{-\epsilon}, 1 - e^{-\epsilon}] \) vanishes at \( u = 0 \), and has positive first derivative and negative second derivative on the interval \([1 - e^{-\epsilon}, 1 - e^{-\epsilon}] \). Hence the maximum of its absolute value is attained at the left end point of the interval. Therefore

\[
|\log(1 + u_i)| \leq |\log(1 + e^{-\epsilon})| = \epsilon. \quad (10.6.16)
\]

Lemma [10.2.3] therefore implies the bound

\[
\sup_{0 < x < 1} |\log \frac{\lambda t - \lambda s}{t - s}| = \sup_{i = 0}^{p} |\log \frac{\lambda \tau_{i+1} - \lambda \tau_i}{\tau_{i+1} - \tau_i}|
\]

\[
= \sup_{i = 0}^{p} |\log(1 + u_i)| \leq \epsilon < 9\epsilon. \quad (10.6.17)
\]

8. We will next prove that

\[
d(x, x' \circ \lambda) \leq 9\epsilon \quad (10.6.18)
\]

on \( \text{domain}(x) \cap \text{domain}(x' \circ \lambda) \). Now let \( i = 0, \ldots, p \) and

\[
v \in \bigcup_{i = 0}^{p} (\tau_i + \tau_{i+1}) \cap \bigcup_{i = 0}^{p} (\lambda^{-1} \tau'_i, \lambda^{-1} \tau'_{i+1}) \cap \text{domain}(x) \cap \text{domain}(x' \circ \lambda)
\]

be arbitrary. There are four possible cases: (i') \( i, i + 1 \in A \), (ii') \( i, i + 1 \in B \), (iii') \( i \in A \) and \( i + 1 \in B \), and (iv') \( i \in B \) and \( i + 1 \in A \).

Consider Case (i'), where \( i, i + 1 \in A \). Then \( \lambda \tau_i \equiv \tau'_i \) and \( \lambda \tau_{i+1} \equiv \tau'_{i+1} \). Hence

\[
\lambda v \in [\lambda \tau_i, \lambda \tau_{i+1}] \subset [\tau'_i, \tau'_{i+1}) \subset \theta'_i.
\]

Consequently,

\[
d(x(v), x'(\lambda v)) \leq d(x(v), z(q)) + d(z(q), z'(q)) + d(z'(q), x'(\lambda v)) < \epsilon + \epsilon + \epsilon = 3\epsilon,
\]

Yuen-Kwok Chan 368 Constructive Probability
10.6. CONTINUITY OF THE RIGHT-LIMIT-EXTENSION CONSTRUCTION

Next consider Case (ii'), where $i, i + 1 \in B$. Then, according to Step 6, we have $1 \leq i < i + 1 \leq p$ and

$$d(z(q_i), z(q_{i-1})) \lor d(z(q_i), z(q_{i-1})) \lor d(z(q_{i+1}), z(q_{i})) \lor d(z(q_{i+1}), z(q_{i})) \leq 6\varepsilon.$$  

Moreover, $\lambda \tau_i \equiv \tau_i$ and $\lambda \tau_{i+1} \equiv \tau_{i+1}$. Hence

$$\lambda v \in [\tau_i, \tau_{i+1}) \subset [q_{i-1}, q_{i+1}) \subset [\tau_i', \tau_{i+1}').$$

Consequently,

$$d(x(v), x'(\lambda v))$$

$$\leq (d(x(v), z(q_i)) + d(z(q_i), z(q_{i-1})) + d(z(q_{i-1}), z'(q_{i-1})) + d(z'(q_{i-1}), x'(\lambda v)))$$

$$\lor (d(x(v), z(q_i)) + d(z(q_i), z'(q_i)) + d(z'(q_i), x'(\lambda v)))$$

$$\lor (d(x(v), z(q_i)) + d(z(q_i), z(q_{i+1})) + d(z(q_{i+1}), z'(q_{i+1})) + d(z'(q_{i+1}), x'(\lambda v)))$$

$$\leq (\varepsilon + 6\varepsilon + \varepsilon + \varepsilon) \lor (\varepsilon + \varepsilon + \varepsilon) \lor (\varepsilon + 6\varepsilon + \varepsilon + \varepsilon) = 9\varepsilon,$$

Now consider Case (iii'), where $i \in A$ and $i + 1 \in B$. Then, according to Step 6, we have $i + 1 \leq p$ and

$$d(z(q_{i+1}), z(q_i)) \lor d(z'(q_{i+1}), z'(q_i)) \leq 6\varepsilon.$$  

Moreover, $\lambda \tau_i \equiv \tau_i$ and $\lambda \tau_{i+1} \equiv \tau_{i+1}$. Hence

$$\lambda v \in [\tau_i, \tau_{i+1}) \subset [q_{i-1}, q_{i+1}) \subset [\tau_i', \tau_{i+2}).$$

Consequently,

$$d(x(v), x'(\lambda v))$$

$$\leq (d(x(v), z(q_i)) + d(z(q_i), z'(q_i)) + d(z'(q_i), x'(\lambda v)))$$

$$\lor (d(x(v), z(q_i)) + d(z(q_i), z(q_{i+1})) + d(z(q_{i+1}), z'(q_{i+1})) + d(z'(q_{i+1}), x'(\lambda v)))$$

$$\leq (\varepsilon + 6\varepsilon + \varepsilon + \varepsilon) \lor (\varepsilon + \varepsilon + \varepsilon) \lor (\varepsilon + 6\varepsilon + \varepsilon + \varepsilon) = 9\varepsilon,$$

Finally, consider Case (iv'), where $i \in B$ and $i + 1 \in A$. Then, according to Step 6, we have $1 \leq i$ and

$$d(z(q_i), z(q_{i-1})) \lor d(z'(q_i), z'(q_{i-1})) \leq 6\varepsilon.$$  

Yuen-Kwok Chan 369 Constructive Probability
Moreover, \( \lambda \tau_i \equiv \tau_i \) and \( \lambda \tau_{i+1} \equiv \tau'_{i+1} \). Hence

\[
\lambda v \in [\tau_i, \tau'_{i+1}) \subset [q_{i-1}, \tau'_{i+1}) \subset [\tau'_{i-1}, \tau'_{i+1}).
\]

Since \( \lambda v \neq \tau_i' \) by assumption, we obtain

\[
\lambda v \in [\tau'_{i-1}, \tau'_{i+1}) \cup [\tau'_i, \tau'_{i+1}) \subset \theta'_i \cup \theta_{i+1}.
\]

Consequently,

\[
d(x(v), \lambda') \leq (d(x(v), z(q_i)) + d(z(q_i), z(q_{i-1})) + d(z(q_{i-1}), z'(q_{i-1})) + d(z'(q_{i-1}), \lambda'))
\]

\[
\lor (d(x(v), z(q_i)) + d(z(q_i), z'(q_{i-1})) + d(z'(q_{i-1}), \lambda'))
\]

\[
\leq (\varepsilon + 6\varepsilon + \varepsilon) \lor (\varepsilon + \varepsilon + \varepsilon) = 9\varepsilon,
\]

where we used relations 10.6.13 and 10.6.14, and inequalities 10.6.12 and 10.6.21.

Summing up, we see that

\[
d(x(v), \lambda') \leq 9\varepsilon \tag{10.6.22}
\]

for each

\[
v \in \bigcup_{i=0}^{\rho} [\tau_i, \tau_{i+1}) \cap \bigcup_{i=0}^{\rho} (\lambda^{-1} \tau'_i, \lambda^{-1} \tau'_{i+1}) \cap \text{domain}(x) \cap \text{domain}(x' \circ \lambda). \tag{10.6.23}
\]

Note that the set \( \bigcup_{i=0}^{\rho} [\tau_i, \tau_{i+1}) \cap \bigcup_{i=0}^{\rho} (\lambda^{-1} \tau'_i, \lambda^{-1} \tau'_{i+1}) \) contain all but finitely many points in the interval \([0,1]\), while the set \( \text{domain}(x) \cap \text{domain}(x' \circ \lambda) \) contains all but countably many points in \([0,1]\), according to Proposition 10.1.4. Hence the set on the right-hand side of expression (10.6.23) contains all but countably many points in \([0,1]\), and is therefore dense in \( \text{domain}(x) \cap \text{domain}(x' \circ \lambda) \). Therefore, by Lemma 10.1.3, inequality 10.6.22 extends to the desired inequality 10.6.18.

9. Therefore, according to Definition 10.2.1 of the Skorokhod metric \( d_H \), inequalities 10.6.17 and 10.6.18 together yield the bound

\[
\tilde{d}_D(X(\cdot, \omega), X'(\cdot, \omega)) = 1 \land d_D(X(\cdot, \omega), X'(\cdot, \omega)) = 1 \land d_D(x, x') \leq 9\varepsilon,
\]

where \( \omega \in H^*H^*G^* \) is arbitrary. It follows that

\[
\rho_{D[0,1]}(X, X') = \int E(d\omega) \tilde{d}_D(X(\cdot, \omega), X'(\cdot, \omega))
\]

\[
\leq P(H \cup H' \cup G) + \int E(d\omega) \tilde{d}_D(X(\cdot, \omega), X'(\cdot, \omega)) 1_{H^*H^*G^*} \leq 3\varepsilon + 9\varepsilon = 12\varepsilon < \varepsilon_0,
\]

which proves inequality 10.6.5 and the theorem. \( \Box \)

The next easy corollary of Theorems 10.5.8 and 10.6.1 gives a construction of an a.u. càdlàg process from a \( D \)-regular family of f.j.d.’s, and shows that the construction given is uniformly continuous on a set of such \( D \)-regular families which share a common modulus of \( D \)-regularity and a common modulus of continuity in probability.
10.6. CONTINUITY OF THE RIGHT-LIMIT-EXTENSION CONSTRUCTION

We will prove the corollary using the Daniell-Kolmogorov-Skorokhod Extension. For that purpose, we fix the sample space

$$(\Omega, L, E) \equiv (\Theta_0, L_0, E_0) \equiv ([0, 1], L_0, \int dx)$$

to be the Lebesgue integration space based on the interval $\Theta_0 \equiv [0, 1]$. Let $\xi \equiv (A_q)_{q=1,2,\cdots}$ be an arbitrarily, but fixed, binary approximation of the locally compact metric space $(S, d(r))$ relative to some fixed reference point $x_0 \in S$.

Recall from Definition 6.2.2 the metric space $(F_n, S, \rho)$ of consistent families of f.j.d.'s with parameter set $Q$, and state space $(S, d)$, where the marginal metric $\rho_{Marg, Q}$ is defined relative to the binary approximation $\xi$ of $(S, d)$. Recall from Definition 10.4.1 its subset $\hat{F}_{Dreg}(Q, S)$ consisting of $D$-regular families, and the subset $\hat{F}_{Dreg, \rho}(Q, S)$ consisting of $D$-regular families with some given modulus of $D$-regularity $\overline{m}$ and some given modulus of continuity in probability $\delta_{C_p}$.

Similarly, recall from Definition 10.4.2 the metric space $(\hat{F}_{Dreg}(0, 1), S, \rho_{CP, \xi}, [0, 1][Q, Q])$ and its subset $\hat{F}_{Dreg, \rho}(0, 1, S)$.

We re-emphasize that $D$-regularity is a condition on individual f.j.d.'s.

**Corollary 10.6.2.** (Construction of a.u. càdlàg process on $[0, 1]$ from $D$-regular family of f.j.d.’s on $[0, 1]$, and continuity of construction). Let

$$(\Theta_0, L_0, L_0) \equiv ([0, 1], L_0, \int dx)$$

denote the Lebesgue integration space based on the interval $\Theta_0 \equiv [0, 1]$. Then there exists a uniformly continuous function

$$\Phi_{aucl, \xi} : \hat{F}_{Dreg, \rho}(0, 1, S), \rho_{CP, \xi}, [0, 1][Q, Q] \rightarrow \hat{D}_{\rho}(\overline{m}, \delta(C_P)) \delta(C_P)[0, 1], \rho_{CP}(0, 1))$$

such that, for each $F \in \hat{F}_{Dreg, \rho}(0, 1, S)$, the a.u. càdlàg process $X \equiv \Phi_{aucl, \xi}(F)$ has marginal distributions given by $F$, and has the modulus of a.u. càdlàg $\delta_{aucl}(\overline{m}, \delta(C_P))$ defined as in Theorem 10.5.8.

Moreover, the function $\Phi_{aucl, \xi}$ has a modulus of continuity

$$\overline{\delta}_{aucl, \xi} \equiv \overline{\delta}_{aucl, \xi}(\overline{m}, \delta(C_P), \||\xi\||)$$

which depends only on $\overline{m}, \delta(C_P)$, and $||\xi||$.

**Proof.** 1. Recall from Definition 6.2.11 the isometry

$$\Phi_{[0, 1][Q, Q]} : \hat{F}_{CP}(0, 1, S), \rho_{CP, \xi}, [0, 1][Q, Q] \rightarrow \hat{F}_{CP}(Q, S), \rho_{Marg, Q, Q}$$

defined by $\Phi_{[0, 1][Q, Q]}(F) \equiv F|_{[0, 1]}$ for each $F \in \hat{F}_{CP}(0, 1, S) \subset \hat{F}_{CP}(0, 1, S)$, we have an isometry

$$\Phi_{[0, 1][Q, Q]} : \hat{F}_{Dreg, \rho}(0, 1, S), \rho_{CP, \xi}, [0, 1][Q, Q] \rightarrow \hat{F}_{CP}(Q, S), \rho_{Marg, Q, Q}$$. 

Yuen-Kwok Chan 371 Constructive Probability
Moreover, for each \( F \in \hat{F}_{\text{Dreg}, \mu, \delta(CP)}([0,1], S) \), we have \( F|_{Q_\infty} \in \hat{F}_{\text{Dreg}, \mu, \delta(CP)}(Q_\infty, S) \), we obtain the isometry
\[
\Phi_{[0,1]|Q_\infty} : \left( \hat{F}_{\text{Dreg}, \mu, \delta(CP)}([0,1], S), \hat{\rho}_{CP, \xi, [0,1]|Q_\infty}(\cdot, \cdot, \cdot) \right) \rightarrow \left( \hat{F}_{\text{Dreg}, \mu, \delta(CP)}(Q_\infty, S), \hat{\rho}_{\text{Marg}, \xi, Q_\infty} \right) \tag{10.6.25}
\]

2. Let
\[
\Phi_{\text{DKS} \xi} : \left( \hat{F}_{\text{Dreg}, \mu, \delta(CP)}(Q_\infty, S), \hat{\rho}_{\text{Marg}, \xi, Q_\infty} \right) \rightarrow \left( \hat{R}(Q_\infty \times \Theta_0, S), \hat{\rho}_{\text{Prob}, Q_\infty} \right)
\]
be the Daniell-Kolmogorov-Skorokhod extension relative to the binary approximation \( \xi \) of \((S, d)\). Let \( F' \in \hat{F}_{\text{Dreg}, \mu, \delta(CP)}(Q_\infty, S) \) be arbitrary. Then the process \( Z \equiv \Phi_{\text{DKS} \xi}(F') \) has marginal distributions given by \( F' \). Hence, by Definition 10.4.1, the process \( Z \), like its family \( F' \) of marginal distributions, is \( D \)-regular, with a modulus of \( D \)-regularity \( m \) and with a modulus of continuity in probability \( \delta_{CP} \). In other words, \( \Phi_{\text{DKS} \xi}(F') \in \hat{R}_{\text{Dreg}, \mu, \delta(CP)}(Q_\infty \times \Theta_0, S) \). Thus we obtain the continuous function
\[
\Phi_{\text{DKS} \xi} : \left( \hat{F}_{\text{Dreg}, \mu, \delta(CP)}(Q_\infty, S), \hat{\rho}_{\text{Marg}, \xi, Q_\infty} \right) \rightarrow \left( \hat{R}_{\text{Dreg}, \mu, \delta(CP)}(Q_\infty \times \Theta_0, S), \hat{\rho}_{\text{Prob}, Q_\infty} \right) \tag{10.6.26}
\]

3. Let
\[
\Phi_{\text{rLim}} : \left( \hat{R}_{\text{Dreg}, \mu, \delta(CP)}(Q_\infty \times \Theta_0, S), \hat{\rho}_{\text{Prob}, Q_\infty} \right) \rightarrow \left( \bar{D}_{\text{rLim}(\cdot, \cdot, \cdot)}(\cdot, \cdot, \cdot), \hat{\rho}_{D(0,1)} \right) \tag{10.6.27}
\]

Denote the extension by right limit, as in Theorem 10.5.3. By Theorem 10.6.1 the mapping \( \Phi_{\text{rLim}} \) is uniformly continuous, with a modulus of continuity \( \delta_{\text{rLim}}(\cdot, \cdot, \cdot, \cdot) \) which depends only on \( m \) and \( \delta_{CP} \).

4. Now define the composite \( \Phi_{\text{aucl} \xi} \equiv \Phi_{\text{rLim}} \circ \Phi_{\text{DKS} \xi} \circ \Phi_{[0,1]|Q_\infty} \) of the three mappings 10.6.25, 10.6.26, and 10.6.27. Thus
\[
\Phi_{\text{aucl} \xi} : \left( \hat{F}_{\text{Dreg}, \mu, \delta(CP)}([0,1], S), \hat{\rho}_{CP, \xi, [0,1]|Q_\infty} \right) \rightarrow \left( \bar{D}_{\text{rLim}(\cdot, \cdot, \cdot)}(\cdot, \cdot, \cdot), \hat{\rho}_{D(0,1)} \right)
\]
is the composite of three uniformly continuous functions. As such, it is uniformly continuous, with a composite modulus of continuity given by
\[
\bar{\delta}_{\text{aucl} \xi} \equiv \bar{\delta}_{\text{aucl} \xi}(\cdot, m, \delta_{CP}, \| \xi \|) \equiv \delta_{\text{DKS}}(\delta_{\text{rLim}}(\cdot, m, \delta_{CP}, \| \xi \|)).
\]

5. Now consider each \( F \in \hat{F}_{\text{Dreg}, \mu, \delta(CP)}([0,1], S) \). Write \( F' \equiv \Phi_{[0,1]|Q_\infty}(F) \equiv F|_{Q_\infty} \), write \( Z \equiv \Phi_{\text{DKS} \xi}(F') \), and \( X \equiv \Phi_{\text{rLim}}(Z) \). Then \( X = \Phi_{\text{aucl} \xi}(F) \). Thus the process \( Z \) has marginal distributions given by \( F' \). Let \( \mathcal{F} \) be the family of marginal distributions of the a.u. càdlàg process \( X \). Then, since \( Z = X|_{Q_\infty} \) by Assertion 2 of Proposition 10.5.7, we have
\[
F|_{Q_\infty} \equiv F' = \mathcal{F}|_{Q_\infty}
\]
Moreover, since a.u. càdlàg processes and \( D \)-regular families of f.j.d.’s are continuous in probability, by definition, so are the families \( F \) and \( \mathcal{F} \). Hence
\[
\hat{\rho}_{CP, \xi, [0,1]|Q_\infty}(F, \mathcal{F}) \equiv \hat{\rho}_{\text{Marg}, \xi, Q_\infty}(F|_{Q_\infty}, \mathcal{F}|_{Q_\infty}) = 0
\]
by the definition of the metric \( \hat{\rho}_{CP, \xi, [0,1]|Q_\infty} \). Therefore \( \mathcal{F} = F \). In other words, the a.u. càdlàg process \( X = \Phi_{\text{aucl} \xi}(F) \) has marginal distributions given by the family \( F \), where \( F \in \hat{F}_{\text{Dreg}, \mu, \delta(CP)}([0,1], S) \) is arbitrary.

The Corollary is proved. \( \square \)
10.7 Strong Right Continuity in Probability

In this section, let \((S, d)\) be a locally compact metric space.

In the previous sections we proved that \(D\)-regularity is a necessary and sufficient condition for a family of f.j.d.’s to be extendable to an a.u. càdlàg process. We remarked that this method is a generalization of the treatment of a Markov process with a Markov semigroup in [Chan 1974]. In the next chapter, we will show that this indeed is the case; we will make precise the notion of a Markov process with a Markov semigroup, and will show, by means of \(D\)-regularity, that they are a.u. càdlàg. In preparation, we will presently introduce a sufficient condition for \(D\)-regularity, which is easily verifiable for such Markov processes. In addition, this sufficient condition will reduce, in the next section, to a simple condition for a martingale with parameter set \([0, 1]\) to be a.u. càdlàg.

Said sufficient condition will consist of two subconditions. The first subcondition will be called, for lack of a better name, strong right continuity in probability. The second subcondition will be called a.u. boundlessness. We emphasize that both subconditions are on f.j.d.’s, or equivalently, on finite samples of the process.

We will note that the a.u. boundlessness condition will always be satisfied if the locally compact metric state space \((S, d)\) is bounded, e.g., if the metric \(d\) is replaced by the equivalent metric \((1 + d)^{-1}\), or if \((S, d)\) is embedded in the one-point compactification \((S \cup \{\Delta\}, \overline{d})\), where \(\overline{d} \leq 1\).

Recall Definition 9.0.2 for the enumerated set \(Q_\infty\) of dyadic rationals in \([0, 1]\), and the enumerated subset

\[ Q_h \equiv \{0, \triangle_h, 2\triangle_h, \ldots, 1\} = \{t_0, t_1, t_2, \ldots, t_{p(h)}\}, \]

where \(p_h \equiv 2^h, \triangle_h \equiv 2^{-h}\), and where \(q_{h,i} \equiv i\triangle_h\) for each \(i = 0, \ldots, p_h\), for each \(h \geq 0\).

Recall also the miscellaneous notations and conventions in Definition 9.0.3. In addition, we will use the following notations.

**Definition 10.7.1. (Natural filtrations and certain first exit times for a process sampled at regular intervals).** In the remainder of the present section, let \(Z : \Omega \times (\Omega, L, E) \rightarrow (S, d)\) be an arbitrary process with marginal distributions given by the family \(F\) of f.j.d.’s.

Let \(h \geq 0\) be arbitrary. Considered the process \(Z|Q_h\), which is the process \(Z\) sampled at the regular interval of \(\triangle_h\). Let

\[ \mathcal{L}^{(h)} \equiv \{L^{(t,h)} : t \in Q_h\} \]

denote the natural filtration of the process \(Z|Q_h\). In other words,

\[ L^{(t,h)} \equiv L(Z_r : r \in [0, t]Q_h) \]

for each \(t \in Q_h\). Let \(\tau\) be an arbitrary simple stopping time with values in \(Q_h\), relative to the filtration \(\mathcal{L}^{(h)}\). Define the probability space

\[ L^{(\tau,h)} \equiv \{Y \in L : Y 1_{\{\tau \leq s\}} \in L^{(s)}\} \text{ for each } s \in Q_h. \]
For each $t \in Q_h$ and $\alpha > 0$, recall from Part 2 of Definition 8.2.7 the simple first exit time $\eta_{t, \alpha, [t, 1][Q(h)]}$

$$\eta_{t, \alpha, [t, 1][Q(h)]} \equiv \sum_{r \in [t, 1][Q(h)]} r 1_{(d(Z(r), Z(r)) > \alpha)} \prod_{s \in [t, r)[Q(h)]} 1_{(d(Z(r), Z(s)) \leq \alpha)}$$

$$+ \prod_{s \in [t, 1)[Q(h)]} 1_{(d(Z(r), Z(s)) \leq \alpha)}$$

(10.7.1)

for the process $Z|[t, 1][Q_h]$ to exit the closed $\alpha$-neighborhood of $Z_t$. Here an empty product is, by convention, equal to 1.

Similarly, for each $\gamma > 0$, define the r.v.

$$\zeta_{h, \gamma} \equiv \sum_{r \in Q(h)} r 1_{(d(x_0, Z(r)) > \gamma)} \prod_{s \in [0, r)[Q(h)]} 1_{d(x_0, Z(s)) \leq \gamma}$$

$$+ \prod_{s \in Q(h)} 1_{d(x_0, Z(s)) \leq \gamma}$$

(10.7.2)

where we recall that $x_0$ is an arbitrary, but fixed reference point in the state space $(S, d)$. It can easily be verified that $\zeta_{h, \gamma}$ is a simple stopping time relative to the filtration $\mathcal{F}_r(h)$. Intuitively, $\zeta_{h, \gamma}$ is the first time $r \in Q_h$ when the process $Z|Q_h$ is outside the bounded set $(d(x_0, \cdot) \leq \gamma)$, with $\zeta_{h, \gamma}$ set to 1 if no such $s \in Q_h$ exists.

Refer to Propositions 8.2.6 and 8.2.8 for basic properties of simple stopping times and simple first exit times.

□

**Definition 10.7.2. (a.u. boundlessness on $Q_\infty$).** Let $(S, d)$ be a locally compact metric space. Suppose the process $Z : Q_\infty \times (\Omega, L, E) \rightarrow (S, d)$ is such that, for each $\epsilon > 0$, there exists $\beta_{auB}(\epsilon) > 0$ so large that

$$P( \bigvee_{r \in Q(h)} d(x_0, Z_r) > \gamma ) < \epsilon$$

(10.7.3)

for each $h \geq 0$, for each $\gamma > \beta_{auB}(\epsilon)$. Then we will say that the process $Z$ and the family $F$ of its marginal distributions are a.u. bounded, with the operation $\beta_{auB}$ as a modulus of a.u. boundlessness, relative to the reference point $x_0 \in S$. Note that this condition is trivially satisfied if $d \leq 1$, in which case we can take $\beta_{auB}(\epsilon) \equiv 1$ for each $\epsilon > 1$.

□

**Definition 10.7.3. (Strong right continuity in probability on $Q_\infty$).** Let $(S, d)$ be a locally compact metric space. Let $Z : Q_\infty \times (\Omega, L, E) \rightarrow (S, d)$ be an arbitrary process. Suppose that, for each $\epsilon, \gamma > 0$, there exists $\delta_{SRcP}(\epsilon, \gamma) > 0$ such that, for arbitrary $h \geq 0$ and $s, r \in Q_h$ with $s \leq r < s + \delta_{SRcP}(\epsilon, \gamma)$, we have

$$P_h(d(Z_s, Z_r) > \alpha) \leq \epsilon,$$

(10.7.4)

for each $\alpha > \epsilon$ and for each $A \in L^{(s, h)}$ with $A \subset (d(x_0, Z_s) \leq \gamma)$ and $P(A) > 0$. Then we will say that the process $Z$ and the family $F$ of its marginal distributions are strongly
right continuous in probability, with the operation $\delta_{SRcp}$ as a modulus of strong right continuity in probability.

Note that the operation $\delta_{SRcp}$ has two variables. Suppose it is independent of the second variable. Equivalently, suppose $\delta_{SRcp}(\varepsilon, \gamma) = \delta_{SRcp}(\varepsilon, 1)$ for each $\varepsilon, \gamma > 0$. Then we say that the process $Z$ and the family $F$ of its marginal distributions are uniformly strongly right continuous in probability.

\[ \square \]

The above definition will next be restated without the assumption of $P(A) > 0$ and the reference to the probability $P_A$.

**Lemma 10.7.4.** (Equivalent definition of strong right continuity in probability). Let $(S, d)$ be a locally compact metric space. Then a process $Z : Q_\infty \times (\Omega, L, E) \to (S, d)$ is strongly right continuous in probability, with a modulus of strong right continuity $\delta_{SRcp}$ iff, for each $\varepsilon, \gamma > 0$, there exists $\delta_{SRcp}(\varepsilon, \gamma) > 0$ such that, for arbitrary $h \geq 0$ and $s, r \in Q_h$ with $s \leq r < s + \delta_{SRcp}(\varepsilon, \gamma)$, we have

\[ P(d(Z_s, Z_r) > \alpha; A) \leq \varepsilon P(A), \]  

(10.7.5)

for each $\alpha > \varepsilon$ and for each $A \in L^{(x, h)}$ with $A \subset (d(x, Z_s) \leq \gamma)$.

**Proof.** Suppose $Z$ is strongly right continuous in probability, with a modulus of strong right continuity $\delta_{SRcp}$. Let $\varepsilon, \gamma > 0$, $h \geq 0$, and $s, r \in Q_h$ be arbitrary with $s \leq r < s + \delta_{SRcp}(\varepsilon, \gamma)$. Consider each $\alpha > 0$ and $A \in L^{(x, h)}$ with $A \subset (d(x, Z_s) \leq \gamma)$. Suppose, for the sake of a contradiction, that

\[ P(d(Z_s, Z_r) > \alpha; A) > \varepsilon P(A). \]

Then $P(A) \geq P(d(Z_s, Z_r) > \alpha; A) > 0$. Hence we can divide both sides of the last displayed inequality by $P(A)$ to obtain

\[ P_A(d(Z_s, Z_r) > \alpha) \equiv P(A)^{-1}P(d(Z_s, Z_r) > \alpha; A) > \varepsilon, \]

which contradicts inequality [10.7.3] in Definition [10.7.2] for the assumed strong right continuity. Hence inequality [10.7.5] holds. Thus the “only if” part of the lemma is proved. The “if” part is equally straightforward and omitted. \[ \square \]

Three more lemmas to prepare for the main theorem of this section. The next two are elementary.

**Lemma 10.7.5.** (Minimum of a real number and a sum of two real numbers). For each $a, b, c \in \mathbb{R}$, we have $a \wedge (b + c) = b + c \wedge (a - b)$, or equivalently, $a \wedge (b + c) - b = c \wedge (a - b)$.

**Proof.** Write $c' \equiv a - b$. Then $a \wedge (b + c) = (b + c') \wedge (b + c) = b + c' \wedge c = b + (a - b) \wedge c$. \[ \square \]

**Lemma 10.7.6.** (Function on two contiguous intervals). Let $Z : Q_\infty \times \Omega \to S$ be an arbitrary process. Let $\alpha > 0$ and $\beta > 2\alpha$ be arbitrary, such that the set

\[ A^\beta_{\alpha, \gamma} \equiv (d(Z_t, Z_\gamma) > \beta) \]  

(10.7.6)

Yuen-Kwok Chan 375 Constructive Probability
is measurable for each $r, s \in \mathbb{Q}_\omega$. Let $\omega \in \cap_{r,s \in Q(\omega)} (A_{r,s}^\beta \cup (A_{r,s}^\beta)^c)$ and let $h \geq 0$ be arbitrary. Let $A_{\omega}, B_{\omega}$ be arbitrary intervals, with end points in $Q_h$ which depend on $\omega$, such that the right end point of $A_{\omega}$ is equal to the left end point of $B_{\omega}$. Let $t, t' \in (A_{\omega} \cup B_{\omega})Q_h$ be arbitrary such that $t < t'$. Suppose there exist $x_{\omega}, y_{\omega} \in S$ with

$$\bigvee_{r \in A(\omega)Q(h)} d(x_{\omega}, Z(r, \omega)) \lor \bigvee_{s \in B(\omega)Q(h)} d(y_{\omega}, Z(s, \omega)) \leq \alpha.$$  \hfill (10.7.7)

Then

$$\omega \in \bigcap_{r,s \in (t, t')Q(h), r \leq s} ((A_{r,s}^\beta \cup A_{s,r}^\beta)(A_{s,r}^\beta \cup A_{r,s}^\beta)(A_{r,r}^\beta \cup A_{r,s}^\beta))^c.$$  \hfill (10.7.8)

**Proof.** With $\omega$ fixed, write $z_r \equiv Z(r, \omega) \in S$ for each $r \in Q_\omega$, and write $A \equiv A_{\omega}, B \equiv B_{\omega}, x \equiv x_{\omega},$ and $y \equiv y_{\omega}$. Then inequality (10.7.7) can be restated as

$$\bigvee_{r \in AQ(h)} d(x, z_r) \lor \bigvee_{s \in BQ(h)} d(y, z_s) \leq \alpha.$$  \hfill (10.7.9)

Let $r, s \in (t, t')Q_h \subset AQ_h \cup BQ_h$ be arbitrary with $r \leq s$. Note that, by assumption, the end points of the intervals $A$ and $B$ are members of $Q_h$. Then, since the right end point of $A$ is equal to the left end point of $B$, there are only three possibilities: (i) $t, r, s \in AQ_h$, (ii) $t, r \in AQ_h$ and $s, t' \in BQ_h$, or (iii) $r, s, t' \in BQ_h$. In Case (i), inequality (10.7.9) implies that

$$d(z_t, z_r) \lor d(z_r, z_s) \leq (d(x, z_t) + d(x, z_r)) \lor (d(x, z_r) + d(x, z_s)) \leq 2\alpha \lor 2\alpha = 2\alpha.$$

Similarly, in Case (ii), we have

$$d(z_t, z_r) \lor d(z_r, z_s) \leq (d(x, z_t) + d(x, z_r)) \lor (d(y, z_r) + d(y, z_s)) \leq 2\alpha \lor 2\alpha = 2\alpha.$$

Similarly, in Case (iii), we have

$$d(z_t, z_r) \lor d(z_r, z_s) \leq (d(y, z_t) + d(y, z_r)) \lor (d(y, z_r) + d(y, z_s)) \leq 2\alpha \lor 2\alpha = 2\alpha.$$

Thus, in all cases, we have

$$(d(z_t, z_r) \lor d(z_r, z_s)), (d(z_t, z_s) \lor d(z_s, z_r)) \lor (d(z_t, z_r) \lor d(z_r, z_s)) \leq 2\alpha \leq \beta,$$

where $r, s \in (t, t')Q_h$ are arbitrary with $r \leq s$. Equivalently, the desired relation (10.7.8) holds. \hfill \square

**Lemma 10.7.7.** (Lower bound for mean waiting time before exit after a simple stopping time) Let $(S, d)$ be a locally compact metric space. Suppose the process $Z : Q_\omega \times \Omega \to S$ is strongly right continuous in probability, with a modulus of strong right continuity in probability $\delta_{SRc}$. Let $\varepsilon, \gamma > 0$ be arbitrary, but fixed. Take any $m \geq 0$ so large that

$$\Delta_m \equiv 2^{-m} < \delta_{SRc}(\varepsilon, \gamma).$$

Yuen-Kwok Chan 376 Constructive Probability
10.7. STRONG RIGHT CONTINUITY IN PROBABILITY

Let

\[ h \geq m \]

be arbitrary. Define the simple stopping time \( \zeta_{h,y} \) to be the first time when the process \( Z|Q_h \) is outside the bounded set \( (d(x, \cdot) \leq \gamma) \), as in Definition 10.7.3. Then the following holds.

1. Let the point \( t \in Q_h \) be arbitrary. Let \( \overline{\tau} \) be an arbitrary simple stopping time with values in \( [t, t + \Delta_m]|Q_h \), relative to the natural filtration \( \mathcal{Z}^{(h)} \) of the process \( Z|Q_h \). Let \( A \in L[\overline{\tau}^{(h)}] \) be an arbitrary measurable set such that \( A \subset (d(x, Z_{\overline{\tau}}) \leq \gamma) \). Then

\[
P(d(Z_{\overline{\tau}}, Z_{1\lor(t+\Delta(m))}) > \alpha; A) \leq \epsilon P(A) \tag{10.7.10}
\]

for each \( \alpha > \epsilon \).

2. Suppose \( \epsilon \leq 2^{-2} \), and let \( \alpha > 2\epsilon \) be arbitrary. For abbreviation, write

\[
\eta_t \equiv \eta_{t,\alpha;[t,1]|Q(h)}
\]

for each \( t \in Q_h \). Let \( \tau \) be an arbitrary simple stopping time with values in \( Q_h \), relative to the filtration \( \mathcal{Z}^{(h)} \). Then the r.r.v.

\[
\overline{\tau}_\tau \equiv \sum_{t \in Q(h)} (\eta_t 1_{\tau(t) < \zeta(h,\gamma)} + 1_{\zeta(h,\gamma) \leq \eta(t)}) 1(\tau = t) \tag{10.7.11}
\]

is a simple stopping time with values in \( Q_h \), relative to the filtration \( \mathcal{Z}^{(h,\tau)} \), which we will loosely call a simple first exit time after the given stopping time \( \tau \). Moreover, we have the upper bound

\[
P(\overline{\tau}_\tau < 1 \land (\tau + \Delta_m)) \leq 2\epsilon \tag{10.7.12}
\]

for the probability of a quick first exit after \( \tau \), and we have the lower bound

\[
E(\overline{\tau}_\tau - \tau) \geq 2^{-1} E((1 - \tau) \land \Delta_m). \tag{10.7.13}
\]

for the mean waiting time before exit after \( \tau \).

We emphasize that the upper bound \(10.7.12\) and the lower bound \(10.7.13\) are independent of \( h \).

**Proof.** 1. Let \( \alpha > \epsilon \) be arbitrary. Let \( t \in Q_h \), the simple stopping time \( \overline{\tau} \) with values in \( [t, t + \Delta_m]|Q_h \), and the set \( A \in L[\overline{\tau}^{(h)}] \) with \( A \subset (d(x, Z_{\overline{\tau}}) \leq \gamma) \) be as given. Write \( r \equiv 1 \land (t + \Delta_m) \). Then \( \overline{\tau} \) has values in \( [t, r]|Q_h \). Let \( s \in [t, r]|Q_h \) be arbitrary. Then

\[
s \leq r \leq t + \Delta_m < s + \delta_{\text{SRc}p}(\epsilon, \gamma)
\]

and \( (\overline{\tau} = s; A) \in L^{(s,h)} \). Therefore, we can apply inequality \(10.7.3\) in Lemma \(10.7.4\) to the modulus of strong right continuity \( \delta_{\text{SRc}p} \), the points \( s, r \in Q_h \), the simple stopping time \( \overline{\tau} \), and the measurable set \( (\overline{\tau} = s; A) \in L^{(s,h)} \), to obtain

\[
P(d(Z_s, Z_r) > \alpha; \overline{\tau} = s; A) \leq \epsilon P(\overline{\tau} = s; A),
\]

where \( s \in [t, r]|Q_h \) is arbitrary. Consequently,

\[
P(d(Z_{\overline{\tau}}, Z_r) > \alpha; A) = \sum_{s \in [t, r]|Q(h)} P(d(Z_s, Z_r) > \alpha; \overline{\tau} = s; A)
\]

Yuen-Kwok Chan 377 Constructive Probability
CHAPTER 10. A.U. CÂDLÀG PROCESSES

\[ \sum_{s \in [t, r]Q(h)} \varepsilon P(\overline{\gamma} = s; A) = \varepsilon P(A). \]

Assertion 1 is proved.

2. To prove Assertion 2, suppose \( \varepsilon \leq 2^{-2} \), and let \( \alpha > 2\varepsilon \) be arbitrary. First consider the special case where \( \tau \equiv t \) for some \( t \in Q_h \). Define the r.v.

\[ \overline{\gamma} \equiv \eta \ 1_{\eta(t) < \zeta(h, \gamma)} + 1_{\zeta(h, \gamma) \leq \eta(t)} \]

which has values in \([t, 1]Q_h\). Note that (i') if \( s \in [0, t]Q_h \), then, trivially,

\[ 1(\overline{\gamma}(t) = s) = 0 \in L^{(s, h)} \]

(ii') if \( s \in [t, 1)Q_h \), then

\[ 1(\overline{\gamma}(t) = s) = 1_{\eta(t) = s, \eta(t) \leq \zeta(h, \gamma)} \in L^{(s, h)} \]

because \( \eta_b \) and \( \zeta_{h, \gamma} \) are simple stopping times with values in \( Q_h \), relative to the filtration \( \mathcal{L}^{(h)} \), and (iii') if \( s = 1 \), then

\[ 1(\overline{\gamma}(t) = s) = 1_{\eta(t) = s, \eta(t) \geq \zeta(h, \gamma)} = 1_{\eta(t) = s} \in L^{(s, h)}. \]

Combining, we see that \( 1(\overline{\gamma}(t) = s) \in L^{(s, h)} \) for each \( s \in Q_h \). Thus \( \overline{\gamma} \) is a simple stopping time with values in \([t, 1]Q_h\), relative to the filtration \( \mathcal{L}^{(h)} \). Intuitively, \( \overline{\gamma} \) is the first time \( s \in [t, 1]Q_h \) when the process \( Z(t) \) exits the \( \alpha \)-neighborhood of \( Z_t \) while staying in the \( \gamma \)-neighborhood of \( x_0 \) over the entire time interval \([t, s]Q_h\); \( \overline{\gamma} \) is set to 1 if no such time \( s \) exists.

Continuing, observe that

\[ (\overline{\gamma} < 1) \subset (\overline{\gamma} = \eta_b < \zeta_{h, \gamma} \leq 1) \]

by the defining equality \[10.7.14\]

Define \( \overline{\gamma} \equiv \overline{\gamma} \wedge r \), where \( r \equiv 1 \wedge (t + \Delta_m) \). Then \( r - t = (1 - t) \wedge \Delta_m \) by Lemma \[10.7.5\] Moreover, the simple stopping time \( \overline{\gamma} \) has values in \([t, r]Q_h\). Let \( A \in L^{(r, h)} \) be arbitrary. Then \( A \in L^{(t, h)} \subset L^{(r, h)} \). We estimate an upper bound for the probability

\[ P(\overline{\gamma} < r; A) \leq P(\overline{\gamma} = \overline{\gamma} < 1; A) \]

\[ \leq P(\overline{\gamma} < 1; \overline{\gamma} = \eta_b < \zeta_{h, \gamma} \leq 1; A) \]

\[ = P(\eta_b < 1; \overline{\gamma} = \overline{\gamma} = \eta_b < \zeta_{h, \gamma} \leq 1; A) \]

\[ \leq P(d(Z_r, Z_{\overline{\gamma}(t)})) > \alpha; \overline{\gamma} = \overline{\gamma} = \eta_b < \zeta_{h, \gamma} \leq 1; A) \]

\[ = P(d(Z_r, Z_{\overline{\gamma}})) > \alpha; \overline{\gamma} = \overline{\gamma} = \eta_b < \zeta_{h, \gamma} \leq 1; A) \]

\[ \leq P(d(Z_r, Z_{\overline{\gamma}})) > \alpha; \tau < \zeta_{h, \gamma}; A) \]

\[ \leq P(d(Z_r, Z_{\overline{\gamma}})) > \alpha; d(x_0, Z_t) \leq \gamma; A) \]
Consequently, 
\[ \leq P(d(Z_t, Z_{\tau}) > \alpha; d(x_0, Z_t) \leq 2^{-1} \alpha; d(x_0, Z_t) \leq \gamma; A) \]
\[ + P(d(Z_t, Z_{\tau}) > 2^{-1} \alpha; d(x_0, Z_t) \leq \gamma; A) \]
\[ \leq P(d(Z_t, Z_{\tau}) > 2^{-1} \alpha; d(x_0, Z_t) \leq \gamma; A) \]
\[ + P(d(Z_t, Z_{\tau}) > 2^{-1} \alpha; d(x_0, Z_t) \leq \gamma; A) \]
\[ (10.7.16) \]
where the second inequality is thanks relation \[10.7.15\] and the third is by the definition of the simple stopping time \( \eta \), and where the fifth inequality is by the definition of the simple stopping time \( \zeta \). Next note that, since \( 2^{-1} \alpha > \epsilon \), we have
\[ P(d(Z_t, Z_{\tau}) > 2^{-1} \alpha; d(x_0, Z_t) \leq \gamma; A) \leq \epsilon P(d(x_0, Z_t) \leq \gamma; A) \]
by applying inequality \[10.7.10\] where \( \alpha, A \) are replaced by \( 2^{-1} \alpha, (d(x_0, Z_t) \leq \gamma; A) \) respectively. Similarly, we have
\[ P(d(Z_t, Z_{\tau}) > 2^{-1} \alpha; d(x_0, Z_t) \leq \gamma; A) \leq \epsilon P(d(x_0, Z_t) \leq \gamma; A) \]
by applying inequality \[10.7.10\] where \( \alpha, A \) are replaced by \( t, 2^{-1} \alpha, (d(x_0, Z_t) \leq \gamma; A) \) respectively. Combining, inequality \[10.7.16\] can be continued to yield
\[ P(\overline{\tau}; r; A) \leq 2 \epsilon P(d(x_0, Z_t) \leq \gamma; A). \]
\[ (10.7.17) \]
Consequently,
\[ E(\overline{\tau} - t; A) \geq E(r - t; \overline{\tau}, r; A) = (r - t) P(\overline{\tau} \geq r; A) \]
\[ = ((1 - t) \wedge \Delta_m)(P(A) - P(\overline{\tau} < r; A)) \]
\[ \geq ((1 - t) \wedge \Delta_m)(P(A) - 2 \epsilon P(d(x_0, Z_t) \leq \gamma; A)), \]
\[ = ((1 - t) \wedge \Delta_m)(E1_A - 2 \epsilon E1(d(x_0, Z_t) \leq \gamma A)), \]
\[ (10.7.18) \]
where the second inequality is by inequality \[10.7.17\].
Taking \( A \equiv \Omega \), inequalities \[10.7.17\] and \[10.7.18\] become, respectively,
\[ P(\overline{\tau} < 1 \wedge (t + \Delta_m)) \leq 2 \epsilon P(d(x_0, Z_t) \leq \gamma) \leq 2 \epsilon, \]
and
\[ E(\overline{\tau} - t) \geq ((1 - t) \wedge \Delta_m)(1 - 2 \epsilon) \geq 2^{-1} ((1 - t) \wedge \Delta_m), \]
where the second inequality is because \( \epsilon \leq 2^{-2} \) by assumption. Thus Assertion 2 is proved for the special case where \( \tau \equiv t \) for some \( t \in Q_h \).

3. To complete the proof of Assertion 2 for the general case, let the simple stopping time \( \tau \) be arbitrary, with values in \( Q_h \), relative to the filtration \( \mathcal{F}^{(h)} \). Then
\[ P(\overline{\tau}_t < 1 \wedge (\tau + \Delta_m)) = \sum_{t \in Q^h} P(\overline{\tau}_t < 1 \wedge (t + \Delta_m); \tau = t) \]
\[ \leq \sum_{t \in Q^h} 2 \epsilon P(d(x_0, Z_t) \leq \gamma; \tau = t) \]
where the inequality is by applying inequality \(10.7.17\) to the measurable set \(A \ni (\tau = t) \in L^{(r,h)}\), for each \(t \in Q_h\). Similarly,

\[
E(\overline{\tau} - \tau) = \sum_{t \in Q(h)} E(\overline{\tau}_t - t; \tau = t)
\]

\[
\geq \sum_{t \in Q(h)} ((1-t) \wedge \Delta_m)(E1(\tau = t) - 2\varepsilon E1(d(x(t),Z(t)) \leq \gamma; \tau = t))
\]

\[
= \sum_{t \in Q(h)} (E((1-t) \wedge \Delta_m)1(\tau = t) - 2\varepsilon E((1-t) \wedge \Delta_m)1(d(x(t),Z(t)) \leq \gamma; \tau = t))
\]

\[
= (E((1-t) \wedge \Delta_m) - 2\varepsilon E((1-t) \wedge \Delta_m)1(d(x(t),Z(t)) \leq \gamma))
\]

\[
\geq 2^{-1} E((1-t) \wedge \Delta_m),
\]

where the first inequality is by applying inequality \(10.7.18\) to the measurable set \(A \ni (\tau = t) \in L^{(r,h)}\), for each \(t \in Q_h\), and where the last inequality is because \(1 - 2\varepsilon \geq 2^{-1}\) by the assumption that \(\varepsilon \leq 2^{-2}\). Summing up, inequalities \(10.7.19\) and \(10.7.20\) yield, respectively, the desired inequalities \(10.7.12\) and \(10.7.13\). The lemma is proved. \(\square\)

**Theorem 10.7.8. (Strong right continuity in probability and a.u. boundlessness together imply \(\delta\)-regularity and extendability by right limit to a.u. càdlàg process)**

Let \((S,d)\) be a locally compact metric space. Then a process \(Z : Q_\infty \times (\Omega, L,E) \to (S,d)\) Suppose the process \(Z : Q_\infty \times \Omega \to S\) is (i) a.u. bounded, with a modulus of a.u. boundlessness \(\beta_{auB}\), and (ii) strongly right continuous in probability, with a modulus of strong right continuity in probability \(\delta_{SRcP}\). Then the following holds.

1. The process \(Z\) is \(\delta\)-regular, with a modulus of continuity in probability

\[
\delta_{Cp}(\cdot; \beta_{auB}, \delta_{SRcP})
\]

and has a modulus of \(\delta\)-regularity \(m \equiv m(\beta_{auB}, \delta_{SRcP})\).

2. The right-limit extension \(X \equiv \Phi_{rLm}(Z) : [0,1] \times \Omega \to S\) is an a.u. càdlàg process, with the same modulus of continuity in probability \(\delta_{Cp}(\cdot; \beta_{auB}, \delta_{SRcP})\), and with a modulus of a.u. càdlàg \(\delta_{aucl}(\cdot; \beta_{auB}, \delta_{SRcP})\). Recall here the right-limit extension \(\Phi_{rLm}\) from Definition \(10.5.6\).

**Proof.** 1. Condition (i), the a.u. boundlessness condition in the hypothesis, says that for each \(\varepsilon > 0\), we have

\[
P(\bigvee_{u \in Q(h)} d(x_u,Z_u) > \gamma) < \varepsilon \quad (10.7.21)
\]

for each \(h \geq 0\), for each \(\gamma > \beta_{auB}(\varepsilon)\).
2. Let \( \varepsilon > 0 \) and \( \alpha \in (2^{-2}\varepsilon, 2^{-1}\varepsilon) \) be arbitrary. Let
\[
\gamma \equiv [\beta_{unb}(2^{-2}\varepsilon)]_1,
\]
\[
m = \lceil - \log_2(1 \land \delta_{SRcP}(2^{-2}\varepsilon, \gamma)) \rceil,
\]
and
\[
\delta_{cP}(\varepsilon) \equiv \delta_{cP}(\varepsilon, \beta_{unb}, \delta_{SRcP}) \equiv \Delta_m \equiv 2^{-m} < \delta_{SRcP}(2^{-2}\varepsilon, \gamma).
\]
We will verify that \( \delta_{cP}(\cdot, \beta_{unb}, \delta_{SRcP}) \) is a modulus of continuity in probability of the process \( Z \). For each \( h \geq 0 \), define the measurable set
\[
\mathcal{T}_h \equiv ( \bigvee_{u \in G(h)} d(x_0, Z_u) > \gamma).
\]
Then, since \( \gamma > \beta_{unb}(2^{-2}\varepsilon) \), inequality \([10.7.21]\) with \( \varepsilon \) replaced by \( 2^{-2}\varepsilon \), yields
\[
P(\mathcal{T}_h) < 2^{-2}\varepsilon,
\]
where \( h \geq 0 \) is arbitrary.

3. Consider each \( s, r \in Q_{\infty} \) with \( |s - r| < \delta_{cP}(\varepsilon) \). Define the measurable set
\[
D_{s,r} \equiv (d(Z_s, Z_r) \leq \alpha) \subset (d(Z_s, Z_r) \leq 2^{-1}\varepsilon).
\]
First assume that \( s \leq r \). Then
\[
s \leq r < s + \delta_{cP}(\varepsilon) \leq s + \delta_{SRcP}(2^{-2}\varepsilon, \gamma).
\]
Take \( h \geq m \) so large that \( s, r \in Q_h \). Since \( \alpha > 2^{-2}\varepsilon \), we can apply inequality \([10.7.24]\) in Lemma \([10.7.3]\) where \( \varepsilon \) and \( A \) are replaced by \( 2^{-2}\varepsilon \) and \( (d(x_0, Z_u) \leq \gamma) \) respectively, to obtain
\[
P(D_{s,r}^c \mathcal{T}_h^c) \leq P(d(Z_s, Z_r) > \alpha; d(x_0, Z_u) \leq \gamma)
\leq 2^{-2}\varepsilon P(d(x_0, Z_u) \leq \gamma) \leq 2^{-2}\varepsilon.
\]
Combining with inequality \([10.7.22]\) we obtain
\[
P(D_{s,r}^c) \leq P(D_{s,r}^c \mathcal{T}_h) + P(\mathcal{T}_h) \leq 2^{-2}\varepsilon + 2^{-2}\varepsilon = 2^{-1}\varepsilon.
\]
Consequently,
\[
E 1 \land d(Z_s, Z_r) \leq P(D_{s,r}^c) + E(1 \land d(Z_s, Z_r); D_{s,r}) \leq P(D_{s,r}^c) + 2^{-1}\varepsilon \leq \varepsilon
\]
By symmetry, the same inequality holds for each \( s, r \in Q_{\infty} \) with \( |s - r| < \delta_{cP}(\varepsilon) \), where \( \varepsilon > 0 \) is arbitrary. Hence the process \( Z \) is continuous in probability, with a modulus of continuity in probability \( \delta_{cP} \equiv \delta_{cP}(\cdot, \beta_{unb}, \delta_{SRcP}) \). Thus the process \( Z \) satisfies Condition 2 of Definition \([10.4.1]\) to be \( D \)-regular.

4. It remains to prove Condition 1 in Definition \([10.4.1]\). To that end, define \( m_{-1} \equiv \kappa_{-1} \equiv 0 \). Let \( n \geq 0 \) be arbitrary. Write
\[
\varepsilon_n \equiv 2^{-n}.
\]
CHAPTER 10. A.U. CÀDLÀG PROCESSES

Take any \( \gamma_n \in (\beta_{uB}(2^{-3} \varepsilon_n), \beta_{uB}(2^{-3} \varepsilon_n) + 1) \).

Define the integers
\[
\kappa_n \equiv [\kappa_{n-1} \vee - \log_2 (1 \wedge \delta_{Rcp}(2^{-3} \varepsilon_n, \gamma_n))]_1, \quad (10.7.25)
\]
\[
m_n \equiv \kappa_n \vee [m_{n-1} \vee - \log_2 (1 \wedge \delta_{Rcp}(2^{-\kappa(n)-n-6} \varepsilon_n, \gamma_n))]_1, \quad (10.7.26)
\]
\[
K_n \equiv 2^{\kappa(n)+n+3},
\]
\[
h_n \equiv m_{n+1},
\]

and the measurable set
\[
G_n \equiv \bigvee_{u \in Q(h(n))} d(x_u, Z_u) > \gamma_n. \quad (10.7.27)
\]

Then, since \( \gamma_n > \beta_{uB}(2^{-3} \varepsilon_n) \), inequality 10.7.21 in the hypothesis implies that
\[
P(G_n) < 2^{-3} \varepsilon_n. \quad (10.7.28)
\]

Moreover,
\[
h_n \equiv m_{n+1} > m_n \geq \kappa_n \geq n \geq 0,
\]

and equality 10.7.26 can be rewritten as
\[
m_n \equiv \kappa_n \vee [m_{n-1} \vee - \log_2 (1 \wedge \delta_{Rcp}(K_n^{-1} 2^{-3} \varepsilon_n, \gamma_n))]_1. \quad (10.7.29)
\]

Furthermore, equalities 10.7.25 and 10.7.29 imply, respectively,
\[
\Delta_{\kappa(n)} \equiv 2^{-\kappa(n)} < \delta_{Rcp}(2^{-3} \varepsilon_n, \gamma_n), \quad (10.7.30)
\]
\[
\Delta_{m(n)} \equiv 2^{-m(n)} < \delta_{Rcp}(K_n^{-1} 2^{-3} \varepsilon_n, \gamma_n). \quad (10.7.31)
\]

5. Now let \( \beta > \varepsilon_n \)

be arbitrary such that the set
\[
A^\beta_{r,s} \equiv (d(Z_r, Z_s) > \beta) \quad (10.7.32)
\]
is measurable for each \( r, s \in Q_m \). Define the exceptional set
\[
D_n \equiv \bigcup_{t \in Q(m(n))} \bigcup_{r,s \in Q(m(n)+1): r \leq s} (A^\beta_{t,r} \cup A^\beta_{t,s} \cup A^\beta_{t',r} \cup A^\beta_{t',s}), \quad (10.7.33)
\]
where, for each \( t \in [0,1) Q(m(n)) \), we write \( t' \equiv t + 2^{-m(n)} \). We need only prove that \( P(D_n) < 2^{-3n} \), as required in Condition 1 of Definition 10.4.1

6. For that purpose, let the simple first stopping time \( \zeta \equiv \zeta_{h(n)}, \gamma(n) \) be as in Definition 10.7.1. Thus \( \zeta \) is the first time \( s \in Q_{h(n)} \) when the process \( Z|Q_{h(n)} \) is outside the

Yuen-Kwok Chan 382 Constructive Probability
\[ \eta_{t} = \eta_{t, a, \beta, Q(h(\alpha))} \]

and define the simple stopping time

\[ \tau_{k} \equiv \eta_{t, k-1} \equiv \sum_{u \in \{Q(h(\alpha))\}} \eta_{t, k-1} \]

relative to the natural filtration \( \mathcal{L}(h) \) of the process \( Z_{h} \). Then \( \tau_{k} \geq \tau_{k-1} \). Intuitively, \( \tau_{1}, \tau_{2}, \ldots, \tau_{h(n)} \) are the successive stopping times when the process \( Z_{h} \) moves away from the previous stopping state \( Z_{\tau_{k-1}}(h) \) by a distance of more than \( \alpha \) while staying within the bounded set \( d(x, \cdot) < \eta_{k} \).

In view of the inequality \[ 10.7.30 \] and the bound

\[ \alpha > 2^{-1} \epsilon_{n} > 2(2^{-3} \epsilon_{n}) \],

we can apply Part 2 of Lemma \[ 10.7.7 \] where \( \epsilon, \gamma, m, h, \tau, \Delta \) are replaced by

\[ 2^{-3} \epsilon_{n}, \gamma_{n}, h_{n}, \tau_{k-1}, \Delta_{k(n)} \]

respectively. Then Lemma \[ 10.7.5 \] and inequality \[ 10.7.12 \] in Lemma \[ 10.7.7 \] together imply

\[ P(\tau_{k} - \tau_{k-1} < (1 - \tau_{k-1}) \land \Delta_{k(n)}) = P(\eta_{t, k-1} < \tau_{k-1} + (1 - \tau_{k-1}) \land \Delta_{k(n)}) \]

\[ = P(\eta_{t, k-1} < 1 \land (\tau_{k-1} + \Delta_{k(n)})) \leq 2(2^{-3} \epsilon_{n}), \] \hspace{1cm} (10.7.35)

while \[ 10.7.13 \] in Lemma \[ 10.7.7 \] yields

\[ E(\tau_{k} - \tau_{k-1}) \equiv E(\eta_{t, k-1} - \tau_{k-1}) \geq 2^{-1} E((1 - \tau_{k-1}) \land \Delta_{k(n)}), \] \hspace{1cm} (10.7.36)

where \( k = 1, \ldots, K_{n} \) is arbitrary. Hence

\[ 1 \geq E(\tau_{k(n)}) = \sum_{k=1}^{K_{n}} E(\tau_{k} - \tau_{k-1}) \]

Yuen-Kwok Chan 383 Constructive Probability
where the last inequality is by applying inequality 10.7.35 to \( \tau \)

\[
\text{inequality 10.7.35 says that each waiting time}
\]

\[
\text{where the second inequality is from inequality 10.7.36. Dividing by 2}
\]

\[
\text{obtain}
\]

\[
\text{where the second inequality is from inequality [10.7.36]}
\]

\[
\text{Dividing by } 2^{-1}K_n\Delta K(n), \text{ we obtain}
\]

\[
P(\tau_{K(n)} - 1 < 1 - \Delta K(n)) < 2K_n^{-1}\Delta K(n)^{-1} 
\]

\[
= 2 \cdot 2^{-(K(n) - n - 3)}2^{K(n)} = 2^{-2} \varepsilon_n.
\]

At the same time,

\[
P(\tau_{K(n)} < 1; \tau_{K(n)} - 1 \geq 1 - \Delta K(n)) = P(\tau_{K(n)} - 1 < 1; \tau_{K(n)} - 1 \geq 1 - \Delta K(n))
\]

\[
\leq P(\tau_{K(n)} - 1 < 1 \land (\tau_{K(n)} - 1 + \Delta K(n))) \leq 2(2^{-3} \varepsilon_n) = 2^{-2} \varepsilon_n,
\]

where the last inequality is by applying inequality [10.7.35] to \( k = K_n \).

8. Next define the exceptional set

\[
H_n \equiv (\tau_{K(n)} < 1).
\]

Then, combining inequalities [10.7.38] and [10.7.37] we obtain

\[
P(H_n) = P(\tau_{K(n)} < 1)
\]

\[
\leq P(\tau_{K(n)} < 1; \tau_{K(n)} - 1 \geq 1 - \Delta K(n)) + P(\tau_{K(n)} - 1 < 1 - \Delta K(n))
\]

\[
\leq 2^{-2} \varepsilon_n + 2^{-2} \varepsilon_n = 2^{-1} \varepsilon_n.
\]

Summing up, except for the small exceptional set \( G_n \cup H_n \), there are at most the finite number \( K_n \) of simple stopping times \( 0 < \tau_1 < \cdots < \tau_{K(n)} = 1 \) each of which is the first time in \( Q_{\alpha(n)} \) when the process \( Z \) strays from the previous stopped state by a distance greater than \( \alpha \), while staying in the bounded set \( (d(x, \cdot) < \gamma_n) \). At the same time, inequality [10.7.35] says that each waiting time \( \tau_{K(n)} - \tau_{K(n) - 1} \) exceeds a certain lower bound with some probability close to 1. We wish, however, to be able to say that, with some probability close to 1, all these \( K_n \) waiting times simultaneously exceed a certain lower bound. For that purpose, we will relax the lower bound and specify two more small exceptional sets, as follows.

9. Define two more exceptional sets,

\[
B_n \equiv \bigcup_{k=1}^{K(n)} (\tau_k - \tau_{k-1} < (1 - \tau_{k-1}) \Delta m(n)), \quad \text{(10.7.39)}
\]
and proceed to estimate $P(B_n)$ and $P(C_n)$.

First, let $k = 1, \cdots, K_n$ be arbitrary. Note that, trivially,

$$\alpha > 2^{-1} \varepsilon_n > 2K_n^{-1} 2^{-3} \varepsilon_n.$$ 

and that, as in inequality [10.7.31]

$$\Delta_m(n) \equiv 2^{-m(n)} < \delta_{RCP}(K_n^{-1} 2^{-3} \varepsilon_n, \gamma_n).$$

Now define the numbers, $m \equiv m_n$, $t \equiv 1 - \Delta_m(n)$, $r \equiv 1 \wedge (t + \Delta_m(n)) = 1$, the simple stopping times

$$\tau \equiv \tau_k \wedge \tau_k \wedge (1 - \Delta_m(n))$$

and $\tau \equiv \tau_k$ with values in $Q_{h(n)}$, and the measurable set $d(x, Z_\tau) \leq \gamma_n \in L[\tau_{1, r}]$. Then $\alpha > 2\varepsilon$ and

$$\Delta_m(n) \equiv 2^{-m(n)} < \delta_{RCP}(\varepsilon, \gamma)$$

according to inequality [10.7.31]. Moreover, the simple stopping time $\tau$ has values in $[t, r]Q_{h(n)}$, relative to the filtration $\mathcal{F}^n$. Hence we can apply Lemma [10.7.7] where $\varepsilon, \gamma, \alpha, m, h, t, r, \tau, A$ are replaced by $K_n^{-1} 2^{-3} \varepsilon_n, \gamma_n, \alpha, m_n, h_n, t, \tau, \tau_k, r, d(x, Z_\tau) \leq \gamma_n$ respectively. Then inequality [10.7.10] of Lemma [10.7.7] yields

$$P(d(Z_\tau, Z_1) > \alpha; d(x, Z_\tau) \leq \gamma_n) \leq K_n^{-1} 2^{-3} \varepsilon_n P(d(x, Z_\tau) \leq \gamma_n) \leq K_n^{-1} 2^{-3} \varepsilon_n.$$

Hence, recalling the defining equalities [10.7.40] and [10.7.29] for the measurable sets $C_n$ and $G_n$ respectively, we immediately obtain

$$P(C_n G_n) \equiv P\left(\bigcup_{k=1}^{K(n)} (d(Z_{\tau(k-1)} \wedge (1-\Delta_m(n)), Z_1) > \alpha; d(x, Z_n) \leq \gamma_n)\right)$$

$$\leq P\left(\bigcup_{k=1}^{K(n)} (d(Z_{\tau(k-1)}, Z_1) > \alpha; d(x, Z_\tau) \leq \gamma_n)\right) \leq \sum_{k=1}^{K(n)} K_n^{-1} 2^{-3} \varepsilon_n = 2^{-3} \varepsilon_n.$$

At the same time, [10.7.12] in Lemma [10.7.7] yields

$$P(\tau_{\tau(k-1)} < 1 \wedge (\tau_k + \Delta_m(n))) \leq 2K_n^{-1} 2^{-3} \varepsilon_n.$$ 

(10.7.41)

Since $\tau_{\tau(k-1)} \equiv \tau_k$, and since

$$1 \wedge (\tau_k + \Delta_m(n)) = \tau_k + \Delta_m(n) \wedge (1 - \tau_k)$$

according to Lemma [10.7.5] inequality [10.7.41] is equivalent to

$$P(\tau_k - \tau_k < \Delta_m(n) \wedge (1 - \tau_k)) \leq 2K_n^{-1} 2^{-3} \varepsilon_n.$$ 

(10.7.42)

Yuen-Kwok Chan 385 Constructive Probability
Hence, recalling the defining equality [10.7.39] for the measurable sets $B_n$, we obtain

$$P(B_n) \equiv \prod_{k=1}^{K(n)} (\tau_k - \tau_{k-1} < \Delta_n \land (1 - \tau_{k-1})) \leq \sum_{k=1}^{K(n)} 2K_n^{-1} 2^{-3} \varepsilon_n = 2^{-3} \varepsilon_n.$$ 

Combining, we see that

$$P(G_n \cup H_n \cup B_n \cup C_n) = P(G_n \cup H_n \cup B_n \cup C_n^c) \leq 2^{-n-3} + 2^{-1} \varepsilon_n + 2^{-3} \varepsilon_n + 2^{-3} \varepsilon_n < \varepsilon_n.$$ 

10. Finally, we will prove that $D_n \subset G_n \cup H_n \cup B_n \cup C_n$. To that end, consider each $\omega \in G_n \cap H_n \cap B_n^c \cap C_n^c$. Then, since $\omega \in G_n^c$, we have $\forall \epsilon \in (0, \alpha(t)) \ d(x_n, Z(\omega)) \leq \gamma$. Consequently, $\cos_h(\omega) = 1$ according to the defining equality [10.7.2]. Hence, by the defining equality [10.7.44] we have

$$\exists \tau_{(k-1)}(\omega) = \exists \tau_k(\omega) = \exists \tau_k(\omega) = \exists \tau_k(\omega),$$

where the second equality is by equality [10.7.43]. Hence basic properties of the simple first exit time $\eta_{\alpha(t)}(\omega)$ implies that

$$d(Z(t, \omega), Z(u, \omega)) \leq \alpha$$

for each $u \in [t, \tau_h(\omega))Q_h$. In other words,

$$d(Z(\tau_{k-1}(\omega), \omega), Z(u, \omega)) \leq \alpha$$

for each $u \in [\tau_{k-1}(\omega), \tau_k(\omega))Q_h$, where $k = 1, \cdots, K_n$ is arbitrary.

Next, let $t \in [0, 1)Q_{m(n)}$ be arbitrary, and write $t' \equiv t + \Delta_{m(n)}$. Consider the following two possible cases (i') and (ii') regarding the number of members in the sequence $\tau_i(\omega), \cdots, \tau_{K(n)-1}(\omega)$ that are in the interval $(t, t')$.

(i'). Suppose the interval $(t, t')$ contains two or more members in the sequence $\tau_1(\omega), \cdots, \tau_{K(n)-1}(\omega)$. Then there exists $k = 1, \cdots, K_n - 1$ such that

$$\tau_{k-1}(\omega) \leq t < \tau_k(\omega) \leq \tau_{k+1}(\omega) \leq t'.$$

It follows that

$$\Delta_{m(n)} \equiv t' - t > \tau_{k+1}(\omega) - \tau_k(\omega) \geq \Delta_{m(n)} \land (1 - \tau_k(\omega)),$$

where the last inequality is because $\omega \in B_n^c$. Consequently $\Delta_{m(n)} > 1 - \tau_k(\omega)$. Hence $\Delta_{m(n)} \land (1 - \tau_k(\omega)) = 1 - \tau_k(\omega)$. Therefore the second half of inequality [10.7.47] yields

$$\tau_{k+1}(\omega) - \tau_k(\omega) \geq 1 - \tau_k(\omega).$$

Yuen-Kwok Chan 386 Constructive Probability
which is equivalent to $1 = \tau_{k+1}(\omega)$. Consequently, inequality (10.7.46) implies that $t' = 1$ and that $\tau_{k}(\omega) > t = 1 - \Delta_{m(n)}$. Therefore

$$
d(Z(\tau_{k}(\omega), Z(1(\omega))) = d(Z(\tau_{k}(\omega), Z(1(\omega))) \leq \alpha, \quad (10.7.48)
$$

where the inequality is because $\omega \in C_n^\alpha$. At the same time,

$$
[\tau_{k}(\omega), 1)Q_{h(n)} = [\tau_{k}(\omega), \tau_{k+1}(\omega)]Q_{h(n)}
$$

\[ \equiv [\tau_{k}(\omega), t_{\tau, k}(\omega)]Q_{h(n)} = [\tau_{k}(\omega), \eta_{\tau, k}(\omega)]Q_{h(n)}, \]

where the last equality follows from equality (10.7.43). Hence, basic properties of the simple first exit time $\eta_{\tau, k}$ implies that

$$
d(Z(\tau_{k}(\omega), \omega), Z(u, u)) \leq \alpha \quad (10.7.49)
$$

for each $u \in [\tau_{k}(\omega), 1)Q_{h(n)}$. Combining with inequality (10.7.48) for the end point 1, we see that

$$
d(Z(\tau_{k}(\omega), \omega), Z(u, u)) \leq \alpha \quad (10.7.50)
$$

for each $u \in [\tau_{k}(\omega), 1)Q_{h(n)}$.

Note that $\beta > 2\alpha$, and that $t, t' \in [\tau_{k-1}(\omega), \tau_{k}(\omega)] \cup [\tau_{k}(\omega), t']$, with $t' = 1$. Hence, in view of inequalities (10.7.45) and (10.7.50) we can apply Lemma 10.7.6 to the contiguous intervals $A_{\omega} \equiv [\tau_{k-1}(\omega), \tau_{k}(\omega)]$ and $B_{\omega} \equiv [\tau_{k}(\omega), t'] = [\tau_{k}(\omega), 1]$, to obtain

$$
\omega \in \bigcap_{r,s \in (t,t')Q_{h(n)\cup r \leq s}} ((A_{r,s}^\beta \cup A_{r,s}^{\beta}) (A_{r,s}^\beta \cup A_{r,s}^{\beta}) (A_{r,s}^\beta \cup A_{r,s}^{\beta}))^c
$$

\[ \equiv \bigcap_{r,s \in (t,t')Q_{h(n)\cup r \leq s}} ((A_{r,s}^\beta \cup A_{r,s}^{\beta}) (A_{r,s}^\beta \cup A_{r,s}^{\beta}) (A_{r,s}^\beta \cup A_{r,s}^{\beta}))^c \subset D_n^c. \quad (10.7.51)

(ii') Now suppose the interval $(t, t']$ contains zero or one member in the sequence

$$
\tau_{1}(\omega), \cdots , \tau_{K(n)-1}(\omega). \quad \text{Then there exists } k = 1, \cdots , K(n) \text{ such that } \tau_{k-1}(\omega) \leq t < t' \leq \tau_{k+1}(\omega). \quad \text{Hence}
$$

$$
t, t' \in [\tau_{k-1}(\omega), \tau_{k}(\omega)) \cup [\tau_{k}(\omega), \tau_{k+1}(\omega)).
$$

Then inequality (10.7.45) holds for both $k$ and $k+1$. Hence we can apply Lemma 10.7.6 to the contiguous intervals $A_{\omega} \equiv [\tau_{k-1}(\omega), \tau_{k}(\omega)]$ and $B_{\omega} \equiv [\tau_{k}(\omega), \tau_{k+1}(\omega)]$, to obtain, again, relation (10.7.51).

11. Summing up, we have proved that $\omega \in D_n^c$ for each $\omega \in G_n^c \cap H_n^c \cap B_n^c \cap C_n$. Consequently $D_n \subset G_n \cup H_n \cup B_n \cup C_n$, whence

$$
P(D_n) \leq P(G_n \cup H_n \cup B_n \cup C_n) < \varepsilon_n = 2^{-n},
$$

where $n \geq 0$ is arbitrary, Condition 1 of Definition (10.4.1) has also been verified. Accordingly, the process $Z$ is $D$-regular, with the sequence $\mu \equiv \langle m_n \rangle_{n=0,1,\cdots}$ as a modulus of $D$-regularity. Assertion 1 is proved.

12. Therefore, by Theorem 10.5.8, the right limit extension $X$ of the process $Z$ is a.u. càdlàg, with a modulus of a.u. càdlàg $\delta_{u\text{ac}l}(\cdot, \cdot, \delta_{u\text{ac}l}) \equiv \delta_{u\text{ac}l}(\cdot, \cdot, \beta_{u\text{ac}l}, \delta_{\text{u}\text{ac}l})$. Assertion 2 is proved..
10.8 A Sufficient Condition for an a.u. Càdlàg Martingale

Using Theorem 10.7.8 in the preceding section, we will prove a sufficient condition for a martingale \( X : [0, 1] \times \Omega \to R \) to be equivalent to one which is a.u. càdlàg.

To that end, recall, from Definition 8.4.3, the special convex function \( \lambda : R \to R \) given by
\[
\lambda(x) \equiv 2x + (e^{-|x|} - 1 + |x|) \quad (10.8.1)
\]
for each \( x \in R \). Theorem 8.4.4 says that the function \( \lambda \) is increasing and strictly convex, with
\[
|x| \leq |\lambda(x)| \leq 3|x| \quad (10.8.2)
\]
for each \( x \in R \).

Lemma 10.8.1. (Each wide-sense submartingale on \( Q_{\infty} \) is a.u. bounded). Let \( Z : Q_{\infty} \times \Omega \to R \) be a wide-sense submartingale relative to some filtration \( \mathcal{L} \equiv \{ L_t : t \in Q_{\infty} \} \). Suppose \( b > 0 \) is an upper bound of \( E|Z_0| \vee E|Z_1| \leq b \). Then the process \( Z \) is a.u. bounded in the sense of Definition 10.7.2, with a modulus of a.u. boundlessness \( \beta_{aub} \equiv \beta_{aub}(|\cdot|, b) \).

Proof. Let \( \varepsilon > 0 \) be arbitrary. Take an arbitrary \( \alpha \in (2^{-1} \varepsilon, 2^{-1} \varepsilon) \). Take an arbitrary real number \( K > 0 \) so large that
\[
6b < \frac{1}{6} \alpha^3 \exp(-3K^{-1}b\alpha^{-1}). \quad (10.8.3)
\]
Such a real number \( K \) exists because the right-hand side of the inequality 10.8.3 is arbitrarily large for sufficiently large \( K \). Define
\[
\beta_{aub}(\varepsilon) \equiv \beta_{aub}(\varepsilon, b) \equiv b\alpha^{-1} + K\alpha.
\]
Then, by inequality 10.8.2 we have
\[
E\lambda(K^{-1}Z_1) - E\lambda(K^{-1}Z_0) \leq E|\lambda(K^{-1}Z_1)| + E|\lambda(K^{-1}Z_0)| \leq 3E|K^{-1}Z_1| + 3E|K^{-1}Z_0| \leq 3K^{-1}b + 3K^{-1}b = 6K^{-1}b < \frac{1}{6}\alpha^3 \exp(-3(E|K^{-1}Z_0| \vee E|K^{-1}Z_1|)\alpha^{-1}), \quad (10.8.4)
\]
where the third inequality is a consequence of inequality 10.8.3. Hence we can apply Theorem 8.4.4 to the wide-sense submartingale \( K^{-1}Z : Q_0 : Q_h \times \Omega \to R \), to obtain
\[
P(\bigvee_{r \in Q(h)} |Z_r - Z_0| > K\alpha) = P(\bigvee_{r \in Q(h)} |K^{-1}Z_r - K^{-1}Z_0| > \alpha) < \alpha, \quad (10.8.5)
\]
for each \( h \geq 0 \). Separately, Chebychev’s inequality implies that
\[
P(|Z_0| > b\alpha^{-1}) \leq b^{-1} \alpha E|Z_0| \leq \alpha.
\]
10.8. A SUFFICIENT CONDITION FOR AN A.U. CÄDLÄG MARTINGALE

Combining with inequality [10.8.5] we obtain
\[
P(\bigvee_{r \in Q(h)} |Z_r| > K\alpha + b\alpha^{-1}) < 2\alpha < \varepsilon.
\]

Consequently, \(P(\bigvee_{r \in Q(h)} |Z_r| > \gamma) < \varepsilon\) for each \(\gamma > K\alpha + b\alpha^{-1} \equiv \beta_{\text{sub}}(\varepsilon)\). In other words, the process \(Z\) is a.u. bounded, with the operation \(\beta_{\text{sub}}\) as a modulus of a.u. boundlessness.

Lemma 10.8.2. (Martingale after an event observed at time \(t\)). Let \(Z : Q_\infty \times (\Omega, L, E) \to R\) be a martingale relative to some filtration \(\mathcal{L} \equiv \{L^{(t)} : t < Q_\infty\}\). Let \(t < Q_\infty\) and \(A \in L^{(t)}\) be arbitrary with \(P(A) > 0\). Recall from Definition 10.6.4 the conditional probability space \((\Omega_a, L_a, E_a)\). Then the process
\[
Z|[t, 1]Q_\infty : [t, 1]Q_\infty \times (\Omega, L, E_A) \to R
\]
is a martingale relative to the filtration \(\mathcal{L}\).

Proof. Consider each \(s, r \in [t, 1]Q_\infty\) with \(s \leq r\). Let \(U \in L^{(s)}\) be arbitrary, with \(U\) bounded. Then \(U1_A \in L^{(s)}\). Hence, since \(Z : Q_\infty \times (\Omega, L, E) \to R\) is a martingale relative to the filtration \(\mathcal{L}\), we have
\[
E_A(Z_U) = P(A)^{-1}E(Z_{U1_A}) = P(A)^{-1}E(Z_{U1_A}) = E_A(Z_U),
\]
where \(Z_U \in L^{(s)}\). Hence \(E_A(Z_U|L^{(s)}) = Z_s\), where \(s, r \in [t, 1]Q_\infty\) are arbitrary with \(s \leq r\). Thus the process
\[
Z|[t, 1]Q_\infty : [t, 1]Q_\infty \times (\Omega, L, E_A) \to R
\]
is a martingale relative to the filtration \(\mathcal{L}\).

Theorem 10.8.3. (Sufficient Condition for of martingale on \(Q_\infty\) to have an a.u. càdlàg martingale extension to \([0, 1]\)). Let \(Z : Q_\infty \times \Omega \to R\) be an arbitrary martingale relative to some filtration \(\mathcal{L} \equiv \{L^{(t)} : t < Q_\infty\}\). Suppose the following conditions are satisfied.

(i). The real number \(b > 0\) is such that \(E[Z_1] \leq b\).

(ii). For each \(\alpha, \gamma > 0\), there exists \(\delta_{Rcp}(\alpha, \gamma) > 0\) such that, for each \(h \geq 1\) and \(t, s \in Q_h\) with \(t \leq s < t + \delta_{Rcp}(\alpha, \gamma)\), and for each \(A \in L^{(t, h)}\) with \(A \subset (|Z_s| \leq \gamma)\) and \(P(A) > 0\), we have
\[
E_A|Z_s| - E_A|Z_t| \leq \alpha,
\]
and
\[
|E_Ae^{-|Z_s|} - E_Ae^{-|Z_t|}| \leq \alpha.
\]

Then the following holds.

1. The martingale \(Z\) is D-regular, with a modulus of continuity in probability \(\delta_{cp} \equiv \delta_{cp}(\cdot, b, \overline{\delta}_{Rcp})\) and with a modulus of D-regularity \(\overline{\delta} \equiv \overline{\delta}(b, \overline{\delta}_{Rcp})\).

2. Let \(X = \Phi_{\text{Lem}}(Z) : [0, 1] \times \Omega \to R\) be the right limit extension of \(Z\). Then \(X\) is an a.u. càdlàg martingale relative to the right-limit extension \(\mathcal{L}^+\) of the given filtration \(\mathcal{L}\), with \(\delta_{cp}(\cdot, b, \overline{\delta}_{Rcp})\) as a modulus of continuity in probability, and with a modulus of a.u. càdlàg \(\delta_{\text{Mar}}(\cdot, b, \overline{\delta}_{Rcp})\).

Yuen-Kwok Chan 389 Constructive Probability
3. Recall from Definition 10.4.1.1 the metric space \( \hat{R}(Q_∞ \times Ω, R) \) of stochastic processes with parameter set \( Q_∞ \), where sequential convergence relative to the metric \( \hat{R}(Q_∞) \) is equivalent to convergence in probability when stochastic processes are viewed as \( \text{r.v.'s} \). Let \( \hat{R}(Ω, R) \) denote the subspace of \( (\hat{R}(Ω, R), \hat{R}(Q_∞)) \) consisting of all martingales \( Z: Q_∞ \times Ω \to R \) satisfying the above conditions (i-ii) with the same bound \( b > 0 \) and same given operation \( \hat{R}(\cdot, R) \). Then the right limit extension function

\[
Φ_{R\hat{Lim}}: (\hat{R}(Ω, R), \hat{R}(Q_∞)) \to (\hat{D}(\cdot, \hat{R}(\cdot, R)), [0, 1], \hat{R}(\cdot, [0, 1]))
\]

(10.8.8)
is uniformly continuous, where

\[
(\hat{D}(\hat{\delta}_\alpha), \hat{\delta}(\cdot, [0, 1]))
\]
is the metric space of \( \text{a.u. càdlàg processes which share the common modulus of continuity in probability } \hat{\delta}_\alpha \equiv \hat{\delta}_\alpha(\cdot, \hat{R}(\cdot, R)), \text{ and which share the common modulus of a.u. càdlàg } \hat{\delta}_\alpha(\cdot, \hat{R}(\cdot, R)). \text{ Moreover, the mapping has a modulus of continuity } \hat{\delta}(\cdot, \hat{\delta}(\cdot, [0, 1])), \text{ depending only on } b \text{ and } \hat{\delta}(\cdot, R).\)

Proof. 1. Note that, because \( Z \) is a martingale, we have \( E|Z_0| \leq E|Z_1| \) by Assertion 4 of Proposition 8.3.2. Hence \( E|Z_0| \leq E|Z_1| \leq b \). Therefore, according to Lemma 10.8.1, the martingale \( Z \) is \( \text{a.u. bounded, with the modulus of a.u. boundedness } \beta_{\text{a.u.b}} = \beta_{\text{a.u.b}}(\cdot, b), \text{ in the sense of Definition } 10.7.2.\)

2. Let \( ε, γ > 0 \) and \( h \geq 0 \) be arbitrary. Consider each \( A \in L^{(t, h)} \subset L^{(t)} \) with \( A \subset (|Z| \leq γ) \) and \( P(A) > 0 \). By Lemma 10.8.1, the process \( Z|_{[t, 1]}Q_∞ : [t, 1]Q_∞ \times (Ω, L_Ω, E_Ω) \to R \) is a martingale relative to the filtration \( \mathcal{F}' \). Define

\[
α \equiv αε, γ \equiv 1 + \frac{1}{12} ε^3 \exp(-3(γ + b + 1)ε^{-1})
\]
and

\[
\hat{\delta}_{R\hat{Lim}}(ε, γ) \equiv \hat{\delta}(\alpha, γ).
\]

3. Now let \( s \in Q_h \) be arbitrary with

\[
t \leq s < t + \hat{\delta}_{R\hat{Lim}}(ε, γ) \equiv t + \hat{\delta}(\alpha, γ).
\]
be arbitrary. Trivially, \( E_A|Z_s| \leq γ \). Therefore, in view of inequality 10.8.6 in the hypothesis, we have

\[
E_A|Z_s| \leq E_A|Z_t| + α ≤ γ + α ≤ γ + 1.
\]
Since \( Z|_{[t, 1]}Q_h : [t, 1]Q_h \times (Ω, L_Ω, E_Ω) \to R \) is a martingale according to Lemma 10.8.1, we have \( E_A|Z_s| = E_A|Z_t| \) and \( E_A|Z_s| \geq E_A|Z_t| \). Hence equality 10.8.1 and inequalities 10.8.6 and 10.8.7 together imply that

\[
E_A\hat{\lambda}(Z_s) - E_A\hat{\lambda}(Z_t) \leq [E_Ae^{-|Z_t|} - E_Ae^{-|Z_t|}] + |E_A|Z_s| - E_A|Z_t|
\]

\[
= |E_Ae^{-|Z_t|} - E_Ae^{-|Z_t|}| + E_A|Z_s| - E_A|Z_t|
\]

Yuen-Kwok Chan 390 Constructive Probability
\[ \leq \alpha + \alpha = 2\alpha \leq \frac{1}{6} \varepsilon^3 \exp(-3(b \vee r + 1)^\varepsilon^{-1}) \]

\[ < \frac{1}{6} \varepsilon^3 \exp(-3b\varepsilon^{-1}) \]

\[ \leq \frac{1}{6} \varepsilon^3 \exp(-3(E_\mathcal{A}|Z_t| \vee E_\mathcal{A}|Z_t|)\varepsilon^{-1}). \]

Therefore we can apply Theorem 8.4.4 to obtain the bound

\[ P_\mathcal{A}(|Z_t - Z_s| > \varepsilon) < \varepsilon, \quad (10.8.9) \]

where \( \varepsilon > 0, \gamma > 0, h \geq 0, s \in Q_h \) with \( t \leq s < t + \delta_{\text{SRCP}}(\varepsilon, \gamma) \) and

\[ A \in L^{(h)} \equiv L(Z_r : r \in [0, t]Q_h) \]

with \( A \subset (|X_t| \leq \gamma) \) and \( P(A) > 0 \) are arbitrary. Thus the process \( Z \) is strongly right continuous in probability in the sense of Definition 10.7.3 with the operation \( \delta_{\text{SRCP}} \) as a modulus of strong right continuity in probability. Assertion 1 is proved.

4. Thus the process \( Z \) satisfies the conditions of Theorem 10.7.8. Accordingly, the process \( Z \) has a modulus of continuity in probability \( \delta_{\text{CP}}(\cdot, \beta_{\text{SRCP}}, \delta_{\text{SRCP}}) \equiv \delta_{\text{CP}}(\cdot, b, \delta_{\text{SRCP}}) \) and a modulus of \( D \)-regularity \( m \equiv m(\beta_{\text{SRCP}}, \delta_{\text{SRCP}}) \equiv m(b, \delta_{\text{SRCP}}) \). Moreover, Theorem 10.7.8 says that its right limit extension \( X \equiv \Phi_{\text{RLim}}(Z) \) is a.u. càdlàg, with the modulus of a.u. càdlàg \( \delta_{\text{aucl}}(\cdot, \beta_{\text{SRCP}}, \delta_{\text{SRCP}}) \equiv \delta_{\text{aucl}}(\cdot, b, \delta_{\text{SRCP}}) \) as defined in Theorem 10.7.8.

5. Separately, since \( 1 \in Q_\omega \), Assertion 4 of Proposition 8.3.2 implies that the family

\[ H \equiv \{Z_u : u \in Q_\omega \} = \{Z_t : t \in [0, 1]Q_\omega \} \]

is uniformly integrable. Now let \( t \in [0, 1] \) be arbitrary. Let \( r \in [0, 1] \) be arbitrary. Suppose \( t < r \). Take any sequence \((u_k)_{k=1,2,...} \) in \([0,r]Q_\omega \) such that \( u_k \to t \). Since the a.u. càdlàg process \( X \) is continuous in probability, we have \( Z_{u(k)} = X_{u(k)} \to X_t \) in probability. Since the subfamily \( \{Z_{u(k)} : k = 1, 2, \cdots \} \) inherits the uniform integrability from the family \( H \), it follows from Proposition 8.1.3 that the r.r.v. \( X_t \) is integrable, with \( E|X_{u(k)} - X_t| \to 0 \). At the same time, \( X_{u(k)} \in L^{(r)} \) for each \( k \geq 1 \), it follows that \( X_t \in L^{(r)} \), where \( r \in [0, 1] \) is arbitrary such that \( t < r \). Hence

\[ X_t \in \bigcap_{r \in [0, 1], r \to t} L^{(r)} \equiv L^{(t+)} \]

6. We will next show that the process \( X \) is a martingale relative to the filtration \( \mathcal{F}^+ \). To that end, let \( t, s \in [0, 1] \) be arbitrary with \( t < s \). Now let \( r, u \in Q_\omega \) be arbitrary such that \( t < r \leq u \) and \( s \leq u \). Let the indicator \( Y \in L^{(t+)} \) be arbitrary. Then \( Y, X_t \in L^{(t+)} \supset L^{(t)} \). Hence, since \( Z \) is a martingale relative to the filtration \( \mathcal{F} \), we have

\[ EYZ_t = EYZ_u. \]

Let \( r \downarrow t \) and \( u \downarrow s \). Then \( E|Z_r - X_t| = E|X_r - X_t| \to 0 \) and \( E|Z_u - X_t| = E|X_u - X_t| \to 0 \). It then follows that

\[ EYX_t = EYX_s, \quad (10.8.10) \]

Yuen-Kwok Chan 391 Constructive Probability
where $t, s \in [0, 1]$ are arbitrary with $t < s$. Consider each $t, s \in [0, 1]$ with $t \leq s$. Suppose $EYX_t \neq EYX_s$. If $t < s$, then equality 10.8.10 would hold, which is a contradiction. Hence $t = s$. Then trivially $EYX_t = EYX$, again a contradiction. We conclude that $EYX_t = EYX_s$ for each $t, s \in [0, 1]$ with $t \leq s$, and for each indicator $Y \in L^1$. Assertion 2 is proved.

6. Assertion 3 remains. Note that, since $Z \in \hat{R}_{Mreg, b, \overline{\mathbf{a}}(Rcp)}(Q_\infty \times \Omega, R)$ is arbitrary, we have proved that

$$\hat{R}_{Mreg, b, \overline{\mathbf{a}}(Rcp)}(Q_\infty \times \Omega, R) \subset \hat{R}_{Mreg, \overline{\mathbf{a}}(cp)}(Q_\infty \times \Omega, S).$$

At the same time, Theorem 10.6.1 says that the right-limit extension function

$$\Phi_{rLim} : \hat{R}_{Mreg, \overline{\mathbf{a}}(cp)}(Q_\infty \times \Omega, S, \overline{\mathbf{a}}_{Prob, Q(\infty)}) \rightarrow (\hat{D}_{\overline{\mathbf{a}}(aucl)}, \overline{\mathbf{a}}(cp)[0, 1], \overline{\mathbf{a}}_{D\overline{\mathbf{p}}[0, 1]}(10.8.11))$$

is uniformly continuous, with a modulus of continuity $\delta_{rLim}(\cdot, \overline{\mathbf{a}}, \overline{\mathbf{a}}_p) \equiv \delta_{rLim}(\cdot, b, \overline{\mathbf{a}}_{Rcp})$. Assertion 3 and the theorem are proved.

Theorem 10.8.3 can be restated in terms of the continuous construction of a.u. càdlàg martingales $X : [0, 1] \times \Omega \rightarrow R$ from their marginal distributions. More precisely, let $\hat{\xi}$ be an arbitrary, but fixed, binary approximation of $\xi$, and for each indicator

$$\delta_{rLim}(\cdot, \overline{\mathbf{a}}_p, \overline{\mathbf{a}}_q) \equiv \delta_{rLim}(\cdot, b, \overline{\mathbf{a}}_{Rcp})$$

Assertion 3 and the theorem are proved.

10.9 A Sufficient Condition for a Right Hölder Process

In this section, we give a sufficient condition, in terms of triple distributions, for a set $\hat{F}$ of consistent families of f.j.d.’s to be $D$-regular. Theorem 10.5.8 is then applied to construct corresponding a.u. càdlàg processes.

As an application, we will prove that, under an additional condition on the modulus of continuity in probability, the a.u. càdlàg process so constructed has sample functions

Yuen-Kwok Chan 392 Constructive Probability
which are right Hölder, in a sense made precise below. This result seems to be hitherto unknown.

In the following, recall Definition 10.9.2 for the notations associated with the enumerated sets \((Q_k)_{k=0,1,\ldots}\) and \(Q_\infty\) of dyadic rationals in \([0,1]\). In particular, \(p_k \equiv 2^k\) and \(\Delta_k \equiv 2^{-k}\) for each \(k \geq 0\). Separately, \((\Omega, L, E) \equiv (\Theta_0, L_0, E_0) \equiv ([0,1], L_0, \int \cdot \, dx)\) denote the Lebesgue integration space based on the interval \(\Theta_0 \equiv [0,1]\). This will serve as the sample space. Let \(\xi \equiv (A_q)_{q=1,2,\ldots}\) be an arbitrarily, but fixed, binary approximation of the locally compact metric space \((S,d)\) relative to some fixed reference point \(x_0 \in S\). Recall the operation \([\cdot]_1\) which assigns to each \(a \in R\) an integer \([a]_1 \in (a, a+2)\). We will repeatedly use the inequality \(a < [a]_1 < a+2\) for each \(a \in R\), without further comments.

The following theorem is in essence due to Kolmogorov.

**Theorem 10.9.1. (Sufficient Condition for D-regularity in terms of triple joint distributions).** Let \(F\) be an arbitrary consistent family of f.d.'s with parameter set \([0,1]\) and state space \((S,d)\). Suppose \(F\) is continuous in probability. Let \(Z : Q \times \Omega \rightarrow S\) be an arbitrary process with marginal distributions given by \(F|Q\). Suppose there exist two sequences \((\gamma_k)_{k=0,1,\ldots}\) and \((\alpha_k)_{k=0,1,\ldots}\) of positive real numbers such that (i) \(\sum_{k=0}^{\infty} 2^k \alpha_k < \infty\) and \(\sum_{k=0}^{\infty} \gamma_k < \infty\), (ii) the set

\[
A_{v,t}^{(k)} \equiv (d(Z_t, Z_s) > \gamma_{k+1})
\]

is measurable for each \(s, t \in Q_\infty\), for each \(k \geq 0\), and (iii)

\[
P(A_{v',t'}^{(k)}A_{v'',t''}^{(k)}) < \alpha_k,
\]

where \(v' \equiv v + \Delta_k\) and \(v'' \equiv v + \Delta_{k+1} = v' - \Delta_{k+1}\), for each \(v \in [0,1)Q_k\), for each \(k \geq 0\).

Then the family \(F|Q_\infty\) of f.d.'s is D-regular. Specifically, let \(m_0 \equiv 0\). For each \(n \geq 1\), let \(m_n \geq m_{n-1} + 1\) be so large that \(\sum_{k=m(n)}^{\infty} 2^k \alpha_k < 2^{-n}\) and \(\sum_{k=m(n)+1}^{\infty} \gamma_k < 2^{-n-1}\). Then the sequence \((m_n)_{n=0,1,\ldots}\) is a modulus of D-regularity of the family \(F|Q_\infty\).

**Proof.** 1. Let \(k \geq 0\) be arbitrary. Define

\[
D_k' \equiv \bigcup_{v \in [0,1)Q(k)} A_{v'',t''}^{(k)}A_{v',t'}^{(k)}.
\]

Then \(P(D_k') \leq 2^k \alpha_k\) according to Condition (iii) in the hypothesis.

2. Inductively, for each \(n \geq 0\), take any

\[
\beta_n \in (2^{-n}, 2^{-n+1})
\]

such that, for each \(s, t \in Q_\infty\), and for each \(k = 0, \ldots, n\), the sets

\[
(d(Z_t, Z_s) > \beta_k + \cdots + \beta_n)
\]

and

\[
A_{v',t'}^{(n)} \equiv (d(Z_t, Z_s) > \beta_{n+1})
\]

are measurable for each \(s, t \in Q_\infty\), for each \(n \geq 0\), and (iii)
are measurable. Note that $\beta_n, \omega \leq 2^{-k+1} = 2^{-n+2}$ for each $n \geq 0$.

3. Let $n \geq 0$ be arbitrary, but fixed until further notice. For ease of notations, suppress some symbols signifying dependence on $n$, to write $q_i \equiv q_{m(n), i} \equiv 2^{-m(n)}$ for each $i = 0, \ldots, m(n)$. Let $\beta > 2^{-n} > \beta_{n+1}$ be arbitrary such that the set

$$A_{\beta}^t \equiv (d(Z_t, Z_\omega) > \beta) \quad (10.9.6)$$

is measurable for each $s, t \in \Omega_m$. Define the exceptional set

$$D_n \equiv \bigcup_{t \in [0,1]Q(m(n)) \setminus \{e(t', )Q(m(n+1)): r \leq s \}} \bigcup_{t \in [0,1]Q(m(n)) \setminus \{e(t', )Q(m(n+1)): r \leq s \}} \bigcup_{t \in [0,1]Q(m(n)) \setminus \{e(t', )Q(m(n+1)): r \leq s \}}$$

$$\subset \bigcup_{t \in [0,1]Q(m(n)) \setminus \{e(t', )Q(m(n+1)): r \leq s \}} \bigcup_{t \in [0,1]Q(m(n)) \setminus \{e(t', )Q(m(n+1)): r \leq s \}} \bigcup_{t \in [0,1]Q(m(n)) \setminus \{e(t', )Q(m(n+1)): r \leq s \}}$$

where, for each $t \in [0,1]Q(m(n))$, write $t' \equiv t + \Delta_{m(n)} \in Q_{m(n)}$. To verify Condition 1 in Definition $[10.4.1]$ for the sequence $(m)_1 = 0, 1, \ldots$ and the process $Z$, we need only show that

$$P(D_n) \leq 2^{-n} \quad (10.9.8)$$

4. To that end, consider each $Q \in (\bigcup_{k=m(n)} Q_{m(n)})$. Let $t \in [0,1]Q(m(n))$ be arbitrary, and write $t' \equiv t + \Delta_{m(n)}$. We will show inductively that, for each $k = m_n, \ldots, m_{n+1}$, there exists $r_k \in (t, t')Q_k$ such that

$$\bigvee_{u \in [t_k - \Delta_k(k)]Q(k)} d(Z_t, Z_u) \leq \sum_{j=m(n)+1}^k \gamma_j \quad (10.9.9)$$

and

$$\bigvee_{v \in [t_k - \Delta_k(k)]Q(k)} d(Z_x, Z_r) \leq \sum_{j=m(n)+1}^k \gamma_j \quad (10.9.10)$$

where an empty sum is, by convention, equal to 0. Start with $k = m_n$. Define $r_k \equiv t'$, whence $r_k - \Delta_k = t$. Then inequalities $[10.9.9]$ and $[10.9.10]$ are trivially satisfied.

Suppose, for some $k = m_n, \ldots, m_{n+1}$, we have constructed $r_k \in (t, t')Q_k$ which satisfies inequalities $[10.9.9]$ and $[10.9.10]$. Note that, according to the defining equality $[10.9.2]$ we have

$$\omega \in D_k \subset (A_{r_k}^{(k)} \cup A_{r_k}^{(k)}(r_k - \Delta_k(k + 1))) \cup (A_{r_k}^{(k)}(r_k - \Delta_k(k + 1))) \cup (A_{r_k}^{(k)}(r_k - \Delta_k(k + 1))) \cup (A_{r_k}^{(k)}(r_k - \Delta_k(k + 1)))$$

Hence, by the defining equality $[10.9.1]$ we have (i')

$$d(Z_{r_k} - \Delta_k(k)), Z_{r_k} - \Delta_k(k + 1) \leq \gamma_{k+1} \quad (10.9.11)$$

or (ii')

$$d(Z_{r_k} - \Delta_k(k + 1), Z_{r_k} \leq \gamma_{k+1} \quad (10.9.12)$$

In Case (i'), define $r_{k+1} \equiv r_k$. In Case (ii'), define $r_{k+1} \equiv r_k - \Delta_k + 1$. Yuen-Kwok Chan 394 Constructive Probability
10.9. A SUFFICIENT CONDITION FOR A RIGHT HOELDER PROCESS

We wish to prove inequalities \[\text{(10.9.9)}\] and \[\text{(10.9.10)}\] for \(k + 1\). For that purpose, first consider each

\[u \in [r, r_{k+1} - \Delta_{k+1}]Q_{k+1}.
\]

(10.9.13)

Suppose \(u \in [r, r_k - \Delta_k]Q_k\). Then inequality \[\text{(10.9.9)}\] in the induction hypothesis trivially implies

\[d(Z_u(\omega), Z_{u'}(\omega)) \leq \sum_{j=m(n)+1}^{k+1} \gamma_j.\]

(10.9.14)

Suppose next that \(u \in [r, r_k - \Delta_k]Q_{k+1}Q_k^c\). Then \(u \leq r_k - \Delta_k - \Delta_{k+1}\). Let \(v \equiv u - \Delta_{k+1}\) and \(v' \equiv v + \Delta_k = u + \Delta_{k+1}\). Then \(v \in [0,1)Q_k\), and so the defining inequality \[\text{(10.9.2)}\] implies that

\[\omega \in D_k^c \subset (A_{v,v'}^k)^c \cup (A_{v,v'}^{k'})^c\]

and therefore that

\[d(Z_u(\omega), Z_v(\omega)) \land d(Z_u(\omega), Z_{v'}(\omega)) \leq \gamma_{k+1}.
\]

It follows that

\[d(Z_u(\omega), Z_v(\omega)) \leq (d(Z_u(\omega), Z_v(\omega)) + d(Z_v(\omega), Z_{v'}(\omega))) \land (d(Z_u(\omega), Z_{v'}(\omega)) + d(Z_{v'}(\omega), Z_v(\omega))) \leq \gamma_{k+1} + d(Z_u(\omega), Z_v(\omega)) \land d(Z_{v'}(\omega), Z_v(\omega)) \leq \gamma_{k+1} + \sum_{j=m(n)+1}^{k+1} \gamma_j = \sum_{j=m(n)+1}^{k+1} \gamma_j,
\]

where the last inequality is due to inequality \[\text{(10.9.9)}\] in the induction hypothesis. Thus we have verified inequality \[\text{(10.9.14)}\] also for each \(u \in [r, r_k - \Delta_k]Q_{k+1}Q_k^c\). Now suppose \(u \in (r_k - \Delta_k, r_{k+1} - \Delta_{k+1}]Q_{k+1}\). Then

\[r_{k+1} > r_k - \Delta_k + \Delta_{k+1} = r_k - \Delta_{k+1},
\]

which, by the definition of \(r_{k+1}\), rules out Case (ii'). Hence Case (i') must hold, where \(r_{k+1} \equiv r_k\). Consequently,

\[u \in (r_k - \Delta_k, r_{k+1} - \Delta_{k+1}]Q_{k+1} = \{r_k - \Delta_{k+1}\}
\]

and so \(u = r_k - \Delta_{k+1}\). Let \(v \equiv r_k - \Delta_k\). Then inequality \[\text{(10.9.11)}\] implies that

\[d(Z_v(\omega), Z_{u'}(\omega)) = d(Z_{r_k - \Delta(k)}(\omega), Z_{r(k) - \Delta(k+1)}(\omega)) \leq \gamma_{k+1}.
\]

(10.9.15)

Hence

\[d(Z_u(\omega), Z_v(\omega)) \leq d(Z_u(\omega), Z_{u'}(\omega)) + d(Z_{u'}(\omega), Z_v(\omega)) \leq \gamma_{k+1} + \sum_{j=m(n)+1}^{k} \gamma_j = \sum_{j=m(n)+1}^{k+1} \gamma_j,
\]

Yuen-Kwok Chan 395 Constructive Probability
where the last inequality is due to inequality (10.9.9) in the induction hypothesis. Combining, we see that inequality (10.9.14) holds for each \( u \in [t, r_{k+1} - \Delta_k + 1] \mathcal{Q}_{k+1} \).

Similarly we can verify that

\[
d(\mathcal{Z}_u(\omega), \mathcal{Z}_r(\omega)) \leq \sum_{j=m(n)+1}^{k+1} \gamma_j.
\]

(10.9.16)

for each \( u \in [r_{k+1}, r'] \mathcal{Q}_{k+1} \). Summing up, inequalities (10.9.9) and (10.9.10) have been verified for \( k + 1 \). Induction is completed. Thus inequalities (10.9.9) and (10.9.10) hold for each \( k = m_n, \ldots, m_{n+1} \).

5. Continuing, let \( r, s \in (t, t') \mathcal{Q}_{m(n+1)} \) be arbitrary with \( r \leq s \). Write \( k \equiv m_{n+1} \).

Then there are three possibilities: (i"") \( r, s \in [t, r_k - \Delta_k] \mathcal{Q}_k \), (ii"") \( r \in [t, r_k - \Delta_k] \mathcal{Q}_k \) and \( s \in [r_k, t'] \mathcal{Q}_k \), or (iii"") \( r, s \in [r_k, t'] \mathcal{Q}_k \). In Case (i""), inequality (10.9.9) applies to \( r, s \), yielding

\[
d(\mathcal{Z}_t(\omega), \mathcal{Z}_r(\omega)) \cup d(\mathcal{Z}_t(\omega), \mathcal{Z}_s(\omega)) \leq \sum_{j=m(n)+1}^{k} \gamma_j < 2^{-n-1} < \beta_{n+1}.
\]

Hence \( \omega \in (A_{x,t}^{(n)} \cup A_{x,t}^{(n)})^c \subset D_n^c \). In Case (ii""), inequalities (10.9.9) and (10.9.10) apply to \( r \) and \( s \) receptively, and yield

\[
d(\mathcal{Z}_t(\omega), \mathcal{Z}_r(\omega)) \cup d(\mathcal{Z}_t(\omega), \mathcal{Z}_s(\omega)) \leq \sum_{j=m(n)+1}^{k} \gamma_j < 2^{-n-1} < \beta_{n+1}.
\]

In other words, \( \omega \in (A_{x,t}^{(n)} \cup A_{x,t}^{(n)})^c \subset D_n^c \). Similarly, in Case (iii""), we can prove that \( \omega \in (A_{x,t}^{(n)} \cup A_{x,t}^{(n)})^c \subset D_n^c \).

6. Summing up, we have shown that \( \omega \in D_n^c \) where \( \omega \in (\bigcup_{k=m(n)}^{m(n+1)} D_k^c)^c \) is arbitrary. Thus \( D_n \subset \bigcup_{k=m(n)}^{m(n+1)} D_k^c \). Hence

\[
P(D_n) \leq \sum_{k=m(n)}^{m(n+1)} P(D_k^c) \leq \sum_{k=m(n)}^{m} 2^k \alpha_k < 2^{-n},
\]

where \( n \geq 0 \) is arbitrary. This proves inequality (10.9.8) and verifies Condition 1 in Definition (10.4.1) for the sequence \( (m)_n=0, \ldots \) and the process \( Z \). At the same time, since the family \( F \) is continuous in probability by hypothesis, Condition 2 of Definition (10.4.1) follows for \( F|\mathcal{Q}_m \) and for \( Z \). We conclude that the family \( F|\mathcal{Q}_m \) of f.j.d.'s is \( D \)-regular, with the sequence \( (m)_n=0, \ldots \) as modulus of \( D \)-regularity. \( \square \)

**Definition 10.9.2. (Right Hölder process)** Let \( C_0 \geq 0 \) and \( \lambda > 0 \) be arbitrary. Let \( X : [0, 1] \times \Omega \rightarrow S \) be an arbitrary a.u. càdlàg process. Suppose, for each \( \epsilon > 0 \), there exist (i) \( \bar{\delta} > 0 \), (ii) a measurable subset \( B \subset \Omega \) with \( P(B^c) < \epsilon \), (iii) for each \( \omega \in B \), there exists a Lebesgue measurable subset \( \bar{\theta}(\omega) \) of \( [0, 1] \) with Lebesgue measure ...
10.9. A SUFFICIENT CONDITION FOR A RIGHT HOELDER PROCESS

\[ \mu \bar{\Theta}(\omega) < \varepsilon, \] such that, for each \( t \in \bar{\Theta}(\omega) \cap \text{domain}(X(\cdot, \omega)) \) and for each \( s \in [t, t + \bar{\delta}) \cap \text{domain}(x) \), we have

\[ d(X(t, \omega), X(s, \omega)) \leq C_0(s-t)^{\lambda}. \]

Then the a.u. càdlàg process \( X \) is said to be right Hoelder, with right Hoelder exponent \( \lambda \), and with right Hoelder constant \( C_0. \]

Part 2 of the next theorem is in essence due to Chentsov [Chentsov 1956]. Part 3, concerning right Hoelder processes, seems hitherto unknown.

**Theorem 10.9.3.** (Sufficient condition for a right Hoelder process). Let \( u \geq 0 \) and \( w, K > 0 \) be arbitrary. Let \( F \) be an arbitrary consistent family of f.j.d.'s with parameter set \([0,1]\) and state space \((S,d)\). Suppose \( F \) is continuous in probability, with a modulus of continuity in probability \( \delta_p \), and suppose

\[ F_{r,s}(\{x,y,z\} \in \mathbb{S}^1 : d(x,y) \wedge d(y,z) > b) \leq b^{-u}(Ks-Kr)^{1+w} \quad (10.9.17) \]

for each \( b > 0 \) and for each \( t \leq r \leq s \) in \([0,1]\). Then the following holds.

1. The family \( F|_{\mathbb{Q}^{\omega}} \) is \( D \)-regular.
2. There exists an a.u. càdlàg process \( X : [0,1] \times \Omega \rightarrow S \) with marginal distributions given by the family \( F \), and with a modulus of a.u. càdlàg dependent only on \( u, w \) and the modulus of continuity in probability \( \delta_p \).
3. Suppose, in addition, that there exist \( \pi, \bar{\lambda} > 0 \) such that

\[ F_{r,s}(d > b) \leq b^{-w}|Ks-Kr|^{\bar{\lambda}} \quad (10.9.18) \]

for each \( b > 0 \) and for each \( t, s \in [0,1] \). Then there exist constants \( \lambda(u,w,\pi,\bar{\lambda}) > 0 \) and \( C(K,u,w,\pi,\bar{\lambda}) > 0 \) such that each a.u. càdlàg process \( X : [0,1] \times \Omega \rightarrow S \) with marginal distribution given by the family \( F \) is right Hoelder, with right Hoelder exponent \( \lambda \), and with right Hoelder constant \( C. \]

Specifically

\[ \lambda(u,w,\pi,\bar{\lambda}) \equiv 2^{-1}w((1 + 2u)(1 + \pi^{-1} \bar{\lambda}^{-1} (1 + \pi)) + w(2 + 3\bar{\lambda}^{-1} (1 + \pi))^{-1}. \quad (10.9.19) \]

**Proof.** 1. Let \( Z : \mathbb{Q}^{\omega} \times \Omega \rightarrow S \) be an arbitrary process with marginal distributions given by \( F|_{\mathbb{Q}^{\omega}} \). Define \( u_0 \equiv u + 2^{-1} \) and \( u_1 \equiv u + 1 \). Then \( \gamma_0 \equiv 2^{-w/u(0)} < \gamma_1 \equiv 2^{-w/u(1)} \). Take an arbitrary \( \gamma \in (\gamma_0, \gamma_1) \) such that the subset

\[ A^{(k)}_{r,s} \equiv (d(Z_r,Z_s) > \gamma^{k+1}) = (d(Z_r,Z_s) \vee \gamma_0^{k+1} > \gamma^{k+1}) \]

\[ = (d(Z_r,Z_s) \vee \gamma_0^{k+1})^{1/(k+1)} > \gamma \quad (10.9.20) \]

of \( \Omega \) is measurable for each \( r, s \in \mathbb{Q}^{\omega} \) and for each \( k \geq 0 \). Then, since \( 2^{-w/\nu} \) is a strictly increasing continuous function of \( v \in (u_0,u_1) \) with range \((\gamma_0, \gamma_1)\), there exists a unique

\[ v \in (u_0, u_1) \equiv (u + 2^{-1}, u + 1) \]

such that

\[ \gamma = 2^{-w/\nu}. \quad (10.9.21) \]

Yuen-Kwok Chan 397 Constructive Probability
CHAPTER 10. A.U. CÀDLÀG PROCESSES

Note that $0 < \gamma < 1$, and that
\begin{equation}
0 < \gamma^{-u}2^{-w} = 2^{iw/\gamma^w} < 2^{w-w} = 1. \tag{10.9.22}
\end{equation}

2. Let $k \geq 0$ be arbitrary. Define the positive real numbers
\begin{align*}
\gamma_k & \equiv \gamma^k, \\
\alpha_k & \equiv K^{1+w}2^{-k}\gamma^{-(k+1)u}2^{-kw}.
\end{align*}
Then
\begin{equation}
\sum_{k=0}^{\infty} \gamma_k = \sum_{k=0}^{\infty} \gamma^k < \infty,
\end{equation}
and, in view of inequality [10.9.22]
\begin{equation}
\sum_{k=0}^{\infty} 2^k \alpha_k = K^{1+w} \gamma^{-u} \sum_{k=0}^{\infty} (\gamma^{-u}2^{-w})^k < \infty.
\end{equation}

Let $t \in [0,1)Q_k$ be arbitrary. Write $t' \equiv t + \Delta_k$ and $t'' \equiv t + \Delta_{k+1} = t' - \Delta_{k+1}$. Then
\begin{align*}
P(A_1^{(k)}A_2^{(k)}) &= P(d(Z_t,Z_{t'}) \land d(Z_{t''},Z_t) > \gamma^{k+1}) \\
&\leq \gamma^{-(k+1)u}(Kt' - Kt)^{1+w} = \gamma^{-(k+1)u}(K\Delta_k)^{1+w} = \gamma^{-(k+1)u}(K2^{-k})^{1+w} \\
&= K^{1+w}2^{-k}\gamma^{-(k+1)u}2^{-kw} \equiv \alpha_k, \tag{10.9.23}
\end{align*}
where the inequality follows from inequality [10.9.17] in the hypothesis. Thus we have verified the conditions in Theorem [10.9.1] for the consistent family $F|Q_n$ of f.j.d.'s to be $D$-regular, with with a modulus of $D$-regularity $(m_n)_{n=0,1,...}$ dependent only on the sequences $(\alpha_k)_{k=0,1,...}$ and $(\gamma_k)_{k=0,1,...}$, which, in turn, depends only on the constants $u,w$.

3. Theorem [10.6.2] can therefore be applied to construct an a.u. càdlàg process $X: [0,1] \times \Omega \to S$ with marginal distributions given by the family $F$, and with modulus of a.u. càdlàg depending only on the modulus of $D$-regularity $(m_n)_{n=0,1,...}$ and the modulus of continuity in probability $\delta_p$. Thus the process $X$ has a modulus of a.u. càdlàg depending only on the constants $u,w$ and the modulus of continuity in probability $\delta_p$. Assertions 1 and 2 have been proved.

4. We proceed to prove Assertion 3. Suppose the positive constants $\gamma$ and $\lambda$ are given and satisfy inequality [10.9.18] and let $\lambda \equiv \lambda(u,w,\overline{u}\lambda)$ be as defined in equality [10.9.19]. Let $X: [0,1] \times \Omega \to S$ be an arbitrary a.u. càdlàg process with marginal distribution given by the family $F$. We need to show that $\lambda$ is a right Hölder exponent of $X$. For abbreviation, define the constants
\begin{align*}
c_0 &= (1+w)\log_2 K - \log_2 (1-\gamma^{-u}2^{-w}), \\
c &= w(1-uv^{-1}) = w-uwv^{-1}, \\
c_1 &= -\log_2 (1-\gamma),
\end{align*}
10.9. A SUFFICIENT CONDITION FOR A RIGHT HOELDER PROCESS

\[ c_2 \equiv -\log_2 \gamma = wv^{-1}, \]
\[ \kappa_0 \equiv \kappa_0(K,u,w) \equiv [(c^{-1}c_0 - 1) \lor c_2^{-1}(c_1 + 1)]_1 \]

and
\[ \kappa \equiv \kappa(u,w) \equiv [c^{-1}]_1 \geq 1. \]

5. Note that, because \( v - u < 1 \), we have \( 1 - uv^{-1} < v^{-1} \), whence \( c < c_2 \) and
\[ \kappa c_2 > \kappa c > 1. \]

Note also that, because \( u + 2^{-1} < v < u + 1 \), we have
\[ (1 + 2u)^{-1} = 1 - u(2^{-1} + u)^{-1} < 1 - uv^{-1} < 1 - u(1 + u)^{-1} = (1 + u)^{-1}, \]
whence
\[ w(1 + 2u)^{-1} < c \equiv w(1 - uv^{-1}) < w(1 + u)^{-1}, \]
or
\[ w^{-1}(1 + 2u) > c^{-1} > w^{-1}(1 + u). \]

Hence, the defining equality \( 10.9.19 \) yields
\[
\lambda = 2^{-1}(w^{-1}(1 + 2u)(1 + \kappa^{-2}(1 + \kappa)))^{-1} \\
< 2^{-1}(c^{-1}(1 + \kappa^{-2}(1 + \kappa)))^{-1} \\
= 2^{-1}(c^{-1} + 2 + \kappa^{-2}(1 + \kappa)(c^{-1} + 3))^{-1} \\
< 2^{-1}(\kappa + \kappa^{-1}(1 + \kappa)(\kappa + 1))^{-1}. \tag{10.9.24}
\]

6. Consider the process \( Z = X|Q_x \). Then \( Z \) is equal to the right-limit extension of
the process \( Z \). Define \( m_0 \equiv 0 \). Let \( n \geq 1 \) be arbitrary. Define
\[ m_n \equiv \kappa_0 + \kappa n. \tag{10.9.25} \]

Then \( m_n \geq m_{n-1} + 1 \). Moreover,
\[
\log_2 \sum_{h=m(n)}^{m(n)+1} 2^h a_h = \log_2 \sum_{h=m(n)}^{m(n)+1} 2^h K^{1+w2^{-h}}\gamma^{-(h+1)w2^{-hw}} \\
= \log_2 \gamma^{-(m(n)+1)w2^{-m(n)+1}wK^{1+w}(1 - \gamma^{-a2^{-w}})^{-1}} \\
= \log_2 2^{-1} \gamma^{-(m(n)+1)w2^{-m(n)+1}wK^{1+w}(1 - \gamma^{-a2^{-w}})^{-1}} \\
= -(m_n + 1)(w - uvv^{-1}) + (1 + w) \log_2 K - \log_2 (1 - \gamma^{-a2^{-w}}) \\
\equiv -(\kappa_0 + \kappa n + 1)c + c_0 < -((c^{-1}c_0 - 1) + 1)c - \kappa cn + c_0 \\
= -\kappa cn < -n.
\]
where the last inequality is thanks to the earlier observation that \( \kappa c_2 > \kappa c > 1 \). Hence
\[
\sum_{k=m(n)}^{\infty} 2^k \alpha_k < 2^{-n}. \tag{10.9.26}
\]
Similarly,
\[
\sum_{k=m(n)+1}^{\infty} \gamma_k < \log_2 \sum_{k=m(n)}^{\infty} \gamma_k = \log_2 \gamma^{(n)}(1-\gamma)^{-1} = m_n \log_2 \gamma - \log_2 (1-\gamma) = -(\kappa_0 + \kappa n) c_2 + c_1
\]
\[
< - \kappa_0 c_2 - \kappa c_2 n + c_1 < - c_2^1 (c_1 + 1) c_2 - \kappa c_2 n + c_1 = -1 - \kappa c_2 n < -1 - n,
\]
whence
\[
\sum_{k=m(n)+1}^{\infty} \gamma_k < 2^{-n-1}. \tag{10.9.27}
\]
In view of inequalities \([10.9.23, 10.9.26]\) and \([10.9.27]\) Theorem \([10.9.1]\) applies, and says that the sequence \( \bar{m} = (m_n)_{n=0,1,...} \) is a modulus of \( D \)-regularity of the family \( F|\Omega_{\infty} \) and of the process \( Z \).

7. More specifically, let \( \varepsilon > 0 \) be arbitrary. Define
\[
\delta_{\varepsilon, p}(\varepsilon) \equiv K^{-1}(2^{-1} \varepsilon)^{1+\gamma}/n. \tag{10.9.28}
\]
Then, for each \( t, s \in [0, 1] \) with \( |s-t| \leq \delta_{\varepsilon, p}(\varepsilon) \), and for each \( b > 2^{-1} \varepsilon \), we have
\[
F_{t,s}(\hat{d}) \leq b + F_{t,s}(\hat{d} > b) \leq b + F_{t,s}(d > b) \leq b + b^{-\pi} K s - K t |\hat{d}|
\]
\[
\leq b + b^{-\pi} K \hat{d} \delta_{\varepsilon, p}(\varepsilon) \hat{d} = b + b^{-\pi} K \hat{d} \hat{d}^{-\pi} (2^{-1} \varepsilon)^{(1+\gamma)} = b + b^{-\pi} (2^{-1} \varepsilon)^{(1+\gamma)},
\]
where the first inequality is because \( \hat{d} \equiv d \wedge 1 \leq 1 \), and where the third inequality is from inequality \([10.9.18]\) in the hypothesis. Letting \( b \downarrow 2^{-1} \varepsilon \), we obtain
\[
F_{t,s}(\hat{d}) \leq 2^{-1} \varepsilon + (2^{-1} \varepsilon)^{-\pi} (2^{-1} \varepsilon)^{(1+\gamma)} = 2^{-1} \varepsilon + 2^{-1} \varepsilon = \varepsilon. \tag{10.9.29}
\]
Thus the operation \( \delta_{\varepsilon, p} \) is a modulus of continuity in probability of the family \( F \) of f.j.d.'s, and of the \( D \)-regular process \( Z \). Hence Theorem \([10.5.8]\) says that the right-limit extension \( X \) of \( Z \) has a modulus of a.u. càdlàg \( \delta_{\text{aucl}} \) defined as follows. Let \( \varepsilon > 0 \) be arbitrary. Let \( n \geq 0 \) be so large that \( 2^{-n+6} < \varepsilon \). Let \( J > n \) be so large that
\[
\Delta_{m(J)} \equiv 2^{-m(J)} < 2^{-2} \delta_{\varepsilon, p}(2^{-2m(n)-2n-10}). \tag{10.9.30}
\]
Then
\[
\delta_{\text{aucl}}(\varepsilon, \bar{m}, \delta_{\varepsilon, p}) \equiv \Delta_{m(J)}. \tag{10.9.31}
\]
8. Let \( h \geq 0 \) be arbitrary. Write \( \varepsilon_h \equiv 2^{-h} \) for short. By Definition \([10.3.2]\) for a modulus of a.u. càdlàg, there exist a measurable set \( A_h \) with
\[
P(A_h) < \varepsilon_h \equiv 2^{-h},
\]
Yuen-Kwok Chan 400 Constructive Probability
10.9. A SUFFICIENT CONDITION FOR A RIGHT HOELDER PROCESS

an integer \( p_h \geq 1 \), and a sequence of r.r.v.’s

\[
0 = \tau_{h,0} < \tau_{h,1} < \cdots < \tau_{h,p(h) - 1} < \tau_{h,p(h)} = 1,
\]

(10.9.32)
such that, for each \( i = 0, \cdots, p_h - 1 \), the function \( X_{(h,i)} \) is a r.v., and such that, for each \( \omega \in A_h \), we have

\[
\bigwedge_{i=0}^{p(h)-1} (\tau_{h,i+1}(\omega) - \tau_{h,i}(\omega)) \geq \delta_{\text{uec}}(\varepsilon_h, \overline{\mathbb{M}}, \delta_{cp}) \equiv \Delta_m(f(h)),
\]

(10.9.33)
with

\[
d(X(\tau_{h,i}(\omega), \omega), X(\cdot, \omega)) \leq \varepsilon_h,
\]

(10.9.34)
on the interval \( \theta_{h,i}(\omega) \equiv [\tau_{h,i}(\omega), \tau_{h,i+1}(\omega)] \) or \( \theta_{h,i}(\omega) \equiv [\tau_{h,i}(\omega), \tau_{h,i+1}(\omega)] \) according as \( i \leq p_h - 2 \) or \( i = p_h - 1 \).

9. Now let \( h \geq 3 \) and \( \omega \in A_h \) be arbitrary. Inequality \eqref{10.9.24} implies

\[
\lambda^{-1} > 2(\kappa + \overline{\lambda}^{-1}(1 + \overline{\nu})(\kappa + 1)) = (2\kappa + \overline{\lambda}^{-1}(1 + \overline{\nu})(2\kappa + 2)),
\]

whence

\[
\eta \equiv \lambda^{-1} - (2\kappa + \overline{\lambda}^{-1}(1 + \overline{\nu})(2\kappa + 2)) > 0.
\]

(10.9.35)
Define

\[
\delta_h \equiv 2^{-(h-2)}\eta.
\]

Then \( \delta_h < 1 \). For each \( i = 0, \cdots, p_h - 1 \), define the subinterval

\[
\overline{\theta}_{h,i}(\omega) \equiv [\tau_{h,i}(\omega), \tau_{h,i+1}(\omega) - \delta_h(\tau_{h,i+1}(\omega) - \tau_{h,i}(\omega))],
\]

of \( \theta_{h,i}(\omega) \), with Lebesgue measure

\[
\mu(\overline{\theta}_{h,i}(\omega)) = (1 - \delta_h)(\tau_{h,i+1}(\omega) - \tau_{h,i}(\omega)).
\]

Note that the intervals \( \overline{\theta}_{h,0}(\omega), \cdots, \overline{\theta}_{h,p-1}(\omega) \) are mutually exclusive. Therefore

\[
\mu\left( \bigcup_{i=0}^{p(h)-1} \overline{\theta}_{h,i}(\omega) \right) = \sum_{i=0}^{p(h)-1} \delta_h(\tau_{h,i+1}(\omega) - \tau_{h,i}(\omega)) = \delta_h.
\]

10. Define the positive integers

\[
b_0 \equiv b_0(u, w, \overline{\nu}, \overline{\lambda}) \equiv 7 \vee [\kappa^{-1}(-\kappa_0 + 2 + \log_2 K + \overline{\lambda}^{-1}(1 + \overline{\nu})(2\kappa_0 + (2\kappa + 2)7 + 11))],
\]

(10.9.36)
\[
b_1 \equiv b_1(u, w, \overline{\nu}, \overline{\lambda}) \equiv [\kappa^{-1}\overline{\lambda}^{-1}(1 + \overline{\nu})(2\kappa + 2)],
\]

(10.9.37)
and

\[
n_h \equiv h + 7.
\]
CHAPTER 10. A.U. CÀDLÀG PROCESSES

Then $2^{-n(h)+b} = 2^{-h-1} < 2^{-b} \equiv \varepsilon_0$, and $J_h \equiv b_0 + b_1 h \geq 7 + h \equiv n_h$. Moreover, according to the defining equalities \(10.9.28\) and \(10.9.37\) we have

$$m_{J(h)} \equiv \kappa_0 + \kappa J_h \equiv \kappa_0 + \kappa b_0 + \kappa b_1 h$$

$$\geq \kappa_0 + (\kappa b_0 + \log_2 \kappa + \frac{1}{1 + \kappa})(1 + \kappa)(2 \kappa + 2) h$$

$$\geq \kappa_0 + (- \kappa_0 + 2 + \log_2 K + \frac{1}{(1 + \kappa)(2 \kappa + 2) h} + \log_2 K + \frac{1}{1 + \kappa})(2 \kappa + 2) h$$

$$= 2 + \log_2 K + \frac{1}{1 + \kappa}(2 \kappa + 2) h$$

$$\equiv 2 + \log_2 K + \frac{1}{1 + \kappa}(2\kappa_0 + (2 \kappa + 2) \kappa + 2) h$$

$$\equiv 2 + \log_2 K + \frac{1}{1 + \kappa}(2\kappa_0 + (2 \kappa + 2) n_h + 11)$$

whence

$$\Delta_{J(h)} \equiv 2^{-m(J(h))}$$

$$\leq 2 - \log_2 K^2(2 - \log_2 K^2 + \frac{1}{1 + \kappa})(2 \kappa + 2) h$$

where the last equality is from the defining equality \(10.9.28\) Therefore

$$\delta_{s}\equiv \kappa_0 + \kappa J_h \equiv \kappa_0 + \kappa b_0 + \kappa b_1 h$$

11. Now let $\varepsilon > 0$ arbitrary. Let $k \geq 3$ be so large that $2^{-k+1} < \varepsilon$ and $2^{-(k-2)} \varepsilon (1 - 2^{-\eta}) < \varepsilon$. Define the measurable subset

$$B_k \equiv \bigcap_{h=k}^{\infty} A_h$$

of $\Omega$, where the measurable set $A_h$ was introduced in Step 8, for each $h \geq k$. Then

$$P (B_k) \leq \sum_{h=k}^{\infty} P (A_h) < \sum_{h=k}^{\infty} 2^{-h} = 2^{-k+1} < \varepsilon.$$ 

Consider each $\omega \in B_k$. Then $\omega \in A_h$ for each $h \geq k$. Define the Lebesgue measurable subset

$$\theta_k (\omega) \equiv \bigcap_{h=k}^{\infty} \bigcup_{i=0}^{p(h)-1} \theta_{h,i} (\omega)$$

of $[0, 1]$. Then the Lebesgue measure $\mu (\theta_k (\omega))$ is bounded by

$$\mu (\theta_k (\omega)) \leq \sum_{h=k}^{\infty} \mu (\bigcup_{i=0}^{p(h)-1} \theta_{h,i} (\omega)) = \sum_{h=k}^{\infty} \delta_h = \sum_{h=k}^{\infty} 2^{-h} \eta = 2^{-(k-2)} \eta (1 - 2^{-\eta}) < \varepsilon.$$ 

Now let $t \in \theta_k (\omega) \cap \text{domain}(X (\cdot, \omega))$ and

$$s \in \bigcup_{h=k}^{\infty} \{ t + \delta_{h+1} \Delta_{J(h+1)}, t + \delta_{h} \Delta_{J(h)} \} \cap \text{domain}(X (\cdot, \omega))$$

Yuen-Kwok Chan 402 Constructive Probability
be arbitrary. Then

\[ s \in (t + \delta_{h+1} \Delta_m(J(h+1)), t + \delta_h \Delta_m(J(h))) \]  \hspace{2cm} (10.9.39)

for some \( h \geq k \geq 3 \). Since \( t \in \overline{\Theta}_h(\omega) \subset \bigcup_{i=0}^{p(h)-1} \Theta_{h,i}(\omega) \), there exists \( i = 0, \cdots, p_h - 1 \) such that

\[ t \in \Theta_{h,i}(\omega) \equiv [\tau_{h,i}(\omega), \tau_{h,i+1}(\omega) - \delta_h(\tau_{h,i+1}(\omega) - \tau_{h,i}(\omega))]. \]

It follows, in view of inequality \( \text{[10.9.33]} \), that

\[ s \in (t; t + \delta_h \Delta_m(J(h))) \subset [\tau_{h,i}(\omega), \tau_{h,i+1}(\omega) - \delta_h(\tau_{h,i+1}(\omega) - \tau_{h,i}(\omega) + \delta_h \Delta_m(J(h))) \]

\[ \subset [\tau_{h,i}(\omega), \tau_{h,i+1}(\omega) - \delta_h(\tau_{h,i+1}(\omega) - \tau_{h,i}(\omega)) + \delta_h(\tau_{h,i+1}(\omega) - \tau_{h,i}(\omega))] \]

\[ = [\tau_{h,i}(\omega), \tau_{h,i+1}(\omega)] \subset \Theta_{h,i}(\omega). \]

Hence inequality \( \text{[10.9.34]} \) implies that

\[ d(X(\tau_{h,i}(\omega), \omega), X(t, \omega)) \leq d(X(\tau_{h,i}(\omega), \omega), X(s, \omega)) \leq \varepsilon_t, \hspace{2cm} (10.9.40) \]

and therefore that

\[ d(X(t, \omega), X(s, \omega)) \leq 2\varepsilon_t = 2^{-h+1}. \hspace{2cm} (10.9.41) \]

At the same time, relation \( \text{[10.9.39]} \) implies

\[ s - t \geq \delta_{h+1} \Delta_m(J(h+1)) \equiv 2^{-\eta(h-1)} 2^{-m(J(h+1))}. \hspace{2cm} (10.9.42) \]

Moreover, from the defining equalities \( \text{[10.9.25]} \) \( \text{[10.9.37]} \) and \( \text{[10.9.36]} \) we have

\[ m_{J(h+1)} = \kappa_0 + \kappa J_{h+1} = \kappa_0 + \kappa b_0 + \kappa b_1 (h+1) \]

\[ < (\kappa_0 + \kappa b_0 + \kappa b_1) + \kappa(\kappa^{-1} \lambda^{-1} (1 + \eta)(2\kappa + 2)) h \]

\[ = (\kappa_0 + \kappa b_0 + \kappa b_1) + (\lambda^{-1} (1 + \eta)(2\kappa + 2)) h. \]

Hence

\[ (h-1)\eta + m_{J(h+1)} < ((\kappa_0 + \kappa b_0 + \kappa b_1) - \eta) + (\eta + \lambda^{-1} (1 + \eta)(2\kappa + 2) + 2\kappa) h \]

\[ \equiv ((\kappa_0 + \kappa b_0 + \kappa b_1) - \eta) \]

\[ + (\lambda^{-1} (2\kappa + \lambda^{-1} (1 + \eta)(2\kappa + 2)) + \lambda^{-1} (1 + \eta)(2\kappa + 2) + 2\kappa) h \]

\[ = (\kappa_0 + \kappa b_0 + \kappa b_1 - \eta) + \lambda^{-1} h, \]

and so

\[ ((h-1)\eta + m_{J(h+1)}) \lambda < (\kappa_0 + \kappa b_0 + \kappa b_1 - \eta) \lambda + h. \]

Consequently, inequalities \( \text{[10.9.41]} \) and \( \text{[10.9.42]} \) together yield

\[ d(X(t, \omega), X(s, \omega)) (s - t)^{-\lambda} \leq 2^{-h+1} (2\eta(h-1) 2^{-m(J(h+1))}) \lambda \]

\[ < 2^{-h+1} 2^{(\kappa(0) + \kappa b(0) + \kappa b(1) - \eta) \lambda + h = C_0 = 2^{\kappa(0) + \kappa b(0) + \kappa b(1) - \eta} \lambda + 1. \]

Yuen-Kwok Chan 403 Constructive Probability
Thus
\[ d(X(t, \omega), X(s, \omega)) \leq C_0(s-t)^\lambda \]  \hspace{1cm} (10.9.43)
where \( \omega \in B_k, t \in \tilde{\theta}_k(\omega) \cap \text{domain}(X(\cdot, \omega)), \) and
\[ s \in G \equiv \bigcup_{h=k}^{\infty} (t + \delta_{h+1}\Delta_m(J(h+1)), t + \delta_h\Delta_m(J(h))) \cap \text{domain}(X(\cdot, \omega)) \]
are arbitrary. Since the set \( G \) is a dense subset of \([t, t + \delta_1\Delta_m(J(1)))] \cap \text{domain}(X(\cdot, \omega))\), the right continuity of the function \( X(\cdot, \omega) \) implies that inequality \( (10.9.43) \) holds for each \( \omega \in B_k, t \in \tilde{\theta}_k(\omega) \cap \text{domain}(X(\cdot, \omega)), \) and \( s \in [t, t + \delta_1\Delta_m(J(1))] \cap \text{domain}(X(\cdot, \omega)). \) Since \( P(B_k^c) < \epsilon \) and \( \mu(\tilde{\theta}_k(\omega)^c) < \epsilon, \) where \( \epsilon > 0 \) is arbitrarily small, the process \( X \) is right Hoelder by Definition \( 10.9.2 \). \hfill \Box

As an easy corollary, the following Theorem \( 10.9.4 \) generalizes the preceding Theorem \( 10.9.3 \). The proof of Part 1 by means of a deterministic time scaling is a new and simple proof of Theorem 13.6 of \cite{Billingsley1999}. Part 2, a condition for right Hoelder property, seems to be new.

**Theorem 10.9.4. (Sufficient condition for a time-scaled right Hoelder process).**
Let \( u \geq 0 \) and \( \omega > 0 \) be arbitrary. Let \( G : [0, 1] \rightarrow \Omega \) be a nondecreasing continuous function. Let \( F \) be an arbitrary consistent family of f.j.d.’s with parameter set \([0, 1] \) and state space \( (S, d) \). Suppose \( F \) is continuous in probability, and suppose
\[ F_{t,x} \{ (x, y, z) \in S^3 : d(x, y) \land d(y, z) > b \} \leq b^{-u}(G(s) - G(t))^{1+w} \]  \hspace{1cm} (10.9.44)
for each \( b > 0 \) and for each \( t \leq r \leq s \) in \([0, 1] \). Then the following holds.
1. There exists an a.u. càdlàg process \( Y : [0, 1] \times \Omega \rightarrow S \) with marginal distributions given by the family \( F \).
2. Suppose, in addition, that there exist \( \pi, \lambda > 0 \) such that
\[ F_{t,x}(d > b) \leq b^{-\pi}(G(s) - G(t))^\lambda \]  \hspace{1cm} (10.9.45)
for each \( b > 0 \) and for each \( t, s \in [0, 1] \). Then \( Y(r, \omega) = X(h(r), \omega) \) for each \( (r, \omega) \in \text{domain}(Y), \) for some right Hoelder process \( X \) and for some continuous increasing function \( h : [0, 1] \rightarrow [0, 1] \).

**Proof.** Write \( a_0 \equiv G(0) \) and \( a_1 \equiv G(1) \). Write \( K \equiv a_1 - a_0 + 1 > 0 \). Define the continuous increasing function \( h : [0, 1] \rightarrow [0, 1] \) by \( h(r) \equiv K^{-1}(G(r) - a_0 + r) \) for each \( r \in [0, 1] \). Then its inverse \( g \equiv h^{-1} \) is also continuous and increasing. Moreover, for each \( s, t \in [0, 1] \) with \( t \leq s \), we have
\[ G(g(s)) - G(g(t)) = Kh(g(s)) - g(s) + a_0 - Kh(g(t)) + g(t) - a_0 \]
\[ = (Ks - Kt) - (g(s) - g(t)) < Ks - Kt. \]  \hspace{1cm} (10.9.46)

1. Since the family \( F \) of f.j.d.’s is, by hypothesis, continuous in probability, there exists, according to Theorem \( 10.1.6 \), a process \( V : [0, 1] \times \Omega \rightarrow S \) with marginal distributions given by the family \( F \). Define the function \( U : [0, 1] \times \Omega \rightarrow S \) by domain(\( U \)) \( \equiv \{ (t, \omega) : (g(t), \omega) \in \text{domain}(V) \} \) and by
\[ U(t, \omega) \equiv V(g(t), \omega) \]  \hspace{1cm} (10.9.47)

Yuen-Kwok Chan 404 Constructive Probability
for each \((t, \omega) \in \text{domain}(U)\). Then \(U(t, \cdot) \equiv V(g(t), \cdot)\) is a r.v. for each \(t \in [0, 1]\). Thus \(U\) is a stochastic process. Let \(F'\) denote the family of its marginal distributions. Then, for each \(b > 0\), we have

\[
F'_{t,s}(x, y, z) = \{ (x, y, z) \in \mathbb{S}^3 : d(x, y) \wedge d(y, z) > b \} = F(d(U_t, U_r) \wedge d(U_r, U_s) > b)
\]

\[
= P(d(V_{g(t)}(r), V_{g(r)}(s)) \wedge d(V_{g(r)}(s), V_{g(s)}(t)) > b) = F_{g(t), g(r), g(s)}(x, y, z) \in \mathbb{S}^3 : d(x, y) \wedge d(y, z) > b) 
\]

\[
\leq b^{-u}(G(g(s)) - G(g(t)))^{1+w} \leq b^{-u}(Ks - Kt)^{1+w},
\]

where the next to last inequality follows from inequality \(10.9.44\) in the hypothesis, and the last inequality is from inequality \(10.9.46\). Thus the family \(F'\) and the constants \(K, u, w\) satisfy the hypothesis of Part 2 of Theorem \(10.9.3\). Accordingly, there exists an a.u. càdlàg process \(X : [0, 1] \times \Omega \to S\) with marginal distributions given by the family \(F'\). Now define a process \(Y : [0, 1] \times \Omega \to S\) by \(\text{domain}(Y) \equiv \{(r, \omega) : (h(r), \omega) \in \text{domain}(X)\}\) and by

\[
Y(r, \omega) \equiv X(h(r), \omega)
\]

for each \((r, \omega) \in \text{domain}(Y)\). Because the function \(h\) is continuous, it can be easily verified that the process \(Y\) is a.u. càdlàg. Moreover, in view of the defining equality \(10.9.47\) we have

\[
V(r, \omega) = U(h(r), \omega)
\]

for each \((r, \omega) \in \text{domain}(V)\). Since the processes \(X\) and \(U\) share the same marginal distributions given by the family \(F'\), the last two displayed equalities imply that the processes \(Y\) and \(V\) share the same marginal distributions. Since the process \(V\) has marginal distributions given by the family \(F\), so does the process \(Y\). Assertion 1 of the theorem is proved.

2. Suppose, in addition, that there exist \(\overline{\pi}, \overline{T} > 0\) inequality \(10.9.45\) holds for each \(b > 0\) and for each \(t, s \in [0, 1]\). Then, for each \(b > 0\), we have

\[
F'_{t,s}(b > b) = P(d(U_t, U_s) > b)
\]

\[
= P(d(V_{g(t)}(r), V_{g(r)}(s)) > b) = F_{g(t), g(r), g(s)}(b > b) 
\]

\[
\leq b^{-\overline{\pi}}|G(g(s)) - G(g(t))|^\overline{T} \leq b^{-\overline{\pi}}(Ks - Kt)^{\overline{T}},
\]

where the first inequality is from inequality \(10.9.45\), and the last is from inequality \(10.9.46\). Thus the family \(F'\) and the constants \(K, \overline{\pi}, \overline{T}\) satisfy the hypothesis of Part 3 of Theorem \(10.9.3\). Accordingly, the a.u. càdlàg process \(X : [0, 1] \times \Omega \to S\) is right Hölder. The theorem is proved. 

\[\square\]

### 10.10 a.u. Càdlàg Processes and a.u. Continuous Processes with Parameter Set \([0, \infty)\)

In the preceding sections, a.u. continuous processes and a.u. càdlàg processes are studied with the unit interval \([0, 1]\) as the parameter set. Generalization to parameter intervals \([0, \infty)\) is straightforward. Specifically, we can study the process piecewise
Chapter 10. A.U. Çàdlàg Processes

on unit subintervals $[M, M + 1]$, for $M = 0, 1, \ldots$, using the results in the preceding sections, and then stitching the results back together.

For a.u. continuous processes, we need only state the next definition.

**Definition 10.10.1.** (a.u. Continuous process on $[0, \infty]$). A process

$$X : [0, \infty) \times (\Omega, L, E) \to S$$

is said to be a.u. continuous if, for each $M \geq 0$, the shifted process $X^M : [0, 1] \times \Omega \to S$, defined by $X^M(t) \equiv X(M + t)$ for each $t \in [0, 1]$, is a.u. continuous, in the sense of Definition 6.1.3, with some modulus of a.u. càdlàg $\delta_{\text{càdlàg}}^M$ and with some modulus of continuity in probability $\delta_{\text{cont}}^M$.

For a.u. càdlàg processes, we will state several related definitions, and give a straightforward proof of the theorem which extends an arbitrary $D$-regular process on $Q_\infty$ to an a.u. càdlàg process on $[0, \infty)$. Recall here that $Q_\infty$ and $Q_\infty$ are the enumerated sets of dyadic rationals in $[0, 1]$ and $[0, \infty)$ respectively.

Let $(\Omega, L, E)$ be a sample space. Let $(S, d)$ be a locally compact metric space, which will serve as the state space. Let $\xi \equiv (A_q)_{q=1,2,\ldots}$ be a binary approximation of $(S, d)$.

Recall that $D[0, 1]$ stands for the space of càdlàg functions on $[0, 1]$, and that $\hat{D}[0, 1]$ stands for the space of a.u. càdlàg processes on $[0, 1]$.

**Definition 10.10.2.** (Skorokhod metric space of càdlàg functions on $[0, \infty]$). Let $x : [0, \infty) \to S$ be an arbitrary function whose domain contains the enumerated set $Q_\infty$ of dyadic rationals. Let $M \geq 0$ be arbitrary. Then the function $x$ is said to be càdlàg on the interval $[M, M + 1]$ if the shifted function $x^M : [0, 1] \to S$, defined by $x^M(t) \equiv x(M + t)$ for each $t$ with $M + t \in \text{domain}(x)$, is a member of $D[0, 1]$. The function $x : [0, \infty) \to S$ is said to be càdlàg if it is càdlàg on the interval $[M, M + 1]$ for each $M \geq 0$. We will write $D[0, \infty)$ for the set of càdlàg functions on $[0, \infty)$.

Recall from Definition 10.2.1 the Skorokhod metric $d_{D[0,1]}$ on $D[0, 1]$. Define the Skorokhod metric on $D[0, \infty)$ by

$$d_{D[0,\infty]}(x, y) \equiv \sum_{M=0}^{\infty} 2^{-M-1} (1 \wedge d_{D[0,1]}(x^M, y^M))$$

for each $x, y \in D[0, \infty)$. We will call $(D[0, \infty), d_{D[0, \infty)})$ the Skorokhod space on $[0, \infty)$.

**Definition 10.10.3.** (D-regular processes with parameter set $Q_\infty$). Let $Z : Q_\infty \times \Omega \to S$ be a stochastic process. Recall from Definition 10.4.1 the metric space $(R_{\text{Dreg}}(Q_\infty \times \Omega, S), R_{\text{Prob}}(Q_\infty))$ of $D$-regular processes with parameter set $Q_\infty$.

Suppose, for each $M \geq 0$, (i) the process $Z : Q_\infty \to S$, defined by $Z^M(t) \equiv Z(M + t)$ for each $t \in Q_\infty$, is a member of the space $R_{\text{Dreg}}(Q_\infty \times \Omega, S)$, with a modulus of $D$-regularity $\overline{m}_M$.

Then the process $Z : Q_\infty \times \Omega \to S$ is said to be $D$-regular, with a modulus of continuity in probability $\delta_{\text{cont}} \equiv (\delta_{\text{cont}}^M)_{M=0,1,\ldots}$, and with a modulus of $D$-regularity $\delta_{\text{reg}} \equiv (\delta_{\text{reg}}^M)_{M=0,1,\ldots}$.
\[ \hat{m} \equiv (\overline{m}(M))_{M=0,1,\ldots} \] Let \( \hat{R}_{Dreg}(\overline{Q}_\infty \times \Omega, S) \) denote the set of all \( D \)-regular processes with parameter set \( \overline{Q}_\infty \). Let \( \hat{R}_{Dreg,\hat{\delta}(C_p),\hat{m}}(\overline{Q}_\infty \times \Omega, S) \) denote the subset whose members share the common modulus of continuity in probability \( \hat{\delta}_{C_p} \) and the common modulus of \( D \)-regularity \( \hat{m} \equiv (\overline{m}(M))_{M=0,1,\ldots} \). If, in addition, \( \delta_{C_p,M} = \delta_{C_p,0} \) and \( \overline{m}(M) = \overline{m}(0) \) for each \( M \geq 0 \), then we say that the process \( Z \) time-uniformly \( D \)-regular on \( \overline{Q}_\infty \).

\[ \square \]

**Definition 10.10.4.** (Metric space of a.u. càdlàg process on \( [0, \infty) \)). Let

\[ X : [0, \infty) \times (\Omega, L, E) \rightarrow S \]

be an arbitrary process. Suppose, for each \( M \geq 0 \), (i) the process \( X|_{[0, M+1]} \) is continuous in probability, with a modulus of continuity in probability \( \delta_{C_p,M} \), and (ii) the shifted process \( X^M : [0,1] \times \Omega \rightarrow S \), defined by \( X(t) = X(M+t) \) for each \( t \in [0, \infty) \), is a member of the space \( \hat{D}[0,1] \), with some modulus of a.u. càdlàg \( \delta_{aucl,M} \).

Then the process \( X \) is said to be a.u. càdlàg on the interval \( [0, \infty) \), with a modulus of a.u. càdlàg \( \delta_{aucl} \equiv (\delta_{aucl}^M)_{M=0,1,\ldots} \) and with a modulus of continuity in probability \( \delta_{C_p} \equiv (\delta_{C_p}^M)_{M=0,1,\ldots} \). If, in addition, \( \delta_{C_p,M} = \delta_{C_p,0} = \delta_{aucl,0} = \delta_{aucl}^M \) for each \( M \geq 0 \), then we say that the process is time-uniformly a.u. càdlàg on the interval \( [0, \infty) \).

We will write \( \hat{D}[0,\infty) \) for the set of a.u. càdlàg processes on \( [0, \infty) \), and equip it with the metric \( \tilde{\rho}_{D[0,\infty)} \) defined by

\[ \tilde{\rho}_{D[0,\infty)}(X,X') \equiv \rho_{Prob,\overline{Q}_\infty}(X|\overline{Q}_\infty, X'|\overline{Q}_\infty) \]

for each \( X, X' \in \hat{D}[0,\infty) \), where, according to Definition 6.4.1 we have

\[ \rho_{Prob,\overline{Q}_\infty}(X|\overline{Q}_\infty, X'|\overline{Q}_\infty) \equiv E \sum_{n=0}^{\infty} 2^{-n-1} (1 \wedge d(X_{u(n)}, X'_{u(n)})) \]

(10.1.10.1)

Thus

\[ \tilde{\rho}_{D[0,\infty)}(X,X') \equiv E \sum_{n=0}^{\infty} 2^{-n-1} (1 \wedge d(X_{u(n)}, X'_{u(n)})) \]

for each \( X, X' \in \hat{D}[0,\infty) \).

Let \( \hat{D}[\delta_{aucl}, \delta(C_p), [0,\infty) \) denote the subspace of the metric space \( (\hat{D}[0,\infty), \tilde{\rho}_{D[0,\infty)} \) whose members share a common modulus of continuity in probability \( \delta_{C_p} \equiv (\delta_{C_p}^M)_{M=0,1,\ldots} \) and share a common modulus of a.u. càdlàg \( \delta_{aucl} \equiv (\delta_{aucl}^M, \overline{m}(M), \delta_{C_p,M})_{M=0,1,\ldots} \).

\[ \square \]

In the following, recall the right-limit extension functions \( \Phi_{rLim} \) and \( \overline{\Phi}_{rLim} \) from Definition 10.5.6

**Lemma 10.10.5.** (The right-limit extension of a \( D \)-regular process on \( \overline{Q}_\infty \) is continuous in probability on \( [0, \infty) \)). Suppose

\[ Z : \overline{Q}_\infty \times (\Omega, L, E) \rightarrow (S, d) \]
is an arbitrary $D$-regular process on $\overline{Q}_\omega$, with a modulus of continuity in probability $\delta_{Cp} \equiv (\delta_{Cp,M})_{M=0,1,\ldots}$. Then the right-limit extension

$$X \equiv \mathcal{F}_{\text{rLim}}(Z) : [0, \infty) \times (\Omega, L, E) \to (S, d)$$

of $Z$ is a well-defined process which is continuous in probability, with the same modulus of continuity in probability $\delta_{Cp} \equiv (\delta_{Cp,M})_{M=0,1,\ldots}$ as $Z$.

**Proof.** Let $N \geq 0$ be arbitrary. Consider each $t, t' \in [0, N + 1]$. Let $(r_k)_{k=1,2,\ldots}$ be a sequence in $[0, N + 1] \overline{Q}_\omega$ such that $r_k \downarrow t$. Since the process $Z$ is continuous in probability on $[0, N + 1] \overline{Q}_\omega$, with a modulus of continuity in probability $\delta_{Cp,N}$, it follows that

$$E(1 \land d(Z_{r_k}, Z_{r(h)}) \downarrow 0$$

as $k, h \to 0$. By passing to a subsequence if necessary, we can assume

$$E(1 \land d(Z_{r(k)}, Z_{r(k+1)}) \leq 2^{-k}$$

for each $k \geq 1$. Then

$$E(1 \land d(Z_{r(k)}, Z_{r(h)}) \leq 2^{-k+1}$$

(10.10.2)

for each $h \geq k \geq 1$. It follows that $Z_{r(k)} \to U_t$ a.u. for some r.v. $U_t$. Consequently $Z_{r(k)}(\omega) \to U_t(\omega)$ for each $\omega$ in some full set $B$. Consider each $\omega \in B$. Since $X \equiv \mathcal{F}_{\text{rLim}}(Z)$ and since $r_k \downarrow t$ with $Z_{r(k)}(\omega) \to U_t(\omega)$, we see that $\omega \in \text{domain}(X_t)$ and that $X_t(\omega) = U_t(\omega)$. In short, $X_t = U_t$ a.s. Consequently $X_t$ is a r.v., where $t \in [0, N + 1]$ and $N \geq 0$ are arbitrary. Since $[0, \infty) = \bigcup_{M=0}^{\infty} [0, M + 1]$, it follows that $X_u$ is a r.v. for each $u \in [0, \infty)$. Thus $X : [0, \infty) \times (\Omega, L, E) \to (S, d)$ is a well-defined process.

Letting $h \to \infty$ in equality (10.10.2) we obtain

$$E(1 \land d(Z_{r(k)}, X_t)) = E(1 \land d(Z_{r(k)}, U_t)) \leq 2^{-k+1}$$

for each $k \geq 1$. Similarly we can construct a sequence $(r'_k)_{k=1,2,\ldots}$ in $[0, N + 1] \overline{Q}_\omega$ such that

$$E(1 \land d(Z_{r'(k)}, X_{t'}) \leq 2^{-k+1}$$

Now let $\varepsilon > 0$ be arbitrary, and suppose $t, t' \in [0, N + 1]$ are such that $|t - t'| < \delta_{Cp,N}(\varepsilon)$. Then $|r_k - r'_k| < \delta_{Cp,N}(\varepsilon)$, whence

$$E(1 \land d(Z_{r(k)}, Z_{r'(k)})) \leq \varepsilon$$

for sufficiently large $k \geq 1$. Combining, we obtain

$$E(1 \land d(X_t, X_{t'}) \leq 2^{-k+1} + \varepsilon + 2^{-k+1}$$

for sufficiently large $k \geq 1$. Hence

$$E(1 \land d(X_t, X_{t'}) \leq \varepsilon$$

where $t, t' \in [0, N + 1]$ are arbitrary with $|t - t'| < \delta_{Cp,N}(\varepsilon)$. Thus we have verified that the process $X$ is continuous in probability, with the modulus of continuity in probability $\delta_{Cp} \equiv (\delta_{Cp,N})_{N=0,1,\ldots}$ which is the same as the modulus of continuity in probability of the given $D$-regular process. □
10.10. A.U. CÀDLÀG PROCESSES AND A.U. CONTINUOUS PROCESSES
WITH PARAMETER SET \([0, \infty)\)

Theorem 10.10.6. (The right-limit extension of a \(D\)-regular process on \(\overline{Q}_\infty\) is an a.u. càdlàg process on \([0, \infty)\)). Suppose
\[
Z : \overline{Q}_\infty \times (\Omega, L, E) \to (S, d)
\]
is an arbitrary \(D\)-regular process on \(\overline{Q}_\infty\), with a modulus of continuity in probability \(\tilde{\delta}_{C_p} \equiv (\delta_{C_{p,M}})_{M=0,1,\ldots}\), and with a modulus of \(D\)-regularity \(\tilde{m} \equiv (\tilde{m}_M)_{M=0,1,\ldots}\). In symbols, suppose
\[
Z \in \tilde{R}_{Dreg,\tilde{\delta}(C_p),\tilde{m}}(\overline{Q}_\infty \times \Omega, S).
\]
Then the right-limit extension
\[
X \equiv \tilde{\Phi}_{lim}(Z) : [0, \infty) \times (\Omega, L, E) \to (S, d)
\]
of \(Z\) is an a.u. càdlàg process, with the same modulus of continuity in probability \(\tilde{\delta}_{C_p} \equiv (\delta_{C_{p,M}})_{M=0,1,\ldots}\) as \(Z\), and with a modulus of a.u. càdlàg \(\tilde{\delta}_{aucl} \equiv \tilde{\delta}_{aucl}(\tilde{m}, \tilde{\delta}_{C_p})\).
In other words,
\[
X \equiv \tilde{\Phi}_{lim}(Z) \in \tilde{D}(\tilde{\delta}_{aucl,\tilde{m},\tilde{\delta}(C_p)}, [0, \infty)) \subset \tilde{D}[0, \infty).
\]

Proof. 1. Lemma [10.10.5] says that the process \(X\) is continuous in probability, with the same modulus of continuity in probability \(\tilde{\delta}_{C_p} \equiv (\delta_{C_{p,M}})_{M=0,1,\ldots}\) as \(Z\). Let \(N \geq 0\) be arbitrary. Then \(Z^N : Q_\infty \times (\Omega, L, E) \to (S, d)\) is a \(D\)-regular process with a modulus of continuity in probability \(\tilde{\delta}_{C_{p,N}}\), and with a modulus of \(D\)-regularity \(\tilde{m}_N\). Theorem [10.5.8] therefore implies that the right-limit extension process
\[
Y_N \equiv \Phi_{lim}(Z^N) : [0, 1] \times (\Omega, L, E) \to (S, d)
\]
is a.u. càdlàg, with the same modulus of continuity in probability \(\tilde{\delta}_{C_{p,N}}\), and with a modulus of a.u. càdlàg \(\tilde{\delta}_{aucl}(\tilde{m}_N, \tilde{\delta}_{C_{p,N}})\). Separately, Proposition [10.5.7] implies that the process \(Y_N\) is continuous a.u., with a modulus of continuity a.u. \(\tilde{\delta}_{aucl}(\tilde{m}_N, \tilde{\delta}_{C_{p,N}})\). Here the reader is reminded that continuity a.u. is not to be confused with the much stronger condition of a.u. continuity. Note that \(Y_N = Z^N\) on \(Q_\infty\), and that \(X = Z\) on \(Q_\infty\).

2. Let \(\kappa \geq 1\) be arbitrary. Define
\[
\tilde{\delta}_{k} \equiv \delta_{aucl}(2^{-k}, \tilde{m}_N, \tilde{\delta}_{C_{p,N}}) \wedge \delta_{aucl}(2^{-k}, \tilde{m}_{N+1}, \tilde{\delta}_{C_{p,N+1}}) \wedge 2^{-k}.
\]
Then, since \(\delta_{aucl}(\cdot, \tilde{m}_N, \tilde{\delta}_{C_{p,N}})\) is a modulus of continuity a.u. of the process \(Y_N\), there exists, according to Definition [6.1.3] a measurable set \(D_{1,k} \subset domain(Y_N)\) with \(P(D_{1,k}) < 2^{-k}\) such that for each \(\omega \in D_{1,k}\) and for each \(r \in domain(Y_N(\cdot, \omega))\) with \(|r-1| < \tilde{\delta}_{k}\), we have
\[
d(Y_N(r, \omega), Z(N+1, \omega)) = d(Y_N(r, \omega), Y_N(1, \omega)) \leq 2^{-k}.
\]
Likewise, since \(\delta_{aucl}(\cdot, \tilde{m}_{N+1}, \tilde{\delta}_{C_{p,N+1}})\) is a modulus of continuity a.u. of the process \(Y_{N+1}\), there exists, according to Definition [6.1.3] a measurable set \(D_{0,k} \subset domain(Y_{N+1})\) with \(P(D_{0,k}) < 2^{-k}\) such that for each \(\omega \in D_{0,k}\) and for each \(r \in domain(Y_{N+1}(\cdot, \omega))\) with \(|r-0| < \tilde{\delta}_{k}\), we have
\[
d(Y_{N+1}(r, \omega), Z(N+1, \omega)) = d(Y_{N+1}(r, \omega), Y_{N+1}(0, \omega)) \leq 2^{-k}.
\]
CHAPTER 10. A.U. CÀDLÀG PROCESSES

Define $D_{k+} = \bigcap_{h=k}^{\infty} D_{k+} D_{k+}$ and $B = \bigcup_{k=1}^{\infty} D_{k+}$. Then $P(D_{k+}) < 2^{-k+2}$. Hence $P(B) = 1$. In words, $B$ is a full set.

3. Consider each $t \in [N,N+1]$. Since $Y_N \equiv \Phi_{r \text{Lim}}(Z^N)$ and $X \equiv \Phi_{r \text{Lim}}(Z)$, we have

$$\text{domain}(Y_{N,N+1}) \equiv \{ \omega \in \Omega : \lim_{s \to t, t \in [t-N, t]} Z^N(\omega) \text{ exists} \}$$

$$= \{ \omega \in \Omega : \lim_{s \to t, t \in [t-N, t]} Z^N(\omega) \text{ exists} \}$$

$$= \{ \omega \in \Omega : \lim_{s \to t, t \in [t-N, t]} Z(\omega) \text{ exists} \}$$

$$= \{ \omega \in \Omega : \lim_{r \to t, t \in [t-N, t]} Z(r, \omega) \text{ exists} \}$$

$$= \{ \omega \in \Omega : \lim_{r \to t, t \in [t-N, t]} Z(r, \omega) \text{ exists} \}$$

$$\equiv \text{domain}(X_t),$$

because each limit which appears in the previous equality exists iff all others exist, in which case they are equal. Hence

$$X_t(\omega) = \lim_{r \to t, t \in [t-N, t]} Z(r, \omega) = \lim_{s \to t, t \in [t-N, t]} Z^N(\omega) = Y_{N,N+1}(\omega)$$

for each $\omega \in \text{domain}(Y_{N,N+1})$. Thus the two functions $X_t$ and $Y_{N,N+1}$ have the same domain, and have equal values on the common domain. In short,

$$X_t = Y_{N,N+1}, \quad (10.10.5)$$

where $t \in [N,N+1]$ is arbitrary. As for the end point $t = N + 1$, we have, trivially,

$$X_{N+1} = Z_{N+1} = Z^N_t = Y_{N+1} = Y_{N,N+1}.$$  

Hence

$$X_t = Y_{N,N+1}, \quad (10.10.6)$$

for each $t \in [N,N+1] \cup \{N + 1\}$.

4. We wish to extend equality (10.10.6) to each $t \in [N,N+1]$. To that end, consider each

$$t \in [N,N+1].$$

We will prove that

$$X_t = Y_{N,N+1} \quad (10.10.7)$$

on the full set $B$.

5. To that end, let $\omega \in B$ be arbitrary. Suppose $\omega \in \text{domain}(X_t)$. Then, since $X \equiv \Phi_{r \text{Lim}}(Z)$, the limit $\lim_{r \to t, t \in [t-N, t]} Z(r, \omega)$ exists and is equal to $X_t(\omega)$. Consequently, each of the following limits

$$\lim_{r \to t, t \in [t-N, t]} Z(r, \omega) = \lim_{N+s \to t, t \in [t-N, t]} Z(N+s, \omega)$$

Yuen-Kwok Chan 410 Constructive Probability
= \lim_{{s \to \infty}} Z(N+s, \omega) = \lim_{{s \to \infty}} Z_N^N(\omega)
exists and is equal to X(\omega). Therefore, since Y_N \equiv \Phi(\lim (Z^N)) \text{ the existence of the last limit implies that } \omega \in \text{domain}(Y_{N,I_N}), \text{ and that } Y_{N,I_N}(\omega) = X(\omega). \text{ Thus}

domain(X) \subset \domain(Y_{N,I_N}) \quad (10.10.8)

and

X = Y_{N,I_N} \quad (10.10.9)
on \domain(X). \text{ We have proved half of the desired equality [10.10.7].}

6. Conversely, suppose \omega \in \domain(Y_{N,I_N}). \text{ Then } y = Y_{N,I_N}(\omega) \in S \text{ is defined. Hence, since } Y_N \equiv \Phi(\lim (Z^N)), \text{ the limit}

\lim_{{s \to \infty}} Z_N^N(s, \omega)
exists, \text{ and is equal to } y. \text{ Let } \epsilon > 0 \text{ be arbitrary. Then there exists } \delta' > 0 \text{ such that}

d(Z_N^N(s, \omega), y) < \epsilon
\text{ for each }
s \in [t - N, \infty) \equiv [t - N, \infty) \cap \mathbb{Q}
such that \ s - (t - N) < \delta'. \text{ In other words,}

d(Z(u, \omega), y) < \epsilon \quad (10.10.10)
\text{ for each } u \in [t, t + \delta'][N, N + 1] \cap \mathbb{Q}.

7. Separately, recall the assumption that \omega \in B \equiv \bigcup_{k=1}^{\infty} D_{k+}.. \text{ Therefore there exists some } \kappa \geq 1 \text{ such that } \omega \in D_{k+} \equiv \bigcap_{k=1}^{\kappa} D_{k+}D_{0,k}. \text{ Take } k \geq \kappa \text{ so large that } 2^{-k} < \epsilon. \text{ Then } \omega \in D_{k+}D_{0,k}. \text{ Therefore, for each } r \in \domain(Y_{N+1}(0, \omega)) \text{ with } |r - 0| < \delta, \text{ we have, according to inequality [10.10.4]}

d(Y_{N+1}(r, \omega), Z(N+1, \omega)) \leq 2^{-k} < \epsilon. \quad (10.10.11)
\text{ Similarly, for each } r \in \domain(Y_N(\cdot, \omega)) \text{ with } |r - 1| < \delta, \text{ we have, according to inequality [10.10.4]}

d(Y_N(r, \omega), Z(N+1, \omega)) \leq 2^{-k} < \epsilon. \quad (10.10.12)

8. Now let \( u, v \in [t, t + \delta] \cap \mathbb{Q} \) be arbitrary with \( u < v \). Then \( u, v \in [t, t + \delta, \infty) \cap \mathbb{Q} \). Since \( u, v \) are dyadic rationals, there are three possibilities: (i) \( u < v \leq N + 1 \), (ii) \( u \leq N + 1 < v \), or (iii) \( N + 1 < u < v \). Consider Case (i). Then \( u, v \in [t, t + \delta') \cap \mathbb{Q} \). \text{ Hence inequality [10.10.10] applies to } u \text{ and } v, \text{ to yield}

d(Z(u, \omega), y) \vee d(Z(v, \omega), y) < \epsilon,
\text{ whence}

d(Z(u, \omega), Z(v, \omega)) < 2\epsilon.
Next consider Case (ii). Then \(|(u - N) - 1| < v - t < \delta_k\). Hence, by inequality \[10.10.12\] we obtain

\[
d(Z(u, \omega), Z(N + 1, \omega)) \equiv d(Z^N(u - N, \omega), Z(N + 1, \omega)) = d(Y_N(u - N, \omega), Z(N + 1, \omega)) < \epsilon.
\]  
\[10.10.13\]

Similarly, \(|(v - (N + 1)) - 0| < v - t < \delta_k\). Hence, by inequality \[10.10.11\] we obtain

\[
d(Z(v, \omega), Z(N + 1, \omega)) \equiv d(Z^{N + 1}(v - (N + 1), \omega), Z(N + 1, \omega)) = d(Y_{N+1}(v - (N + 1), \omega), Z(N + 1, \omega)) < \epsilon.
\]  
\[10.10.14\]

Combining \[10.10.13\] and \[10.10.14\] we obtain

\[
d(Z(u, \omega), Z(v, \omega)) < 2\epsilon
\]
also in Case (ii).

Now consider Case (iii). Then \(|(u - (N + 1)) - 0| < v - t < \delta_k\) and \(|(v - (N + 1)) - 0| < v - t < \delta_k\). Hence inequality \[10.10.11\] implies

\[
d(Z(u, \omega), Z(N + 1, \omega)) = d(Z^{N + 1}(u - (N + 1), \omega), Z(N + 1, \omega)) = d(Y_{N+1}(u - (N + 1), \omega), Z(N + 1, \omega)) < \epsilon.
\]  
\[10.10.15\]

and, similarly,

\[
d(Z(v, \omega), Z(N + 1, \omega)) < \epsilon.
\]  
\[10.10.16\]

Hence

\[
d(Z(u, \omega), Z(v, \omega)) < 2\epsilon
\]
also in Case (iii).

9. Summing up, we see that \(d(Z(u, \omega), Z(v, \omega)) < 2\epsilon\) for each \(u, v \in [t, t + \delta_k \land \delta']\) with \(u < v\). Since \(\epsilon > 0\) is arbitrary, we conclude that \(\lim_{u \to t, v \to t} Z(u, \omega)\) exists. Thus

\[t, \omega \in \text{domain}(\Phi_{e, \text{Lim}}(Z)) \equiv \text{domain}(X)\]

In other words, we have \(\omega \in \text{domain}(X_t)\), where \(\omega \in B \cap \text{domain}(Y_{N,t-N})\) is arbitrary. Hence

\[B \cap \text{domain}(Y_{N,t-N}) \subset \text{domain}(X_t) \subset \text{domain}(Y_{N,t-N})\]

where the second inclusion is by relation \[10.10.8\] in Step 5 above. Consequently

\[B \cap \text{domain}(Y_{N,t-N}) = B \cap \text{domain}(X_t)\]

while, according to equality \[10.10.9\]

\[
X^N_{t-N} = X_t = Y_{N,t-N}
\]  
\[10.10.17\]

on \(B \cap \text{domain}(X_t)\). In other words, on the full subset \(B\), we have \(X^N_{t-N} = Y_{N,t-N}\) for each \(t \in [N, N + 1]\). Equivalently, \(X^N = Y_N\) on the full subset \(B\). Since the process

\[Y_N \equiv \Phi_{e, \text{Lim}}(Z^N) : [0, 1] \times (\Omega, L, E) \to (S, d)\]

Yuen-Kwok Chan 412 Constructive Probability
10.10. A.U. CÀDLÀG PROCESSES AND A.U. CONTINUOUS PROCESSES
WITH PARAMETER SET \([0, \infty)\)

is a.u. càdlàg, with a modulus of a.u. càdlàg \(\delta_{\text{aucl}}(\cdot, m_N, \delta_{C,P,N})\), so is the process \(X^N\). Thus, by Definition [10.10.4], the process \(X\) is a.u. càdlàg, with modulus of continuity in probability \(\delta_{C,P} \equiv (\delta_{C,P,M})_{M=0,1,\ldots}\), and with a modulus of a.u. càdlàg \(\delta_{\text{aucl}}(\cdot, m_M, \delta_{C,P,M})\). In other words,

\[
X \in \tilde{\mathcal{D}}(\delta_{\text{aucl}}, \delta(C_P))[0, \infty).
\]

The theorem is proved. \(\square\)

The next theorem is straightforward, and is verified here for ease of future reference.

**Theorem 10.10.7.** (\(\mathcal{T}_{\text{rLim}}\) is an isometry on a properly restricted domain). Recall from Definition [10.10.3] the metric space \((\tilde{R}_{\text{Dreg}}, \tilde{\delta}(C_P), \tilde{m}, \tilde{\mathcal{Q}}_\infty \times \Omega, S, \tilde{\rho}_{\text{Prob}}, \tilde{\mathcal{Q}}(\infty))\) of \(D\)-regular processes whose members \(Z\) share a given modulus of continuity in probability \(\delta_{C,P} \equiv (\delta_{C,P,M})_{M=0,1,\ldots}\), and share a given modulus of \(\delta_{\text{aucl}}(\cdot, m_M, \delta_{C,P,M})\)\).

Recall from Definition [10.10.4] the metric space \((\tilde{D}(0, \infty), \tilde{\rho}_{\tilde{D}(0, \infty)})\) of a.u. càdlàg processes on \([0, \infty)\), where

\[
\tilde{\rho}_{\tilde{D}(0, \infty)}(X, X') \equiv \tilde{\rho}_{\text{Prob}, \tilde{\mathcal{Q}}(\infty)}(X|\tilde{\mathcal{Q}}_\infty, X'|\tilde{\mathcal{Q}}_\infty)
\]

for each \(X, X' \in \tilde{D}(0, \infty)\).

Then the function

\[
\mathcal{T}_{\text{rLim}} : (\tilde{R}_{\text{Dreg}}, \tilde{\delta}(C_P), \tilde{m}, \tilde{\mathcal{Q}}_\infty \times \Omega, S, \tilde{\rho}_{\text{Prob}, \tilde{\mathcal{Q}}(\infty)}) \to (\tilde{D}(0, \infty), \tilde{\rho}_{\tilde{D}(0, \infty)})
\]

is a well-defined isometry on its domain, where the modulus of a.u. càdlàg \(\delta_{\text{aucl}} \equiv \delta_{\text{aucl}}(\tilde{m}, \delta_{C,P})\) is defined in the proof below.

**Proof.** 1. Let \(Z \in \tilde{R}_{\text{Dreg}}, \tilde{\delta}(C_P), \tilde{m}, \tilde{\mathcal{Q}}_\infty \times \Omega, S\) be arbitrary. In other words,

\[
Z : \tilde{\mathcal{Q}}_\infty \times (\Omega, L, E) \to (S, d)
\]

is a \(D\)-regular process, with a modulus of continuity in probability \(\delta_{C,P} \equiv (\delta_{C,P,M})_{M=0,1,\ldots}\), and with a modulus of \(D\)-regularity \(\tilde{m} \equiv (\tilde{m}_M)_{M=0,1,\ldots}\). Consider each \(N \geq 0\). Then the shifted processes \(Z^N : \tilde{\mathcal{Q}}_\infty \times (\Omega, L, E) \to (S, d)\) is \(D\)-regular, with modulus of continuity in probability \(\delta_{C,P,N}\) and modulus of \(D\)-regularity \(\tilde{m}_N\). In other words,

\[
Z^N \in (\tilde{R}_{\text{Dreg}}, \tilde{m}, \tilde{\mathcal{Q}}_\infty \times \Omega, S, \tilde{\rho}_{\text{Prob}, \tilde{\mathcal{Q}}(\infty)})
\]

Hence, by Theorem [10.6.1] the processes \(Y^N \equiv \Phi_{\text{rLim}}(Z^N)\) is a.u. càdlàg, with a modulus of continuity in probability \(\delta_{C,P,N}\), and with a modulus of a.u. càdlàg \(\delta_{\text{aucl}}(\cdot, \tilde{m}_N, \delta_{C,P,N})\). It is therefore easily verified that \(X \equiv \mathcal{T}_{\text{rLim}}(Z)\) is a well defined process on \([0, \infty)\), with

\[
X^N \equiv \mathcal{T}_{\text{rLim}}(Z)^N = \Phi_{\text{rLim}}(Z^N)
\]

Yuen-Kwok Chan 413 Constructive Probability
for each \( N \geq 0 \). In other words, \( \Phi_{rLim}(Z) \equiv X \in \hat{D}(0, \infty) \). Hence the function \( \Phi_{rLim} \) is well-defined on \( \hat{R}_{\text{reg}, \hat{\delta}(C_p), \tilde{m}}(\Omega_\infty \times \Omega, S) \). In other words, \( X \equiv \Phi_{rLim}(Z) \in \hat{D}_{\hat{\delta}(\text{aucl}), \hat{\delta}(C_p)}(0, \infty) \), where \( \tilde{\delta}_{C_p} \equiv (\delta_{C_p,M})_{M=0,1,\ldots} \) and where \( \tilde{\delta}_{aucl} \equiv (\delta_{aucl}(\cdot, \tilde{m}_M, \delta_{C_p,M}))_{M=0,1,\ldots} \).

2. It remains to prove that the function \( \Phi_{rLim} \) is uniformly continuous on its domain. To that end, let \( Z, Z' \in \hat{R}_{\text{reg}, \hat{\delta}(C_p), \tilde{m}}(\Omega_\infty \times \Omega, S) \) be arbitrary. Define \( X \equiv \Phi_{rLim}(Z) \) and \( X' \equiv \Phi_{rLim}(Z') \) as in the previous step. Then

\[
\tilde{\rho}_{\hat{D}(0, \infty)}(X, X') \equiv \mathbb{E} \sum_{n=0}^{\infty} 2^{-n-1} (1 \wedge d(X_{u(n)}, X'_{u(n)})
\]

\[
= \mathbb{E} \sum_{n=0}^{\infty} 2^{-n-1} (1 \wedge d(Z_{u(n)}, Z'_{u(n)}) \equiv \tilde{\rho}_{\text{Prob}, \Omega_\infty}(Z, Z').
\]

Hence the function \( \Phi_{rLim} \) is an isometry on its domain. \( \Box \)
Chapter 11

Markov Process

In this chapter, we will construct an a.u. càdlàg Markov process from a given Mrekov semigroup of transition distributions, and show that the construction is a continuous mapping.

**Definition 11.0.1. (Specification of state space).** In this chapter, let $(S, d)$ be a locally compact metric space, with an arbitrary, but fixed reference point. Let $\xi \equiv (A_k)_{k=1,2,\ldots}$ be a given binary approximation of $(S, d)$ relative to $x_0$. Let $\pi \equiv \{\{g_{k,x} : x \in A_k\}\}_{k=1,2,\ldots}$ be the partition of unity of $(S, d)$ determined by $\xi$, as in Definition 3.2.4.

**Definition 11.0.2. (Notations for dyadic rationals).** Recall from Definition 9.0.2 the notations related to the enumerated set $Q_0 \equiv \{t_0, t_1, \cdots\}$ of dyadic rationals in the interval $[0, 1]$, and the enumerated set $Q_\infty \equiv \{u_0, u_1, \cdots\}$ of dyadic rationals in the interval $[0, \infty)$.

In particular, for each $m \geq 0$, recall the notations $p_m \equiv 2^m$ and $\Delta_m \equiv 2^{-m}$, and

$$Q_m \equiv \{t_0, t_1, \cdots, t_{p(m)}\} = \{q_{m,0}, \cdots, q_{m,p(m)}\} = \{0, \Delta_m, 2\Delta_m, 3\Delta_m, \cdots, 1\},$$

where the second equality is equality for sets, and

$$\overline{Q}_m \equiv \{u_0, u_1, \cdots, u_{p(2m)}\} \equiv \{0, 2^{-m}, 2 \cdot 2^{-m}, \cdots, 2^m\} \subset [0, 2^m],$$

and

$$\overline{Q}_\infty = \bigcup_{m=0}^{\infty} \overline{Q}_m \equiv \{u_0, u_1, \cdots\},$$

where the second equality is equality for sets.

Unless otherwise specified, we will let $Q$ denote one of the three parameter sets $\{0, 1, \cdots\}$, $\overline{Q}_\infty$, or $[0, \infty)$.}

□

To ease the burden on notations, for real-valued expressions $a, b, c$, we will write the expressions $a = b \pm c$ interchangeably with $|a - b| \leq c$. 415
11.1 Filtrations, Stopping Times, and Markov Processes

Filtrations, stopping times, and related objects were introduced in Sections 8.1 and 8.2. Hitherto we have used only simple stopping times, which have values in a finite and discrete parameter set. In this section, we will prove the basic properties of stopping times with values in $[0, \infty)$ relative to some right continuous filtration. Then we will define Markov processes and strong Markov processes.

**Proposition 11.1.1. (Basic properties of stopping times relative to a right continuous filtration).** Let $\mathcal{L} = \{L^{(t)} : t \in [0, \infty)\}$ be an arbitrary right continuous filtration on some probability space $(\Omega, L, E)$. All stopping times in the following will be relative to this filtration and will have values in $[0, \infty)$.

Let $\tau'$, $\tau''$ be arbitrary stopping times. Then the following holds.

1. (Approximating stopping time by stopping times which have regularly spaced dyadic values). Let $\tau$ be an arbitrary stopping time. Then for each regular point $t$ of the r.r.v. $\tau$, we have $(\tau < t), (\tau = t) \in L^{(t)}$. Moreover, there exists a nonincreasing sequence $(\eta_h)_{h=0, 1, \ldots}$ of stopping times, such that, for each $h \geq 0$, the stopping time $\eta_h$ has values in

$$A_h \equiv \{s_0, s_1, s_2, \ldots\} \equiv \{0, \Delta_h, 2\Delta_h, \ldots\}$$

where $\Delta_h \equiv 2^{-h}$ and $s_j \equiv j\Delta_h$ for each $j \geq 0$, and such that

$$\tau \leq \eta_h < \tau + 2^{-h+2},$$

(11.1.1)

for each $h \geq 0$. Consequently, $\eta_h \to \tau$ a.u. and $\eta_h \to \tau$ in probability.

2. (Construction of stopping time as right-limit of given stopping times). Conversely, suppose $(\eta_h)_{h=0, 1, \ldots}$ is a sequence of stopping times such that, for some r.r.v. $\tau$, we have (i) $\tau \leq \eta_h$ for each $h \geq 0$, and (ii) $\eta_h \to \tau$ in probability. Then $\tau$ is a stopping time.

3. $\tau' \land \tau''$, $\tau' \lor \tau''$, and $\tau' + \tau''$ are stopping times.

4. If $\tau' \leq \tau''$ then $L^{(\tau')} \subset L^{(\tau'')}$. 

5. Suppose $\tau$ is a stopping time. Define $L^{(\tau+)} \equiv \bigcap_{s > 0} L^{(\tau+s)}$. Then $L^{(\tau+)} = L^{(\tau)}$.

**Proof.** 1. Suppose $\tau$ is a stopping time. Let $t$ be an arbitrary regular point of the r.r.v. $\tau$. Then, according to Definition 5.1.2, there exists an increasing sequence $(r_k)_{k=1, 2, \ldots}$ of regular points of $\tau$ such that $r_k \uparrow t$ and such that $P(\tau \leq r_k) \uparrow P(\tau < t)$. Consequently, $E[1_{\tau \leq r_k} - 1_{\tau < t}] \to 0$. Since $1_{\tau \leq r_k} \in L^{(r_k)} \subset L^{(t)}$ for each $k \geq 1$, we conclude that $1_{\tau \leq t} \in L^{(t)}$. In other words, $(\tau < t) \in L^{(t)}$. Therefore $(\tau = t) = (\tau \leq t)(\tau < t)^c \in L^{(t)}$.

Separately, let $h \geq 0$ be arbitrary. For convenience, define $r_0 \equiv -\Delta_h$. For each $j \geq 1$, take a regular point

$$r_j \in (s_{j-1}, s_j) \equiv ((j - 1)\Delta_h, j\Delta_h)$$

of the r.r.v. $\tau$. Then the r.r.v.

$$\xi_h \equiv \sum_{j=1}^{\infty} s_j 1_{(r(j-1) < \tau \leq r(j))}$$

Yuen-Kwok Chan 446 Constructive Probability
has values in $A_h$. Moreover, for each $j \geq 1$, we have, on the measurable set $(r_{j-1} < \tau \leq r_j)$, the inequality
\[
\tau \leq r_j < s_j = \zeta_h < r_{j+1} < r_j + (\tau - r_{j-1}) < s_j + (\tau - s_{j-2}) = \tau + 3\Delta_h < \tau + 2^{-h+2}.
\]
Since $\bigcup_{j=1}^{r_j} (r_{j-1} < \tau \leq r_j)$ is a full set because $\tau$ is a nonnegative r.r.v. and because $r_j \uparrow \infty$ as $j \to \infty$, inequality (11.1.2) implies that
\[
\tau < \zeta_h < \tau + 2^{-h+2}
\]
as r.r.v.'s. Consider each possible value $s_j$ of the r.r.v. $\zeta_h$, for some $j \geq 1$. Then
\[
(\zeta_h = s_j) = (r_{j-1} < \tau \leq r_j) = (\tau \leq r_j)(\tau \leq r_{j-1})^\epsilon \in L^{(r(j))} \subset L^{(s(j))},
\]
because $\tau$ is a stopping time relative to $\mathcal{F}$ and because $r_{j-1}$ and $r_j$ are regular points of $\tau$. Hence
\[
(\zeta_h \leq s_j) = \bigcup_{k=1}^{j} (\zeta_h = s_k) \in L^{(s(j))}.
\]
Thus $\zeta_h$ is a stopping time, with values in $A_h$. Therefore the sequence $(\zeta_h)_{h=0,1,\ldots}$ would be the desired result, except for the lack of monotonicity.

To fix that, let $h \geq 0$ be arbitrary, and define the r.r.v.
\[
\eta_h \equiv \zeta_0 \land \zeta_1 \land \cdots \land \zeta_h
\]
with values in $A_0 \cup A_1 \cup \cdots \cup A_h = A_h$. Then, for each possible value $t \in A_h$ of the r.r.v. $\eta_h$, we have
\[
(\eta_h \leq t) = \bigcup_{i=0}^{h} (\zeta_i \leq t) \in L^{(t)}.
\]
Hence $\eta_h$ is a stopping time with values in $A_h$. Moreover, equality (11.1.4) implies that $(\eta_h)_{h=0,1,\ldots}$ is a nonincreasing sequence, while inequality (11.1.3) implies that
\[
\tau < \eta_h < \tau + 2^{-h+2}.
\]
Assertion 1 is proved.

2. Conversely, suppose $(\eta_h)_{h=0,1,\ldots}$ is a sequence of stopping times such that (i) $\tau \leq \eta_h$ for each $h \geq 0$, and (ii) $\eta_h \to \tau$ in probability. Let $t \in R$ be a regular point of the r.r.v. $\tau$. Consider each $r > t$. Let $\epsilon > 0$ be arbitrary. Let $s \in (t,r)$ be an arbitrary regular point of all the r.r.v.'s in the countable set \{\tau, \eta_0, \eta_1, \cdots\}. Then, by Conditions (i) and (ii), there exists $k \geq 0$ such that
\[
P(s < \eta_h)(\tau \leq t) \leq P(s-t < \eta_h - \tau) \leq \epsilon
\]
for each $h \geq k$. Hence, for each $h \geq k$, we have
\[
E[1_{\tau \leq t} - 1_{\eta(h) \leq s}] \leq E[1_{\tau \leq t} < s < \eta(h)] \leq \epsilon.
\]
Thus \( E[1_{\tau \leq s}] = 1_{\eta(h) \leq s} \) → 0 as \( h \to \infty \). Because \( \eta_h \) is a stopping time we have \( 1_{\eta(h) \leq s} \in L^r \). Hence \( 1_{\tau \leq s} \in L^r \), where \( r > t \) is arbitrary. Thus
\[
1_{\tau \leq s} \in \bigcap_{r > t} L^r \equiv L^{(t+)} = L^{(t)},
\]
where the last equality is thanks to the assumption that the filtration \( \mathcal{F} \) is right continuous. We have verified that \( \tau \) is a stopping time relative to the filtration \( \mathcal{F} \). Assertion 2 is proved.

3. By hypothesis, \( \tau', \tau'' \) are stopping times. Consider each regular point \( t \in R \) of the r.r.v. \( \tau' \land \tau'' \). Let \( r > t \) be arbitrary. Take any common regular point \( s > t \) of the three r.r.v.’s \( \tau', \tau', \land \tau'' \). Then \( (\tau' \leq s) \cup (\tau' > s) \) and \((\tau'' \leq s) \cup (\tau'' > s) \) are full sets. Hence
\[
(\tau' \land \tau'' \leq s)
= (\tau' \land \tau'' \leq s) \cap ((\tau' \leq s) \cup (\tau' > s)) \cap ((\tau'' \leq s) \cup (\tau'' > s))
= (\tau' \land \tau'' \leq s) \cap (\tau' \leq s) \cap (\tau'' \leq s)
= (\tau' \leq s) \cap (\tau'' \leq s) \in L^s \subset L^r.
\]
(11.1.6)

Now let \( s \downarrow t \). Then, since \( t \) is a regular point of the r.r.v. \( \tau' \land \tau'' \), we have \( E1_{(\tau' \land \tau'' \leq s)} \downarrow E1_{(\tau' \land \tau'' \leq s)} \). The Monotone Convergence Theorem therefore implies that \( E[1_{(\tau' \land \tau'' \leq s)}] \to 0 \). Consequently, since \( 1_{(\tau' \land \tau'' \leq s)} \in L^r \) for each common regular point \( s > t \) of the three r.r.v.’s \( \tau', \tau', \land \tau'' \), according to relation 11.1.6, it follows that \( 1_{(\tau' \land \tau'' \leq s)} \in L^r \), where \( r > t \) is arbitrary. Hence
\[
1_{(\tau' \land \tau'' \leq s)} \in \bigcap_{t \leq (t, \infty)} L^r \equiv L^{(t+)} = L^{(t)},
\]
where the last equality is thanks to the right continuity of the filtration \( \mathcal{F} \). Thus \( \tau' \land \tau'' \) is a stopping time relative to \( \mathcal{F} \). Similarly we can prove that \( \tau' \lor \tau'' \), and \( \tau' + \tau'' \) are stopping times relative to \( \mathcal{F} \). Assertion 3 is verified.

4. Suppose the stopping times \( \tau', \tau'' \) are such that \( \tau' \leq \tau'' \). Let \( Y \in L^\tau \) be arbitrary. Consider each regular point \( t'' \) of the stopping time \( \tau'' \). Take an arbitrary regular point \( t' \) of \( \tau' \) such that \( t' \neq t'' \). Then
\[
Y1_{(\tau'' \leq t'')} = Y1_{(\tau' \leq t' < \tau'' \leq t'')} + Y1_{(\tau' \leq t < \tau'' \leq t'')} + Y1_{(\tau' \leq t < \tau'' \leq t'')} + Y1_{(t < \tau'' \leq t'')}.
\]
Consider the first summand in the last sum. Since \( Y \in L^\tau \) by assumption, we have \( Y1_{(\tau' \leq t' < \tau'' \leq t'')} \in L^{(t'')} \). At the same time \( 1_{(\tau'' \leq t'')} \in L^{(t'')} \). Hence \( Y1_{(\tau' \leq t')1_{(\tau'' \leq t'')}} \in L^{(t'')} \). Similarly all the other summands in the last sum are members of \( L^{(t'')} \). Consequently the sum \( Y1_{(\tau'' \leq t'')} \) is a member of \( L^{(t'')} \), where \( t'' \) is an arbitrary regular point of the stopping time \( \tau'' \). In other words, \( Y \in L^\tau \). Since \( Y \in L^\tau \) is arbitrary, we conclude that \( L^\tau \subset L^\tau \), as alleged in Assertion 4.
11.1. FILTRATIONS, STOPPING TIMES, AND MARKOV PROCESSES

5. Suppose \( \tau \) is a stopping time relative to the right continuous filtration \( \mathcal{L} \). Let \( Y \in L^{(\tau +)} = \bigcap_{s > 0} L^{(\tau + s)} \) be arbitrary. Let \( t \) be an arbitrary regular point of the stopping time \( \tau \). Consider each \( s > t \). Then \( Y \in L^{(\tau + s)} \). Hence \( Y_{1(\tau \leq t)} \in L^{(\tau +)} \). Consequently,

\[
Y_{1(\tau \leq t)} \in \bigcap_{s > 0} L^{(\tau + s)} = L^{(\tau +)} = L^{(t)}
\]

where the last equality is because the filtration \( \mathcal{L} \) is right continuous. Thus \( Y \in L^{(t)} \) for each \( Y \in L^{(\tau +)} \). Equivalently, \( L^{(\tau +)} \subset L^{(t)} \). In the other direction, we have, trivially, \( L^{(t)} \subset L^{(\tau +)} \). Summing up \( L^{(t)} = L^{(\tau +)} \) as alleged in Assertion 5.

Definition 11.1.2. (Markov process). Let \((S, d)\) be an arbitrary locally compact metric space. Let \( Q \) denote one of the three parameter sets \( \{0, 1, \cdots\}, \overline{Q}_m \), or \([0, \infty)\). Let \( \mathcal{L} \equiv \{L^{(t)} : t \in Q\} \) denote an arbitrary right continuous filtration of the sample space \((\Omega, L, E)\). Let

\[
X : Q \times (\Omega, L, E) \rightarrow (S, d)
\]

be an arbitrary process which is adapted to the filtration \( \mathcal{L} \).

Suppose, for each \( t \in Q \), for each nondecreasing sequence \( t_0 \equiv 0 \leq t_1 \leq \cdots \leq t_m \) in \( Q \), and for each function \( f \in C(S^{m+1}, d^{m+1}) \), we have (i) the conditional expectation of \( E(f(X_{t_0+0}, X_{t_1+1}, \cdots, X_{t_m+m}))|L^{(t)} \) exists, (ii) the conditional expectation of \( E(f(X_{t_0+0}, X_{t_1+1}, \cdots, X_{t_m+m}))|X_t \) exists, and (iii)

\[
E(f(X_{t_0+0}, X_{t_1+1}, \cdots, X_{t_m+m}))|L^{(t)} = E(f(X_{t_0+0}, X_{t_1+1}, \cdots, X_{t_m+m}))|X_t.
\]

Then the process \( X \) is called a Markov process relative to the filtration \( \mathcal{L} \). We will refer to Conditions (i-iii) as the Markov property. In the special case where \( \mathcal{L} \) is the natural filtration of the process \( X \), we will omit the reference to \( \mathcal{L} \) and simply say that \( X \) is a Markov process.

Definition 11.1.3. (Strong Markov process). Let \((S, d)\) be an arbitrary locally compact metric space. Let \( Q \) denote one of the three parameter sets \( \{0, 1, \cdots\}, \overline{Q}_m \), or \([0, \infty)\). Let \( \mathcal{L} \equiv \{L^{(t)} : t \in Q\} \) denote an arbitrary right continuous filtration of the sample space \((\Omega, L, E)\). Let

\[
X : Q \times (\Omega, L, E) \rightarrow (S, d)
\]

be an arbitrary process which is adapted to the filtration \( \mathcal{L} \). Suppose, for each stopping time \( \tau \) with values in \( Q \) relative to the filtration \( \mathcal{L} \), the following two conditions hold.

1. The function \( X_\tau \) is a well defined r.v. relative to \( L^{(\tau)} \), with values in \((S, d)\).

2. For each nondecreasing sequence \( t_0 \equiv 0 \leq t_1 \leq \cdots \leq t_m \) in \( Q \), and for each function \( f \in C(S^{m+1}, d^{m+1}) \), we have (i) the conditional expectation of \( E(f(X_{\tau+t_0+0}, X_{\tau+t_1+1}, \cdots, X_{\tau+t_m+m}))|L^{(\tau)} \) exists, (ii) the conditional expectation of \( (f(X_{\tau+t_0+0}, X_{\tau+t_1+1}, \cdots, X_{\tau+t_m+m})|X_\tau \) exists, and (iii)

Yuen-Kwok Chan 419 Constructive Probability
\[ E(f(X_{\tau + t(0)}, X_{\tau + t(1)}, \cdots, X_{\tau + t(m)})|L(t)) = (f(X_{\tau + t(0)}, X_{\tau + t(1)}, \cdots, X_{\tau + t(m)})|X_\tau). \]

(11.1.8)

Then the process \( X \) is called a **strong Markov process** relative to the filtration \( \mathcal{L} \).

Since each constant time \( t \in Q \) is a stopping time, each strong Markov process is clearly a Markov process.

\[ \square \]

### 11.2 Transition Distributions

**Definition 11.2.1. (Transition distribution).** Let \((S_0, d_0)\) and \((S_1, d_1)\) be compact metric spaces, with \(d_0 \leq 1\) and \(d_1 \leq 1\), and with fixed reference points \(x_{0,0}\) and \(x_{1,0}\) respectively. Let

\[ T : C(S_1, d_1) \rightarrow C(S_0, d_0) \]

be an arbitrary nonnegative linear function. Write

\[ T^x = T(\cdot)(x) : C(S_1, d_1) \rightarrow R \]

for each \( x \in S_0 \). Suppose, (i) for each \( x \in S_0 \), the function \( T^x \) is a distribution on \((S_1, d_1)\), in the sense of Definition 5.2.1, and (ii) for each \( f \in C(S_1, d_1) \) with a modulus of continuity \( \delta_f \), the function \( T^x f \in C(S_0, d_0) \) has a modulus of continuity \( \alpha(\delta_f) : (0, \infty) \rightarrow (0, \infty) \) which depends only on \( \delta_f \), and otherwise not on the function \( f \).

Then the function \( T \) is called a **transition distribution** from \((S_0, d_0)\) to \((S_1, d_1)\). The operation \( \alpha \) is then called a **modulus of smoothness of the transition distribution** \( T \).

\[ \square \]

**Lemma 11.2.2. (Composite transition distributions).** For each \( j = 0, 1, 2 \), let \((S_j, d_j)\) be a compact metric space with \(d_j \leq 1\). For each \( j = 0, 1 \), let \( T_{j+1} \) be a transition distribution from \((S_j, d_j)\) to \((S_{j+1}, d_{j+1})\), with modulus of smoothness \( \alpha_{j+1} \). Then the composite function

\[ T_{0,2} \equiv T_{0,1}T_{1,2} \equiv T_{0,1} \circ T_{1,2} : C(S_2, d_2) \rightarrow C(S_0, d_0) \]

is a transition distribution from \((S_0, d_0)\) to \((S_2, d_2)\), with a modulus of smoothness \( \alpha_{0,2} \) defined by

\[ \alpha_{0,2}(\delta_f) = \alpha_{0,1}(\alpha_{1,2}(\delta_f)) : (0, \infty) \rightarrow (0, \infty) \]

for each modulus of continuity \( \delta_f \).

We will call \( T_{0,2} \equiv T_{0,1}T_{1,2} \) the **composite transition distribution of** \( T_{0,1} \) and \( T_{1,2} \), and call \( \alpha_{0,2} \equiv \alpha_{0,1} \circ \alpha_{1,2} \) the **composite modulus of smoothness of** \( T_{0,1}T_{1,2} \).

**Proof.** 1. Being the composite of two linear functions, the function \( T_{0,2} \) is linear. Let \( f \in C(S_2, d_2) \) be arbitrary, with a modulus of continuity \( \delta_f \) and with \(|f| \leq 1\). Then \( T_{1,2} f \in C(S_1, d_1) \) has a modulus of continuity \( \alpha_{1,2}(\delta_f) \). Hence the function \( T_{0,1}(T_{1,2} f) \) has a modulus of continuity \( \alpha_{0,1}(\alpha_{1,2}(\delta_f)) \).
2. Consider each \( x \in S_0 \). Suppose \( f \in C(S_2, d_2) \) is such that \( T_{0,2}^y f > 0 \). Then \( T_{0,1}^x T_{1,2}^y f = T_{0,2}^y f > 0 \). Therefore, since \( T_{0,1}^x \) is a distribution, there exists \( y \in S_1 \) such that \( T_{0,1}^y f \equiv T_{1,2}^y f(y) > 0 \). Since \( T_{1,2}^y \) is a distribution, there exists, in turn, some \( z \in S_2 \) such that \( f(z) > 0 \). Thus \( T_{0,2}^y \) is an integration on \((S_2, d_2)\) in the sense of Definition 4.2.1. Since \( 1 \in C(S_2, d_2) \) and \( d_2 \leq 1 \), it follows that \( T_{0,2}^y \) is a distribution on \((S_2, d_2)\) in the sense of Definition 5.2.1 where \( x \in S_0 \) is arbitrary. The conditions in Definition 11.2.1 have been verified for \( T_{0,2} \) to be a transition distribution.

By Definition 11.2.1 the domain and range of a transition distribution are spaces of continuous functions. We next extend both to spaces of integrable functions. Recall that, for each \( x \in S \), we let \( \delta_x \) denote the distribution concentrated at \( x \).

**Proposition 11.2.3. (Complete extension of a transition distribution relative to an initial distribution).** Let \((S_0, d_0)\) and \((S_1, d_1)\) be compact metric spaces, with \( d_0 \leq 1 \) and \( d_1 \leq 1 \). Let \( T \) be a transition distribution from \((S_0, d_0)\) to \((S_1, d_1)\). Let \( E_0 \) be a distribution on \((S_0, d_0)\). Define the composite function

\[ E_1 \equiv E_0 T : C(S_1) \to R \quad (11.2.1) \]

Then the following holds.

1. \( E_1 \equiv E_0 T \) is a distribution on \((S_1, d_1)\).

2. For each \( i = 0, 1 \), let \( (S_i, L_{E(i)}, E_i) \) be the complete extension of \((S_i, C(S_i), E_i)\).

Let \( f \in L_{E(1)} \) be arbitrary. Define the function \( T f \) on \( S_0 \) by

\[ \text{domain}(T f) \equiv \{ x \in S_0 : f \in L_{\delta(x) T} \} \quad (11.2.2) \]

and by

\[ (T f)(x) \equiv (\delta_x T) f \quad (11.2.3) \]

for each \( x \in \text{domain}(T f) \). Then (i) \( T f \in L_{E(0)} \), and (ii) \( E_0(T f) = E_1 f \equiv (E_0 T) f \).

3. Moreover, the extended function

\[ T : L_{E(1)} \to L_{E(0)}, \]

thus defined, is a contraction mapping, hence continuous, relative to the norm \( E_1 \| \cdot \| \) on \( L_{E(1)} \) and the norm \( E_0 \| \cdot \| \) on \( L_{E(0)} \).

**Proof.** 1. By the defining equality \( 1.2.2 \) the function \( E_1 \) is clearly linear and nonnegative. Suppose \( E_1 f \equiv E_0 T f > 0 \) for some \( C(S_1, d_1) \). Then, since \( E_0 \) is a distribution, there exists \( x \in S_0 \) such that \( T^x f > 0 \). In turn, since \( T^x \) is a distribution, there exists \( y \in S_1 \) such that \( f(y) > 0 \). Thus \( E_1 \) is an integration. Since \( 1 \in C(S_1, d_1) \) and \( d_1 \leq 1 \), it follows that \( E_1 \) is a distribution.

2. For each \( i = 0, 1 \), let \( (S_i, L_{E(i)}, E_i) \) be the complete extension of \((S_i, C(S_i), E_i)\). Let \( f \in L_{E(1)} \) be arbitrary. Define the function \( T f \) on \( S_0 \) by equalities \( 1.2.2 \) and \( 1.2.3 \).

Then, by Definition 4.4.1 of complete extensions, there exists a sequence \( (f_n)_{n=1,2,\ldots} \) in \( C(S_1) \) such that \((i')\) \( \sum_{n=1}^{\infty} E_0 T f_n = \sum_{n=1}^{\infty} E_1 f_n < \infty \), (ii')

\[ \{ x \in S_1 : \sum_{n=1}^{\infty} |f_n(x)| < \infty \} \subset \text{domain}(f), \]

Yuen-Kwok Chan

421 Constructive Probability
and (iii’) \( f(x) = \sum_{n=1}^{\infty} f_n(x) \) for each \( x \in S_1 \) with \( \sum_{n=1}^{\infty} |f_n(x)| < \infty \). Condition (i’) implies that the subset

\[
D_0 \equiv \{ x \in S_0 : \sum_{n=1}^{\infty} T|f_n|(x) < \infty \} \equiv \{ x \in S_0 : \sum_{n=1}^{\infty} T^n|f_n| < \infty \}
\]

of the probability space \((S_0, L_{E(0)}, E_0)\) is a full subset. It implies also that the function \( g \equiv \sum_{n=1}^{\infty} T f_n \), with domain \( g \equiv D_0 \), is a member of \( L_{E(0)} \). Now consider an arbitrary \( x \in D_0 \). Then

\[
\sum_{n=1}^{\infty} |T^x f_n| \leq \sum_{n=1}^{\infty} T^n|f_n| < \infty, \quad (11.2.4)
\]

Together with Condition (iii’), this implies that \( f \in L_{\delta(x)} \), with \( \delta(x) = \sum_{n=1}^{\infty} \delta(T) f_n \). Hence, according to the defining equalities [11.2.2] and [11.2.3], we have \( x \in \text{domain}(T f) \), with

\[
(T f)(x) = \sum_{n=1}^{\infty} T f_n(x) = g(x).
\]

Thus \( T f = g \) on the full subset \( D_0 \) of \((S_0, L_{E(0)}, E_0)\). Since \( g \in L_{E(0)} \), it follows that \( T f \in L_{E(0)} \). The desired Condition (i) is verified. Moreover,

\[
E_0(T f) = E_0 g = E_0 \sum_{n=1}^{\infty} T f_n = E_0 T \sum_{n=1}^{\infty} f_n = E_1 f,
\]

where the third and fourth equality are both justified by Condition (i’). The desired Condition (ii) is also verified. Thus Assertion 2 is proved.

3. Let \( f \in L_{E(1)} \) be arbitrary. Then, in the notations of the previous step, we have

\[
E_0 |T f| = E_0 |g| = \lim_{N \to \infty} E_0 \sum_{n=1}^{N} T f_n = \lim_{N \to \infty} E_0 T \sum_{n=1}^{N} f_n
\]

\[
\leq \lim_{N \to \infty} E_0 T \sum_{n=1}^{N} f_n = \lim_{N \to \infty} E_1 \sum_{n=1}^{N} f_n = E_1 |f|.
\]

In short, \( E_0 |T f| \leq E_1 |f| \). Thus the mapping \( T : L_{E(1)} \to L_{E(0)} \) is a contraction, as alleged in Assertion 3.

**Definition 11.2.4. (Convention regarding automatic completion of transition distributions).** We hereby make the convention that, given each transition distribution \( T \) from a compact metric space \((S_0, d_0)\) to a compact metric space \((S_1, d_1)\) with \( d_0 \leq 1 \) and \( d_1 \leq 1 \), and given each initial distribution \( E_0 \) on \((S_0, d_0)\), the transition distribution

\[
T : C(S_1, d_1) \to C(S_0, d_0)
\]

is automatically completely extended to the nonnegative linear function

\[
T : L_{E(1)} \to L_{E(0)}
\]
11.2. TRANSITION DISTRIBUTIONS

in the manner of Proposition 11.2.3 where \( E_1 \equiv E_0 T \), and where \((S_i, L_{E(0)}, E_i)\) is the complete extension of \((S_i, C(S_i), E_i)\), for each \( i = 0, 1 \).

Thus \( T f \) is integrable relative to \( E_0 \) for each integrable function \( f \) relative to \( E_0 T \), with \( (E_0 T) f = E_0 (T f) \). In the special case where \( E_0 \) is the point mass distribution \( \delta_x \) concentrated at some \( x \in S_0 \), we have \( x \in \text{domain}(T f) \) and \( T^x f = (T f)^x \), for each integrable function \( f \) relative to \( T^x \).

\[ \square \]

Lemma 11.2.5. (One-step transition distributions). Let \((S, d)\) be a compact metric space with \( d \leq 1 \). Let \( T \) be a transition distribution from \((S, d)\) to \((S, d)\), with a modulus of smoothness \( \alpha_T \). Define \( 1 T \equiv T \). Let \( m \geq 2 \) and \( f \in C(S^m, d^m) \) be arbitrary. Define a function \((m-1) T f\) on \( S^{m-1} \) by

\[
(m-1) T f(x_1, \ldots, x_{m-1}) \equiv \int T^{x(m-1)}(dx_m)f(x_1, \ldots, x_{m-1}, x_m)
\]

(11.2.5)

for each \( x \equiv (x_1, \ldots, x_{m-1}) \in S^{m-1} \). Then the following holds for each \( m \geq 1 \).

1. If \( f \in C(S^m, d^m) \) has values in \([0, 1]\) and has modulus of continuity \( \delta_f \), then the function \((m-1) T f\) is a member of \( C(S^{m-1}, d^{m-1}) \), with values in \([0, 1]\), and has the modulus of continuity

\[
\overline{\alpha}_{\alpha(T), \xi}(\delta_f) : (0, \infty) \to (0, \infty)
\]

defined by

\[
\overline{\alpha}_{\alpha(T), \xi}(\delta_f)(\varepsilon) \equiv \alpha_f(\delta_f)(2^{-1}\varepsilon) \wedge \delta_f(2^{-1}\varepsilon)
\]

(11.2.6)

for each \( \varepsilon > 0 \).

2. For each \( x \equiv (x_1, \ldots, x_{m-1}) \in S^{m-1} \), the function

\[
m-1 T : C(S^m, d^m) \to C(S^{m-1}, d^{m-1})
\]

is a transition distribution from \((S^{m-1}, d^{m-1})\) to \((S^m, d^m)\), with modulus of smoothness \( \overline{\alpha}_{\alpha(T), \xi} \).

We will call \( m-1 T \) the one-step transition distribution at step \( m \) according to \( T \).

Proof. 1. Let \( f \in C(S^{m+1}, d^{m+1}) \) be arbitrary, with values in \([0, 1]\) and with a modulus of continuity \( \delta_f \). Since \( T \) is a transition distribution, \( T^{x(m-1)} \) is a distribution on \((S, d)\) for each \( x_{m-1} \in S \). Hence the integration on the right-hand side of equality \( 11.2.5 \) makes sense and has values in \([0, 1]\). Therefore the left-hand side is well defined and has values in \([0, 1]\). We need to prove that the function \((m-1) T f\) is a continuous function.

2. To that end, let \( \varepsilon > 0 \) be arbitrary. Define

\[
d^{m-1}((x_1, \ldots, x_{m-1}), (x'_1, \ldots, x'_{m-1})) < \overline{\alpha}_{\alpha(T), \xi}(\delta_f)(\varepsilon)
\]

For abbreviation, write \( x \equiv (x_1, \ldots, x_{m-2}) \in S^{m-2} \), where the sequence is by convention empty if \( m = 2 \). Write \( y \equiv x_{m-1} \). Define the abbreviations \( x', y' \) similarly.
With \( x, y \) fixed, the function \( f(x, y, \cdot) \) also has a modulus of continuity \( \delta_f \). Hence the function \( T f(x, y, \cdot) \) has a modulus of continuity \( \alpha_f(\delta_f) \), by Definition \[11.2.1\] Therefore, since
\[
d(y, y') \leq d^{m-1}(x_1, \cdots, x_{m-1}, (x'_1, \cdots, x'_{m-1})) < \bar{\alpha}_{\alpha(T), \xi}(\delta_f)(\varepsilon) \leq \alpha_f(\delta_f)(2^{-1}\varepsilon),
\]
it follows that
\[
|(T f(x, y, \cdot))(y) - (T f(x, y, \cdot))(y')| < 2^{-1}\varepsilon.
\]
In other words
\[
\int T^y(dz) f(x, y, z) = \int T^{y'}(dz) f(x, y, z) \pm 2^{-1}\varepsilon \tag{11.2.7}
\]
At the same time, for each \( z \in S \), since
\[
d^m((x, y), (x', y', z)) = d^{m-1}((x, y), (x', y')) < \delta_f(2^{-1}\varepsilon)
\]
we have \(|f(x, y, z) - f(x', y', z)| < 2^{-1}\varepsilon\). Hence
\[
\int T^{y'}(dz) f(x, y, z) = \int T^y(dz) (f(x', y', z) \pm 2^{-1}\varepsilon) = \int T^y(dz) f(x', y', z) \pm 2^{-1}\varepsilon.
\]
Combining with equality \[11.2.7\] we obtain
\[
\int T^y(dz) f(x, y, z) = \int T^{y'}(dz) f(x', y', z) \pm \varepsilon.
\]
In other words,
\[
((m^{-1}T)f)(x, y) = ((m^{-1}T)f)(x', y') \pm \varepsilon.
\]
Thus \((m^{-1}T)f\) is continuous, with modulus of continuity \(\bar{\alpha}_{\alpha(T), \xi}(\delta_f)\). Assertion 1 has been proved.

By linearity, we see that \((m^{-1}T)f \in C(S^m, d^m)\) for each \(f \in C(S^{m+1}, d^{m+1})\). Therefore the function
\[
m^{-1}T : C(S^m, d^m) \to C(S^{m-1}, d^{m-1})
\]
is a well-defined. It is clearly linear and nonnegative from the defining formula \[11.2.5\] Consider each \( x \equiv (x_1, \cdots, x_{m-1}) \in S^{m-1} \). Suppose \((m^{-1}T)^i f \equiv \int T^{x(m-i)}(dy) f(x, y) > 0\). Then, since \(T^{x(m-i)}\) is a distribution, there exists \( y \in S \) such that \( f(x, y) > 0\). Hence \((m^{-1}T)^x\) is an integration on \((S^{m-1}, d^{m-1})\) in the sense of Definition \[4.2.1\] Since \(d^{m-1} \leq 1\) and \(1 \in C(S^{m-1}, d^{m-1})\), the function \((m^{-1}T)^x\) is a distribution on \((S^{m-1}, d^{m-1})\) in the sense of Definition \[5.2.1\]. We have verified the conditions in Definition \[11.2.1\] for \(m^{-1}T\) to be a transition distribution. Assertion 2 is proved. \(\square\)

### 11.3 Markov Semigroup

Recall that \(Q\) denotes one of the three parameter sets \(\{0, 1, \cdots, \bar{\Omega}_m\}\), or \([0, \infty)\).

Yuen-Kwok Chan 424 Constructive Probability
Definition 11.3.1. (Markov semigroup). Let \((S,d)\) be a compact metric space with \(d \leq 1\). Unless otherwise specified, the symbol \(\|\cdot\|\) will stand for the supremum norm for the space \(C(S,d)\). Let \(T \equiv \{T_t : t \in Q\}\) be a family of transition distributions from \((S,d)\) to \((S,d)\), such that \(T_0\) is the identity mapping. Suppose the following three conditions are satisfied.

1. (Smoothness). For each \(N \geq 1\), for each \(t \in [0,N]Q\), the transition distribution \(T_t\) has some modulus of smoothness \(\alpha_{T,N}\), in the sense of Definition 11.2.1. Note that the modulus of smoothness \(\alpha_{T,N}\) is dependent on the finite interval \([0,N]\), but is otherwise independent of \(t\).

2. (Semigroup property). For each \(s,t \in Q\), we have \(T_{t+s} = T_t T_s\).

3. (Strong continuity). For each \(f \in C(S,d)\) with a modulus of continuity \(\delta_f\) and with \(\|f\| \leq 1\), and for each \(\varepsilon > 0\), there exists \(\delta_T(\varepsilon,\delta_f) > 0\) so small that, for each \(t \in [0,\delta_T(\varepsilon,\delta_f)]Q\), we have

\[
\|f - T_tf\| \leq \varepsilon. \tag{11.3.1}
\]

Note that this strong continuity condition is trivially satisfied if \(Q = \{0,1,\cdots\}\).

Then we call the family \(T\) a Markov semigroup of transition distributions with state space \((S,d)\) and parameter space \(Q\). For abbreviation, we will simply call \(T\) a semigroup. The operation \(\delta_T\) is called a modulus of strong continuity of \(T\). The sequence \(\alpha_T \equiv (\alpha_{T,N})_{N=1,2,\cdots}\) is called the modulus of smoothness of the semigroup \(T\). \(\square\)

Remark 11.3.2. (No loss of generally in restricting state space to compact space). Even though we have defined transition distributions and Markov semigroups only for compact metric spaces \((S,d)\) with \(d \leq 1\), there is no loss of generality because a locally compact metric space \((S_00,d_00)\) can be embedded into its one-point compactification \((S,d) \equiv (S_00 \cup \{\Delta_00\},d_00)\) where \(\Delta_00\) is the point at infinity, and where \(\Delta_00 \leq 1\). The assumption of compactness simplifies proofs.

The next lemma strengthens the continuity of \(T_t\) at \(t = 0\) to uniform continuity over \(t \in Q\). Its proof is somewhat longer than its one-lined classical counterpart.

Lemma 11.3.3. (Uniform strong continuity on the parameter set). Suppose \(Q\) is one of the three parameter sets \([0,1,\cdots]\), \([0,\infty]\), or \([0,\infty]\). Let \(T\) be an arbitrary semigroup with parameter set \(Q\), and with a modulus of strong continuity \(\delta_T\). Let \(f \in C(S,d)\) be arbitrary, with a modulus of continuity \(\delta_f\), and with \(\|f\| \leq 1\). Let \(\varepsilon > 0\) and \(r,s \in Q\) be arbitrary with \(|r - s| < \delta_T(\varepsilon,\delta_f)\). Then \(\|T_rf - T_sf\| \leq \varepsilon\).

Proof. 1. The case where \(Q = \{0,1,\cdots\}\) is trivial.

2. Suppose \(Q = [0,\infty]\) or \([0,\infty]\). Let \(\varepsilon > 0\) and \(r,s \in Q\) be arbitrary with \(0 \leq s - r < \delta_T(\varepsilon,\delta_f)\). Then, for each \(x \in S\), we have

\[
\|T_rf - T_sf\| = \|T_r^s(T_{s-r}f - f)\| \leq \|T_{s-r}f - f\| \leq \varepsilon,
\]

where the equality is by the semigroup property, where the first inequality is because \(T_r^s\) is a distribution on \((S,d)\), and where the last inequality is by the definition of \(\delta_T\) as a modulus of strong continuity. Thus

\[
\|T_rf - T_sf\| \leq \varepsilon. \tag{11.3.2}
\]
3. Let \( \varepsilon > 0 \) and \( r, s \in \Omega_\infty \) be arbitrary with \(|s - r| < \delta_T(\varepsilon, \delta_f)\). Either \( 0 \leq s - r < \delta_T(\varepsilon, \delta_f) \), in which case inequality \(\text{[11.3.2]}\) holds according to Step 2, or \( 0 \leq r - s < \delta_T(\varepsilon, \delta_f) \), in which case inequality \(\text{[11.3.2]}\) holds similarly. Thus the lemma is proved if \( Q = \overline{\Omega}_\infty \).

4. Now suppose \( Q = [0, \infty) \). Let \( \varepsilon > 0 \) and \( r, s \in [0, \infty) \) be arbitrary with \(|r - s| < \delta_T(\varepsilon, \delta_f)\). Let \( \varepsilon' > 0 \) be arbitrary. Let \( t, \nu \in \overline{\Omega}_\infty \) be arbitrary such that (i) \( r \leq t < r + \delta_T(\varepsilon', \delta_f) \), (ii) \( s \leq \nu < s + \delta_T(\varepsilon', \delta_f) \) and (iii) \( |t - \nu| < \delta_T(\varepsilon, \delta_f) \). Then, according to inequality \(\text{[11.3.2]}\) in Step 2, we have \( \|T_t f - T_\nu f\| \leq \varepsilon' \), \( \|T_t f - T_r f\| \leq \varepsilon' \). According to Step 3, we have \( \|T_t f - T_r f\| \leq \varepsilon \). Combining, we obtain

\[
\|T_t f - T_r f\| \leq \|T_t f - T_\nu f\| + \|T_\nu f - T_r f\| < \varepsilon' + \varepsilon' + \varepsilon.
\]

Letting \( \varepsilon' \to 0 \), we obtain \( \|T_t f - T_r f\| \leq \varepsilon \). Thus the lemma is also proved for the case where \( Q = [0, \infty) \).

\[\Box\]

11.4 Markov Transition f.j.d.’s

In this section, we will define consistent family of f.j.d.’s generated by an initial distribution and a semigroup. The parameter set \( Q \) is assumed to be one of the three sets \( \{0, 1, \cdots\}, \Omega_\infty, \text{or} [0, \infty) \). We will refer informally to the first two as the discrete parameter sets. The state space \((S, d)\) is assumed to be compact with \( d \leq 1 \). Let \( \xi \equiv (A_k)_{k=1,2,\cdots} \) be a binary approximation of \((S, d)\) relative to \( x_0 \). Let

\[
\pi \equiv \{ (g_{k,x} : x \in A_k) \}_{k=1,2,\cdots}
\]

be the partition of unity of \((S, d)\) determined by \( \xi \), as in Definition \(\text{[3.2.4]}\).

**Definition 11.4.1. (Family of transition f.j.d.’s generated by an initial distribution and a Markov semigroup).** Let \( Q \) be one of the three sets \( \{0, 1, \cdots\}, \Omega_\infty, \text{or} [0, \infty) \). Let \( T \) be an arbitrary Markov semigroup, with the compact state space \((S, d)\) where \( d \leq 1 \), and with parameter set \( Q \). Let \( E_0 \) be an arbitrary distribution on \((S, d)\). For arbitrary \( m \geq 1, f \in C(S^m, d^m) \), and nondecreasing sequence \( r_1 \leq \cdots \leq r_m \) in \( Q \), define

\[
F_{r(1),\cdots,r(m)}^E(0:T) f = \int E_0(dx_0) \int T_{r(1)}^x(dx_1) \int T_{r(2) - r(1)}^x(dx_2) \cdots \int T_{r(m) - r(m-1)}^x(dx_m) f(x_1,\cdots,x_m).
\]

(11.4.1)

In the special case where \( E_0 = \delta_{x_0} \) is the distribution which assigns probability 1 to some point \( x \in S \), we will simply write

\[
F_{r(1),\cdots,r(m)}^x(T) = \int \delta_{x_0}(x) \int F_{r(1),\cdots,r(m)}^x(T) = F_{r(1),\cdots,r(m)}^x(T).
\]

The next theorem will prove that \( F_{r(1),\cdots,r(m)}^E(T) : C(S^m, d^m) \to C(S, d) \) is then a well-defined transition distribution.
An arbitrary consistent family
\[
\{F_{r(1),\ldots,r(m)}f : m \geq 0; r_1, \ldots, r_m \in Q\}
\]
of f.j.d.’s satisfying Condition [11.4.3] is said to be generated by the initial distribution \(E_0\) and the semigroup \(T\).

A process
\[
X : Q \times (\Omega, L, E) \to (S, d),
\]
whose marginal distributions are given by a consistent family generated by the initial distribution \(E_0\) and the semigroup \(T\), will be called a process generated by the initial distribution \(E_0\) and semigroup \(T\). We will see later that such processes are Markov processes.

\[\square\]

**Theorem 11.4.2.** (Construction of family of transition f.j.d.’s from initial distribution and semigroup, for discrete parameters). Let \((S, d)\) be a compact metric space with \(d \leq 1\). Let \(Q\) be one of the three sets \(\{0, 1, \cdots\}, \overline{Q}_{\infty}\), or \([0, \infty)\). Let \(T\) be an arbitrary semigroup with state space \((S, d)\) and with parameter set \(Q\), and with a modulus of strong continuity \(\delta_T\) and with a modulus of smoothness \(\alpha_T \equiv (\alpha_{T,N})_{N=1,2,\cdots}\) in the sense of Definition [11.3.2]. Let \(E_0\) be an arbitrary distribution on \((S, d)\). Then the following holds.

1. For each \(m \geq 1\) and for each nondecreasing sequence \(r_1 \leq \cdots \leq r_m \in [0,N]Q\), the function
\[
F^{+T}_{r(1),\ldots,r(m)} : C(S^m,d^m) \to C(S,d),
\]
in Definition [11.4.1] is a well-defined transition distribution. More precisely, if \(f \in C(S^m,d^m)\) has values in \([0,1]\) and has modulus of continuity \(\delta_f\), then the function \(F^{+T}_{r(1),\ldots,r(m)}f\) is a member of \(C(S,d)\), with values in \([0,1]\) and with a modulus of continuity \(\tilde{\alpha}^{(m)}_{\alpha(T,N),\xi}(\delta_f)\), where the operation \(\tilde{\alpha}^{(m)}_{\alpha(T,N),\xi}\) is the \(m\)-fold composite product operation
\[
\tilde{\alpha}^{(m)}_{\alpha(T,N),\xi} \equiv \alpha_{\alpha(T,N),\xi} \circ \cdots \circ \alpha_{\alpha(T,N),\xi},
\]
where each factor on the right-hand side is as defined in Lemma [11.2.3].

2. For each \(m \geq 1\) and \(\varepsilon > 0\) there exists \(\delta_m(\varepsilon, \tilde{\alpha}_f, \tilde{\alpha}_T, \alpha_T) > 0\) such that, for arbitrary \(f \in C(S^m,d^m)\) with values in \([0,1]\) and with modulus of continuity \(\delta_f\), and for arbitrary nondecreasing sequences \(r_1 \leq \cdots \leq r_m\) and \(s_1 \leq \cdots \leq s_m\) in \(Q\) with \(\forall m \geq 1 \mid r_i - s_i \mid < \delta_m(\varepsilon, \tilde{\alpha}_f, \tilde{\alpha}_T, \alpha_T)\), we have
\[
\left\| F^{+T}_{r(1),\ldots,r(m)}f - F^{+T}_{s(1),\ldots,s(m)}f \right\| \leq \varepsilon.
\]

3. In the special case where \(Q = \{0, 1, \cdots\}\) or \(Q = \overline{Q}_{\infty}\), the family
\[
F^{E(0),T} \equiv \{F^{E(0),T}_{r(1),\ldots,r(m)}f : m \geq 1; r_1, \ldots, r_m \in Q\}
\]
can be uniquely extended to a consistent family
\[
\Phi_{S,\text{fjd}}(E_0, T) \equiv F^{E(0),T} \equiv \{F^{E(0),T}_{r(1),\ldots,r(m)}f : m \geq 1; r_1, \ldots, r_m \in Q\}
\]
CHAPTER 11. MARKOV PROCESS

of f.j.d.’s with parameter set \( Q \) and state space \( (S,d) \). Moreover, the consistent family \( \Phi_{Sg,fjd}(E_0,T) \) is generated by the initial distribution \( E_0 \) and the semigroup \( T \), in the sense of Definition 11.4.1. Thus, in the special case where \( Q = \{0,1,\cdots\} \) or \( Q = \overline{Q}_\infty \), we have a mapping

\[
\Phi_{Sg,fjd} : \tilde{J}(S,d) \times \mathcal{S} \to \tilde{F}(Q,S),
\]

where \( \tilde{J}(S,d) \) is the space of distributions \( E_0 \) on \( (S,d) \), where \( \mathcal{S} \) is the space of semigroups with state space \( (S,d) \) and with parameter set \( Q \), and where \( \tilde{F}(Q,S) \) is the set of consistent families of f.j.d.’s with parameter set \( Q \) and state space \( S \).

4. In the special case where \( E_0 = \delta_x \) for some \( x \in S \), we simply write

\[
\Phi_{Sg,fjd}(x,T) \equiv \Phi_{Sg,fjd}(\delta_x,T) \equiv F^xT.
\]

Then we have a function

\[
\Phi_{Sg,fjd} : S \times \mathcal{S} \to \tilde{F}(Q,S).
\]

5. Let \( m \geq 1 \) and let the sequence \( 0 \equiv r_0 \leq r_1 \leq \cdots \leq r_m \) in \( Q \) be arbitrary. Then we have

\[
F^{x,T}_{r(1),\cdots,r(m)} = \int T^{x(0)}_{r(1)}(dx_1) \int T^{x(1)}_{r(2)-r(1)}(dx_2) \cdots \int T^{x(m-1)}_{r(m)-r(m-1)}(dx_m) f(x_1,\cdots,x_m), \quad (11.4.3)
\]

for each \( x \in S \).

**Proof.** 1. Let \( N \geq 0, m \geq 1 \) and let the sequence \( 0 \equiv r_0 \leq r_1 \leq \cdots \leq r_m \) in \( Q[0,N] \) be arbitrary. By the defining equality 11.4.1, we have

\[
F^{E(0),T}_{r(1),\cdots,r(m)} f
\]

\[
= \int E_0(dx_0) \int T^{x(0)}_{r(1)}(dx_1) \int T^{x(1)}_{r(2)-r(1)}(dx_2) \cdots \int T^{x(m-1)}_{r(m)-r(m-1)}(dx_m) f(x_1,\cdots,x_m). \quad (11.4.4)
\]

By the defining equality 11.2.5 of Lemma 11.2.5, the right-most integral is equal to

\[
\int T^{x(m-1)}_{r(m)-r(m-1)}(dx_m) f(x_1,\cdots,x_m,1_x) \equiv (T^{x(m-1)}_{r(m)-r(m-1)} f)(x_1,\cdots,x_m,1_x). \quad (11.4.5)
\]

Recursively backward, we obtain

\[
F^{E(0),T}_{r(1),\cdots,r(m)} f = \int E_0(dx_0) (T^{r(1)-r(0)} f) \cdots (T^{r(m)-r(m-1)} f).
\]

In particular,

\[
F^{x,T}_{r(1),\cdots,r(m)} f = (T^{r(1)-r(0)} f) \cdots (T^{r(m)-r(m-1)} f).
\]
for each \( x \in S \). In other words,
\[
F_{r(1), \ldots, r(m)}^T x = (1_{T_r(1) = r(0)}) (2_{T_r(2) = r(1)}) \cdots (m_{T_r(m) = r(m-1)}).
\] (11.4.6)

This proves Assertion 5 of the present Theorem.

2. Now Lemma 8.2.3 says the factors \((1_{T_r(1) = r(0)}), (2_{T_r(2) = r(1)}) \cdots, (m_{T_r(m) = r(m-1)})\)
on the right-hand side are transition distributions with the modulus of smoothness \( \alpha_{\alpha(T,N), \xi} \).
Hence the composite \( F_{r(1), \ldots, r(m)}^T \) is a composite transition distribution, according to repeated applications of Lemma 11.2.2, with the modulus of smoothness which is the \( m \)-fold composite operation
\[
\tilde{\alpha}_{\alpha(T,N), \xi}^{(m)} = \tilde{\alpha}_{\alpha(T,N), \xi} \circ \cdots \circ \tilde{\alpha}_{\alpha(T,N), \xi}.
\]

This proves Assertion 1 of the present theorem.

3. Proceed to prove Assertion 2 by induction on \( m \). In the case where \( m = 1 \), define
\[
\delta_1 = \delta_0(\varepsilon, \delta_f, \delta_T, \alpha_T) \equiv \delta_T(\varepsilon, \delta_f).
\]
Suppose \( r_1, s_1 \) in \( Q \) are such that
\[
|r_1 - s_1| < \delta_1(\varepsilon, \delta_f, \delta_T, \alpha_T) \equiv \delta_T(\varepsilon, \delta_f).
\]
Then
\[
\left\| F_{r(1)}^T f - F_{s(1)}^T f \right\| = \left\| 1_{T_r(1) = r(0)} f - 1_{T_s(1) = s(0)} f \right\| = \left\| T_r(1) f - T_s(1) f \right\| \leq \varepsilon
\]
where the inequality is by Lemma 11.3.3. Assertion 2 is thus proved for the starting case \( m = 1 \).

4. Suppose it has been proved for \( m - 1 \) for some \( m \geq 2 \), and the operation
\[
\delta_{m-1}(-, \delta_f, \delta_T, \alpha_T)
\]
has been constructed with the desired properties. Let \( f \in C(S^m, d^m) \) be arbitrary with values in \([0, 1]\) and with modulus of continuity \( \delta_f \). Define
\[
\delta_m(\varepsilon, \delta_f, \delta_T, \alpha_T) \equiv 2^{-1} \delta_{m-1}(2^{-1} \varepsilon, \delta_f, \delta_T, \alpha_T) \wedge \delta_m(\varepsilon, \delta_f, \delta_T, \alpha_T)
\] (11.4.7)
Suppose
\[
\bigvee_{i=1}^m |r_i - s_i| < \delta_m(\varepsilon, \delta_f, \delta_T, \alpha_T).
\] (11.4.8)

Define the function
\[
h \equiv (2_{T_r(2) = r(1)}) \cdots (m_{T_r(m) = r(m-1)}) f \in C(S, d).
\] (11.4.9)
Then, by the induction hypothesis for \((m - 1)\)-fold composite, the function \( h \) has modulus of continuity \( \delta_1(-, \delta_f, \delta_T, \alpha_T) \). We emphasize here that, as \( m \geq 2 \), the modulus of smoothness of the one-step transition distribution \( 2_{T_r(2) = r(1)} \), on the right-hand side of equality (11.4.9) actually depends on the modulus \( \alpha_T \), according to Lemma 11.2.3.
Hence the modulus of continuity of function \( h \) indeed depends on \( \alpha_T \), which justifies the notation.

Yuen-Kwok Chan 429 Constructive Probability
At the same time, inequality [11.4.8] and the defining equality [11.4.7] together imply that
\[ |r_1 - s_1| < \delta_m(\varepsilon, \delta_f, \delta_T, \alpha_T) \leq \cdots \leq \delta_1(\varepsilon, \delta_f, \delta_T, \alpha_T). \]

Hence
\[ \left\| (1^{T}(r_1) - r(0))h - (1^{T}(s_1) - s(0))h \right\| = \left\| F_{r(1)}^{s}h - F_{s(1)}^{s}h \right\| \leq 2^{-1}\varepsilon, \tag{11.4.10} \]

where the inequality is by the induction hypothesis for the starting case where \( m = 1 \).

5. Similarly, inequality [11.4.8] and the defining equality [11.4.7] together imply that
\[ \bigvee_{i=2}^{m} |(r_i - r_{i-1}) - (s_i - s_{i-1})| \leq 2\sqrt{m} |(r_i - s_i| < \delta_{m-1}(2^{-1}\varepsilon, \delta_f, \delta_T, \alpha_T). \]

Hence
\[ \left\| (2^{T}(r_2) - r(1)) \cdots (m^{T}(r(m) - r(m-1))f - (2^{T}(s_2) - s(1)) \cdots (m^{T}(s(m) - s(m-1))f \right\|
\[ \equiv \left\| F_{r(2), \cdots, r(m)}^{s} - F_{s(2), \cdots, r(m)}^{s} \right\| \leq 2^{-1}\varepsilon, \tag{11.4.11} \]

where the inequality is by the induction hypothesis for the case where \( m = 1 \).

5. Combining, we estimate, for each \( x \in S \), the bound
\[ \left| F_{r(1), \cdots, r(m)}^{s} - F_{s(1), \cdots, r(m)}^{s} \right|
\[ = \left| (1^{T}(r_1) - r(0))\cdots (m^{T}(r(m) - r(m-1))f - (1^{T}(s_1) - s(0))\cdots (m^{T}(s(m) - s(m-1))f \right|
\[ \equiv \left| (1^{T}(r_1) - r(0))\cdots (m^{T}(s(m) - s(m-1))f \right|
\[ \leq 2^{-1}\varepsilon + |(1^{T}(s_1) - s(0))\cdots (m^{T}(s(m) - s(m-1))f \right|
\[ \leq 2^{-1}\varepsilon + |(2^{T}(s_2) - s(1))\cdots (m^{T}(s(m) - s(m-1))f \right|
\[ < 2^{-1}\varepsilon + 2^{-1}\varepsilon = \varepsilon, \]

where the second inequality is by inequality [11.4.10] and where the last inequality is by inequality [11.4.11]. Since \( x \in S \) is arbitrary, it follows that
\[ \left\| F_{r(1), \cdots, r(m)}^{s} - F_{s(1), \cdots, r(m)}^{s} \right\| \leq \varepsilon. \]

Induction is completed, and Assertion 2 is proved.

6. We still need to prove Assertion 3. In other words, assuming that \( Q = \{0, 1, \cdots \} \) or \( Q = \overline{Q}_{m} \), we need to prove that the family
\[ \{ F_{r(1), \cdots, r(m)}^{E(0)}, m \geq 1; r_1, \cdots, r_m \in Q; r_1 \leq \cdots \leq r_m \} \]

Yuen-Kwok Chan 430 Constructive Probability
can be uniquely extended to a consistent family
\[ \{ F^{E(0)}_{s(1), \ldots, s(m)} : m \geq 1; s_1, \ldots, s_m \in Q \} \]
of f.j.d.'s with parameter set \( Q \). We will give the proof only for case where \( Q = \overline{Q}_m \), the case of \( \{0, 1, \cdots\} \) being similar. So assume in the following that \( Q = \overline{Q}_m \).

7. Because \( F^{E(0)}_{r(1), \ldots, r(m)} \) is a transition distribution, Proposition 11.2.3 says that the composite function
\[ F^{E(0)}_{r(1), \ldots, r(m)} = E_0 F^{E(0)}_{r(1), \ldots, r(m)} = E_0 (T_{r(1)-r(0)}(T_{r(2)-r(1)}) \cdots (T_{r(m)-r(m-1)}). \]
is a distribution on \( (S^m, d^m) \), for each \( m \geq 1 \), and for each sequence \( 0 \equiv r_0 \leq r_1 \leq \cdots \leq r_m \) in \( \overline{Q}_m \) is arbitrary.

8. To proceed, let \( m \geq 2 \) and \( r_1, \ldots, r_m \in \overline{Q}_m \) be arbitrary, with \( r_1 \leq \cdots \leq r_m \). Let \( n = 1, \ldots, m \) be arbitrary. Define the sequence
\[ \kappa \equiv \kappa_{n,m} \equiv (\kappa_1, \ldots, \kappa_{m-1}) \equiv (1, \ldots, r, \ldots, m), \]
where the caret on the top of an element in a sequence signifies the omission of that element in the sequence. Let \( \kappa^* \equiv \kappa^*_{m,n} : S^m \to S^{m-1} \) denote the dual function of the sequence \( \kappa \), defined by
\[ \kappa^*(x_1, \ldots, x_m) \equiv \kappa^*(x) \equiv \kappa \circ \kappa = (x_{\kappa(1)}, \ldots, x_{\kappa(m-1)}) = (x_1, \ldots, \widehat{x_r}, \ldots, x_m) \]
for each \( x \equiv (x_1, \ldots, x_m) \in S^m \). Let \( f \in C(S^{m-1}) \) be arbitrary. We will prove that
\[ F^{E(0)}_{r(1), \ldots, r(m)} f = F^{E(0)}_{r(1), \ldots, r(m)} f \circ \kappa^*_{n,m}. \]

To that end, note that equality 11.4.4 yields
\[ F^{E(0)}_{r(1), \ldots, r(m)} f \]
\[ \equiv \int E_0(dx_0) \int T_{r(1)}^{x(0)}(dx_1) \cdots \int T_{r(n)}^{x(n-1)}(dy_n) \{ \int T_{r(n+1)-r(n)}^{y(n)}(dy_{n+1}) \cdots \int T_{r(m)-r(m-1)}^{y(m-2)}(dy_{m-1}) f(x_1, \ldots, x_{n-1}, y_n, \ldots, y_{m-1}) \} \]
For each fixed \( (x_1, \ldots, x_{n-1}) \), the expression in braces is a continuous function of the one variable \( y_n \). Call this function \( g_{x(1), \ldots, x(n-1)} \in C(S, d) \). Then the last displayed equality can be continued as
\[ \equiv \int E_0(dx_0) \int T_{r(1)}^{x(0)}(dx_1) \cdots ( \int T_{r(n+1)-r(n-1)}^{x(n-1)}(dy_n) g_{x(1), \ldots, x(n-1)}(y_n) ) \]
\[ = \int E_0(dx_0) \int T_{r(1)}^{x(0)}(dx_1) \cdots ( \int T_{r(n+1)-r(n-1)}^{x(n-1)}(dy_n) \int T_{r(n+1)-r(n)}^{x(n)}(dy_n) g_{x(1), \ldots, x(n-1)}(y_n) ) \]
Theorem 11.5.1. (Construction of Markov Process with initial distribution and a distribution. First the discrete parameters. In this section, we construct Markov processes from a Markov semigroup and an initial semigroup, assuming discrete parameters.)

Thus equality [11.4.1] has been proved for the family

$$\{F^{E(0)}_{r_1, \ldots, r_m} : m \geq 1; s_1, \ldots, s_m \in Q; r_1 \leq \cdots \leq r_m \}$$

of f.j.d.'s. Consequently, the conditions in Lemma [6.2.3] are satisfied, to yield a unique extension of this family to a consistent family

$$\{F^{E(0)}_{s_1, \ldots, s_m} : m \geq 0; s_0, \ldots, s_m \in Q \}$$

of f.j.d.'s with parameter set $Q$. Equality [11.4.4] says that $F^{E(0)}_{r_1, \ldots, r_m}$ is generated by the initial distribution $E_0$ and the semigroup $T$. Assertion 3 is proved. 

\[\square\]

11.5 Construction of Markov Process from Semigroup

In this section, we construct Markov processes from a Markov semigroup and an initial distribution. First the discrete parameters.

Theorem 11.5.1. (Construction of Markov Process with initial distribution and a semigroup, assuming discrete parameters). Let $(S, d)$ be a compact metric space with $d \leq 1$. Suppose $Q$ is one of the two parameter sets $\{0, 1, \cdots \}$ or $\overline{Q}_\infty$. Let

$$\langle \Theta_0, L_0, L_0 \rangle \equiv ([0, 1], L_0, \int \cdot dx)$$

denote the Lebesgue integration space based on the unit interval $\Theta_0$.

Yuen-Kwok Chan 432 Constructive Probability
Let $E_0$ be an arbitrary initial distribution on $(S, d)$, and let $T = \{T_t : t \in Q\}$ be an arbitrary Markov semigroup with state space $(S, d)$, with a modulus of strong continuity $\delta_T$. Let

$$F^{E(0), T} = \Phi_{S\delta, fjd}(E_0, T)$$

be the corresponding consistent family of f.j.d.'s constructed in Theorem [11.4.2]. Let

$$Z^{E(0), T} = \Phi_{DKS, \xi}(F^{E(0), T}) : Q \times \Theta_0 \to S$$

be the Compact Daniell-Kolmogorov-Skorokhod Extension of the consistent family $F^{E(0), T}$, as constructed in Theorem [11.4.2].

Then the following holds.

1. The process $Z^{E(0), T}$ is generated by the initial distribution $E_0$ and semigroup $T$, in the sense of Definition [11.4.7].

2. The process $Z = Z^{E(0), T}$ is a Markov process relative to its natural filtration $\mathcal{F} \equiv \{L(t) : t \in Q\}$. More precisely, let $t \in Q$ be arbitrary, and define

$$L(t) = L(Z^{E(0), T}_0, \cdots, Z^{E(0), T}_m) : s \in [0, t]Q \subset L_0.$$ 

Let the nondecreasing sequence $0 \equiv s_0 \leq s_1 \leq \cdots \leq s_m$ in $Q$, the function $f \in C(S^{m+1}, d^{m+1})$, and $t \in Q$ be arbitrary. Then

$$I_0(f(Z_{t+s_0}, Z_{t+s_1}, \cdots, Z_{t+s_m})|L(t)) = I_0(f(Z_{t+s_0}, \cdots, Z_{t+s_m})|Z_t) = F^{E(0), T}_{s_0, \cdots, s_m}(f)$$

as r.v.'s, where $F^{E(0), T}_{s_0, \cdots, s_m}$ is the transition distribution in Definition [11.4.7].

3. The process $Z^{E(0), T}$ is continuous in probability, with a modulus of continuity in probability $\delta_T$ which is completely determined by $\delta_T$.

Proof. 1. Let $t \in Q$ be arbitrary. Let $0 \equiv n_0 \leq n_1 \leq \cdots \leq n_m \equiv t$ and $0 \equiv s_0 \leq s_1 \leq \cdots \leq s_m$ be arbitrary sequences in $Q$. Write $r_{n+j} \equiv t + s_j$ for each $j = 0, \cdots, m$. Thus $s_j = r_{n+j} - r_n$ for each $j = 0, \cdots, m$. Consider each $f \in C(S^{m+1}, d^{m+1})$. Let $h \in C(S^{n+1}, S^{n+1})$ be arbitrary. Then, since the process $Z = Z^{E(0), T} = \Phi_{DKS, \xi}(F^{E(0), T})$ has marginal distributions given by the family $F^{E(0), T}$, we have

$$I_0 h(Z_{r_0}, \cdots, Z_{r_m}) f(Z_{r_m}, \cdots, Z_{r_m+1})$$

$$= \int F^{E(0), T}_{r_0, \cdots, r_m}(d(x_0, \cdots, x_{n+m}) h(x_0, \cdots, x_n) f(x_n, \cdots, x_{n+m})$$

$$= \int E_0(dx_0) \int T_{r_1-1}(d(x_1)) \int T_{r_2-2}(d(x_2)) \cdots \int T_{r_{n+m-1}-1}(d(x_{n+m}) h(x_1, \cdots, x_n) f(x_n, \cdots, x_{n+m})$$

$$= \int E_0(dx_0) \int T_{r_1-1}(d(x_1)) \int T_{r_2-2}(d(x_2)) \cdots \int T_{r_{n+m-1}-1}(d(x_{n+m}) h(x_1, \cdots, x_n) f(x_n, \cdots, x_{n+m}) \cdots \int T_{r_{n+m-1}}(d(x_{n+m})) f(x_n, x_{n+1}, \cdots, x_{n+m})$$

(11.5.2)
CHAPTER 11. MARKOV PROCESS

The term inside the braces in the last expression is, by changing the names of the dummy integration variables, equal to

\[
\int T_{x(t+1)}^{r(2)}(dy_1) \int T_{x(t+2)}^{r(3)}(dy_2) \cdots \int T_{x(t+n)}^{r(n+1)}(dy_n) f(x_n, y_1, \ldots, y_m)
\]

\[
= \int T_x^{r(1)}(dy_0) \int T_{s(1)}^{r(2)}(dy_2) \cdots \int T_{s(n)}^{r(n+1)}(dy_n) f(x_n, y_1, \ldots, y_m)
\]

\[
= F_s^{r(1)}, \ldots, s(n) f.
\]

Substituting back into equality \[11.5.2\] we obtain

\[
I_0 h(Z_{r(0)}, \ldots, Z_{r(n)}) f(Z_{r(n)}, \ldots, Z_{r(n+m)})
\]

\[
= \int E_0(dx_0) \int T_{x(0)}^{r(1)}(dx_1) \int T_{x(1)}^{r(2)}(dx_2) \cdots \int T_{x(t)}^{r(n)}(dx_n) f(Z_s^{r(n)}, T) f.
\]

\[
= I_0 h(Z_{r(0)}, \ldots, Z_{r(n)}) f(Z_s^{r(n)}, T).
\]

where \(F_s^{r(1)}, \ldots, s(n) f \in C(S, d)\) because \(F_s^{r(1)}, \ldots, s(n) f\) is a transition distribution according to Theorem 11.4.2.

2. Next note that the set of r.v.'s \(h(Z_{r(0)}, \ldots, Z_{r(n)})\), with arbitrary \(0 \leq r_0 \leq r_1 \leq \cdots \leq r_n \equiv t\) and arbitrary \(h \in C(S^{n+1}, d^{n+1})\), is dense in \(L^1\) relative to the norm \(I_0 |·|\). Hence equality \[11.5.3\] implies, by continuity relative to the norm \(I_0 |·|\), that

\[
I_0 Y f(Z_{r(0)}, \ldots, Z_{r(n+m)}) = I_0 Y F_s^{r(n), T} f
\]

for each \(Y \in L^1\). It follows that

\[
I_0 (f(Z_{r(0)}, \ldots, Z_{r(n+m)})|L^1) = F_s^{r(n), T} f
\]

or, equivalently,

\[
I_0 (f(Z_t, Z_{t+s(1)}, \ldots, Z_{t+s(n)})|L^1) = F_s^{r(n), T} f.
\]

In the special case where \(Y\) is arbitrary in \(L(Z_t) \subset L^1\), inequality \[11.5.4\] holds, whence

\[
I_0 (f(Z_t, Z_{t+s(1)}, \ldots, Z_{t+s(n)})|Z_t) = F_s^{r(n), T} f.
\]

Equalities \[11.5.6\] and \[11.5.7\] together prove Assertions 1 and 2.

2. It remains to prove that the process \(Z\) is continuous in probability. We need only give the proof in the case where \(Q = \mathbb{T}\), the case where \(Q = \{0, 1, \ldots\}\) being trivial.

To that end, recall that \(d \leq 1\). Consider each \(x \in S\). Then the function \(f = 1 - d(\cdot, x) \in C(S, d)\) has a modulus of continuity \(\delta_f\) defined by \(\delta_f(\varepsilon) \equiv t(\varepsilon) \equiv \varepsilon\) for each \(\varepsilon > 0\).

Now let \(\varepsilon > 0\) be arbitrary. Let \(t \in \mathbb{T}\) be arbitrary with

\[
t < \delta_{\phi_t, \phi_t} \equiv \delta_t(\varepsilon, t) \equiv \delta_t(\varepsilon, \delta_f).
\]

Yuen-Kwok Chan 434 Constructive Probability
Then, by Lemma 11.3.3 we have
\[ |d(\cdot, x) - T_t d(\cdot, x)| = |f - T_t f| \leq \varepsilon, \tag{11.5.8} \]
where \( x \in S \) is arbitrary. Now let \( r_1, r_2 \in \mathcal{Q} \) be arbitrary with \( |r_2 - r_1| < \delta_{Cp}(\varepsilon) \). Then
\[
I_0 d(Z_{r_1(1)}, Z_{r_2(2)}) = I_0 d(Z_{r_1(1) \lor r_2(2)}, Z_{r_2(1) \lor r_2(2)}) = F_{0, r_1(1) \lor r_2(2), r_1(1) \lor r_2(2)}^{E(0)} \cdot d
\]
\[
= \int E_0(\cdot | x_0) \int T_{r_1(1) \lor r_2(2)}(d x_1) \int T_{r_2(1) \lor r_2(2)}(d x_2) d(x_1, x_2)
\]
\[
= \int E_0(\cdot | x_0) \int T_{r_1(1) \lor r_2(2)}(d x_1) \int T_{r_2(1) \lor r_2(2)}(d x_2) d(x_1, x_2)
\]
\[
\leq \int E_0(\cdot | x_0) \int T_{r_1(1) \lor r_2(2)}(d x_1) (d(x_1, x_1) + \varepsilon)
\]
\[
= \int E_0(\cdot | x_0) \int T_{r_1(1) \lor r_2(2)}(d x_1) \varepsilon = \varepsilon,
\]
where the inequality is by applying inequality 11.5.8 to \( t \equiv |r_2 - r_1| \) and \( x = x_0 \). Thus we have shown that \( \delta_{Cp, \delta(T)} \equiv \delta_T(\cdot, t) \) is a modulus of continuity in probability for the process \( Z \), according to Definition 6.1.3. Note here that \( \delta_{Cp, \delta(T)} \) is an operation dependent only on \( \delta_T \). Assertion 3 is proved.

The next proposition says that each Markov process \( Z : \mathcal{Q}_\infty \times (\Omega, L, E) \rightarrow (S,d) \) with a semigroup can be extended by right limit to an a.u. càdlàg process \( X : [0, \infty) \times (\Omega, L, E) \rightarrow (S,d) \).

**Proposition 11.5.2. (Process with semigroup on dyadic rationals is \( D \)-regular, extendable to time-uniformly a.u. càdlàg process).** Let \( (S,d) \) be a compact metric space with \( d \leq 1 \). Suppose \( Q = \mathcal{Q}_\infty \). Let \( E_0 \) be an arbitrary initial distribution on \( (S,d) \), and let \( T \equiv \{ T : t \in \mathcal{Q}_\infty \} \) be an arbitrary Markov semigroup with state space \( (S,d) \) and with a modulus of strong continuity \( \delta_T \). Let
\[
Z : \mathcal{Q}_\infty \times (\Omega, L, E) \rightarrow (S,d)
\]
be an arbitrary process generated by the initial distribution \( E_0 \) and semigroup \( T \).

Let \( N \geq 0 \) be arbitrary. Define the shifted process \( Z^N : \mathcal{Q}_\infty \times \Omega \rightarrow S \) by \( Z^N(t, \cdot) \equiv Z(N + t, \cdot) \) for each \( t \in \mathcal{Q}_\infty \). Then the following holds.

1. The process \( Z^N \) is continuous in probability, with a modulus of continuity in probability \( \delta_{Cp, \delta(T)} \equiv \delta_T(\cdot, \delta_T) \) which is completely determined by \( \delta_T \).

2. The process \( Z^N \) is strongly right continuous in probability, in the sense of Definition 10.7.3 with a modulus of strong right continuity in probability given by the operation \( \delta_{SRc, \delta(T)} \) defined by
\[
\delta_{SRc, \delta(T)}(\varepsilon, \gamma) = \delta_{Cp}(\varepsilon^2, \delta_T)
\]
for each \( \varepsilon, \gamma > 0 \). Note that \( \delta_{SRc, \delta(T)}(\varepsilon, \gamma) \) is actually independent of \( \gamma \) or \( N \).
3. The process $Z^N : Q_m \times \Omega \rightarrow S$ is D-regular, with a modulus of D-regularity $\overline{m}_\delta(T) = \overline{m}_\delta'(T)$.
4. The process $Z$ is time-uniformly D-regular in the sense of Definition [10.10.3] with a modulus of continuity in probability $\overline{\delta}_{C_p,\delta}(T) \equiv (\delta_{C_p,\delta}(T), \ldots)$ and with a modulus of D-regularity $\overline{m}_\delta(T) \equiv (\overline{m}_\delta(T), \overline{m}_\delta'(T), \ldots)$.
5. The right-limit extension

$$X \equiv \overline{r}_\text{lim}(Z) : [0, \infty) \times \Omega \rightarrow (S, d)$$

is a time-uniformly a.u. càdlàg process in the sense of Definition [11.5.1] with a modulus of a.u. càdlàg $\overline{\delta}_{\text{aucl}, \delta}(T) \equiv (\overline{\delta}_{\text{aucl}, \delta}(T), \overline{\delta}_{\text{aucl}, \delta}(T), \ldots)$ and with a modulus of continuity in probability $\overline{\delta}_{C_p,\delta}(T)$. Here we recall the function $\overline{r}_\text{lim}$ from Definition [11.5.1].

In other words,

$$X \equiv \overline{r}_\text{lim}(Z) \in \hat{D}(\overline{\delta}_{\text{aucl}, \delta}(T), \overline{\delta}_{C_p,\delta}(T)) \mid [0, \infty).$$

**Proof.** 1. By hypothesis, the process $Z$ has initial distribution $E_0$ and Markov semi-group $T$. In other words, the process $Z$ has marginal distributions given by the consistent family $F^{\mathcal{E}(0)}_{\cdot, T}$ of f.d.'s. as in Definition [11.4.1]. Hence the process $Z$ is equivalent to the process $Z^{E(0)}_{\cdot, T}$ constructed in Theorem [11.5.1]. Therefore, by Assertion 3 of the Theorem [11.5.1], the process $Z$ is continuous in probability, with a modulus of continuity in probability $\overline{\delta}_{C_p,\delta}(T) \equiv \overline{\delta}_{C_p}(\cdot, \overline{\delta}_T)$ which is completely determined by $\overline{\delta}_T$.

2. Hence, trivially, the shifted process

$$Y \equiv Z^N : Q_m \times \Omega \rightarrow S$$

is continuous in probability, with a modulus of continuity in probability $\overline{\delta}_{C_p,\delta}(T) \equiv \overline{\delta}_{C_p}(\cdot, \overline{\delta}_T)$ which is completely determined by $\overline{\delta}_T$. Assertion 1 is proved.

3. To prove Assertion 2, let $\varepsilon, \gamma > 0$ be arbitrary. Define

$$\overline{\delta}_{S^R, \overline{\delta}(T)}(\varepsilon, \gamma) \equiv \overline{\delta}_T(\varepsilon^2, 1)$$

(11.5.9)

where the operation $\cdot$ is defined by $\cdot(\varepsilon') \equiv \varepsilon'$ for each $\varepsilon' > 0$.

Let $h \geq 0$ and $s, r \in Q_h$ be arbitrary with $s \leq r < s + \overline{\delta}_{S^R, \overline{\delta}(T)}(\varepsilon, \gamma)$. Then

$$Q_h = \{0, \Delta_h, 2\Delta_h, \ldots, 1\} \equiv \{q_{h,0}, \ldots, q_{h,p_h}\}$$

where $\Delta = 2^{-h}, p_h = 2^h$, and $q_{h,i} \equiv i\Delta$, for each $i = 0, \ldots, p_h$. Moreover, $s = q_{h,i}$ and $r = q_{h,j}$ for some $i, j = 0, \ldots, p_h$ with $i \leq j$. Now let $g \in C(S^{h+1}, d^{h+1})$ be arbitrary. Then

$$\int E_g(Y_{q_{h,0}}, \ldots, Y_{q_{h,i+1}})d(Y_s, Y_t) = E_g(Y_{q_{h,0}}, \ldots, Y_{q_{h,i}})d(Y_{q_{h,i}}, Y_{q_{h,i+1}})$$

$$= \int E_0(dx_0) \int F^{u(0)}_{s, T} F^{u(0)}_{s, T}(d(x_0, \ldots, x_i, x_j))g(x_0, \ldots, x_i)dx(x_i, x_j)$$

Yuen-Kwok Chan 436 Constructive Probability
where the next-to-last equality is because the family $F^{(0)}_g$ of f.j.d.’s is generated by the initial state $x_0$ and Markov semigroup $T$, for each $x_0 \in S$. Now consider each $x_1 \in S$. Since the function $d(x_i, \cdot)$ has modulus of continuity 1, and since

$$
(j - i)\Delta = r - s < \delta_{S\cap p_{\alpha}}(1, \epsilon, 1) \equiv \delta_{T}(\epsilon^2, t),
$$

we have, according to the definition of $\delta_{T}$ as the modulus of strong continuity of $T$, the bound

$$
|d(x_i, \cdot) - T_{(j-i)\Delta}d(x_i, \cdot)| \leq \epsilon^2
$$

as functions on $S$. In particular,

$$
|d(x_i, x_i) - T_{(j-i)\Delta}d(x_i, \cdot)| \leq \epsilon^2.
$$

Consequently $T_{(j-i)\Delta}^\delta d(x_i, \cdot) \leq \epsilon^2$ where $x_i \in S$ is arbitrary. Hence equality $\int$ can be continued to yield

$$
Eg(Y_{q(h,0)}, \ldots, Y_{q(h,i)})d(Y_s, Y_r) \leq \int E0(dx_0) \int T_{(j-i)\Delta}^\delta d(x_i, \cdot) \leq \epsilon^2 g(Y_{q(h,0)}, \ldots, Y_{q(h,i)}),
$$

where $g \in C(S^{i+1}, d^{i+1})$ is arbitrary. It follows that

$$
EUd(Y_s, Y_r) \leq \epsilon^2 EU
$$

for each $U \in L(Y_{q(h,0)}, Y_{q(h,1)}, \ldots, Y_{q(h,i)})$. Now let $\gamma > 0$ be arbitrary, and take an arbitrary measurable set

$$
A \in L^{(s,h)} = L(Y_r : r \in [0, s])Q_h = L(Y_{q(h,0)}, Y_{q(h,1)}, \ldots, Y_{q(h,i)})
$$

with $A \subset (d(x_s, Y_s) \leq \gamma)$, and with $P(A) > 0$. Let $U \equiv 1_A$ denote the indicator of $A$. Then, in view of the relation $\int$ we have $U \equiv 1_A \in L(Y_{q(h,0)}, Y_{q(h,1)}, \ldots, Y_{q(h,i)})$. Hence equality $\int$ holds, to yield

$$
E1_Ad(Y_s, Y_r) \leq \epsilon^2 E1_A
$$

Equivalently

$$
E_Ad(Y_s, Y_r) \leq \epsilon^2
$$

where $E_A$ is the conditional expectation given the event $A$. Chebychev’s inequality therefore implies

$$
P_A(d(Y_s, Y_r) > \alpha) \leq \epsilon
$$

for each $\alpha > 0$. Here $h \geq 0$, $\epsilon, \gamma > 0$, and $s, r \in Q_h$ are arbitrary with $s \leq r < s + \delta_{S\cap p_{\alpha}}(1, \epsilon, \gamma)$. Summing up, the process $Y$ is strongly right continuous in the sense

Yuen-Kwok Chan 437 Constructive Probability
of Definition \([10.7.3]\) with a modulus of strong right continuity \(\delta_{SRc,p,\delta(T)}\). Assertion 2 is proved.

4. Proceed to prove Assertions 3-5. To that end, recall that \(d \leq 1\) by hypothesis. Hence the process \(Y \equiv Z^N : Q_\infty \times \Omega \to (S,d)\) is trivially a.u. bounded, with a trivial modulus of a.u. boundlessness

\[
\beta_{auB}(\cdot, \delta_T) \equiv 1.
\]

Combining with Assertion 2, we see that the conditions for Theorem \([10.7.8]\) are satisfied for the process

\[
Y \equiv Z^N : Q_\infty \times \Omega \to (S,d)
\]
to be \(D\)-regular, with a modulus of \(D\)-regularity

\[
m_{\delta(T)} \equiv m(\beta_{auB}, \delta_{SRc,p,\delta(T)}) \equiv m(1, \delta_{SRc,p,\delta(T)})
\]
and a modulus of continuity in probability \(\delta_{Cp,\delta(T)}\), and for the process \(Y \equiv Z^N\) to be extendable by right-limit to an a.u. càdlàg process

\[
\Phi_{rLim}(Z^N) : [0,1] \times \Omega \to S
\]
which has the same modulus of continuity in probability \(\delta_{Cp,\delta(T)}\) and \(\delta_{SRc,p,\delta(T)}\) as \(Z^N\), and which has a modulus of a.u. càdlàg

\[
\delta_{aucl,\delta(T)} \equiv \delta_{aucl}(\cdot, \beta_{auB}, \delta_{SRc,p,\delta(T)}) \equiv \delta_{aucl}(\cdot, 1, \delta_{SRc,p,\delta(T)}).
\]
Recall here the right-limit extension \(\Phi_{rLim}\) from Definition \([10.5.6]\) Assertion 3 is proved.

5. Moreover, since the moduli \(\delta_{Cp,\delta(T)}\) and \(m_{\delta(T)}\) are independent of the interval \([N,N+1]\), we see that the process

\[
Z : Q_\infty \times \Omega \to (S,d)
\]
is time-uniformly \(D\)-regular in the sense of Definition \([10.10.5]\) with modulus of continuity in probability \(\delta_{Cp,\delta(T)} \equiv (\delta_{Cp,\delta(T)}, \delta_{Cp,\delta(T)}, \cdots)\), and with a modulus of \(D\)-regularity \(m_{\delta(T)} \equiv (m_{\delta(T)}, m_{\delta(T)}, \cdots)\). This proves Assertion 4 of the present theorem is proved.

6. To prove the remaining Assertion 5. Consider the right-limit extension process

\[
X \equiv \Phi_{rLim}(Z) : [0,\infty) \times (\Omega, L, E) \to (S,d).
\]
Consider each \(N \geq 0\). Then clearly \(X^N = \Phi_{rLim}(Z^N)\) on the interval \([0,1]\). Near the end point 1, things are a bit more subtle. We need to recall that, since \(\Phi_{rLim}(Z^N)\) is a.u. càdlàg, it is continuous a.u. on \([0,1]\). Hence, for a.s. \(\omega \in \Omega\), the function \(Z(\cdot, \omega)\) is continuous at \(1 \in [0,1]\). It therefore follows that \(X^N = \Phi_{rLim}(Z^N)\) on the interval \([0,1]\). We saw in Step 4 that the process \(\Phi_{rLim}(Z^N)\) is a.u. càdlàg, with a modulus of a.u. càdlàg \(\delta_{aucl,\delta(T)}\).

7. Now note that, as an immediate consequence of Step 5, the process \(Z|[0,N+1]\) is continuous in probability with modulus of continuity continuity in probability \(\delta_{Cp,\delta(T)}\).
11.5. CONSTRUCTION OF MARKOV PROCESS FROM SEMIGROUP

It follows that the process \( X|_{[N+1]} \) is continuous in probability with modulus of continuity continuity in probability \( \delta_{C_p,\delta(T)} \).

8. Summing up the results in Steps 7 and 6, we see that the process \( X \) time-uniformly a.u. càdlàg in the sense of Definition \([10,10.4]\), with modulus of continuity in probability \( \tilde{\delta}_{C_p,\delta(T)} = (\delta_{C_p,\delta(T)}, \delta_{C_p,\delta(T)}, \cdots) \), and with a modulus of a.u. càdlàg \( \delta_{\text{aucl}}(T) \equiv (\delta_{\text{aucl},\delta(T)}, \delta_{\text{aucl},\delta(T)}, \cdots) \). Assertions 5 and the theorem are proved. □

**Theorem 11.5.3.** (Construction of a.u. càdlàg Markov Process from an initial distribution and a semigroup, with parameter set \([0,\infty)\).) Let \((S,d)\) be a compact metric space with \( d \leq 1 \). Let \( E_0 \) be an arbitrary initial distribution on \((S,d)\), and let \( T \equiv \{ T_t : t \in [0,\infty) \} \) be an arbitrary Markov semigroup with state space \((S,d)\), with a modulus of strong continuity \( \delta_T \), and with a modulus of smoothness \( \alpha_T \equiv (\alpha_T(x))_{x=1,2,\cdots} \) in the sense of Definition \([11.3]\). Let

\[
(\Theta_0, L_0, I_0) \equiv (\Theta_0, \{0,1\}, L_0, \int \cdot dx)
\]
denote the Lebesgue integration space based on the interval \( \Theta_0 \). Let

\[
Z^{E(0),T} \equiv \mathcal{F}_{\text{DKS}}(F^{E(0),T}\overline{\Theta}) : \overline{\Theta} \times \Theta_0 \to S
\]

be the Markov process with initial distribution \( E_0 \) and Markov semigroup \( T|_{\overline{\Theta}} \), as constructed in Assertion 2 of Theorem \([11.5.1]\).

Then the following holds.

1. The right-limit extension

\[
X^{E(0),T} \equiv \mathcal{F}_{\text{lim}}(Z^{E(0),T}|_{\overline{\Theta}}) : [0,\infty) \times \Theta_0 \to (S,d)
\]
is a time-uniformly a.u. càdlàg process.

2. The process \( X^{E(0),T} \) is Markov relative to its natural filtration \( \mathcal{F} \equiv \{ \mathcal{F}^T \} : t \in [0,\infty) \}. Specifically, let \( n \geq 0 \) and let \( t_0 \equiv 0 \leq t_1 \leq \cdots \leq t_m \) be an arbitrary sequence in \([0,\infty)\), with \( m \geq 1 \). Then

\[
I_0(f(X_{t_{1+m}}), \cdots, X_{t_{1+m}})) = I_0(f(X_{t_{1+m}}), \cdots, X_{t_{1+m}})) = \mathcal{F}^T_{0, t_1, \cdots, t_{m+1}}
\]

where \( \mathcal{F}^T_{0, t_1, \cdots, t_{m+1}} \) is the transition distribution in Definition \([11.5.1]\).

3. Let \( F^{E(0),T} \) denote the family of marginal f.j.d.’s of the process \( X \). In the special case where \( E_0 \equiv \delta \), assigns probability 1 to some point \( x \in S \), write \( F^{x,T} \equiv F^{\delta(x),T} \). Then the family \( F^{E(0),T} \) is generated by the initial distribution \( E_0 \) and the semigroup \( T \), in the sense of Definition \([11.3]\). In particular, the family \( F^{x,T} \) is generated by the initial state \( x \) and the semigroup \( T \).

**Proof.** To minimize notational clutter, we will write \( a = b \pm c \) to mean \( |a-b| \leq c \), for arbitrary real-valued expressions \( a, b, c \). Let \( v \geq 0 \) and the sequence \( t_0 \equiv 0 \leq t_1 \leq \cdots \leq t_m \) in \([0,\infty)\) be arbitrary, but fixed. Let \( n \geq 1 \) and \( v_0 \equiv 0 \leq v_1 \leq \cdots \leq v_{n-1} \in [0,v] \) be arbitrary. Define \( v_{n+i} \equiv v + t_i \) for each \( i = 0,\cdots, m \). Note that

\[
v_0 \equiv 0 \leq v_1 \leq \cdots \leq v_{n+m}.
\]
CHAPTER 11. MARKOV PROCESS

Fix any integer \( N \geq 0 \) so large that \( v_{n+m} \in [0, N-1] \).

1. Assertion 1 of the present theorem is merely a restatement of Assertion 5 of Proposition 11.5.2 which says that the right-limit extension \( X \equiv X^{E(0)} \) is a time-uniformly a.u. càdlàg process, with a modulus of a.u. càdlàg \( \delta \) of \( X \) as r.r.v.'s, where \( F \in g \equiv (\delta_{aucl}(X), \delta_{aucl}(X), \cdots) \) and with a modulus of continuity in probability \( \tilde{\delta}_{CP,0}(X) \equiv (\delta_{CP,0}(X), \delta_{CP,0}(X), \cdots) \). In particular, the process \( X \cdot [0, N+1] \) is continuous in probability, with a modulus of continuity in probability \( \tilde{\delta}_{CP,0}(X) \).

2. Proceed to prove Assertion 2, by extending the Markov property of the process \( Z \) to the process \( X \). First, let \( \mathscr{L} \equiv \{ L^{(t)} : t \in \mathbb{Q}_{\infty} \} \) be the natural filtration of the process \( Z \equiv Z^{E(0), T} \). Assertion 2 of Theorem 11.5.1 says that the process \( Z \) is a Markov process relative to the filtration \( \mathscr{L} \). Specifically, let the nondecreasing sequence \( 0 \equiv s_0 \leq s_1 \leq \cdots \leq s_m \in \mathbb{Q}_{\infty} \), the function \( f \in C(S^m+1, d^{m+1}) \), and the pointy \( t \in \mathbb{Q}_{\infty} \) be arbitrary. Then

\[
I_0(f(Z_{r+s(0)}, Z_{r+s(1)}, \cdots, Z_{r+s(m)})) = I_0(f(Z_{r+s(0)}, Z_{r+s(1)}, \cdots, Z_{r+s(m)})|Z_t)) = F^{Z(t),T}_{r+s(0),\cdots, s(m)}(f) \tag{11.5.17}
\]
as r.r.v.'s, where \( F^{x,T}_{r+s(0), \cdots, s(m)} \) is the transition distribution as in Definition 11.4.1.

3. Next, let \( \mathscr{P} \equiv \{ P^{(t)} : t \in [0, \infty) \} \) be the natural filtration of the process \( X \). Let the sequence \( 0 \equiv r_0 \leq r_1 \leq \cdots \leq r_p \leq \cdots \leq r_{n+m} \in [0, N]\mathbb{Q}_{\infty} \) be arbitrary. Let the function \( g \in C(S^m+1, d^{m+1}) \) be arbitrary, with values in \([0, 1]\) and with modulus of continuity \( \delta_R \) and \( \delta_I \) respectively. Then equality (11.5.17) implies that

\[
I_0 g(Z_{r_0}, \cdots, Z_{r_n}) f(Z_{r_0}, \cdots, Z_{r_{n+m}}) \]

\[
I_0(I_0 g(Z_{r_0}, \cdots, Z_{r_n}) f(Z_{r_0}, \cdots, Z_{r_{n+m}})) = I_0 g(Z_{r_0}, \cdots, Z_{r_n}) F^{X(r_n), T}_{r_0, r_1, \cdots, r_n, r_{n+m}+1} f. \tag{11.5.18}
\]

4. Next let \( r_i \downarrow v_i \) for each \( i = 0, \cdots, n+m \). Then the left-hand side of equality (11.5.18) converges to the limit

\[
I_0 g(X_{r_0}, \cdots, X_{r_n}) f(X_{r_0}, \cdots, X_{r_{n+m}}),
\]
thanks to the continuity in probability of the process \( X \cdot [0, N+1] \).

5. Consider the right-hand side of equality (11.5.18). Let \( \varepsilon > 0 \) be arbitrary. As observed in Step 1 above, the process \( X \cdot [0, N+1] \) has a modulus of continuity in probability \( \tilde{\delta}_{CP,0}(X) \). Consequently, there exists \( \tilde{\delta}_0 > 0 \) so small that

\[
I_0 |g(X_{r_0}, \cdots, X_{r_n}) - g(X_{v_0}, \cdots, X_{v_n})| < \varepsilon \tag{11.5.19}
\]

provided that \( \bigvee_{i=0}^{n} (r_i - v_i) < \tilde{\delta}_0 \).

Yuen-Kwok Chan 440 Constructive Probability
11.5. CONSTRUCTION OF MARKOV PROCESS FROM SEMIGROUP

6. Separately, Assertion 2 of Theorem 11.4.2 implies that there exists \( \delta_{m+1}(\varepsilon, \delta_f, \delta_T, \alpha_T) > 0 \) such that, for arbitrary nondecreasing sequences \( 0 \equiv \tau_0 \leq \tau_1 \leq \cdots \leq \tau_m \) and \( 0 \equiv \tau_0 \leq \bar{\tau}_1 \leq \cdots \leq \bar{\tau}_m \in [0, \infty) \) with

\[
\sum_{i=0}^{m} |\tau_i - \bar{\tau}_i| < \delta_{m+1}(\varepsilon, \delta_f, \delta_T, \alpha_T),
\]

we have

\[
\left\| F_{\tau(0),\tau(1),\ldots,\tau(m)}^T f - F_{\bar{\tau}(0),\bar{\tau}(1),\ldots,\bar{\tau}(m)}^T f \right\| < \varepsilon. \tag{11.5.20}
\]

7. Suppose

\[
\sum_{i=0}^{n+m} (r_i - v_i) < 2^{-1} \delta_{m+1}(\varepsilon, \delta_f, \delta_T, \alpha_T) \wedge \delta_{C_p,\delta(T)}(\varepsilon \delta_f(\varepsilon)) \wedge \delta_0.
\]

Let \( \tau_i \equiv r_{n+i} - r_n \) and \( \bar{\tau}_i \equiv v_{n+i} - v_n \) for each \( i = 0, \ldots, m \). Then \( \tau, \bar{\tau} \in [0, N] \), with

\[
\sum_{i=0}^{m} |\tau_i - \bar{\tau}_i| \leq 2 \sum_{i=0}^{n+m} (r_i - v_i) < \delta_{m+1}(\varepsilon, \delta_f, \delta_T, \alpha_T).
\]

Hence inequality \( 11.5.20 \) holds. For abbreviation, define

\[
h \equiv F_{\tau(0),\tau(1),\ldots,\tau(m)}^T f
\]

and

\[
\bar{\tau} \equiv F_{\bar{\tau}(0),\bar{\tau}(1),\ldots,\bar{\tau}(m)}^T f.
\]

Then inequality \( 11.5.20 \) can be rewritten as

\[
\left\| h - \bar{\tau} \right\| < \varepsilon. \tag{11.5.22}
\]

8. Since \( 0 \equiv \tau_0 \leq \tau_1 \leq \cdots \leq \tau_m \) is a sequence in \([0, N] \cap [0, \infty)\), Assertion 1 of Theorem 11.4.2 implies that the function \( h \equiv F_{\tau(0),\tau(1),\ldots,\tau(m)}^T f \) is a member of \( C(S, d) \), with values in \([0, 1]\) and with a modulus of continuity \( \delta_h \equiv \delta^{(m)}_{\alpha(\tau(N),\varepsilon)}(\delta_f) \), where the operation \( \delta^{(m)}_{\alpha(\tau(N),\varepsilon)} \) is the \( m \)-fold composite product operation

\[
\delta^{(m)}_{\alpha(\tau(N),\varepsilon)} \equiv \delta_{\alpha(\tau(N),\varepsilon)} \circ \cdots \circ \delta_{\alpha(\tau(N),\varepsilon)},
\]

where each factor on the right-hand side is as defined in Lemma 11.2.5.

9. Now suppose, in addition to the bound \( 11.5.21 \) we also have

\[
\sum_{i=0}^{n+m} (r_i - v_i) < \delta_{C_p,\delta(T)}(\varepsilon \delta_f(\varepsilon)) \equiv \delta_{C_p,\delta(T)}(\varepsilon \delta^{(m)}_{\alpha(\tau(N),\varepsilon)}(\delta_f)(\varepsilon)). \tag{11.5.23}
\]

Then, in particular, we have

\[
r_n - v_n < \delta_{C_p,\delta(T)}(\varepsilon \delta_f(\varepsilon)).
\]
Hence

\[ I_0d(X_{r(n)}, X_{v(n)}) < \varepsilon \delta_h(\varepsilon) \]

by the definition of \( \delta_{C_0, \delta(T)} \) as a modulus of continuity in probability of the process \( X_i \). Therefore Chebychev’s inequality yields a measurable set \( A \subset \Theta_0 \) with \( I_0A^c < \varepsilon \) such that

\[ A \subset (d(X_{r(n)}, X_{v(n)}) < \delta_h(\varepsilon)). \]  

(11.5.24)

10. Since the function \( h \) has modulus of continuity \( \delta_h \), relation \( [11.5.24] \) immediately extends to

\[ A \subset (d(X_{r(n)}, X_{v(n)}) < \delta_f(\varepsilon)) \subset (|h(X_{r(n)}) - h(X_{v(n)})| < \varepsilon). \]

As a result, we obtain the estimate

\[
I_0g(X_{r(0)}, \cdots, X_{r(n)}) = \sum_{r_0, r_1, \cdots, r_{n+m} < r(n)} f^{X(r(n)), T} \left( I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A^c} \right) + \left( I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A} \right) \pm \varepsilon
\]

\[
= (I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A}) \pm \varepsilon
\]

\[
= I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A} \pm \varepsilon. \]  

(11.5.25)

At this point, note that the bound \( [11.5.21] \) implies that \( \sum_{i=0}^{m} (r_i - \bar{v}_i) < \delta_h \). Hence inequality \( [11.5.19] \) holds, and leads to

\[
I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A} = (I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A}) \pm \varepsilon.
\]

Therefore equality \( [11.5.25] \) can be continued, to yield

\[
I_0g(X_{r(0)}, \cdots, X_{r(n)})f^{X(r(n)), T} \left( I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A^c} \right) + \left( I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A} \right) \pm 2\varepsilon
\]

\[
= (I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A}) \pm 2\varepsilon
\]

\[
= I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A} \pm 2\varepsilon
\]

\[
= I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A} \pm 3\varepsilon
\]

\[
= I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A} \pm 3\varepsilon
\]

\[
= I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A} \pm 4\varepsilon.
\]

where we used the condition that the functions \( f, g, h \) have values in \([0, 1]\), and where the fourth equality is thanks to equality \( [11.5.22] \). Summing up, we have proved that

\[
|I_0g(X_{r(0)}, \cdots, X_{r(n)})f^{X(r(n)), T} \left( I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A^c} \right) + \left( I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A} \right)| \leq 4\varepsilon
\]

provided that the bounds \( [11.5.21] \) and \( [11.5.22] \) are satisfied. Since \( \varepsilon > 0 \) is arbitrarily small, we have proved the convergence of the right-hand side of equality \( [11.5.18] \) with, specifically,

\[
I_0g(X_{r(0)}, \cdots, X_{r(n)})f^{X(r(n)), T} \left( I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A^c} \right) + \left( I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)})1_{A} \right) \rightarrow I_0g(X_{r(0)}, \cdots, X_{r(n)})h(X_{r(n)}). \]

Yuen-Kwok Chan 442 Constructive Probability
as \( r_i \downarrow v_i \) for each \( i = 0, \cdots, n + m \). In view of the convergence of the left-hand side of the same equality \([11.5.18]\) as observed in Step 4, the two limits are equal. Thus

\[
I_0g(X_{v(0)}, \cdots, X_{v(n)}).f(X_{v(n)}), \cdots, X_{v(n+m)})) = I_0g(X_{v(0)}, \cdots, X_{v(n)}).\overline{T}(X_{v(n)}), \tag{11.5.26}
\]

where the function \( g \in C(S^{n+1}, d^{n+1}) \) is arbitrary with values in \([0,1]\), and where the integer \( n \geq 1 \) and the sequence \( 0 \equiv v_0 \leq v_1 \leq \cdots \leq v_{n-1} \) are arbitrary. Hence, by linearity, equality \([11.5.26]\) implies that

\[
I_0Yf(X_{v(n)}, \cdots, X_{v(n+m)}) = I_0Y\overline{T}(X_{v(n)})
\]

for each r.r.v. \( Y \) in the family

\[
G_{v(n)} = \{ g(X_{v(0)}, \cdots, X_{v(n-1)}, X_{v(n)}), g \in C(S^{n+1}, d^{n+1}); \langle v_0, \cdots, v_{n-1} \rangle \in S^n; v_0 \leq v_1 \leq \cdots \leq v_{n-1} \leq v_n \}
\]

Since the family \( G_{v(n)} \) is dense in the space \( \overline{L}^{(v(n))} = \overline{L}^{(v)} \) relative to the norm \( I_0| \cdot | \), it follows that

\[
I_0Yf(X_{v(n)}, \cdots, X_{v(n+m)}) = I_0Y\overline{T}(X_{v(n)}) \tag{11.5.27}
\]

for each \( Y \in \overline{L}^{(v)} \). Since \( \overline{T}(X_{v(n)}) \in G_{v(n)} \subset \overline{L}^{(v)} \), we obtain the conditional expectation

\[
I_0(f(X_{v(n)}, \cdots, X_{v(n+m)}))\overline{T}^{(v)} = \overline{T}(X_{v(n)}) = F_{X_{v(n)}; T_{\pi(0), \pi(1), \cdots, \pi(m)}}(f). \tag{11.5.28}
\]

In the special case of an arbitrary \( Y \in L(X_v) \subset \overline{L}^{(v)} \), equality \([11.5.27]\) holds. Hence

\[
I_0(f(X_{v(n)}, \cdots, X_{v(n+m)}))|X_v) = \overline{T}(X_{v(n)}) = F_{X_{v(n)}; T_{\pi(0), \pi(1), \cdots, \pi(m)}}(f). \tag{11.5.29}
\]

Recall that \( v_{n+i} \equiv v + t_i \) and \( \pi_i \equiv t_i \), for each \( i = 0, \cdots, m \), and recall that \( t_0 \equiv 0 \). Equalities \([11.5.28]\) and \([11.5.29]\) can then be rewritten as

\[
I_0(f(X_{v+n+0}), \cdots, X_{v+n+i})|X_v) = F_{X_{v+n+0}; T_{\pi(0), \cdots, \pi(m)}}(f). \tag{11.5.30}
\]

and

\[
I_0(f(X_{v+n+0}, \cdots, X_{v+n+i})|X_v) = F_{X_{v+n+0}; T_{\pi(0), \cdots, \pi(m)}}(f). \tag{11.5.31}
\]

The last two equality together yield the desired equality \([11.5.16]\). Assertion 2 is proved.

11. Finally, note that, by Assertion 2 of Theorem \([11.4.2]\) the consistent family \( F_{E(0); T_i^{(m)}}(\omega) \) is generated by the initial distribution \( E_0 \) and the semigroup \( T_i^{(m)} \), in the sense of Definition \([11.4.7]\). Hence, for each sequence \( 0 \equiv r_0 \leq r_1 \leq \cdots \leq r_n \leq \cdots \leq r_{n+m} \) in \( \omega \) and for each \( f \in C(S^n, d^n) \), we have

\[
F_{E(0); T_i^{(m)}} = I_0f(X_{r(0)}, \cdots, X_{r(m)}) = I_0f(Z_{r(0)}, \cdots, Z_{r(m)})
\]

\[
= \int E_0(dx_0) \int T_{r(1)}(dx_1) \int T_{r(2)}^{(1)}(dx_2) \cdots \int T_{r(m-1)}^{(m-1)}(dx_m) f(x_1, \cdots, x_m). \tag{11.5.32}
\]
CHAPTER 11. MARKOV PROCESS

Because the process is continuous in probability, and because the semigroup is strongly continuous, this equality extends to

\[ F^{E(0),T}_{r(1),\ldots,r(m)}f = \int E_0(\text{d}x_0) \int T_{r(1)}^{x(0)}(\text{d}x_1) \int T_{r(2)-r(1)}^{x(1)}(\text{d}x_2) \cdots \int T_{r(m)-r(m-1)}^{x(m-1)}(\text{d}x_m) f(x_1, \ldots, x_m) \]

(11.5.33)

for each sequence 0 \equiv r_0 \leq r_1 \leq \cdots \leq r_n \leq \cdots \leq r_{n+m} \text{ in } [0, \infty). Thus the family is \( F^{E(0),T} \) is generated by the initial distribution \( E_0 \) and the semigroup \( T \), in the sense of Definition 11.4.1. Assertion 3 and the theorem are proved. \( \square \)

11.6 Continuity of Construction

In this section, we will prove that the construction in Theorem 11.5.3 of a Markov process from an initial state \( x \) and a semigroup \( T \) is uniformly metrically coontinuous over each subspace of semigroups \( T \) whose members share a common modulus of strong continuity and share a common modulus of smoothness. We will limit the discussion to the parameter set \( Q = \overline{Q}_\infty \) or \( Q = [0, \infty) \). The case of \( Q = \{0,1,\cdots\} \) being similar.

First we specify a compact state space, and define a metric on the space of Markov semigroups.

Definition 11.6.1. (Specification of state space, its binary approximation, and partition of unity). In this section, unless otherwise specified, \((S,d)\) will denote a given compact metric space, with \( d \leq 1 \), and with a fixed reference point \( x_0 \in S \). Recall that \( \xi \equiv (A_k)_{k=1,2,\cdots} \) is a binary approximation of \((S,d)\) relative to \( x_0 \), and that

\[ \pi \equiv \{ \{g_{k,x} : x \in A_k\} \}_{k=1,2,\cdots} \]

is the partition of unity of \((S,d)\) determined by \( \xi \), as in Definition 5.2.2. Recall that \( |A_k| \) denotes the number of elements in the discrete finite subset \( A_k \subset S \), for each \( k \geq 1 \).

For each \( n \geq 1 \) let \( \xi^n \) denote the \( n \)-th power of \( \xi \), and let \( \pi^{(n)} \) denote the corresponding partition of unity for \((S^n,d^n)\). Thus, for each \( n \geq 1 \), the sequence \( \xi^n \equiv (A_k^{(n)})_{k=1,2,\cdots} \) is the product binary approximation for \((S^n,d^n)\) relative to the reference point \( x_0^{(n)} \equiv (x_0, \ldots, x_0) \in S^n \), and

\[ \pi^{(n)} \equiv \{ \{g_{k,x}^{(n)} : x \in A_k^{(n)}\} \}_{k=1,2,\cdots} \]

is the partition of unity of \((S^n,d^n)\) determined by the binary approximation \( \xi \equiv (A_k)_{k=1,2,\cdots} \equiv (A_k^{(1)})_{k=1,2,\cdots} \) of \((S,d)\). For each \( k \geq 1 \), the set \( A_k^{(n)} \) is an \( 2^k \)-approximation of the bounded subset

\[ (d^n(\cdot, (x_0, \ldots, x_0)) \leq 2^k) \subset S^n. \]

To lessen the burden of subscripts, we write \( A_k^{(n)} \) and \( A_{n,k} \) interchangeably, for each \( n \geq 1 \).

We will use the notations in Definitions 11.0.2 related to the enumerated set \( \overline{Q}_n \equiv \{ u_0, u_1, \cdots \} \).

Yuen-Kwok Chan 444 Constructive Probability
11.6. CONTINUITY OF CONSTRUCTION

□

Definition 11.6.2. (Metric space of Markov semigroups). Let \((S,d)\) be the specified compact metric space, with \(d \leq 1\). Suppose \(Q = \overline{Q}_\infty\) or \(Q = [0,\infty)\). Let \(\mathcal{F}\) be family of all Markov semigroups on the parameter set \(Q\) and with the compact metric state space \((S,d)\). For each \(n \leq 0\) write \(\Delta_n = 2^{-n}\). Define the metric \(\rho_\mathcal{F} = \rho_{\mathcal{F},\xi}\) on the family \(\mathcal{F}\) by

\[
\rho_\mathcal{F}(\mathbf{T},\mathbf{\bar{T}}) \equiv \rho_{\mathcal{F},\xi}(\mathbf{T},\mathbf{\bar{T}}) \equiv \sum_{n=0}^{\infty} 2^{-n-1} \sum_{k=1}^{2^n} |A_k|^{-1} \sum_{z \in A(k)} \|T_{\Delta(n)\delta_{k,z}} - T_{\Delta(n)\delta_{k,z}}\|
\]

for arbitrary members \(\mathbf{T} \equiv \{T_t : t \in Q\}\) and \(\mathbf{\bar{T}} \equiv \{\bar{T}_t : t \in Q\}\) of the family \(\mathcal{F}\). Here \(\|\cdot\|\) stands for the supremum norm on \(C(S,d)\).

It follows easily from the strong continuity of the semigroups \(\mathbf{T}\) that \(\rho_\mathcal{F}\) is in fact a metric. Note that \(\rho_\mathcal{F} \leq 1\). Let \((S \times \mathcal{F}, d \otimes \rho_\mathcal{F})\) denote the product metric metric space of \((S,d)\) and \((\mathcal{F}, \rho_\mathcal{F})\).

For each \(\mathbf{T} \equiv \{T_t : t \in Q\} \in \mathcal{F}\), define the semigroup \(\mathbf{T}|\overline{Q}_\infty \equiv \{\bar{T}_t : t \in \overline{Q}_\infty\}\). Then

\[
\rho_{\mathcal{F},\xi}(\mathbf{T}|\overline{Q}_\infty, \mathbf{\bar{T}}|\overline{Q}_\infty) = \rho_{\mathcal{F},\xi}(\mathbf{T}, \mathbf{\bar{T}}).
\]

In other words, the mapping

\[
\Psi : (\mathcal{F}, \rho_{\mathcal{F},\xi}) \to (\mathcal{F}|\overline{Q}_\infty, \rho_{\mathcal{F},\xi}),
\]

defined by \(\Psi(\mathbf{T}) \equiv \mathbf{T}|\overline{Q}_\infty\) for each \(\mathbf{T} \in \mathcal{F}\), is an isometry.

□

The next theorem proves the promised continuity of construction in the case where the parameter set is \(\overline{Q}_\infty\). Then the subsequent Theorem 11.6.4 will prove a similar continuity in the case where the parameter set \([0,\infty)\).

Theorem 11.6.3. (Continuity of construction of family of transition f.j.d.'s from initial state and semigroup, for discrete parameters). Let \((S,d)\) be the specified compact metric space, with \(d \leq 1\). Let \(\mathcal{F}(\overline{\mathcal{D}},\overline{\mathcal{A}})\) be an arbitrary family of Markov semigroups with parameter set \(\overline{Q}_\infty\) and state space \((S,d)\), such that all its members \(\mathbf{T} \in \mathcal{F}(\overline{\mathcal{D}},\overline{\mathcal{A}})\) share a common modulus of strong continuity \(\delta_\mathbf{T} = \overline{\delta}\), and share a modulus of smoothness \(\alpha_\mathbf{T} = \overline{\alpha}\), in the sense of Definition 11.3.1. Thus \(\mathcal{F}(\overline{\mathcal{D}},\overline{\mathcal{A}})\) is a subset of \((\mathcal{F}, \rho_\mathcal{F})\), and, as such, inherits the metric \(\rho_{\mathcal{F},\xi}\) introduced in Definition 11.6.2. Recall from Definition 11.2.7 the metric space \((\hat{F}(\overline{Q}_\infty, S), \hat{P}_{\text{Marg}}, \hat{\xi}|\overline{Q}_\infty)\) of consistent families of f.j.d.'s with parameter set \(\overline{Q}_\infty\) and state space \((S,d)\).

Then the mapping

\[
\Phi_{\text{Spec},\xi} : (S \times \mathcal{F}(\overline{\mathcal{D}},\overline{\mathcal{A}}), d \otimes \rho_{\mathcal{F},\xi}) \to (\hat{F}(\overline{Q}_\infty, S), \hat{P}_{\text{Marg}}, \hat{\xi}|\overline{Q}_\infty)\]

constructed in Assertion 4 of Theorem 11.4.2 is uniformly continuous, with a modulus of continuity \(\delta_{\text{Spec},\xi}(\cdot, \overline{\mathcal{D}}, \overline{\mathcal{A}}, \|\xi\|)\) determined by the moduli \(\overline{\delta}, \overline{\alpha}\) and by the modulus of local compactness \(\|\xi\|\) of \((\mathcal{F}, \rho_{\mathcal{F},\xi})\).
CHAPTER 11. MARKOV PROCESS

Proof. 1. Let \((x,T),(\bar{x},\bar{T})\) be arbitrary. For abbreviation, write \(F \equiv F^{x,T} \equiv \Phi_{\mathcal{S},fjd}(x,T)\) and \(\bar{F} \equiv F^{\bar{x},\bar{T}} \equiv \Phi_{\mathcal{S},fjd}(\bar{x},\bar{T})\). Define the distance

\[
\bar{\rho}_0 = (d \otimes \rho_\sigma)((x,T),(\bar{x},\bar{T})) = d(x,T) \vee \rho_\sigma(T,\bar{T})
\]  \hspace{1cm} (11.6.1)

2. Let \(\varepsilon_0 > 0\) be arbitrary, but fixed till further notice. Take \(M \geq 0\) so large that \(2^{-M-1} < \frac{1}{4}\varepsilon_0\), where \(N \equiv p_{2M} \equiv 2^M\). Write \(\Delta \equiv \Delta_M \equiv 2^{-M}\) for abbreviation. Then, in the notations of Definitions \(11.0.2\) we have

\[
\mathcal{Q}_M \equiv \{u_0,u_1,\cdots,u_{p(2M)}\} \equiv \{u_0,u_1,\cdots,u_N\} = \{0,\Delta,2\Delta,\cdots,N\Delta\}
\]  \hspace{1cm} (11.6.2)

as enumerated sets. Thus \(u_n = n\Delta\) for each \(n = 0,\cdots,N\). For abbreviation, also write \(K \equiv N+1\), and

\[
\gamma_N = (N+1)^{-1}2^{-N-2}.
\]

Then \(2^{-K} = 2^{-N-1} < \frac{1}{4}\varepsilon_0\).

3. By Definition \(6.2.7\) we have

\[
\hat{\rho}_{\text{Marg},\mathcal{Q}_M}(F,\bar{F}) \equiv \sum_{n=0}^{\infty} 2^{-n-1} \rho_{\text{Dist},\xi_{n+1}}(F_{u(0),\cdots,u(n)},\bar{F}_{u(0),\cdots,u(n)})
\]

\[
\leq \sum_{n=0}^{N} 2^{-n-1} \rho_{\text{Dist},\xi_{n+1}}(F_{u(0),\cdots,u(n)},\bar{F}_{u(0),\cdots,u(n)}) + 2^{-N-1}
\]

\[
\leq \sum_{n=0}^{N} 2^{-n-1} \rho_{\text{Dist},\xi_{n+1}}(F_{0,\Delta,\cdots,n\Delta},\bar{F}_{0,\Delta,\cdots,n\Delta}) + \frac{1}{3}\varepsilon_0.
\]  \hspace{1cm} (11.6.3)

For each \(n \geq 0\), the metric \(\rho_{\text{Dist},\xi_{n+1}}\) was introduced in Definition \(5.3.3\) for the space of distributions on \((S^{n+1},\mathfrak{d}^{n+1})\), where it is observed that \(\rho_{\text{Dist},\xi_{n+1}} \leq 1\) and that sequential convergence relative to \(\rho_{\text{Dist},\xi_{n+1}}\) is equivalent to weak convergence.

4. We will prove that the \(n\)-th summand in the last sum in equality is bounded by \(2^{-n-1}\varepsilon_0\), for each \(n = 0,\cdots,N\), provided that the distance \(\bar{\rho}_0\) is sufficiently small.

To that end, let \(n = 0,\cdots,N\) be arbitrary, but fixed till further notice. Then, in the \(n\)-th summand on the right-hand side of inequality \(11.6.3\) we have

\[
\rho_{\text{Dist},\xi_{n+1}}(F_{0,\Delta,\cdots,n\Delta},\bar{F}_{0,\Delta,\cdots,n\Delta})
\]

\[
\equiv \sum_{k=1}^{K} 2^{-k}|A_{n+1,k}|^{-1} \sum_{y \in A(n+1,k)} |F_{0,\Delta,\cdots,n\Delta}s_{k,y}^{(n+1)} - \bar{F}_{0,\Delta,\cdots,n\Delta}s_{k,y}^{(n+1)}|
\]

\[
\leq \sum_{k=1}^{K} 2^{-k}|A_{n+1,k}|^{-1} \sum_{y \in A(n+1,k)} |F_{0,\Delta,\cdots,n\Delta}s_{k,y}^{(n+1)} - \bar{F}_{0,\Delta,\cdots,n\Delta}s_{k,y}^{(n+1)}| + 2^{-K},
\]

\[
< \sum_{k=1}^{K} 2^{-k}|A_{n+1,k}|^{-1} \sum_{y \in A(n+1,k)} |F_{0,\Delta,\cdots,n\Delta}s_{k,y}^{(n+1)} - \bar{F}_{0,\Delta,\cdots,n\Delta}s_{k,y}^{(n+1)}| + \frac{1}{3}\varepsilon_0
\]  \hspace{1cm} (11.6.4)
where the first equality is from Definition 11.6.4 for the distribution metric $\rho_{dist,z^{n+1}}$, and
where, for each $k \geq 1$ and each $y \in A_{n+1,k}$, the basis function $s_k^{(n+1)} \in C(S^{n+1},d^{n+1})$ is
from the partition of unity
\[
\pi^{(n+1)} = \{ \{ s_k^{(n+1)} : y \in A_{n+1,k} \} \}_{k=1,2,...}
\]
of $(S^{n+1},d^{n+1})$ relative to the $2^{-k}$-approximation $A_{n+1,k}$ of the metric space $(S^{n+1},d^{n+1})$,
as specified in Definition 11.6.1.
5. Next, with $n = 0, \cdots, N$ arbitrary but fixed, we will show that
\[
|F_{0,\Delta_{n}} - F_{0,\Delta_{n}}| \leq 3^{-n} \epsilon_0
\]
for each $k = 0, \cdots, K$ and for each $y \in A_{n+1,k}$. Note that, according to Assertion 5 of
Theorem 11.4.2 we have
\[
F_{0,\Delta_{n}} = F_{0,\Delta_{n}} = (T_\Delta)(T_\Delta)^{2}(T_\Delta)^{3} \cdots (T_\Delta)
\]
where the factors on the right hand side are one-step transition distributions
according to $T_\Delta$, as defined in Lemma 11.2.3. A similar equality holds for $F_{0,\Delta_{n}}$ and $T_\Delta$.
Therefore it suffices to prove that
\[
|(T_\Delta)^{2}(T_\Delta)^{3} \cdots (T_\Delta)^{n|s_k^{(n+1)} - (T_\Delta)^{2}(T_\Delta)^{3} \cdots (T_\Delta)|s_k^{(n+1)}| \leq 3^{-n} \epsilon_0
\]
for each $k = 0, \cdots, K$ and for each $y \in A_{n+1,k}$.
6. To that end, let $p = 0, \cdots, n$ be arbitrary. Define the finite family
\[
G_p = \{ (p+1,T_\Delta)^{n}(T_\Delta)^{n+1} : k = 0, \cdots, K \text{ and } y \in A_{n+1,k} \} \subset C(S^{p+1},d^{p+1}),
\]
with the understanding that the composite mapping $(p+1,T_\Delta)^{n}(T_\Delta)$ stands for the
identity mapping if $p = n$. Thus
\[
G_n = \{ s_k^{(n+1)} : k = 0, \cdots, K \text{ and } y \in A_{n+1,k} \} \subset C(S^{n+1},d^{n+1}).
\]
7. We will prove by backward induction, that, for each $p = n, n-1, \cdots, 0$, there
exists an operation $\rho_p : (0,\infty) \to (0,\infty)$ and an operation $\delta_p : (0,\infty) \to (0,\infty)$ such that
(i) $\delta_p$ is a modulus of continuity of each of the members of $G_p$, and (ii) if $p < n$, then
for each $\epsilon' > 0$, we have
\[
\sup_{g \in G_p} \| (p+1,T_\Delta)g - (p+1,T_\Delta)g \| < \epsilon'
\]
provided that the distance $\rho_0$ is bounded by
\[
\rho_0 < \rho_p(\epsilon').
\]
8. Start with $p = n$. Arbitrarily define $\rho_n \equiv 1$. Then the operation $\rho_n$ trivially
satisfies Condition (ii) in Step 7. Consider each $g \in G_n$. Then $g = s_k^{(n+1)}$ for some
CHAPTER 11. MARKOV PROCESS

\( k = 0, \ldots, K \) and \( y \in A_{n+1,k} \). According to Proposition \([3.2.3]\) the basis function \( g_{k,y}^{(n+1)} \in C(S^{n+1}, d^{n+1}) \) has Lipschitz constant \( 2 \cdot 2^k \leq 2^{K+1} = 2^{N+2} \), and has values in \([0, 1]\).

Thus the function \( g \) has modulus of continuity \( \delta \) defined by \( \overline{\delta}(\varepsilon') = 2^{-N-2}\varepsilon' \) for each \( \varepsilon' > 0 \). Since \( g \in G_n \) is arbitrary, the modulus \( \delta \) satisfies Condition (i) in Step 7. The pair \( \delta, \rho \) has been constructed to satisfy Conditions (i) and (ii), in the case where \( p = n \).

9. Suppose, for some \( p = n, n-1, \ldots, 1 \), the pair of operations \( \delta, \rho \) has been constructed to satisfy the Conditions (i) and (ii) in Step 7. We proceed to construct the pair \( \delta_{p-1}, \rho_{p-1} \). Let \( \varepsilon' > 0 \) be arbitrary. Consider each

\[
g \in G_{p-1} \equiv \{(T_{(A)}) \cdot (T_{(A)}) g_{k,y}^{(n+1)} : k = 0, \ldots, K \text{ and } y \in A_{n+1,k}\}
\]

Then \( g = (T_{(A)}) \mathcal{R} \) for some \( \mathcal{R} \in G_p \). By Condition (ii) in the backward induction hypothesis, the function \( \mathcal{R} \) has modulus of continuity \( \delta \). Lemma \([11.2.5]\) therefore says that the function \( g = (T_{(A)}) \mathcal{R} \) has modulus of continuity given by

\[
\overline{\delta}_{p-1} \equiv \alpha_{(A(T(A))}, \xi (\delta),
\]

where the modulus of smoothness \( \alpha_{(A(T(A))}, \xi \) is as defined in Lemma \([11.2.5]\). Since \( g \in G_{p-1} \) is arbitrary, we see that \( \delta_{p-1} \) satisfies Condition (i) in Step 7. It remains to construct \( \rho_{p-1} \) to satisfy Condition (ii) in Step 7.

10. To that end, let \( \varepsilon' > 0 \) be arbitrary. Take \( h \geq 1 \) so large that

\[
2^{-h} < \frac{1}{2} \delta (\frac{1}{3} \varepsilon').
\]

Define

\[
\rho_{p-1} (\varepsilon') \equiv \rho_p (\varepsilon') \land 2^{-M-1}2^{-h}|A_h|^{-1} \varepsilon'.
\]

Consider each \( g \in G_{p-1} \). By Step 9 above, the function \( g \) has modulus of continuity \( \delta_{p-1} \). Let \( (w_1, \ldots, w_{p-1}) \in S^{p-1} \) be arbitrary, and consider the function \( \mathcal{R} \equiv g(w_1, \ldots, w_{p-1}, \cdot) \in C(S, d) \). Then clearly \( \mathcal{R} \) has the same modulus of continuity \( \delta_{p-1} \).

Recall that \( \{g_{h,z} : z \in A_h\} \) is a \( 2^{-h} \)-partition of unity corresponding to \( A_h \), where \( A_h \) is a \( 2^{-h} \)-approximation of the compact metric space \( (S, d) \). Hence, by Definition, we have \([3.1.1]\)

\[
S \subset (d(\cdot, x_0) \leq 1) \subset (d(\cdot, x_0) \leq 2^h) \subset \bigcup_{z \in A(h)} (d(\cdot, z) \leq 2^{-h})
\]

Therefore, trivially, the function \( \mathcal{R} \in C(S, d) \) has the set \( \bigcup_{z \in A(h)} (d(\cdot, z) \leq 2^{-h}) \) as support. Hence, in view of inequality \([11.6.6]\) the conditions in the hypothesis of Proposition \([3.2.6]\) are satisfied. Accordingly,

\[
\left\| \mathcal{R} - \sum_{z \in A(h)} \mathcal{R}(z) g_{h,z} \right\| \leq \varepsilon'
\]

Yuen-Kwok Chan 448 Constructive Probability
11.6. CONTINUITY OF CONSTRUCTION

on $S$. Consequently,

$$\left\| T_a \mathcal{F} - \sum_{z \in A(h)} \mathcal{F}(z) T_a g_{h,z} \right\| \leq \varepsilon' \quad (11.6.9)$$

and, similarly,

$$\left\| T_a \mathcal{F} - \sum_{z \in A(h)} \mathcal{F}(z) T_a g_{h,z} \right\| \leq \varepsilon'. \quad (11.6.10)$$

11. Now suppose $\overline{p}_0 < \rho_{p-1}(\varepsilon')$. Then

$$\sum_{j=0}^{\infty} 2^{-j-1} \sum_{h' \in A(h')} 2^{-h'} |A_h|^{-1} \sum_{z \in A(h')} \left\| T_{\Delta(j)} g_{h',z} - T_{\Delta(j)} g_{h',z} \right\| = p_{\overline{p}_0}(T, T) = \overline{p}_0 < \rho_{p-1}(\varepsilon').$$

Consequently,

$$2^{-M-1} 2^{-h} |A_h|^{-1} \sum_{z \in A(h)} \left\| T_{\Delta(M)} g_{h,z} - T_{\Delta(M)} g_{h,z} \right\| < \rho_{p-1}(\varepsilon').$$

Recall that $\Delta_M \equiv 2^{-M} \equiv \Delta$. The last inequality can be rewritten as

$$2^{-M-1} 2^{-h} |A_h|^{-1} \sum_{z \in A(h)} \left\| T_a g_{h,z} - T_a g_{h,z} \right\| < \rho_{p-1}(\varepsilon').$$

Therefore, since the function $\mathcal{F}$ has values in $[0, 1]$, we have

$$\left\| \sum_{z \in A(h)} \mathcal{F}(z) T_a g_{h,z} - \sum_{z \in A(h)} \mathcal{F}(z) T_a g_{h,z} \right\| \leq \sum_{z \in A(h)} \left\| \mathcal{F}(z) T_a g_{h,z} - \mathcal{F}(z) T_a g_{h,z} \right\| \leq \sum_{z \in A(h)} \left\| T_a g_{h,z} - T_a g_{h,z} \right\| < 2^{M+1} 2^h |A_h| \rho_{p-1}(\varepsilon') \leq \varepsilon', \quad (11.6.11)$$

where the last inequality follows from the defining formula $11.6.7$.

12. Combining inequalities $11.6.11$, $11.6.10$ and $11.6.9$ we obtain, by the triangle inequality,

$$\left\| T_a \mathcal{F} - T_a \mathcal{F} \right\| \leq 3\varepsilon'.$$

In other words,

$$\left\| T_a g_{(w_1, \cdots, w_{p-1}, \cdot)} - T_{\Delta g_{(w_1, \cdots, w_{p-1}, \cdot)}} \right\| \leq 3\varepsilon',$$

where $(w_1, \cdots, w_{p-1}) \in S^p$ is arbitrary. Consequently

$$\left\| p^{-1} T_a g - p^{-1} T_{\Delta g} \right\| \leq 3\varepsilon'.$$

where $\varepsilon' > 0$ and $g \in G_{p-1}$ are arbitrary, provided that $\overline{p}_0 < \rho_{p-1}(\varepsilon')$.

13. In short, the operation $\rho_{p-1}$ has been constructed to satisfy Condition (ii) in Step 7. The backward induction is completed, and we have obtained the pair $(\tilde{\delta}_p, \rho_p)$.
CHAPTER 11. MARKOV PROCESS

for each \( p = n, n-1, \ldots, 0 \) to satisfy Conditions (i) and (ii) in Step 7. In particular, we obtained the pair \( (\tilde{\delta}_0, \rho_0) \) of operations.

14. Now let \( \epsilon' \equiv 3^{-1}(n+2)^{-1} \eta_0 \). Suppose

\[
\overline{\rho_0} < \delta_{\overline{\delta}, f, j, d}(\epsilon_0, \overline{x}, \overline{x}, ||\xi||) \equiv \rho_0(\epsilon') \wedge \tilde{\delta}_0(\epsilon').
\]

Let \( p = 1, \ldots, n \) and \( g \in G_p \), be arbitrary. Then

\[
(\overline{p}T_\Delta)g \in G_{p-1},
\]

(11.6.12)

Moreover, as a result of the built-in monotonicity of the operations \( \rho_p \) in the defining formula [11.6.7] we have \( \overline{\rho}_0 < \rho_p(\epsilon') \). Hence, by Condition (ii) in Step 7, we have

\[
(\overline{p}T_\Delta)g = (\overline{p}T_\Delta)g \pm \epsilon'.
\]

Therefore, since the transition distributions \( (1T_\Delta), \ldots, (p^{-1}T_\Delta) \) are contraction mappings, it follows that

\[
(1T_\Delta)(2T_\Delta) \cdots (p^{-2}T_\Delta)(p^{-1}T_\Delta)(pT_\Delta)g
= (1T_\Delta)(2T_\Delta) \cdots (p^{-2}T_\Delta)(p^{-1}T_\Delta)(pT_\Delta)g \pm \epsilon'
\]

(11.6.13)

15. Finally, let \( k = 0, \ldots, K \) and \( y \in A_{n+1, k} \). Be arbitrary. Let \( g \equiv g_{k,y}^{(n+1)} \in G_n \). Hence, using equality [11.6.13] repeatedly, we obtain

\[
F_{0, \Delta, \ldots, nT}(1T_\Delta)(2T_\Delta) \cdots (n^{-1}T_\Delta)(nT_\Delta)g
= (1T_\Delta)(2T_\Delta) \cdots (n^{-1}T_\Delta)(nT_\Delta)(nT_\Delta)g \pm \epsilon'
= (1T_\Delta)(2T_\Delta) \cdots (n^{-1}T_\Delta)(nT_\Delta)(nT_\Delta)g \pm 2\epsilon'
= \cdots
= (1T_\Delta)(2T_\Delta) \cdots (n^{-1}T_\Delta)(nT_\Delta)(nT_\Delta)g \pm (n+1)\epsilon'
= F_{0, \Delta, \ldots, nT}g \pm (n+1)\epsilon'.
\]

(11.6.14)

16. Moreover, by Condition (i) in Step 7, the function

\[
F_{0, \Delta, \ldots, nT}g = (1T_\Delta)(2T_\Delta) \cdots (n^{-1}T_\Delta)(nT_\Delta)g \in G_0
\]

has modulus of continuity \( \tilde{\delta}_0 \). Therefore

\[
F_{0, \Delta, \ldots, nT}g = F_{0, \Delta, \ldots, nT}g \pm \epsilon'
\]

because

\[
d(x, \overline{x}) \leq \overline{\rho}_0 < \delta_{\overline{\delta}, f, j, d}(\epsilon_0, \overline{x}, \overline{x}, ||\xi||) \equiv \rho_0(\epsilon') \wedge \tilde{\delta}_0(\epsilon') \leq \tilde{\delta}_0(\epsilon').
\]

By symmetry,

\[
F_{0, \Delta, \ldots, nT}g = F_{0, \Delta, \ldots, nT}g \pm \epsilon'.
\]

(11.6.15)
11.6. CONTINUITY OF CONSTRUCTION

\[ F_{n, \Delta}^{x} \cdot n \Delta g = F_{n, \Delta}^{x} g + (n + 1) \varepsilon' = F_{n, \Delta}^{x} \left( g + (n + 1) \varepsilon' \right) \]
\[ = F_{n, \Delta}^{x} g + (n + 1) \varepsilon' \equiv F_{n, \Delta}^{x} g + 3^{-1} \varepsilon_0, \]

Equivalently,
\[ (T_{n, \Delta})^{2} \cdots (T_{k, \Delta})^{(n+1)} = (T_{k, \Delta}^{x})^{2} \cdots (T_{n, \Delta})^{(n+1)} + 3^{-1} \varepsilon_0 \quad (11.6.16) \]

where \( k = 0, \cdots, K \) and \( y \in A_{n+1, k} \). The desired equality follows for each \( n = 0, \cdots, N \). In turn, inequalities [11.6.4] and [11.6.3] then imply that
\[
\bar{\rho}_{\text{Marg}, \xi, \|\xi\|} (\Phi_{S_{\gamma}, \hat{f}jd}(x, T), \Phi_{S_{\gamma}, \hat{f}jd}(x, T))
\]
\[ = \bar{\rho}_{\text{Marg}, \xi, \|\xi\|} (F, T) \leq 3^{-1} \varepsilon_0 + 3^{-1} \varepsilon_0 + 3^{-1} \varepsilon_0 = \varepsilon_0, \]

provide that the distance \( \bar{\rho}_0 = (d \otimes \rho_{\mathcal{F}})((x, T), (x, T)) \) is bounded by
\[ \bar{\rho}_0 < \delta_{S_{\gamma}, \hat{f}jd}(\varepsilon_0, \bar{\delta}, \|\xi\|). \]

Summing up, \( \delta_{S_{\gamma}, \hat{f}jd}(\bar{\omega}, \|\xi\|) \) is a modulus of continuity of the mapping \( \Phi_{S_{\gamma}, \hat{f}jd} \). The theorem is proved.

Following is the main theorem of the section. It proves the continuity of construction in the case where the parameter set is \([0, \infty)\).

**Theorem 11.6.4.** (Construction of time-uniformly a.u. càdlàg Markov process from an initial state and a Markov semigroup on \([0, \infty)\), and continuity of said construction.) Let \((S, d)\) be the specified compact metric space, with \( d \leq 1 \). Let \( \mathcal{F} (\bar{\delta}, \bar{\omega}) \) be an arbitrary family of Markov semigroups with parameter set \([0, \infty)\) and state space \((S, d)\), such that all its members \( T \in \mathcal{F} (\bar{\delta}, \bar{\omega}) \) share a common modulus of strong continuity \( \delta_T = \bar{\delta}, \) and share a common modulus of smoothness \( \alpha_T = \bar{\omega}, \) in the sense of Definition [11.3.1]. Thus \( \mathcal{F} (\bar{\delta}, \bar{\omega}) \) is a subset of \( (\mathcal{F}, \rho_{\mathcal{F}}) \), and, as such, inherits the metric \( \rho_{\mathcal{F}} \) introduced in Definition [11.6.2]. Recall from [10.2.9] the space \( \hat{C}_{CP}([0, \infty), S) \) of consistent families of f.j.d.’s which are continuous in probability, equipped with the metric \( \hat{\rho}_{CP, \xi}([0, \infty), \|\xi\|) \) introduced in Definition [11.2.7]. Then the following holds.

1. There exists a uniformly continuous mapping
\[ \tilde{\Phi}_{S_{\gamma}, \hat{f}jd} : (S \times \mathcal{F} (\bar{\delta}, \bar{\omega}), d \otimes \rho_{\mathcal{F}}) \to (\hat{C}_{CP}([0, \infty), S), \hat{\rho}_{CP, \xi}([0, \infty), \|\xi\|)) \]

such that, for each \((x, T) \in S \times \mathcal{F} (\bar{\delta}, \bar{\omega})\), the family \( T = \tilde{\Phi}_{S_{\gamma}, \hat{f}jd}(x, T) \) of f.j.d.’s is generated by the initial state \( x \) and the semigroup \( T \), in the sense of Definition [11.4.1].

Roughly speaking, we can generate, from an initial state and a semigroup the corresponding f.j.d.'s, and the generation is continuous. We will write \( T^{x} = \tilde{\Phi}_{S_{\gamma}, \hat{f}jd}(x, T) \) and call it the family of f.j.d.’s generated by the initial state and the semigroup \( T \).

In particular, for each \( T \in \mathcal{F} (\bar{\delta}, \bar{\omega}) \), the function
\[ F^{x, T} = \tilde{\Phi}_{S_{\gamma}, \hat{f}jd}(\cdot, T) : (S, d) \to (\hat{C}_{CP}([0, \infty), S), \hat{\rho}_{CP, \xi}([0, \infty), \|\xi\|)) \]

Yuen-Kwok Chan 451 Constructive Probability
is uniformly continuous. Consequently, for each \( m \geq 1 \), \( f \in C(S^m, d^m) \), and nondecreasing sequence \( r_1 \leq \cdots \leq r_m \) in \([0, \infty)\), the function

\[
F^{x, T}_{r(1), \ldots, r(m)}: (S, d) \to R
\]

is uniformly continuous on \((S, d)\).

2. There exists a uniformly continuous mapping

\[
\Phi_{Sg, clMk}: (S \times \mathcal{F}(\delta, \mathcal{U}), d \otimes \rho_{\mathcal{F}, \mathcal{U}}) \to (\bar{D}(0, \infty), \bar{\rho}_{\bar{D}(0, \infty)}),
\]

where \((\bar{D}(0, \infty), \bar{\rho}_{\bar{D}(0, \infty)})\) is the metric space of a.u. càdlàg process with some sample space \((\Omega, L, E)\) and with parameter set \([0, \infty)\), as defined in Definition \([10.10.4]\). Specifically

\[
\Phi_{Sg, clMk} = \mathcal{F}_r \circ \mathcal{F}_{DKS, \xi} \circ \Phi_{Sg, \varepsilon r} \circ \Psi,
\]

where the component mappings on the right-hand side have been previously defined and will be recalled in detail in the proof. Roughly speaking, we can construct, from an initial state and a semigroup, a corresponding a.u. càdlàg process \(X^{x, T} \equiv \Phi_{Sg, clMk}(x, T)\), and prove that the construction is continuous.

Moreover, \(X^{x, T}\) has a modulus of a.u. càdlàg \(\hat{\delta}_{aucl, \mathcal{U}} \equiv (\hat{\delta}_{aucl, \mathcal{U}}, \hat{\delta}_{aucl, \mathcal{U}}, \cdots)\) and has a modulus of continuity in probability \(\hat{\delta}_{C_p, \mathcal{U}} \equiv (\hat{\delta}_{C_p, \mathcal{U}}, \hat{\delta}_{C_p, \mathcal{U}}, \cdots)\). In other words, \(X^{x, T} \in \bar{D}_{\hat{\delta}_{aucl, \mathcal{U}}, \hat{\delta}_{C_p, \mathcal{U}}}(0, \infty)\). Hence the function \(\Phi_{Sg, clMk}\) has range in \(\bar{D}_{\hat{\delta}_{aucl, \mathcal{U}}, \hat{\delta}_{C_p, \mathcal{U}}}(0, \infty)\), and we can regard it as a uniformly continuous mapping

\[
\Phi_{Sg, clMk}: (S \times \mathcal{F}(\delta, \mathcal{U}), d \otimes \rho_{\mathcal{F}, \mathcal{U}}) \to \bar{D}_{\hat{\delta}_{aucl, \mathcal{U}}, \hat{\delta}_{C_p, \mathcal{U}}}(0, \infty).
\]

3. Let \((x, T) \in S \times \mathcal{F}(\delta, \mathcal{U})\) be arbitrary. Then the process

\[
X^{x, T} \equiv \Phi_{Sg, clMk}(x, T): [0, \infty) \times (\Omega, L, E) \to (S, d),
\]

constructed in Assertion 2 above, is Markov relative to its natural filtration \(\bar{\mathcal{U}}\). More precisely, for each \( t \geq 0 \), define

\[
\mathcal{L}^{(t)} = L(X^{x, T}_s: s \in [0, t])
\]

and define \(\bar{\mathcal{U}} = \{\mathcal{L}^{(t)}: t \geq 0\}\). Let the nondecreasing sequence \(0 = s_0 \leq s_1 \leq \cdots \leq s_m\) in \([0, \infty)\), the function \(f \in C(S^m, d^m+1)\), and \(t \geq 0\) be arbitrary. Then

\[
E(f(X_{t+s(0)}, X_{t+s(1)}, \cdots, X_{t+s(m)}))|\mathcal{L}^{(t)})
\]

\[
= E(f(X_{t+s(0)}, X_{t+s(1)}, \cdots, X_{t+s(m)})|X_t) = F^{X^{(t, T)}_{s(0), \ldots, s(m)}}(f)
\]

(11.6.17)

as r.v.'s.
11.6. CONTINUITY OF CONSTRUCTION

Proof. We will prove Assertion 2 first, then Assertions 3 and 1. To that end, let

\[(\Omega, L, E) \equiv (\Theta_0, L_0, I_0) \equiv ([0, 1], I_0, \int \cdot \, dx)\]

denote the Lebesgue integration space based on the unit interval \(\Theta_0\).

1. Let \(T \in \mathcal{F}(\overline{\delta}, \overline{\alpha})\) be arbitrary. Then, since \(T\) is a Markov semigroup with parameter set \([0, \infty)\), it is trivial to verify the conditions in Definition \[11.3.1\] for its restriction \(T|_{\overline{Q}_\omega}\) to be a Markov semigroup with parameter set \(\overline{Q}_\omega\), with the same modulus of strong continuity \(\overline{\delta}_T = \overline{\delta}\) and modulus of smoothness \(\overline{\alpha}_T = \overline{\alpha}\).

2. Define the set \(\mathcal{F}(\overline{\delta}, \overline{\alpha})|_{\overline{Q}_\omega} = \{T|_{\overline{Q}_\omega} : T \in \mathcal{F}(\overline{\delta}, \overline{\alpha})\}\), and equip it with the metric \(\rho_{\mathcal{F}, \overline{\delta}}\) introduced in Definition \[11.6.2\]. As observed in Step 1 above, members of the family \(\mathcal{F}(\overline{\delta}, \overline{\alpha})|_{\overline{Q}_\omega}\) share the common \(\overline{\delta}\) and common \(\overline{\alpha}\). As observed in Definition \[11.6.2\] the mapping

\[\Psi : (\mathcal{F}(\overline{\delta}, \overline{\alpha}), \rho_{\mathcal{F}, \overline{\delta}}) \to (\mathcal{F}(\overline{\delta}, \overline{\alpha})|_{\overline{Q}_\omega}, \rho_{\mathcal{F}, \overline{\delta}}),\]

defined by \(\Psi(T) \equiv T|_{\overline{Q}_\omega}\) for each \(T \in \mathcal{F}(\overline{\delta}, \overline{\alpha})\), is trivially an isometry. Hence the mapping

\[\overline{\Psi} : (S \times \mathcal{F}(\overline{\delta}, \overline{\alpha}), d \otimes \rho_{\mathcal{F}, \overline{\delta}}) \to (S \times \mathcal{F}(\overline{\delta}, \overline{\alpha})|_{\overline{Q}_\omega}, d \otimes \rho_{\mathcal{F}, \overline{\delta}}),\]

defined by \(\overline{\Psi}(x, T) \equiv (x, \Psi(T))\) for each \((x, T) \in S \times \mathcal{F}(\overline{\delta}, \overline{\alpha})\), is, in turn, trivially uniformly continuous.

3. Theorem \[11.6.3\] therefore says that the mapping

\[\Phi_{Sg, \text{jd}} : (S \times \mathcal{F}(\overline{\delta}, \overline{\alpha})|_{\overline{Q}_\omega}, d \otimes \rho_{\mathcal{F}, \overline{\delta}}) \to (\overline{F}(\overline{Q}_\omega, S), \overline{\rho}_{\text{Marg}, \overline{\delta}, \overline{Q}_\omega}),\]

constructed in Assertion 4 of Theorem \[11.4.2\] is uniformly continuous, with a modulus of continuity \(\delta_{Sg, \text{jd}}(\cdot, \overline{\delta}, \overline{\alpha}, \|\xi\|)\) completely determined by the moduli \(\overline{\delta}, \overline{\alpha}\) and the modulus of local compactness \(\|\xi\| \equiv \{\lambda_n\}_{n=1,2,\ldots}\) of \((S, d)\).

4. Separately, Theorem \[6.4.3\] says that the Compact Daniell-Kolmogorov-Skorokhod Extension

\[\overline{\Phi}_{DKS, \xi} : (\overline{F}(\overline{Q}_\omega, S), \overline{\rho}_{\text{Marg}, \overline{\delta}, \overline{Q}_\omega}) \to (\overline{R}(\overline{Q}_\omega \times \Theta_0, S), \overline{\rho}_{\text{Prob}, \overline{Q}_\omega})\]

is uniformly continuous with a modulus of continuity \(\overline{\delta}_{DKS}(\cdot, \|\xi\|)\) dependent only on \(\|\xi\|\).

5. Combining, we see that the composite mapping \(\overline{\Phi}_{DKS, \xi} \circ \Phi_{Sg, \text{jd}} \circ \overline{\Psi}\) is uniformly continuous. Now consider the range of this composite mapping. Specifically, take an arbitrary \((x, T) \in S \times \mathcal{F}\) and consider the image

\[Z \equiv \overline{\Phi}_{DKS, \xi}(\Phi_{Sg, \text{jd}}(\overline{\Psi}(x, T))).\]

where

\[F \equiv \Phi_{Sg, \text{jd}}(x, T|_{\overline{Q}_\omega})\]

is the consistent family constructed in Assertion 3 of Theorem \[11.4.2\] and is generated by the initial state \(x\) and the semigroup \(T|_{\overline{Q}_\omega}\) in the sense of Definition \[11.4.7\].
notations of Theorem 11.4.2, we have \( F \equiv F^{x,T} \). Thus \( Z \equiv \mathcal{D}_{\text{DKS}, \xi} (F^{x,T}) \). By the definition of the mapping \( \mathcal{D}_{\text{DKS}, \xi} \), the process \( Z \) has marginal distributions given by the family \( F^{x,T} \). In particular \( Z_0 = x \).

6. Since the semigroup \( T \) has modulus of strong continuity \( \delta \), Assertion 1 of Theorem 11.5.1 implies that the process \( Z \equiv \mathcal{D}_{\text{DKS}, \xi} (F^{x,T}) \) is generated by the initial state \( x \) and semigroup \( T \), in the sense of Definition 10.10.3. Hence, by Assertions 4 of Proposition 11.5.2, the process \( Z \) is time-uniformly \( D \)-regular in the sense of Definition 10.10.3, with some modulus of continuity in probability \( \delta_{C_p, \xi} \equiv (\delta_{C_p, \xi}, \delta_{C_p, \xi}, \cdots) \) and with some modulus of \( D \)-regularity \( m_{\xi} \equiv (m_{\xi}, m_{\xi}, \cdots) \). In the notations of Theorem 11.5.1 implies that the process \( Z \) has modulus of strong continuity \( \delta \). Summing up, we see that the range of the composite mapping \( \mathcal{D}_{\text{DKS}, \xi} \circ \Phi_{Sg, fjd} \circ \Psi \) is contained in the subset \( \tilde{R}_{\text{Dreg}, \delta_{C_p, \xi}, m_{\xi}} (\Omega_\infty \times \Omega, S) \) of \( (\tilde{R}(\Omega_\infty \times \Theta_0, S), \tilde{\rho}_{\text{Prob}, \Omega_\infty}) \). Thus we have the uniformly continuous mapping

\[
\mathcal{D}_{\text{DKS}, \xi} \circ \Phi_{Sg, fjd} \circ \Psi : (S \times \mathcal{T}(\tilde{\delta}, \tilde{\alpha}, d \otimes \rho_{\tilde{\xi}}) \to \tilde{R}_{\text{Dreg}, \delta_{C_p, \xi}, m_{\xi}} (\Omega_\infty \times \Omega, S), \tilde{\rho}_{\text{Prob}, \Omega_\infty}).
\]

In the notations of Theorem 11.5.1, we defined \( Z^{x,T} \) \( \equiv \mathcal{D}_{\text{DKS}, \xi} (F^{x,T}) \). Hence \( Z = Z^{x,T} \). Therefore, by the definition of \( \mathcal{D}_{\text{DKS}, \xi} \), the process \( Z \) has marginal distributions given by the family \( F^{x,T} \).

7. Moreover, by Assertions 5 Proposition 11.5.2, the right-limit extension

\[
X \equiv \mathcal{F}_{\text{rLim}}(Z) = [0, \infty) \times (\Omega, L, E) \to (S, d)
\]

is a well-defined time-uniformly a.u. càdlàg process on \( [0, \infty) \), in the sense of Definition 10.10.4, with some modulus of a.u. càdlàg \( \delta_{acl, \xi} \equiv (\delta_{acl, \xi}, \delta_{acl, \xi}, \cdots) \) and with the modulus of continuity in probability \( \delta_{C_p, \xi} \). In short \( X = \mathcal{F}_{\text{rLim}}(Z) \) is \( \tilde{D}(0, \infty) \).

8. Since \( (x, T) \in S \times \mathcal{T} \) is arbitrary, the composite mapping \( \mathcal{F}_{\text{rLim}} \circ \mathcal{D}_{\text{DKS}, \xi} \circ \Phi_{Sg, fjd} \circ \Psi \) is well defined. We have already seen that the mapping \( \mathcal{D}_{\text{DKS}, \xi} \circ \Phi_{Sg, fjd} \circ \Psi \) is uniformly continuous. In addition, Theorem 10.10.7 says that

\[
\mathcal{F}_{\text{rLim}} : (R_{\text{Dreg}, \delta_{C_p, \xi}, m_{\xi}} (\Omega_\infty \times \Omega, S), \tilde{\rho}_{\text{Prob}, \Omega_\infty}) \to (\tilde{D}(0, \infty), \tilde{\rho}_{\tilde{D}(0, \infty)}).
\]

is a well-defined isometry. Summing up, we see that the composite construction mapping

\[
\Phi_{Sg,clMk} \equiv \mathcal{F}_{\text{rLim}} \circ \mathcal{F}_{\text{DKS}, \xi} \circ \Phi_{Sg, fjd} \circ \Psi : (S \times \mathcal{T}(\tilde{\delta}, \tilde{\alpha}, d \otimes \rho_{\tilde{\xi}}) \to (\tilde{D}(0, \infty), \tilde{\rho}_{\tilde{D}(0, \infty)})
\]

is well-defined and is uniformly continuous. Assertion 2 of the present theorem has been proved.

9. Next, note that Assertion 3 of Theorem 11.5.3 says that the process \( X^{x,T} = \mathcal{F}_{\text{rLim}}(Z^{x,T}) = X \) is Markov relative to its natural filtration \( \mathcal{F} \equiv \{ \mathcal{L}(t) : t \in [0, \infty) \} \), and that, specifically, for each \( \nu \geq 0 \) and for each sequence \( t_0 \equiv 0 \leq t_1 \leq \cdots \leq t_m \) in \( [0, \infty) \), we have

\[
I_0(f(X_{\nu+t_0}(0), \cdots, X_{\nu+t_m}(m)) | \mathcal{L}(\nu)) = I_0(f(X_{\nu+t_0}(0), \cdots, X_{\nu+t_m}(m)) | X_\nu) = F^{X(\nu), T}_{0, t_1, \cdots, t_m, f}. \tag{11.6.18}
\]
11.7. A.U. Càdlàg Markov Processes are Strongly Markov

Assertion 3 of the present theorem is proved. 

10. To prove Assertion 1, define \( \mathcal{T}_{\mathcal{S},f,jd}(x,T) \) to be the family \( \mathcal{T} \) of marginal distributions of the process \( X = X^{x,T} \equiv \mathcal{T}_{\mathcal{S},\lim}(Z^{x,T}) \). In the special case where \( v = 0 \), equality 11.6.18 then yields

\[
\mathcal{T}_{0,t(1)\cdots t(m)}f \equiv E f(X_{t(1)}, \cdots, X_{t(m)}) = E(E f(X_{t(1)}, \cdots, X_{t(m)}|\mathcal{T}(0))) = E f_{0,t(1)\cdots t(m)}f = f_{x,T}^{x,T} f,
\]

(11.6.19)

where the last equality holds because \( X_0 = Z_0 = x \) a.s. If members of the sequence \( t_0 = 0 \leq t_1 \leq \cdots \leq t_m \) are in \( \mathcal{Q}_m \), then Assertion 5 of Theorem 11.4.2 implies

\[
E f_{0,t(1)\cdots t(m)}f = \int T^x_{t(1)}(dx_1) \int dT^{x(m-1)}_{t(m-1)}(dx_{m-1}) \cdots \int dT^x_{t(1)}(dx_2) \int dT^x_{t(1)}(dx_1) \int dT^{x(m-1)}_{t(m-1)}(dx_{m-1}) f(x_0, \cdots, x_m).
\]

(11.6.20)

Hence, by continuity in the time parameters, this same equality holds for an arbitrary sequence \( t_0 = 0 \leq t_1 \leq \cdots \leq t_m \) in \([0,\infty)\). Combining with equality 11.6.19 we obtain

\[
\mathcal{T}_{0,t(1)\cdots t(m)}f = \int T^x_{t(1)}(dx_1) \int dT^{x(m-1)}_{t(m-1)}(dx_{m-1}) \cdots \int dT^x_{t(1)}(dx_2) \int dT^x_{t(1)}(dx_1) \int dT^{x(m-1)}_{t(m-1)}(dx_{m-1}) f(x_0, \cdots, x_m).
\]

Thus the family \( \mathcal{T}_{\mathcal{S},f,jd}(x,T) \) is generated by the initial state \( x \) and the semigroup \( T \), in the sense of Definition 11.4.1. Continuity of the function \( \mathcal{T}_{\mathcal{S},f,jd} \) then follows easily from the continuity of \( \mathcal{T}_{\mathcal{S},C,jMk} \) established in Step 8. Assertion 1 and the theorem have been proved. \( \square \)

11.7 a.u. Càdlàg Markov Processes are Strongly Markov

Definition 11.7.1. (Specification of state space, parameter sets, Markov semigroup, and related objects). In this section, unless otherwise specified, let \((S,d)\) be a given compact metric space, with \( d \leq 1 \). Let \( T \) be denote an arbitrary Markov semigroup with parameter set \([0,\infty)\) and state space \((S,d)\), with a modulus of strong continuity \( \delta_T \) and a modulus of smoothness \( \alpha_T \equiv \alpha_{TX} \). For each \( x \in S \), let \( F(x,T) \) denote the family of transition f.j.d.’s, with parameter set \([0,\infty)\), generated by the initial state \( x \) and semigroup \( T \), as defined and constructed in Theorem 11.6.4. We will use results in the previous sections regarding these objects, without further comments.

Refer also to Definition 11.1.1 for the a specified binary approximation \( \xi \) of the compact metric space \((S,d)\). Refer to Definition 11.0.2 for notations related to the sets \( \mathcal{Q}_1, \mathcal{Q}_2, \ldots, \mathcal{Q}_m \) of dyadic rationals in \([0,\infty)\), and to the sets \( \mathcal{Q}_1, \mathcal{Q}_2, \ldots, \mathcal{Q}_m \) of dyadic rationals in \([0,1]\).

Lemma 11.7.2. (Each a.u. càdlàg Markov process is a.u. right continuous at each stopping time with regularly spaced dyadic values). Let \( x \in S \) be arbitrary.

\[
X : [0,\infty) \times (\Omega,L,E) \rightarrow (S,d)
\]

be an arbitrary a.u. càdlàg Markov process generated by the initial state \( x \) and with semigroup \( T \) which is adapted to some filtration \( \mathcal{F} \equiv \{L^t : t \in [0,\infty)\} \). Let \( k \geq 0 \) be arbitrary. Then there exists \( m_k \equiv m_k(\delta_T) \geq 0 \) with the following properties.

Yuen-Kwok Chan 455 Constructive Probability
CHAPTER 11. MARKOV PROCESS

Let \( \eta \) be an arbitrary stopping time with values in \( \overline{Q}_h \) for some \( h \geq 0 \), relative to the filtration \( \mathcal{F} \). Then the function

\[
V_{\eta,k} \equiv \sup_{s \in [0, \Delta(m(k))] } d(X_\eta, X_{\eta+s})
\]

is a well defined r.r.v., with

\[
EV_{\eta,k} \leq 2^{-k+1}.
\]

Recall here that \( \Delta_m(k) \equiv 2^{-m(k)} \). We emphasize that \( m_k \) depends only on \( \delta_1 \), and is independent of \( \eta, h \) or the initial state \( x \). Furthermore, by inductively replacing \( m_k \) with \( m_k \vee (m_{k-1} + 1) \) for each \( k \geq 1 \), we may assume that the sequence \( (m_k)_{k=0,1,...} \) of integers is increasing.

Proof. 1. Define \( Z \equiv X|Q_\infty \). Then \( X = \Phi_{rLim}(Z) \). Let \( M \geq 0 \) be arbitrary. Define the shifted process

\[
X^M \equiv [0,1] \times (\Omega, L, E) \to (S, d)
\]

by \( X^M(t) \equiv X(M+t) \) for each \( t \in [0,1] \). Similarly, define the shifted process

\[
Z^M \equiv Q_\infty \times (\Omega, L, E) \to (S, d)
\]

by \( Z^M(t) \equiv X(M+t) \) for each \( t \in Q_\infty \). Then \( X^M = \Phi_{rLim}(Z^M) \).

2. Thanks to Theorem 11.6.4 the a.u. càdlàg Markov process \( X \) is time-uniformly a.u. càdlàg in the sense of Definition 10.10.4 with a modulus of continuity in probability \( \delta_{C_p, \delta(T)} \equiv \delta_{C_p, \delta(T)}(\delta_{aucl, \delta(T)}) \) and a modulus of a.u. càdlàg \( \delta_{aucl, \delta(T)} \equiv \delta_{aucl, \delta(T)}(\delta_{aucl, \delta(T)}) \). In other words, the shifted process \( X^M \) has a modulus of a.u. càdlàg \( \delta_{aucl, \delta(T)} \) and a modulus of continuity in probability \( \delta_{C_p, \delta(T)} \) which are independent of \( M \) and of the initial state \( x \). In particular, the process \( X|[0,1] = X^0 \) has a modulus of a.u. càdlàg \( \delta_{aucl, \delta(T)} \). Take an arbitrary increasing sequence \( m_k \equiv (m_k)_{k=0,1,2,...} \) of integers such that

\[
\Delta_m(k) \equiv 2^{-m(k)} \leq \delta_{aucl, \delta(T)}(2^{-k}) \tag{11.7.1}
\]

for each \( k \geq 0 \). Then, by Theorem 10.4.3, the process \( Z|Q_\infty = Z^0 \) has a modulus of \( D \)-regularity given by the sequence \( m_{-1} \equiv m_0 \).

3. Let \( k \geq 0 \) be arbitrary, but fixed till further notice. By Condition 3 in Definition 10.5.2 there exist a measurable set \( A \) with \( P(A^c) < 2^{-k} \) and a r.r.v. \( \tau_1 \) with values in \([0,1]\) such that, for each \( \omega \in A \), we have

\[
\tau_1(\omega) \geq \delta_{aucl, \delta(T)}(2^{-k}) > 2^{-m(k)} \equiv \Delta_m(k), \tag{11.7.2}
\]

and

\[
d(X(0, \omega), X(\cdot, \omega)) \leq 2^{-k}, \tag{11.7.3}
\]

on the interval \( \theta_0(\omega) \equiv [0, \tau_1(\omega)) \). Then inequalities 11.7.3 and 11.7.2 together imply that, for each \( \omega \in A \), we have

\[
d(X_0(\omega), X_u(\omega)) \leq 2^{-k}
\]

Yuen-Kwok Chan 456 Constructive Probability
Then inequality 11.7.6 can be rewritten compactly as
\[ J(k) \]
\[
\sup_{j=0}^{J(k)} d(X_0, X_{j\Delta(k)})I_A \leq 2^{-k},
\]
where \( J(k) \equiv 2^{m(k) - m(k)} \). Therefore, with the function \( f_k \in C(S^{J(k) + 1}, d^{J(k) + 1}) \) defined by
\[
f_k(x_0, x_1, \ldots, x_{J(k)}) \equiv \sup_{j=0}^{J(k)} d(x_0, x_j)
\]
for each \( (x_0, x_1, \ldots, x_{J(k)}) \in S^{J(k) + 1} \), we have
\[
E f_k(X_0, X_{\Delta(k)}, \ldots, X_{J(k)\Delta(k)}) \equiv E \sup_{j=0}^{J(k)} d(X_0, X_{j\Delta(k)})
\]
\[
\leq E \sup_{j=0}^{J(k)} d(X_0, X_{j\Delta(k)})I_A + P(A^c) \leq 2^{-k} + 2^{-k} = 2^{-k+1}, \tag{11.7.4}
\]
In terms of marginal distributions, inequality [11.7.4] can be rewritten as
\[
F^{x, T}_{0, \Delta(k), \ldots, J(k)\Delta(k)} f_k \leq 2^{-k+1}, \tag{11.7.5}
\]
where the family \( F^{x, T} \) of transition f.j.d.'s are as constructed in [11.6.4]. Recall here that \( F^{x, T}_{0, \Delta(k), \ldots, J(k)\Delta(k)} f_k \) is continuous in \( x \in (S, d) \).

3. Separately, Assertion 2 of Lemma [10.5.5] applies to \( \nu \equiv 0 \) and \( \nu' \equiv \Delta_{m(k)} \), to show that the supremum
\[
V_{0,k} \equiv \sup_{u \in [0, \Delta(m(k))]} d(Z_0, Z_u) = \sup_{u \in [0, \Delta(m(k))]} d(X_0, X_u) = \sup_{u \in [0, \Delta(m(k))]} d(X_0, X_u)
\]
is a well defined r.r.v, where the last equality is by the right continuity of the a.u. càdlàg process \( X \). Consider each \( \kappa \geq k \). Assertion 3 of Lemma [10.5.5] then applies to \( \nu \equiv 0 \), \( \nu' \equiv \Delta_{m(k)} \), and \( \nu \equiv \kappa \), to yield
\[
0 \leq E \sup_{u \in [0, \Delta(m(k))] \cap Q(\infty)} d(Z_0, Z_u) - E \sup_{u \in [0, \Delta(m(k))] \cap Q(m(k))} d(Z_0, Z_u) \leq 2^{-\kappa+5}. \tag{11.7.6}
\]
Define the r.r.v.
\[
V_{0,k,k} \equiv \sup_{u \in [0, \Delta(m(k))] \cap Q(m(k))} d(Z_0, Z_u) \equiv \sup_{u \in [0, \Delta(m(k))] \cap Q(m(k))} d(X_0, X_{u\Delta(k)}) \equiv f_k(X_0, X_{\Delta(k)}, \ldots, X_{J(k)\Delta(k)})
\]
Then inequality [11.7.6] can be rewritten compactly as
\[
0 \leq EV_{0,k} - EV_{0,k,k} \leq 2^{-\kappa+5}. \tag{11.7.7}
\]
Hence for each \( \kappa' \geq \kappa \geq k \), we have \( V_{0,k,k+1} \geq V_{0,k,k} \) and
\[
0 \leq EV_{0,k,k'} - EV_{0,k,k} \leq 2^{-\kappa+5}. \tag{11.7.8}
\]
Equivalently,
\[
0 \leq F_{0,\Delta(\kappa')}^T \cdots F_{0,\Delta(\kappa')}^T \Delta \kappa' - F_{0,\Delta(\kappa')}^T \cdots F_{0,\Delta(\kappa')}^T \Delta \kappa \leq 2^{-\kappa+5}, \tag{11.7.9}
\]
where \( x \in S \) is the arbitrary initial state.

4. Now let \( \eta \) be an arbitrary stopping time with values in \( \Omega_h \) for some \( h \geq 0 \), relative to the filtration \( \mathcal{F}_t \). Define
\[
V_{\eta,k,k} \equiv \bigvee_{u(0,\Delta(m(k))\{|Q(m(k)} d(X_{\eta},X_{\eta+k})
\]
\[
\equiv \bigvee_{j=0} J(\kappa) d(X_{\eta},X_{\eta+j(\Delta(\kappa)}) \equiv f_{\kappa}(X_{\eta},X_{\eta+\Delta(\kappa)}, \cdots, X_{\eta+J(\Delta(\kappa)})).
\]
Then
\[
0 \leq E(V_{\eta,k,k'} - V_{\eta,k,k}) = E(f_{\kappa'}(X_{\eta},X_{\eta+\Delta(\kappa)}), \cdots, X_{\eta+J(\Delta(\kappa)}) - f_{\kappa}(X_{\eta},X_{\eta+\Delta(\kappa)}, \cdots, X_{\eta+J(\Delta(\kappa)}) )
\]
\[
= E(F_{X(\eta),T}^T \cdots F_{X(\eta),T}^T \Delta \kappa' - EF_{X(\eta),T}^T \cdots F_{X(\eta),T}^T \Delta \kappa \leq 2^{-\kappa+5},
\]
where the last inequality is thanks to inequality \([11.7.9]\).

Hence
\[
V_{\eta,k,k} \uparrow U \quad \text{a.u.}
\]
for some r.r.v. \( U \in L \), as \( \kappa \to \infty \). Let \( \omega \in \text{domain}(U) \) be arbitrary. Then the limit
\[
\lim_{k \to \infty} V_{\eta,k,k}(\omega) \equiv \lim_{k \to \infty} \bigvee_{u(0,\Delta(m(k))\{|Q(m(k)} d(X_{\eta}(\omega),X_{\eta+k}(\omega))
\]
exists and is equal to \( U(\omega) \). Hence
\[
\sup_{u(0,\Delta(m(k))\{|Q(m(k)) d(X_{\eta}(\omega),X_{\eta+k}(\omega)) = U(\omega).
\]
Consequently, by the right continuity of \( X(\cdot, \omega) \) at \( \eta(\omega) \), we obtain
\[
V_{\eta,k}(\omega) \equiv \sup_{u(0,\Delta(m(k))\{|Q(m(k)) d(X_{\eta}(\omega),X_{\eta+k}(\omega)) = U(\omega)
\]
We conclude that the function \( V_{\eta,k} = U \) on a full set, and therefore that \( V_{\eta,k} \) is an integrable r.r.v. Moreover
\[
EV_{\eta,k} = EU = \lim_{k \to \infty} EV_{\eta,k,k} \equiv \lim_{k \to \infty} F_{X(\eta),T}^T \cdots F_{X(\eta),T}^T \Delta \kappa \leq 2^{-\kappa+1},
\]
where the inequality follows from inequality \([11.7.5]\). The lemma is proved. \( \square \)
Lemma 11.7.3. (Observability of a.u. càdlàg Markov process at stopping time).
Let \( x \in S \) be arbitrary. Let
\[
X : [0, \infty) \times (\Omega, L, E) \to (S, d)
\]
be an arbitrary a.u. càdlàg Markov process generated by the initial state \( x \) Markov semigroup \( T \), and which is adapted to some right continuous filtration \( \mathcal{L} = \{ L(t) : t \in [0, \infty) \} \). Let \( \tau \) be an arbitrary stopping time with values in \([0, \infty)\), relative to \( \mathcal{L} \). Then the following holds.

1. The function \( X \) is a well defined r.v. which is measurable relative to \( L^{(\tau)} \).
2. Specifically, let \( (\eta_h)_{h=0,1,\ldots} \) be an arbitrary non increasing sequence of stopping times such that, for each \( h \geq 0 \), the r.v. \( \eta_h \) has values in \( \mathcal{Q}_h \), relative to the filtration \( \mathcal{L} \), and such that \( \tau \leq \eta_h < \tau + 2^{-h+2} \).

Note that such a sequence exists according to Assertion 1 of Proposition [11.1.1]. Then \( X_{\eta(k)} \) to \( X \) a.u. as \( h \to \infty \).

Proof. 1. Let \( (\eta_h)_{h=0,1,\ldots} \) be an arbitrary sequence of stopping times as in the hypothesis of Assertion 2. Let \( k \geq 0 \) be arbitrary. Let \( m_k \equiv m_k(\delta_T) \geq 0 \) be the integer constructed in Lemma [11.7.2] relative to the Markov semigroup \( T \). For abbreviation, write \( h_k \equiv (m_k + 3) \) and \( \zeta_k \equiv \eta_h(k) \). Then \( \zeta_k \) is a stopping time with values in \( \mathcal{Q}_h(k) \), relative to the filtration \( \mathcal{L} \). Hence Lemma [11.7.2] applied to the stopping time \( \zeta_k \), says that the function
\[
V_k \equiv V_{\zeta(k),k} \equiv \sup_{s \in [0,\Delta(m(k)]} d(X_{\zeta(k)}, X_{\zeta(k)+s})
\]
with
\[
EV_k \leq 2^{-k+1}.
\]

2. At the same time, inequality [11.7.11] implies that
\[
\tau \leq \eta_h(k) \equiv \zeta_k < \tau + 2^{-h(k)+3} \equiv \tau + 2^{-m(k)} = \tau + \Delta(m(k)),
\]
whence \( \zeta_k \downarrow \tau \) uniformly as \( k \to \infty \). Note that \( \zeta_{k+1} \leq \zeta_k \) because \( \eta_{h(k+1)} \leq \eta_{h(k)} \).
Hence inequality [11.7.12] leads to
\[
\tau \leq \zeta_{k+1} \leq \zeta_k < \tau + \Delta(m(k)) \leq \zeta_{k+1} + \Delta(m(k)),
\]
An immediate consequence is that, for each \( \kappa \geq k \), we have
\[
(\tau, \tau + \Delta(m(k)) \mathring{\mathcal{Q}}_{\infty}) \subset (\tau, \zeta_{k+1} + \Delta(m(k)) \mathring{\mathcal{Q}}_{\infty})
\]

\[
= (\bigcup_{j=\kappa}^{\infty} [\zeta_{j+2}, \zeta_{j+1}] \mathring{\mathcal{Q}}_{\infty}) \cup [\zeta_{k+1}, \zeta_{k+1} + \Delta(m(k)) \mathring{\mathcal{Q}}_{\infty})
\]

\[
\subset (\bigcup_{j=\kappa}^{\infty} [\zeta_{j+2}, \zeta_{j+2} + \Delta(m(j+1)) \mathring{\mathcal{Q}}_{\infty}) \cup [\zeta_{k+1}, \zeta_{k+1} + \Delta(m(k)) \mathring{\mathcal{Q}}_{\infty})
\]

Yuen-Kwok Chan 459 Constructive Probability
3. For each \( j \geq 0 \), take any \( \varepsilon_j \in (2^{-j/2-1}, 2^{-j/2}] \) such that the set \( A_j \equiv (V_j > \varepsilon_j) \) is measurable. Then

\[
P(A_j) \leq \varepsilon_j^{-1}EV_j \leq \varepsilon_j^{-1}2^{-j+1} < 2^{j/2+1}2^{-j+1} = 2^{-j/2+2},
\]

where the first inequality is by Chebychev’s inequality, and where the second inequality is by inequality 11.7.14. Therefore, we can define the measurable set \( A_{k+} \equiv \bigcup_{j=k}^\infty A_j \), with

\[
P(A_{k+}) < \sum_{j=k}^\infty P(A_j) < \sum_{j=k}^\infty 2^{-j/2+2} = 2^{-k/2+2}(1 - 2^{-1/2})^{-1} < 2^{-k/2+4}
\]

4. Now let \( \omega \in A_{k+}^{C} \) be arbitrary. Consider each \( j \geq k \) and each

\[
t \in [\zeta_{j+1}(\omega), \zeta_{j+1}(\omega) + \Delta_m(j)]\overline{Q}_\infty.
\]

Then \( u \equiv t - \zeta_{j+1}(\omega) \in [0, \Delta_m(j)]\overline{Q}_\infty \). Hence

\[
d(X_{\zeta_{j+1}}(\omega), X_{\omega}) = d(X_{\zeta_{j+1}}(\omega), X_{\zeta_{j+1}+u}(\omega))
\]

\[
\leq \sup_{x \in [0, \Delta_m(j)]} d(X_{\zeta_{j+1}}(\omega), X_{\zeta_{j+1}+x}(\omega)) = V_{j+1}(\omega) \leq \varepsilon_{j+1},
\]

where the last inequality is because \( \omega \in A_{k+}^C \subset A_{j+1}^C \). Note that

\[
\zeta_j(\omega) \in [\zeta_{j+1}(\omega), \zeta_{j+1}(\omega) + \Delta_m(j)]\overline{Q}_\infty
\]

thanks to inequality 11.7.13. Hence inequality 11.7.15 applies to \( \zeta_j(\omega) \) in the place of \( t \), to yield

\[
d(X_{\zeta_{j+1}}(\omega), X_{\zeta_{j}}(\omega)) \leq \varepsilon_{j+1},
\]

where \( j \geq k \) is arbitrary. Since \( \sum_{j=0}^\infty \varepsilon_{j+1} < \infty \), it follows that \( X_{\zeta_{j}}(\omega) \rightarrow x_\omega \) for some \( x_\omega \in S \), as \( j \rightarrow \infty \), with

\[
d(x_\omega, X_{\zeta_{j}}(\omega)) \leq \sum_{i=j}^\infty \varepsilon_{i+1} \leq \sum_{i=j}^\infty 2^{-(i+1)/2} = 2^{-(j+1)/2}(1 - 2^{-1/2})^{-1} < 2^{-(j+1)/2+4}.
\]

5. Now consider each \( t \in (\tau(\omega), \tau(\omega) + \Delta_m(k)]\overline{Q}_\infty \). Then, according to relation 11.7.14 there exists \( j \geq k \) such that

\[
t \in [\zeta_{j+1}(\omega), \zeta_{j+1}(\omega) + \Delta_m(j)]\overline{Q}_\infty.
\]

Therefore

\[
d(x_\omega, X_{\omega}) \leq d(x_\omega, X_{\zeta_{j}}(\omega)) + d(X_{\zeta_{j}}(\omega), X_{\zeta_{j+1}}(\omega)) + d(X_{\zeta_{j+1}}(\omega), X_{\omega})
\]

Yuen-Kwok Chan 460 Constructive Probability
11.7. A.U. CÄDLÄG MARKOV PROCESSES ARE STRONGLY MARKOV

\[ \leq \sum_{j=1}^{\infty} |\varepsilon_{i+1} + \varepsilon_{j+1} + \varepsilon_{j+1}| < 2^{-(j+1)/2+\varepsilon} \leq 2^{-(k+1)/2+\varepsilon} \]

where \( t \in (\tau(\omega), \tau(\omega) + \Delta_{m(k)}) \overline{Q}_\infty \) is arbitrary. Since the set \( (\tau(\omega), \tau(\omega) + \Delta_{m(k)}) \overline{Q}_\infty \) is a dense subset of \( (\tau(\omega), \tau(\omega) + \Delta_{m(k)}) \cap \text{domain}(X(\cdot, \omega)) \), and since the function \( X(\cdot, \omega) \) is right continuous on \( \text{domain}(X(\cdot, \omega)) \) according to Condition 1 in Definition \ref{10.10.4}, it follows that

\[ d(x_0, X_t(\omega)) \leq 2^{-(k+1)/2+\varepsilon} \quad (11.7.18) \]

for each \( t \in (\tau(\omega), \tau(\omega) + \Delta_{m(k)}) \cap \text{domain}(X(\cdot, \omega)) \), where \( 2^{-(k+1)/2+\varepsilon} \) is arbitrarily small. Thus \( \lim_{t \to \tau(\omega)^+} \tau(\omega)^+ X(t, \omega) \) exists and is equal \( x_0 \in S \). Therefore, by Condition 2 in Definition \ref{10.10.4} the right-completeness condition, we have \( \tau(\omega) \in \text{domain}(X(\cdot, \omega)) \). Then, by Condition 1 in Definition \ref{10.10.4} the right-continuity condition, we have \( X_T(\omega) = X(\tau(\omega), \omega) = x_0 \).

Inequality \[11.7.17\] can be rewritten as

\[ d(X_T(\omega), X_{\xi(j)}(\omega)) \leq 2^{-(j+1)/2+\varepsilon} \]

where \( j \geq k \) and \( \omega \in A_{k+}^c \) are arbitrary. Thus \( X_{\xi(j)} \to X_t \) uniformly on \( A_{k+}^c \), as \( j \to \infty \), where \( P(A_{k+}^c) < 2^{-k/2+\varepsilon} \) is arbitrarily small for sufficiently large \( k \geq 0 \). We conclude that \( X_{\xi(j)} \to X_t \) a.u. as \( j \to \infty \), it follows that \( X_T \) is a r.v.

6. We will next verify that \( X_T \) is measurable relative to the probability subspace \( L(\bar{\mathcal{S}}) \). To that end, let \( s > 0 \) be arbitrary. Take \( k \geq 0 \) so large that \( \Delta_{m(k)} < s \). Then, for each \( j \geq k \), we have

\[ \xi_j \leq \tau + \Delta_{m(j)} \leq \tau + \Delta_{m(k)} < \tau + s, \]

whence the r.v. \( X_{\xi(j)} \) is measurable relative to the probability subspace \( L(\tau + s) \). Hence, as \( j \to \infty \), the limiting r.v. \( X_T \) is measurable relative to \( L(\tau + s) \), where \( s > 0 \) is arbitrary. Therefor \( X_T \) is measurable relative to the probability subspace

\[ \cap_{s>0} L(\tau + s) = L(\tau), \]

where the last equality follows from \[11.7.1\] in view of the assumed right continuity of the filtration \( \mathcal{S} \). Assertion 1 is proved.

7. Inequality \[11.7.18\] can be rewritten as

\[ d(X_T(\omega), X_t(\omega)) \leq 2^{-(k+1)/2+\varepsilon} \quad (11.7.19) \]

for each \( t \in (\tau(\omega), \tau(\omega) + \Delta_{m(k)}) \cap \text{domain}(X(\cdot, \omega)) \). By the right continuity of the function \( X(\cdot, \omega) \), we therefore obtain

\[ d(X_T(\omega), X_t(\omega)) \leq 2^{-(k+1)/2+\varepsilon} \quad (11.7.20) \]

for each \( t \in [\tau(\omega), \tau(\omega) + \Delta_{m(k)}) \cap \text{domain}(X(\cdot, \omega)) \). Now let \( h \geq h_k \) be arbitrary. Then

\[ \tau \leq \eta h \leq \eta h_k < \tau + \Delta_{m(k)}, \quad (11.7.21) \]

according to inequality \[11.7.12\]. Hence inequality \[11.7.20\] implies that

\[ d(X_T(\omega), X_{\eta(h_k)}(\omega)) \leq 2^{-(k+1)/2+\varepsilon}, \quad (11.7.22) \]
for each $h \geq h_k$, where $k$ and $\omega \in \mathcal{A}^r_{h_k}$ are arbitrary. Since $2^{-(k+1)/2+6}$ and $P(A_{h_k}) < 2^{-k/2+4}$ are arbitrarily small, we conclude that $X_{\eta(h)} \rightarrow X_t \ a.u.$ The lemma is proved. 

Theorem 11.7.4. (Each a.u. càdlàg Markov process is a strong Markov process). 
Let $x \in S$ be arbitrary. Let

$$X : [0, \infty) \times (\Omega, L, E) \rightarrow (S, d)$$

be an arbitrary a.u. càdlàg Markov process generated by the initial state $x$ and the Markov semigroup $T$, and adapted to some right continuous filtration $\mathcal{F} \equiv \{ L^{(i)} : t \in [0, \infty) \}$. All stopping times will be understood to be relative to this filtration $\mathcal{F}$.

Then the following holds.

1. Let $\tau$ be an arbitrary stopping time with values in $[0, \infty)$. Then the function $X_\tau$ is a r.v. relative to $L^{(\tau)}$.

2. The process $X$ is strongly Markov relative to filtration $\mathcal{F}$. Specifically, let $\tau$ be an arbitrary stopping time with values in $[0, \infty)$. Let $0 \equiv r_0 \leq r_1 \leq \cdots \leq r_m$ be an arbitrary nondecreasing sequence in $[0, \infty)$, and let $f \in \mathcal{C}(S^{m+1}, d^{m+1})$ be arbitrary. Then

$$E(f(X_{\tau+r(0)}, X_{\tau+r(1)}, \cdots, X_{\tau+r(m)})) | L^{(\tau)}$$

$$= E(f(X_{\tau+r(0)}, X_{\tau+r(1)}, \cdots, X_{\tau+r(m)})) | X_\tau \equiv F^{X_{\tau+r(0)}, \cdots, X_{\tau+r(m)}}_{X_\tau} (f) \quad (11.7.23)$$

as r.v.'s

Proof. For ease of notations, we present the proof only for the case where $n = 2$, the general case being similar.

1. Assertion 1 is merely a restatement of Assertion 1 of Lemma 11.7.3.

2. To prove Assertion 2, let $\tau$ be an arbitrary stopping time with values in $[0, \infty)$. Let $0 \equiv r_0 \leq r_1 \leq r_2$ be an arbitrary nondecreasing sequence in $[0, \infty)$, and let $f \in \mathcal{C}(S^3, d^3)$ be arbitrary. As in Assertion 1 of Proposition 11.1.1, construct a nonincreasing sequence $(\eta_h)_{h=0,1, \cdots}$ of stopping times such that, for each $h \geq 0$, the r.v. $\eta_h$ is a stopping time with values in $\Omega_h$, and such that

$$\tau \leq \eta_h < \tau + 2^{-h+1}. \quad \text{(11.7.24)}$$

Let $h \geq 0$ and $i = 1, 2$ be arbitrary. Take any $s_{h,i} \in [r_i, r_i + 2^{-h+1}] \Omega_h$. Take $s_{h,0} \equiv 0$. Then

$$\tau + r_i \leq \eta_h + s_{h,i} < \tau + r_i + 2^{-h+2}. \quad \text{(11.7.25)}$$

where $i = 0, 1, 2$ is arbitrary.

3. Consider each indicator $U \in L^{(\tau)}$. Then $U \in L^{(\eta(h))}$ because $\tau \leq \eta_h$. Hence $U_1(\eta(h) = r) \in L^{(r)}$ for each $r \in \Omega_h$. Therefore

$$E(f(X_{\eta(h)}, X_{\eta(h) + s(h, 1)}, X_{\eta(h) + s(h, 2)}) | U)$$

$$= \sum_{r \in \Omega(h)} E(f(X_{\eta(h)}, X_{\eta(h) + s(h, 1)}, X_{\eta(h) + s(h, 2)}) | U_1(\eta(h) = r))$$

Yuen-Kwok Chan 462 Constructive Probability
11.7. A.U. CÀDLÀG MARKOV PROCESSES ARE STRONGLY MARKOV

\[ = \sum_{r \in Q(h)} E(f(X_r, X_{r+s(h,1)}, X_{r+s(h,2)})U 1_{(\eta(h)=r)} \]

\[ = \sum_{r \in Q(h)} E(F^{X(r)}_{0, s(h,1), s(h,2))}f)U 1_{(\eta(h)=r)} \]

\[ = \sum_{r \in Q(h)} E(F^{X(\eta(h))}_{0, s(h,1), s(h,2), f})U 1_{(\eta(h)=r)} \]

\[ = E(F^{X(\eta(h))}_{0, s(h,1), s(h,2), f})U \sum_{r \in Q(h)} 1_{(\eta(h)=r)} \]

\[ = E(F^{X(\eta(h))}_{0, s(h,1), s(h,2), f})U. \quad (11.7.26) \]

4. Consider each \( i = 0, 1, 2 \). Then we can apply Assertion 2 of Lemma \[11.7.3 \]
where \( \tau, (\eta_h)_{h=0,1,\ldots} \) are replaced by \( \tau + r, (\eta_h + s_h)_{h=0,1,\ldots} \) respectively, to obtain

\[ X_{\eta(h)+s(h,i)} \rightarrow X_{\tau+r(i)} \quad \text{a.u.} \quad (11.7.27) \]

as \( h \to \infty \). Hence, we have, for the left-hand side of equality \[11.7.26 \]

\[ E(f(X_{\eta(h)}, X_{\eta(h)+s(h,1)}, X_{\eta(h)+s(h,2)})U) \rightarrow E(f(X_{\eta}, X_{\tau+r(1), X_{\tau+r(2)})}U. \]

5. For convergence of the right-hand side, let \( \varepsilon > 0 \) be arbitrary. There is no loss of generality to assume that the function \( f \in C(S, d) \) has values in \([0, 1]\) and has a modulus of continuity \( \delta_f \). Then Theorem \[11.4.2 \]
yields some \( \delta_3(\varepsilon, \delta_f, \delta_T, \alpha_T) > 0 \) such that

\[ \left\| F^{+, T}_{\tau(h), s(h,1), s(h,2)}f - F^{+, T}_{\tau(0), r(1), r(2)}f \right\| \leq \varepsilon \]

provided that

\[ \sqrt{\sum_{i=0}^2 |s_{h,i} - r_i| < \delta_3(\varepsilon, \delta_f, \delta_T, \alpha_T). \quad (11.7.28) \]

Hence

\[ |E(F^{X(\eta(h))}_{0, s(h,1), s(h,2), f}) - E(F^{X(\eta(h))}_{0, s(h,1), s(h,2), f})| \leq |E(F^{X(\tau)}_{0, s(h,1), s(h,2), f}) - E(F^{X(\eta(h))}_{0, s(h,1), s(h,2), f})| \leq \varepsilon \]

provided that inequality \[11.7.28 \]
holds.

6. At the same time, Theorem \[11.4.2 \]
implies that the function \( F^{+, T}_{\tau(0), r(1), r(2)}f \) is a member of \( C(S, d) \). Hence, since \( X_{\eta(h)} \rightarrow X_{\tau} \quad \text{a.u.} \), we have

\[ E(F^{X(\eta(h))}_{0, s(h,1), s(h,2), f})U \rightarrow E(F^{X(\eta(h))}_{0, s(h,1), s(h,2), f})U \]

as \( h \to \infty \). Therefore there exists \( h_0 \geq 0 \) so large that

\[ |E(F^{X(\eta(h))}_{0, s(h,1), s(h,2), f})U - E(F^{X(\eta(h))}_{0, s(h,1), s(h,2), f})U| < \varepsilon \]

for each \( h \geq h_0 \). Combining with inequality \[11.7.28 \]
we obtain

\[ |E(F^{X(\eta(h))}_{0, s(h,1), s(h,2), f})U - E(F^{X(\eta(h))}_{0, s(h,1), s(h,2), f})U| < 2\varepsilon \]
provided that \( h \geq h_0 \) is so large that inequality \[11.7.28\] holds. Since \( \varepsilon > 0 \) is arbitrary, we see that
\[
E(F_{0,u(h,1),s(h,2)}^{X(\eta(h))}T) \to E(F_{r(0),r(1),r(2)}^{X(\tau)}T)U
\]
as \( h \to \infty \).

7. Thus we have convergence also of the right-hand side of equality \[11.7.26\]. The limits on each side, found in Steps 4 and 6 respectively, must therefore be equal, namely
\[
Ef(X_\tau,X_{\tau+r(1)},X_{\tau+r(2)})U = Ef(F_{r(0),r(1),r(2)}^{X(\tau)}T)U,
\]
(11.7.30)
where the indicator \( U \in L(\tau) \) is arbitrary. Hence, since \( F_{r(0),r(1),r(2)}^{X(\tau)}Tf \in L(\tau) \), we have
\[
Ef(f(X_\tau,X_{\tau+r(1)},X_{\tau+r(2)})|L(\tau)) = Ef(F_{r(0),r(1),r(2)}^{X(\tau)}Tf).
\]
In particular, equality \[11.7.30\] holds for each indicator \( U \in L(X_\tau) \). Hence
\[
Ef(f(X_\tau,X_{\tau+r(1)},X_{\tau+r(2)})|X_\tau) = Ef(F_{r(0),r(1),r(2)}^{X(\tau)}Tf).
\]
Thus the desired equality \[11.7.23\] is proved for the case \( m = 2 \), with a similar proof for the general case. We conclude that the process \( X \) is strongly Markov. \( \square \)

### 11.8 Abundance of Stopping Times for a.u. càdlàg Markov Processes

**Definition 11.8.1. (First exit time).** Let \((S,d)\) be an arbitrary locally compact metric space. Let \( X : [0,\infty) \times (\Omega,L,E) \to (S,d) \) be an arbitrary a.u. càdlàg process which is adapted to some right continuous filtration \( \mathcal{F} \equiv \{ L(t) : t \in [0,\infty) \} \).

Let \( f : (S,d) \to R \) be an arbitrary function which is continuous on compact subsets of \((S,d)\), such that \( f(X_0) \leq a_0 \) for some \( a_0 \in R \). Let \( a \in (a_0,\infty) \) and \( M \geq 1 \) be arbitrary. Suppose \( \tau \) is a stopping time relative to \( \mathcal{F} \) and with values in \([0,M]\) such that the function \( X_\tau \) is a well-defined r.v. relative to \( L(\tau) \). Suppose, for each \( \omega \in \text{domain}(X_\tau) \), we have
1. \( f(X(\cdot,\omega)) < a \) on the interval \([0,\tau(\omega))\), and
2. \( f(X(\tau(\omega))) \geq a \) if \( \tau(\omega) < M \).

Then we say that \( \tau \) is the **first exit time** in \([0,M]\) of the open subset \( (f < a) \) by the process \( X \), and write \( \tau_{f,a,M} \equiv \tau_{f,a,M}(X) \equiv \tau \).

Note that there is no requirement that the process actually exits \((f < a)\) ever. It is stopped at time \( M \) if it does not exit by then. \( \square \)

Before proving the existence of these first exit times, the next proposition make precise some intuitions.

**Lemma 11.8.2. (Basics of first exit times).** Let \((S,d)\) be an arbitrary locally compact metric space. Let \( X : [0,\infty) \times (\Omega,L,E) \to (S,d) \) be an arbitrary a.u. càdlàg process.
11.8. ABUNDANCE OF STOPPING TIMES FOR A.U. CÀDLÀG MARKOV PROCESSES

which is adapted to some right continuous filtration \( \mathcal{L} \equiv \{ L(t) : t \in [0, \infty) \} \). Let \( f : (S, d) \to R \) be an arbitrary function which is continuous on compact subsets of \((S, d)\), such that \( f(x_0) \leq a_0 \) for some \( a_0 \in R \). Let \( a \in (a_0, \infty) \) and \( M \geq 1 \) be arbitrary.

Let \( a \in (a_0, \infty) \) be such that the first exit time \( \tau_{f,a,M} \) exists for each \( M \geq 1 \). Consider each \( M \geq 1 \). Let \( r \in (0,M) \) and \( N \geq M \) be arbitrary. Then the following holds.

1. \( \tau_{f,a,M} \leq \tau_{f,a,N} \).
2. \( (\tau_{f,a,M} < M) \subset (\tau_{f,a,N} = \tau_{f,a,M}) \).
3. \( (\tau_{f,a,N} \leq r) = (\tau_{f,a,M} \leq r) \).

Proof. 1. Let \( \omega \in \text{domain}(\tau_{f,a,M}) \cap \text{domain}(\tau_{f,a,M}) \) be arbitrary. For the sake of a contradiction, suppose \( t \equiv \tau_{f,a,M}(\omega) > s \equiv \tau_{f,a,N}(\omega) \). Then \( s < \tau_{f,a,M}(\omega) \). Hence we can apply Condition (i) to \( M \), to obtain \( f(x_s(\omega)) < a \). At the same time, \( \tau_{f,a,N}(\omega) < t \leq N \). Hence we can apply Condition (ii) to \( N \), to obtain \( f(x_{\tau_{f,a,N}}(\omega)) \geq a \). In other words, \( f(x_s(\omega)) \geq a \), a contradiction. We conclude that \( \tau_{f,a,N}(\omega) \geq \tau_{f,a,M}(\omega) \) where \( \omega \in \text{domain}(\tau_{f,a,M}) \cap \text{domain}(\tau_{f,a,M}) \) is arbitrary. Assertion 1 is proved.

2. Next, suppose \( t \equiv \tau_{f,a,M}(\omega) < M \). Then Condition (ii) implies that \( f(x_t(\omega)) \geq a \). For the sake of a contradiction, suppose \( t < \tau_{f,a,N}(\omega) \). Then Condition (i) implies that \( f(x_t(\omega)) < a \), a contradiction. We conclude that \( \tau_{f,a,M}(\omega) \equiv t \geq \tau_{f,a,N}(\omega) \). Combining, with Assertion 1, we obtain \( \tau_{f,a,M}(\omega) = \tau_{f,a,N}(\omega) \). Assertion 2 is proved.

3. Note that

\[
(\tau_{f,a,N} \leq r) \subset (\tau_{f,a,M} \leq r) = (\tau_{f,a,M} < M) \subset (\tau_{f,a,M} = \tau_{f,a,N} \leq r) = (\tau_{f,a,N} \leq r),
\]

where we used the just established Assertions 1 and 2 repeatedly. Since the left-most set and the right-most set in set relation 11.8.1 are the same, the inclusion relations can be replaced by equality. Assertion 3 then follows.

Definition 11.8.3. (Specification of a filtered a.u. càdlàg Markov process, and notations for related objects). In the remainder of this section, let \((S, d)\) denote a compact metric space with \( d \leq 1 \). Let \( T \) be a Markov semigroup with parameter set \([0, \infty)\) and state space \((S, d)\), and with a modulus of strong continuity \( \delta_T \). Let \( \mathcal{L} \equiv \{ L(t) : t \in [0, \infty) \} \) be a right continuous filtration on a given sample space \((\Omega, L, E)\).

Let \( x \in S \) be arbitrary. Let

\( X : [0, \infty) \times (\Omega, L, E) \to (S, d) \)

be an a.u. càdlàg Markov process generated by the initial state \( x \) and the Markov semigroup \( T \) which is adapted to the filtration \( \mathcal{L} \).

Note that, then, the process \( X \) is equivalent to the process \( X^x \) constructed in has a modulus of continuity in Theorem 11.6.4 and is therefore continuous in probability with a modulus of continuity in probability \( \delta_{\epsilon,T}(\parallel \parallel) \). Moreover, for each \( N \geq 0 \), the shifted process \( X_N^x : [0, 1] \times (\Omega, L, E) \to (S, d) \), defined by \( X_{N+r}^x = X_{N+r} \) for each \( r \in [0, 1] \), has a modulus of a.u. càdlàg \( \delta_{\text{ucl}, T}(\epsilon) \). Define the operation \( \delta_{\epsilon,T}(\epsilon) \) by

\[
\delta_{\epsilon,T}(\epsilon) \equiv \delta_{\epsilon,T}(2^{-2}\epsilon) > 0.
\]
for each \( \varepsilon > 0 \). Note the lower-case in the subscript of \( \delta_{c.p,\delta(T)} \), in contrast to the subscript in \( \delta_{c.p,\delta(T)} \).

Proposition 10.3.2 then says that, for each \( N \geq 0, \varepsilon > 0, \) and \( t, s \in [0, 1] \) with \( |s-t| < \delta_{c.p,\delta(T)}(\varepsilon) \), there exists a measurable set \( D_{i,s} \) with \( P(D_{i,s}^c) \leq \varepsilon \) such that

\[
d(X^N(t, \omega), X^N(s, \omega)) \leq \varepsilon
\]

for each \( \omega \in D_{i,s} \).

Theorem 11.8.4. (Abundance of first exit times for Markov processes). Let the objects \((S,d), T, (\Omega, L, E), \mathcal{L}', x, \text{ and } X\) be as specified. In particular \((S,d)\) is a compact metric space with \( d \leq 1 \). Let \( f \in C(S,d) \) be arbitrary such that \( f(X_0) = f(x) \leq a_0 \) for some \( a_0 \in R \).

Then there exists a countable subset \( G \) of \( R \) such that, for each \( M \geq 1 \) and for each \( a \in (a_0, \infty)G \), the first exit time \( \tau_{f,a,M}(X) \) exists as defined in Definition 11.8.7. Here \( G \) denotes the metric complement of \( G \) in \( R \). Moreover, the set \( G \) of exceptional points is completely determined by the function \( f \) and the marginal \( f \) d's of the process \( X \).

Proof. 1. Let \( \delta_f \) be a modulus of continuity of the function \( f \). Let \( N \geq 0 \) be arbitrary, but fixed till further notice. Consider the a.u. càdlàg process \( X^N : [0, 1] \times \Omega \rightarrow S \), with modulus of continuity in probability \( \delta_{C_p,\delta(T)} \) and with modulus of a.u. càdlàg \( \delta_{aucl,\delta(T)} \). Definition 11.3.2 says that there exists a full set \( B \subset \bigcap_{N \rightarrow \infty} \text{domain}(X_t) \) with the following properties. Each \( \omega \in B \) satisfies the right-continuity condition and the right-completeness condition in Definition 11.3.2. Moreover, for each \( k \geq 0 \) and \( \varepsilon_k > 0 \), there exist (i) \( \delta_k \equiv \delta_{aucl,\delta(T)}(\varepsilon_k) > 0 \), (ii) a measurable set \( A_k \subset B \) with \( P(A_k^c) < \varepsilon_k \), (iii) an integer \( h_k \geq 1 \), and (iv) a sequence of r.r.v.'s

\[
0 = \tau_{k,0} < \tau_{k,1} < \cdots < \tau_{k,h_k-1} < \tau_{k,h_k} = 1,
\]

such that, for each \( i = 0, \cdots, h_k-1 \), the function \( X_{\tau_{k,i}}^N \) is a r.v., and such that, (v) for each \( \omega \in A_k \), we have

\[
\bigwedge_{i=0}^{h_k-1} (\tau_{k,i+1}(\omega) - \tau_{k,i}(\omega)) \geq \delta_k,
\]

with

\[
d(X^N(\tau_{k,i}(\omega), X^N(\cdot, \omega)) \leq \varepsilon_k
\]

on the interval \( \theta_{k,i}(\omega) = [\tau_{k,i}(\omega), \tau_{k,i+1}(\omega)] \) or \( \theta_{k,i}(\omega) = [\tau_{k,i}(\omega), \tau_{k,i+1}(\omega)] \) according as \( 0 \leq i \leq h_k-2 \) or \( i = h_k-1 \).

2. For each \( k \geq 0 \), let

\[
\varepsilon_k \equiv 2^{-k} \land 2^{2} \delta_f(2^{-k}).
\]

Then Conditions (i-v) in the previous step hold. Separately, write \( n-1 \equiv 0 \). Inductively, for each \( k \geq 0 \), take an integer \( n_k \geq n_{k-1} + 1 \) so large that

\[
2^{-n(k)} < \delta_k \equiv \delta_{aucl,\delta(T)}(\varepsilon_k).
\]
3. Now let \( s \in (0,1]Q_{n(k)} \) be arbitrary. Then there exists \( k \geq 0 \) so large that \( s \in (0,1]Q_{n(k)} \). Consider each \( \omega \in A_k \). Let

\[
r \in G_{k,\omega} \equiv [0,s] \cap \bigcup_{i=0}^{h(k)-1} \theta_{k,i}(\omega) \cap Q_{n(k)}
\]

be arbitrary. Then there exists \( i = 0, \cdots , h(k) - 1 \) such that \( r \in [0,s] \cap \theta_{k,i}(\omega) \). Since, according to inequality 11.8.3, we have

\[
|\theta_{k,i}(\omega)| \equiv \tau_{k,i+1}(\omega) - \tau_{k,i}(\omega) \geq \delta_k > 2^{-n(k)},
\]

there exists some \( t \in \theta_{k,i}(\omega) \cap Q_{n(k)} \). Either \( t \leq s \) or \( s < t \).

Consider the case where \( t \leq s \). Then \( t,r \in \theta_{k,i}(\omega) \). Hence

\[
d(X^N(\tau_{k,i}(\omega),\omega),X^N(t,\omega)) \leq \varepsilon_k \leq 2^{-2} \delta_f(2^{k-2})
\]

and

\[
d(X^N(\tau_{k,i}(\omega),\omega),X^N(r,\omega)) \leq \varepsilon_k \leq 2^{-2} \delta_f(2^{k-2}),
\]

according to inequality 11.8.3. Consequently

\[
d(X^N(t,\omega),X^N(r,\omega)) \equiv d(X^N(\tau_{k,i}(\omega),\omega),X^N(t,\omega)) \leq 2^{-1} \delta_f(2^{k-2}) < \delta_f(2^{k-2}).
\]

Therefore

\[
f(X^N_s(\omega)) < f(X^N_s(\omega)) + 2^{-k} \leq \bigvee_{u \in [0,s]Q_{n(k)}} f(X^N_u(\omega)) + 2^{-k},
\]

where the last inequality is because \( t \in [0,s]Q_{n(k)} \).

Now consider the case where \( t > s \). Then \( r,s \in \theta_{k,i}(\omega) \). Hence

\[
d(X^N(\tau_{k,i}(\omega),\omega),X^N(s,\omega)) \leq \varepsilon_k \leq 2^{-2} \delta_f(2^{k-2})
\]

and

\[
d(X^N(\tau_{k,i}(\omega),\omega),X^N(r,\omega)) \leq \varepsilon_k \leq 2^{-2} \delta_f(2^{k-2}),
\]

according to inequality 11.8.3. Consequently

\[
d(X^N(r,\omega),X^N_s(\omega)) \equiv d(X^N(s,\omega),X^N(r,\omega)) \leq 2^{-1} \delta_f(2^{k-2}) < \delta_f(2^{k-2}).
\]

Therefore

\[
f(X^N_r(\omega)) < f(X^N_r(\omega)) + 2^{-k} \leq \bigvee_{u \in [0,s]Q_{n(k)}} f(X^N_u(\omega)) + 2^{-k},
\]

where the last inequality is because \( s \in [0,s]Q_{n(k)} \).

Either way, we obtain

\[
f(X^N_r(\omega)) \leq \bigvee_{u \in [0,s]Q_{n(k)}} f(X^N_u(\omega)) + 2^{-k},
\]
where \( r \in G_{k,0} \) is arbitrary. Since the set \( G_{k,0} \) is dense in

\[
G_{0} \equiv [0, s] \cap \text{domain}(X^{N}(\cdot, \omega)),
\]

the last displayed inequality holds for each \( r \in G_{0} \), thanks to the right continuity of the function \( X^{N}(\cdot, \omega) \). In particular,

\[
f(X^{N}_{r}(\omega)) \leq \bigvee_{u \in [0, s]Q(n(k))} f(X^{N}_{u}(\omega)) + 2^{-k},
\]

for each \( r \in [0, s]Q(n(k)) \subset G_{0} \), where \( \omega \in A_{k} \) is arbitrary. Thus

\[
\bigvee_{r \in [0, s]Q(n(k+1))} f(X^{N}_{r}) \leq \bigvee_{u \in [0, s]Q(n(k))} f(X^{N}_{u}) + 2^{-k}
\]

on \( A_{k} \). Consequently,

\[
0 \leq \bigvee_{r \in [0, s]Q(n(k+1))} f(X^{N}_{r}) - \bigvee_{u \in [0, s]Q(n(k))} f(X^{N}_{u}) \leq 2^{-k+1}
\]

on \( A_{k} \), where \( P(A_{k}^{c}) < \varepsilon_{k} \leq 2^{-k} \), and where \( k \geq 0 \) is arbitrary. Since \( \sum_{k=0}^{\infty} 2^{-k} < \infty \), it follows that the a.u.- and \( L_{1} \)-limit

\[
Y_{N,s} \equiv \lim_{k \to \infty} \bigvee_{u \in [0, s]Q(n(k))} f(X^{N}_{u})
\]

(11.8.5)

exists is a r.r.v. Hence, for each \( \omega \) in the full set \( \text{domain}(Y_{N,s}) \), the supremum

\[
\sup_{u \in [0, s]Q(\omega)} f(X^{N}_{u}(\omega))
\]

exists and is given by \( Y_{N,s}(\omega) \). Now the function \( X^{N}(\cdot, \omega) \) is right continuous for each \( \omega \) in the full set \( B \). Hence, by right continuity, we have

\[
\sup_{u \in [0, s]} f(X^{N}_{u}) = \sup_{u \in [0, s]Q(\omega)} f(X^{N}_{u})
\]

(11.8.6)

on the full set \( \text{domain}(\sup_{u \in [0, s]Q(\omega)} f(X^{N}_{u}(\omega))) \). Therefore \( \sup_{u \in [0, s]} f(X^{N}_{u}) \) is a well-defined r.r.v., where \( N \geq 0 \) and \( s \in (N, N+1]Q_{\omega} \) are arbitrary. Moreover, from equality [11.8.5] we see that \( Y_{N,s} \) is the \( L_{1} \)-limit of a sequence in \( L_{1}^{(\omega)} \). Hence \( \sup_{u \in [0, s]} f(X^{N}_{u}) \in L_{1}^{(\omega)} \).

4. Next let \( s \in Q_{\omega} \) be arbitrary. Then \( s \in [N, N+1]Q_{\omega} \) for some \( N \geq 0 \). There are three possibilities: (i) \( s = 0 \), in which case, trivially

\[
\sup_{u \in [N,s]} f(X_{u}) \equiv f(X_{0})
\]

(11.8.7)

is a r.r.v., (ii) \( N = 0 \) and \( s \in (N, N+1] \), in which case, by Step 3 above, we have

\[
\sup_{u \in [N,s]} f(X_{u}) \equiv \sup_{u \in [N,s]} f(X^{N}_{u})
\]

(11.8.8)
11.8. ABUNDANCE OF STOPPING TIMES FOR A.U. CÂDLÀG MARKOV PROCESSES

is a r.r.v, or (iii) where \( N \geq 1 \), in which case, again by Step 3 above, we have

\[
\sup_{u \in [0,s]} f(X_u) = \sup_{u \in [0,1]} f(X_u) \lor \sup_{u \in [1,2]} f(X_u) \lor \cdots \lor \sup_{u \in [N-1,N]} f(X_u) \lor \sup_{u \in [N,s]} f(X_u)
\]

\[
\equiv \sup_{u \in [0,1]} f(X_u^0) \lor \sup_{u \in [0,1]} f(X_u^1) \lor \cdots \lor \sup_{u \in [0,s-N]} f(X_u^{N-1}) \lor \sup_{u \in [0,s-N]} f(X_u^N)
\]  \hspace{1cm} (11.8.9)

is a r.r.v. In all three case, we see that

\[
V_s \equiv \sup_{u \in [0,s]} f(X_u)
\]  \hspace{1cm} (11.8.10)

is a r.r.v., with

\[
V_s \in L(s),
\]  \hspace{1cm} (11.8.11)

for each \( s \in \overline{Q}_\infty \). Summing up, \( V : \overline{Q}_\infty \times (\Omega, L, E) \rightarrow R \) is a nondecreasing real-valued process adapted to the filtration \( \mathcal{L} \).

5. Since the set \( \{ V_s : s \in \overline{Q}_\infty \} \) of r.r.v.'s is countable, there exists a countable subset \( G \) of \( (0, \infty) \) such that each point \( a \in (0, \infty)G_c \) is a regular point of the r.r.v.'s in the set \( \{ V_s : s \in \overline{Q}_\infty \} \), where

\[
G_c \equiv \{ a \in (0, \infty) : |a - b| > 0 \text{ for each } b \in G \}
\]

is the metric complement of \( G \) in \( (0, \infty) \). Note from the equalities \( [11.8.6, 11.8.7, 11.8.9, 11.8.10] \) that the distribution of the r.r.v. \( V_s \) depends only on the function \( f \) and on the family of marginal f.j.d.'s of the process \( X \), for each \( s \in \overline{Q}_\infty \). Therefore the set \( G \) of exceptional points is completely determined by the function \( f \) and the marginal f.j.d.'s of the process \( X \).

6. Consider each \( a \in G_c \). Then, by the definition of the countable set \( G \), we see that \( a \in (a_0, \infty)G_c \) is a regular point of the r.r.v. \( V_s \) for each \( s \in \overline{Q}_\infty \). Hence the set \( \{ V_s < a \} \) is measurable for each \( s \in \overline{Q}_\infty \).

7. Now let \( M \geq 1 \) and \( k \geq 0 \) be arbitrary. Recall that \( \Delta_n(k) \equiv 2^{-n(k)} \) and that \( \overline{n(k)} \equiv \{ 0, \Delta_n(k), 2\Delta_n(k), \cdots \} \). According to Definition \( [8.2.7] \) define the r.r.v.

\[
\eta_k \equiv \sum_{u \in (0,M(\overline{n(k)}))} u^1_{(V(u) \geq a)} \prod_{s \in (0,M(\overline{n(k)})) \setminus (a \in a \cup M)} 1_{(V(s) < a)} + M \prod_{s \in (0,M(\overline{n(k)}))} 1_{(V(s) < a)}
\]  \hspace{1cm} (11.8.12)

Because the real-valued process \( V \) is nondecreasing, the defining equality \( [11.8.12] \) simplifies to

\[
\eta_k = \sum_{u \in (0,M(\overline{n(k)}))} u^1_{(V(u) \geq a)} 1_{(V(a - \Delta n(k)) < a)} + M 1_{(V(M) < a)}
\]  \hspace{1cm} (11.8.13)

In words, \( \eta_k \) is the first time in \( [0,M(\overline{n(k)})] \) for the real-valued nondecreasing process \( V \) to exit the interval \( (a_0, a) \), with \( \eta_k \) set to \( M \) if no such time exists. Note that \( \eta_k \) is a r.r.v. with values in the finite set \( [0,M(\overline{n(k)})] \). Moreover, from the defining equality \( [11.8.13] \) we see that \( (\eta_k = u) \in L(c) \) for each \( u \in [0,M(\overline{n(k)})] \). Thus \( \eta_k \) is a stopping time relative to the filtration \( \mathcal{L} \).

Yuen-Kwok Chan 469 Constructive Probability
8. Since \(\eta_k - \Delta_n(k)\) has values in \([0, M] \cap \{k\}\), we have \(V_{\eta_k - \Delta_n(k)} < a\) by equality \(11.8.13\). Consequently, equality \(11.8.13\) applied to the stopping time \(\eta_{k+1}\) in the place of \(\eta_k\), yields

\[
\eta_k - \Delta_n(k) < \eta_{k+1}.
\]

(11.8.14)

Moreover, \(\eta_k - \Delta_n(k), \eta_{k+1}\) have values in \(\Omega\). Then equality \(11.8.13\) implies that

\[
\eta_k - \Delta_n(k) \leq \eta_{k+1} - \Delta_n(k+1).
\]

(11.8.14)

Suppose, for the sake of a contradiction, that \(u \equiv \eta_k(\omega) < \eta_{k+1}(\omega)\) for some \(\omega \in \Omega\). Then \(\eta_{k+1} < M\), whence \(V_u(\omega) \geq a\) by the defining formula \(11.8.13\). Consequently, since \(u \in (0, M] \cap \{k\}\), we have \(\eta_{k+1}(\omega) \leq u\) by applying the defining formula \(11.8.13\) to \(\eta_{k+1}(\omega)\). This is a contradiction. Thus \(\eta_{k+1}(\omega) \leq \eta_k(\omega)\). Roughly speaking, if we sample more frequently, we observe any exit no later.

9. Combining, we get

\[
\eta_k - \Delta_n(k) \leq \eta_{k+1} - \Delta_n(k+1) < \eta_{k+1} \leq \eta_k.
\]

(11.8.15)

Iterating, we obtain

\[
\eta_k - \Delta_n(k) \leq \eta_k - \Delta_n(k) \leq \eta_k \leq k
\]

(11.8.16)

for each \(k \geq k + 1\). It follows that \(\eta_k \downarrow \tau\) a.u. for some r.r.v. \(\tau\) with

\[
\eta_k - \Delta_n(k) \leq \tau \leq \eta_k
\]

(11.8.17)

where \(k \geq 0\) is arbitrary. Consequently, Assertion 2 of Proposition \(11.1.1\) implies that \(\tau\) is a stopping time relative to the filtration \(\mathcal{F}\). Moreover, note that \(\Delta_n(k) \equiv 2^{-n(k)} \leq 2^{-k} < 2^{-k+2}\). Hence inequality \(11.8.17\) implies that

\[
\tau \leq \eta_k < \tau + 2^{-k+2}.
\]

(11.8.18)

Therefore Lemma \(11.7.3\) implies \(X_\tau\) is a well defined r.r.v., and that \(X_{\eta(k)} \rightarrow X_\tau\) a.u. as \(k \rightarrow \infty\).

10. Now consider each \(\omega \in \text{domain}(X_\tau)\). Then \(\omega \in \text{domain}(\tau)\) and

\[
\tau(\omega) \in \text{domain}(X(\cdot, \omega)).
\]

Let \(t \in \text{domain}(X(\cdot, \omega)) \cap [0, \tau(\omega))\) be arbitrary. Then, for some sufficiently large \(k \geq 0\), we have

\[
t < \tau(\omega) - 2^{-n(k)+1} \leq \eta_k(\omega) - 2\Delta_n(k)
\]

Hence there exists \(s \in (t, \eta_k(\omega)) \cap \{\omega\}\). Because \(s \in \{\omega\}\) is before the simple first exit time \(\eta_k(\omega)\), we have \(V_s(\omega) < a\), as can more precisely be verified from to the defining equality \(11.8.12\). Consequently,

\[
f(X(t, \omega)) \leq \sup_{u \in [0, a]} f(X_u(\omega)) \equiv V_s(\omega) < a.
\]
where \( t \in \text{dom}(X(\cdot, \omega)) \cap [0, \tau(\omega)) \) is arbitrary. Condition (i) of Definition 11.8.1 is proved for the stopping time \( \tau \) to be the first exit time in \([0, M]\) of the open subset \((f < a)\).

12. We will next verify Condition (ii) of Definition 11.8.1. To that end, suppose \( \tau(\omega) < M \). Then, in view of inequality \([11.8.17]\), there exists \( k \geq 0 \) so large that \( \tau(\omega) \leq r = \eta_k(\omega) < M \). Because successful exit occurs at \( r \in [0,M]\), we have \( V_r(\omega) \geq a \), as can more precisely be verified from the defining equality \([11.8.12]\). Consequently,

\[
f(X_\tau(\omega)) = f(X_\tau(\omega)) = f(X_\omega(\omega)) \leq \sup_{\omega \in [0,r]} f(X_\omega(\omega)) = V_r(\omega) \equiv V_{\eta_k}(\omega) \geq a.
\]

Condition (ii) of Definition \([11.8.1]\) is also verified for the stopping time \( \tau \) to be the first exit time in \([0, M]\) of the open subset \((f < a)\). Accordingly, \( \tau_{f,a,M}(X) \equiv \tau \) is the first exit time in \([0, M]\) of the open subset \((f < a)\). The theorem is proved. \( \Box \)

### 11.9 Feller Semigroup and Feller Process

**Definition 11.9.1. (Specification of locally compact state space and related objects).** In this section, let \((S, d)\) be a locally compact metric space, as specified in Definition \([11.0.1]\) along with related objects including a reference point \( x_0 \in S \) and a binary approximation \( \xi \). In addition, for each \( n \geq 0 \) and for each \( y \in S \), define the function

\[
h_{y,n} \equiv (1 \wedge (1 + n - d(\cdot, y)))_+ \in C(S, d).
\]

Clearly, for each fixed \( y \in S \), we have \( h_{y,n} \uparrow 1 \) as \( n \to \infty \), uniformly on compact subsets of \((S, d)\). Define

\[
\overline{h}_{y,n} \equiv 1 - h_{y,n} \in C_{a,b}(S, d).
\]

The continuous functions \( h_{y,n} \) and \( \overline{h}_{y,n} \) are surrogates for the indicators \( 1_{d(y, \cdot) \leq n} \) and \( 1_{d(y, \cdot) > n} \), respectively.

Let \((\overline{S}, \overline{d}) \equiv (S \cup \{\Delta\}, \overline{d})\) be a one-point compactification of the metric space \((S, d)\), where \( \overline{d} \leq 1 \) and where \( \Delta \) is called the point at infinity. For ease of reference, we list almost verbatim from Definition \([5.3.1]\) the conditions for the one-point compactification \((\overline{S}, \overline{d})\).

**Condition 1.** \( S \cup \{\Delta\} \) is dense in \((S, \overline{d})\). Moreover, \( \overline{d} \leq 1 \).

**Condition 2.** For each compact subset \( K \) of \((S, d)\), there exists \( c > 0 \) such that \( \overline{d}(x, \Delta) \geq c \) for each \( x \in K \).

**Condition 3.** Let \( K \) be an arbitrary compact subset of \((S, d)\). Let \( \epsilon > 0 \) be arbitrary. Then, there exists \( \delta_K(\epsilon) > 0 \) such that for each \( y \in K \) and \( z \in S \) with \( \overline{d}(y, z) < \delta_K(\epsilon) \), we have \( d(y, z) < \epsilon \). In particular, the identity mapping \( \overline{1} : (S, \overline{d}) \to (S, d) \) is uniformly continuous on each compact subset of \( S \).

**Condition 4.** The identity mapping \( \overline{1} : (S, d) \to (S, \overline{d}) \), defined by \( \overline{1}(x) \equiv x \) for each \( x \in S \), is uniformly continuous on \((S, d)\). In other words, for each \( \epsilon > 0 \), there exists \( \delta_K(\epsilon) > 0 \) such that \( \overline{d}(x, y) < \epsilon \) for each \( x, y \in S \) with \( d(x, y) < \delta_K(\epsilon) \).

**Condition 5.** For each \( n \geq 1 \), we have

\[
(d(\cdot, x_o) > 2^{n+1}) \subset (\overline{d}(\cdot, \Delta) \leq 2^{-n}).
\]
CHAPTER 11. MARKOV PROCESS

Refer to Definition [11.0.2] for notations related to the enumerated sets $\mathcal{O}_0, \mathcal{O}_1, \ldots, \mathcal{O}_\infty$ of dyadic rationals in $[0, \infty)$, and to the enumerated sets $Q_0, Q_1, \ldots, Q_\infty$ of dyadic rationals in $[0, 1]$.

□

Definition 11.9.2. (Feller Semigroup). Let $V = \{V_t : t \in [0, \infty)\}$ be an arbitrary family of nonnegative linear mappings from $C_{ab}(S, d)$ to $C_{ab}(S, d)$ such that $V_0$ is the identity mapping. Suppose, for each $t \in [0, \infty)$ and for each $y \in S$, that the function

$$V_t^y \equiv V_t(\cdot)(y) : C_{ab}(S, d) \rightarrow R$$

is a distribution on the locally compact space $(S, d)$. Suppose, in addition, the following four conditions are satisfied.

1. (Smoothness). For each $N \geq 1$, for each $t \in [0, N]$, and for each $f \in C_{ab}(S, d)$ with a modulus of continuity $\delta_f$ and with $|f| \leq 1$, the function $V_t f \in C_{ab}(S, d)$ has a modulus of continuity $\alpha_{V, N}(\delta_f)$ which depends on the finite interval $[0, N]$ and on $\delta_f$, and otherwise not on the function $f$.

2. (Semigroup property). For each $s, t \in [0, \infty)$, we have $V_{t+s} = V_t V_s$.

3. (Strong continuity). For each $f \in C_{ab}(S, d)$ with a modulus of continuity $\delta_f$ and with $|f| \leq 1$, and for each $\varepsilon > 0$, there exists $\delta_V(\varepsilon, \delta_f) > 0$ so small that, for each $t \in [0, \delta_V(\varepsilon, \delta_f))$, we have

$$|f - V_t f| \leq \varepsilon \quad (11.9.1)$$

as functions on $(S, d)$.

4. (Non-explosion). For each $N \geq 1$, for each $t \in [0, N]$, and for each $\varepsilon > 0$, there exists an integer $\kappa_{V, N}(\varepsilon) > 0$ so large that, if $n \geq \kappa_{V, N}(\varepsilon)$ then

$$V_{t/\kappa_{V,n}} \leq \varepsilon$$

for each $y \in S$.

Then we call the family $V$ a Feller semigroup. The operation $\delta_V$ is called a modulus of strong continuity of $V$. The sequence $\alpha_V \equiv (\alpha_{V, N})_{N=1, 2, \ldots}$ of operations is called a modulus of smoothness of $V$. The sequence $\kappa_V \equiv (\kappa_{V, N})_{N=1, 2, \ldots}$ of operations is called a modulus of non-explosion of $V$.

In order to use results developed in previous sections for Markov semigroups and Markov processes, where the state space is assumed to be compact, we embed each given Feller semigroup on the locally compact state space $(S, d)$ into a Markov semigroup on the one-point compactification $(\overline{S}, \overline{d})$ state space, in the following sense.

Theorem 11.9.3. (Compactification of Feller semigroup into a Markov semigroup with a compact state space). Let $V \equiv \{V_t : t \in [0, \infty)\}$ be an arbitrary Feller semigroup on the locally compact metric space $(S, d)$, with moduli $\delta_V, \alpha_V, \kappa_V$ as in Definition 11.9.2. Let $t \in [0, \infty)$ be arbitrary. Define the function

$$T_t : C(\overline{S}, \overline{d}) \rightarrow C(\overline{S}, \overline{d})$$

by

$$(T_t g)(\Delta) \equiv T_t^\Delta g \equiv g(\Delta),$$

Yuen-Kwok Chan 472 Constructive Probability
and by
\[ (T_t g)(y) = T^y_t g = \int_{z \in \overline{S}} T^y_t (dz) g(z) = \int_{z \in S} T^y_t (dz) g(z) \] (11.9.2)
for each \( y \in S \), for each \( g \in C(\overline{S}, \overline{d}) \). Equality (11.9.2) is equivalent to
\[ T^y_t g = V^y_t (g|S) = V_t (g|S)(y). \]
for each \( y \in S \), for each \( g \in C(\overline{S}, \overline{d}) \).

Then the family \( T \equiv \{ T_t : t \in [0, \infty) \} \) is a Markov semigroup with state space \( (\overline{S}, \overline{d}) \). This Markov semigroup \( T \) will be called the compactification of the given Feller semigroup \( V \).

Proof. Let \( t \in [0, \infty) \) be arbitrary. Let \( N \geq 1 \) be such that \( t \in [0, N] \). Let \( g \in C(\overline{S}, \overline{d}) \) be arbitrary, with modulus of continuity \( \overline{\delta}_g \). There is no loss of generality in assuming that \( g \) has values in \([0, 1]\). For abbreviation, write \( f \equiv g|S \in C_{ab}(S, d) \).

Let \( \epsilon > 0 \) be arbitrary.

1. Let \( \overline{\delta}_g \) be the operation listed in Condition 4 of Definition 11.9.1. Take arbitrary points \( y, z \in S \) with \( d(y, z) < \delta_{2^k} \). Then, according to Condition 4 of Definition 11.9.1 we have \( d(y, z) < \delta_{2^k}(\epsilon) \). Hence
   \[ |f(y) - f(z)| = |g(y) - g(z)| < \epsilon. \]
Thus the function \( f \equiv g|S \) has a modulus of continuity \( \delta_{2^k} \). Therefore, according to the definition of the modulus of smoothness \( \alpha_V \) in Definition 11.9.2 the function \( V_t f \in C_{ab}(S, d) \) has modulus of continuity \( \alpha_V, N(\delta_{2^k} \circ \delta_{2^k}) \).

2. Let \( k \geq 0 \) be so large that
   \[ 2^{-k+1} < \delta_{2^k}(\epsilon) \] (11.9.3)
Let
\[ n \equiv 2^{k+1} \vee \kappa_{V, N}(\epsilon). \]
Then
\[ V^y_t \overline{h}_{y,n} = \pm \epsilon \] (11.9.4)
for each \( y \in S \).

3. By Condition 5 of Definition 11.9.1 we have, for each \( u \in S \), if \( d(u, x_o) > n = 2^{k+1} \) then \( d(u, \Delta) \leq 2^{-k} < \delta_{2^k}(\epsilon) \), whence \( f(u) = g(u) = g(\Delta) \pm \epsilon \).

4. Take an arbitrary \( a \in (2n + 1, 2n + 2) \) such that the set
   \[ K \equiv \{ u \in S : d(x_o, u) \leq a \} \]
is a compact subset of \((S, d)\). Let
\[ K^c \equiv \{ u \in S : d(x_o, u) > 2n + 1 \} \cup \{ \Delta \}. \] (11.9.5)

Then \( \overline{S} = K \cup K^c \).
5. Define
\[ \varepsilon' = \alpha_{\nu,N}(\tilde{\delta}_\nu \circ \tilde{\delta}_\nu)(\varepsilon). \]
Then, by Condition 3 of Definition \[11.9.1\] there exists \( \delta_K(\varepsilon') > 0 \) such that, for each \( y \in S \) and \( z \in S \) with
\[ d(y, z) < \delta_K(\varepsilon'), \]
we have \( d(y, z) < \varepsilon' \), whence, in view of the last statement in Step 1, we have
\[ |V^y_t f - V^y_t f| < \varepsilon. \quad (11.9.6) \]

6. Let \( y \in K^c \) be arbitrary. Suppose \( y \in S \). Then \( d(x_0, y) > 2n + 1 \) by the defining equality \[11.9.5\]. Therefore, for each point \( u \in S \) with \( h_{y,n}(u) > 0 \), we have \( d(y, u) \leq n + 1 \), and so \( d(u, x_0) > n \). In view of Step 3, it follow that, for each point \( u \in S \) with \( h_{y,n}(u) > 0 \), we have \( f(u) = g(\Delta) \pm \varepsilon \). Therefore
\[
(T_t g)(y) = V^y_t f = V^y_t h_{y,n} f + V^y_t \overline{h}_{y,n} f = V^y_t h_{y,n} f + V^y_t \overline{h}_{y,n} f
\]
\[
= V^y_t h_{y,n} f \pm \varepsilon = V^y_t ((g(\Delta) \pm \varepsilon) h_{y,n} \pm \varepsilon = g(\Delta)V^y_t h_{y,n} \pm 2\varepsilon
\]
\[
= g(\Delta)V^y_t (1 - \overline{h}_{y,n}) \pm 2\varepsilon = g(\Delta) \pm 2\varepsilon
\]
\[
= g(\Delta) \pm 3\varepsilon,
\]
where we have used equality \[11.9.4\] twice. In short
\[ (T_t g)(y) = g(\Delta) \pm 3\varepsilon \quad (11.9.7) \]
Suppose \( y = \Delta \). Then trivially equality \[11.9.7\] also holds. Combining equality \[11.9.7\] also holds for each \( y \in K^c \).

7. Proceed to examine a pair of points \( y, z \in S \) with
\[ d(y, z) < \delta_K(\alpha_{\nu,N}(\tilde{\delta}_\nu \circ \tilde{\delta}_\nu)(\varepsilon)) = \delta_K(\varepsilon'), \]
Suppose first that \( y, z \in K^c \). Then, by inequality \[11.9.7\] we have
\[ |(T_t g)(y) - (T_t g)(z)| \leq 6\varepsilon. \]

8. Suppose, on the other hand, that \( y \in K \) or \( z \in K \). Then, by inequality \[11.9.6\] we obtain
\[ |(T_t g)(y) - (T_t g)(z)| = |V^y_t f - V^z_t f| < \varepsilon. \quad (11.9.9) \]

9. Combining, we see that, in either case, we have
\[ |(T_t g)(y) - (T_t g)(z)| = |V^y_t f - V^z_t f| \leq 6\varepsilon, \]
provided that the bound \[11.9.8\] holds.

10. Summing up, the function \( T_t g \) is continuous on \( \overline{(S, d)} \), with a modulus of continuity \( \alpha_{\nu,N}(\overline{\delta}_\nu) \) defined by
\[
\alpha_{\nu,N}(\overline{\delta}_\nu) = \delta_K \circ \alpha_{\nu,N} \circ \delta(\overline{\delta}_\nu)
\]
Yuen-Kwok Chan 474 Constructive Probability
11.9. FELLER SEMIGROUP AND FELLER PROCESS

where \( \overline{\delta}_g \) is the modulus of continuity of the arbitrary function \( g \in C(\overline{S}, d) \).

11. In particular, \( T_t : C(\overline{S}, d) \to C(\overline{S}, d) \) is a well-defined function. From the defining equality \[ 11.9.2 \] it is obvious that it is a nonnegative linear function, with \( T_t 1 = 1 \). Hence, for each \( y \in \overline{S} \), the linear, nonnegative, function \( T_t^y \) is an integration with \( T_t^y 1 = 1 \). Moreover, \( T_t g \) for each \( s, t \in [0, \infty) \) with modulus of continuity \( \overline{\delta}_g \), the function \( T_t g \) has a modulus of continuity \( \alpha_{T,N}(\overline{\delta}_g) \) defined in Step 10. We conclude that \( T_t \) is a transition distribution from \( (\overline{S}, d) \) to \((\overline{S}, d)\), where \( N \geq 1 \) and \( t \in [0, N] \) are arbitrary. It is also clear from the defining equality \[ 11.9.2 \] that \( T_0 \) is the identity mapping.

12. It remains to verify the conditions in Definition \[ 11.3.1 \] for the family \( T \equiv \{ T_t : t \in [0, \infty) \} \) to be a Markov semigroup. The smoothness condition follows immediately from Step 10, where we found that the operation \( \alpha_{T,N} \) is a modulus of smoothness for the transition distribution \( T_t \), for each each \( N \geq 1 \), for each \( t \in [0, N] \).

13. For the semigroup property, consider each \( s, t \in [0, \infty) \). Let \( y \in S \) be arbitrary. Then, by inequality \[ 11.9.4 \] we have

\[
T^y_t h_{y,k} = V^y_{t} h_{y,k} + 1
\]

and \( h_{y,k} \uparrow 1 \) as \( k \to \infty \). Consequently, \( S \) is a full subset, and \{\( \Delta \)\} is a null subset of \( \overline{S} \) relative to the distribution \( T^y_t \). Hence according to the defining equality \[ 11.9.2 \] we have

\[
T^y_t g = V^y_t (g|S) + g(\Delta) 1_{\{\Delta\}} = V^y_{t} (g|S) + 0
\]

as integrable functions on \( (\overline{S}, d) \) relative to the distribution \( T^y_t \). Therefore

\[
T^y_s (T_t g) \equiv T^y_s (V_t (g|S) 1_S + g(\Delta) 1_{\{\Delta\}}) = T^y_s (V_t (g|S)) = V^y_{s+t} (g|S),
\]

where the last equality is by the semigroup property of the Feller semigroup \( V \). Applying equality \[ 11.9.11 \] with \( t, s \), replaced by \( 0, t+s \) respectively, we obtain \( T^{y'}_{s+t} (g) = V^{y'}_{s+t} (g|S) \). Combining with equality \[ 11.9.11 \] we in turn obtain

\[
T^y_s (T_t g) = T^{y'}_{s+t} (g)
\]

where \( y \in S \) is arbitrary. At the same time, we have, trivially

\[
T^\Delta_s (T_t g) \equiv (T_t g)(\Delta) = T^\Delta_s (g).
\]

Thus we proved that \( T_s (T_t g) = T_{s+t} (g) \) on \( (\overline{S}, d) \), where \( g \in C(\overline{S}, d) \) is arbitrary. The semigroup property is proved for the family \( T \).

14. It remains to verify strong continuity of the family \( T \). To that end, let \( \varepsilon > 0 \) be arbitrary, and let \( g \in C(\overline{S}, d) \) be arbitrary, with a modulus of continuity \( \overline{\delta}_g \) and with \( \|g\| \leq 1 \). We wish to prove that

\[
\|g - T_t g\| \leq \varepsilon,
\]

provided that \( t \in [0, \overline{\delta}_t (\varepsilon, \overline{\delta}_g)] \). First note that, trivially,

\[
g(\Delta) - (T_t g)(\Delta) = 0.
\]
CHAPTER 11. MARKOV PROCESS

Next, recall from Step 1 that the function $g|S$ has a modulus of continuity $\delta_T \circ \overline{\delta}_g$. Hence, by the strong continuity of the Feller semigroup, there exists $\delta_T(\epsilon, \delta_T \circ \overline{\delta}_g) > 0$ so small that, for each $t \in [0, \delta_T(\epsilon, \delta_T \circ \overline{\delta}_g))$, we have

$$\left|(g|S) - V_t(g|S)\right| \leq \epsilon.$$  \hspace{1cm} (11.9.14)

Define

$$\delta_T(\epsilon, \delta_T) \equiv \delta_T(\epsilon, \delta_T \circ \overline{\delta}_g)$$

Then, for each $y \in S$, we have

$$\left|\tau_T^y g - g(y)\right| \equiv \left|V_t^y(g|S) - g(y)\right| \leq \epsilon.$$  

Combining with equality [11.9.13] we obtain

$$\|\tau_T^y g - g\| \leq \epsilon,$$

provided that $t \in [0, \delta_T(\epsilon, \delta_T \circ \overline{\delta}_g))$, where $g \in C(\overline{S}, \overline{\Omega})$ is arbitrary, with a modulus of continuity $\overline{\delta}_g$ and with $\|g\| \leq 1$. Thus we have verified also the strong continuity condition in Definition [11.9.1] for the family $T \equiv \{T_t : t \in [0, \infty)\}$ to be a Markov semigroup.

Corollary 11.9.4. (Nonexplosion of Feller process in finite time intervals). Let $V \equiv \{V_t : t \in [0, \infty)\}$ be an arbitrary Feller semigroup on the locally compact metric space $(S, d)$, with moduli $\delta_T, \delta_T^{\ast}, \delta_T, \kappa_T$ as in Definition [11.9.2]. Let $T \equiv \{T_t : t \in [0, \infty)\}$ be the compactification of $V$. Let

$$X \equiv X^{\ast T} : [0, \infty) \times (\Omega, L, E) \rightarrow (\overline{S}, \overline{d})$$

be an a.u. càdlàg Markov process generated by the initial state $x$ and semigroup $T$, as constructed in [11.6.4]. Let $\mathcal{L} \equiv \{L(t) : t \in [0, \infty)\}$ an arbitrary right continuous filtration to which $X^{\ast T}$ is adapted. All stopping times will be understood to be relative to this filtration $\mathcal{L}$. Theorem [11.7.4] says that $X^{\ast T}$ is a strong Markov process relative to the filtration $\mathcal{L}$.

Let $\tau$ be an arbitrary stopping time with values in $[0, M]$. Then the following holds.

1. Let $\epsilon > 0$ be arbitrary. Then there exists $c > 0$ so small that

$$P(\overline{\tau}(\Delta, X_\tau) > c) > 1 - \epsilon.$$  

And there exist a compact subset $K$ of $(S, d)$ which depends on $\epsilon, x$ and $V$, such that

$$P(X_\tau \in K) > 1 - \epsilon.$$  

Since $\epsilon > 0$ is arbitrary, we have $P(X_\tau \in S) = 1$.

2. For each $y \in S$, and for each $N \geq M$, we have

$$T_M^y \overline{\tau}_{2n} = V_M^y \overline{\tau}_{2n}$$  \hspace{1cm} (11.9.15)

as r.v.'s.

3. For each $y \in S$, and for each $N \geq M \vee \kappa_T(N, \epsilon)$, we have

$$T_M^y \overline{\tau}_{2n} \leq \epsilon$$  \hspace{1cm} (11.9.16)

as r.v.'s.

4. For each $v \in [0, \infty)$, the function $X_v : (\Omega, L, E) \rightarrow (S, d)$ is a r.v.
Proof. 1. Lemma \[11.7.3\] says that the function \(X\) is a well defined r.v. with values in \(\mathcal{F}\), which is measurable relative to \(L^1\), and that there exists a nonincreasing sequence \((\eta_j)_{j=0,1,\ldots}\) of stopping times such that, (i) for each \(j \geq 0\), the r.r.v. \(\eta_j\) has values in \(\mathcal{Q}_j\), (ii) 
\[
\tau \leq \eta_j < \tau + 2^{-j+2}.
\]
and (iii) \(X_{\eta(j)} \to X\) a.u. as \(j \to \infty\). By assumption, we have \(\tau \leq M\). Hence, by replacing \(\eta_j\) with \(\eta_j \wedge M\) if necessary, we may assume that \(\eta_j\) has values in the finite set \(\mathcal{Q}_j[0,M]\), for each \(j \geq 0\).

2. Since \(X_{\eta(j)} \to X\) a.u. and since \(\mathcal{F} \leq 1\), we have \(E\mathcal{F}(X_{\eta(j)},X) \to 0\).

3. Let \(\varepsilon > 0\) be arbitrary. Consider each \(n \geq \kappa_{\varepsilon,M}(\varepsilon)\). Let \(v \in [0,M]\) be arbitrary. Since \(x \in S\), we have 
\[
E(h_{x,n}(X_v)) = T_v^\ast h_{x,n} = V_v^\ast h_{x,n} = 1 - V_v^\ast \mathcal{F}_{x,n} \geq 1 - \varepsilon.
\]
Now let \(v \in \mathcal{Q}_j[0,M]\) be arbitrary. Take any regular point \(a \in (n-1,n)\) of the r.r.v.'s in the finite family \(\{\mathcal{F}(\Delta,X_v) : \in \mathcal{Q}_j[0,M]\}\), such that the subset \(K \equiv (d(\cdot,X_v) \leq a) \subset (S,d)\) is a compact subset of \((S,d)\), and such that the set \(d(X_v,x) \leq a\) is measurable. Then 
\[
P(X_v \in K) = P(d(X_v,x) \leq a) \geq E(h_{x,n}(X_v)) \geq 1 - \varepsilon.
\]
4. Condition 2 of Definition \[11.9.1\] implies that there exists \(c > 0\) such that \(\mathcal{F}(x,\Delta) > c\) for each \(x \in K\). Then 
\[
P(\mathcal{F}(\Delta,X_v) > c) \geq P(X_v \in K) > 1 - \varepsilon.
\]
Hence, for each \(j \geq 0\), we have 
\[
P(\mathcal{F}(\Delta,X_{\eta(j)}) > c) = \sum_{v \in \mathcal{Q}_j[0,M]} P(\eta_j = v; \mathcal{F}(\Delta,X_{\eta(j)}) > c)
\[
= \sum_{v \in \mathcal{Q}_j[0,M]} P(\eta_j = v; \mathcal{F}(\Delta,X_v) > c)
\[
> \sum_{v \in \mathcal{Q}_j[0,M]} P(\eta_j = v)(1 - \varepsilon) = 1 - \varepsilon.
\]
Since \(\mathcal{F}(X_{\eta(j)},X) \to 0\) a.u. and since \(\mathcal{F} \leq 1\), it follows that 
\[
P(\mathcal{F}(\Delta,X_v) > c) \geq 1 - \varepsilon.
\]
Similarly, \(P(X_v \in K) > 1 - \varepsilon\), where \(\varepsilon > 0\) is arbitrary. Consequently \(P(X_v \in S) = 1\).

5. Proceed to prove Assertion 2. Let \(y \in S\) and \(N \geq M\) be arbitrary. Then 
\[
T_M^\ast \mathcal{F}_{x,y} = \sum_{v \in \mathcal{Q}_j[0,M]} 1_{\eta(j) = v} T_M^\ast \mathcal{F}_{x,y}
\[
= \sum_{v \in \mathcal{Q}_j[0,M]} 1_{\eta(j) = v} V_M^\ast \mathcal{F}_{x,y} = V_M^\ast \mathcal{F}_{x,y}.
\]

Yuen-Kwok Chan 477 Constructive Probability
CHAPTER 11. MARKOV PROCESS

Letting $j \to \infty$ and $\eta_j \downarrow \tau$, the uniform continuity of $T_{\nu}^y$ in the subscript variable $w \in [0,M]$ yields

$$T_{M-\eta(j)}^y \mathbb{P}_{\nu,N} = V_{M-\eta(j)}^y \mathbb{P}_{\nu,N}.$$  

Assertion 2 is proved.

6. Now suppose, in addition, that $N \geq M \lor \kappa_{\nu,N}(\varepsilon)$. Then $V_{M-\eta(j)}^y \mathbb{P}_{\nu,N} \leq \varepsilon$ for each $v \in \mathcal{F}_M[0,M]$. Hence equality \ref{eq:11.9.18} yields $T_{M-\eta(j)}^y \mathbb{P}_{\nu,N} = V_{M-\eta(j)}^y \mathbb{P}_{\nu,N} \leq \varepsilon$. With $j \to \infty$, we obtain the desired inequality \ref{eq:11.9.16} Assertion 3 and is proved.

7. Finally, let $v \in [0,\infty)$ be arbitrary. Let $M \geq 1$ be so large that $v \in [0,M]$. Then, in view of Assertion 1, on a full set, $X_v$ is a function with values in $S$. Let $f \in C_{ub}(S,d)$ be arbitrary with $1 \geq f \geq 0$. Then

$$E((\mathbb{P}_{\nu,N}(X_v)) = T_v^y(\mathbb{P}_{\nu,N}(f)) = V_v^y(\mathbb{P}_{\nu,N}(f)) \leq V_v^y(\mathbb{P}_{\nu,N}) \downarrow 0.$$  

Therefore the limit $E((h_{\nu,N}(f))(X_v))$ exists as $n \to \infty$. Hence the Monotone Convergence Theorem implies that the function $f(X_v)$ is integrable. By linearity, the function $g(X_v)$ is integrable for each $g \in C_{ub}(S,d)$. In particular, $E(h_{\nu,N}(X_v) \uparrow 1$. Thus $X_v$ is a r.v. with values in $(S,d)$. Assertion 4 and the Corollary are proved. 

\begin{theorem}
(Construction of Feller process from Feller semigroup). Let $V \equiv \{V_t : t \in [0,\infty)\}$ be an arbitrary Feller semigroup on the locally compact metric space $(S,d)$. Then the following holds.

1. Let $x \in (S,d)$ be arbitrary. Then there exists an a.u. càdlàg process

$$X \equiv X^{x,V} : [0,\infty) \times (\Omega,L,E) \to (S,d),$$  

whose family of marginal distributions $F^{x,V}$ is generated by the initial state $x$ and Feller semigroup $V$ in the following sense. For arbitrary $m \geq 1$, $f \in C_{ub}(S^m,d^m)$, and nondecreasing sequence $r_1 \leq \cdots \leq r_m$ in $[0,\infty)$, we have

$$F^{x,V}_{r(1),\cdots,r(m)}f \quad (11.9.19)$$

2. For arbitrary $m \geq 1$, $f \in C_{ub}(S^m,d^m)$, and nondecreasing sequence $r_1 \leq \cdots \leq r_m$ in $[0,\infty)$, the function $F^{x,V}_{r(1),\cdots,r(m)}f$ is continuous on compact subsets $K \subset (S,d)$, relative to the metric $d$.

3. Let $\mathcal{L} \equiv \{L_t : t \in [0,\infty)\}$ be an arbitrary right continuous filtration. Let $x \in (S,d)$ be arbitrary. Suppose the a.u. càdlàg Markov process $X^{x,V}$ is adapted to the filtration $\mathcal{L}$. Then the process $X \equiv X^{x,V}$ is strongly Markov relative to the Feller semigroup $V$ in the following sense.

Let $\tau$ be an arbitrary stopping time with values in $[0,\infty)$. Let $0 \equiv \tau_0 \leq \tau_1 \leq \cdots \leq \tau_m$ be an arbitrary nondecreasing sequence in $[0,\infty)$, and let $f \in C(S^{m+1},d^{m+1})$ be arbitrary. Then (i) $X_\tau$ is a r.v. relative to $L^{(\tau)}$, and (ii)

$$E(f(X_{\tau+r(0)},X_{\tau+r(1)},\cdots,X_{\tau+r(m)})|L^{(\tau)}) = E(f(X_{\tau+r(0)},X_{\tau+r(1)},\cdots,X_{\tau+r(m)})|X_\tau) = F^{x,V}_{r(0),\cdots,r(m)}(f) \quad (11.9.20)$$

as r.v.'s

Yuen-Kwok Chan 478 Constructive Probability
Proof. Let
\[ (\Omega, L, E) \equiv (\Theta_0, L_0, I_0) \equiv ([0, 1], L_0, \int dx) \]
denote the Lebesgue integration space based on the unit interval \( \Theta_0 \).

1. Let \( T = \{ T_t : t \in [0, \infty) \} \) be the compactification of the Feller semigroup as constructed in Theorem \[ 11.9.3 \]. Thus \( T \) is a Markov semigroup with the compact metric state space \( (\bar{S}, d) \), where \( d \leq 1 \). Moreover, \( T \) has the modulus of smoothness \( \alpha_T \equiv (\alpha_T)_{N=1,2,...} \) and the modulus of strong continuity \( \delta_T \) as constructed in the proof of Theorem \[ 11.9.3 \].

2. Let \( x \in (S, d) \) be arbitrary. Let
\[ \Xi \equiv \Xi^{x,T} : [0, \infty) \times (\Theta_0, L_0, I_0) \to (\bar{S}, \bar{d}) \] \hspace{1cm} \[ (11.9.21) \]
be the a.u. càdlàg Markov process generated by the initial state \( x \) and semigroup \( T \), as constructed in Theorem \[ 11.5.3 \].

3. Let \( t \in [0, \infty) \) be arbitrary. Assertion 4 of Corollary \[ 11.9.4 \] implies that, \( (\bar{X}_t)_{t \in \mathbb{S}} \) is a full set. Define the function \( X_t : (\Theta_0, L_0, I_0) \to (S, d) \) by \( \text{domain}(X_t) = (\bar{X}_t)_{t \in \mathbb{S}} \) and by \( X_t = \bar{X}_t \) on \( \text{domain}(X_t) \). Then \( X_t \) is a r.v. with values in \( (S, \bar{d}) \). Since the identity mapping \( t : (S, d) \to (S, d) \) is continuous, the function \( X_t \) is a r.v. with values in \( (S, d) \). Thus the function
\[ X \equiv X^{x,V} : [0, \infty) \times (\Theta_0, L_0, I_0) \to (S, d) \] \hspace{1cm} \[ (11.9.22) \]
is a well-defined process with state space \( (S, d) \). Let \( F^{x,V} \) denote the family of marginal f.d.'s of this process \( X \equiv X^{x,V} \).

4. Let the integer \( m \geq 1 \), the function \( f \in C(\bar{S}, \bar{d}^{\infty}) \), and the nondecreasing sequence \( r_1 \leq \cdots \leq r_m \) in \( [0, \infty) \) be arbitrary. Then Theorem \[ 11.6.4 \] says that the function
\[ F_{r_1,\cdots,r_m}^{x,T} : (\bar{S}, \bar{d}) \to R \]
is uniformly continuous on \( (\bar{S}, \bar{d}) \). Hence it is uniformly continuous on compact subsets of \( (S, d) \), relative to the metric \( d \). At the same time,
\[ F_{r_1,\cdots,r_m}^{x,V} = I_0 f (X_{r_1}, \cdots, X_{r_m}) = I_0 f (\Xi^{x}_{r_1}, \cdots, \Xi^{x}_{r_m}) = F_{r_1,\cdots,r_m}^{x,T} \]
\[ = \int_{x(1) \in \mathbb{S}} T^{x(1)}_{r_1}(dx_1) \int_{x(2) \in \mathbb{S}} T^{x(1)}_{r_2-r_1}(dx_2) \cdots \int_{x(m) \in \mathbb{S}} T^{x(m-1)}_{r_m-r_{m-1}}(dx_m) f(x_1, \cdots, x_m) \]
\[ = \int_{x(1) \in \mathbb{S}} V^{x(1)}_{r_1}(dx_1) \int_{x(2) \in \mathbb{S}} V^{x(1)}_{r_2-r_1}(dx_2) \cdots \int_{x(m) \in \mathbb{S}} V^{x(m-1)}_{r_m-r_{m-1}}(dx_m) f(x_1, \cdots, x_m) \]
\[ = \int V^{x(1)}_{r_1}(dx_1) \int V^{x(1)}_{r_2-r_1}(dx_2) \cdots \int V^{x(m-1)}_{r_m-r_{m-1}}(dx_m) f(x_1, \cdots, x_m). \] \hspace{1cm} \[ (11.9.23) \]
where the fifth equality is thanks to equality \[ 11.9.19 \] in Assertion 1. We have yet to complete the proof of Assertion 1, pending the a.u. càdlàg property of the process \( X \).

5. It was observed in Step 4 that the function \( F_{r_1,\cdots,r_m}^{x,T} \) is continuous on compact subsets \( K \) of \( (S, d) \), relative to the metric \( d \). Hence, in view of equality \[ 11.9.23 \]

Yuen-Kwok Chan 479 Constructive Probability
the function \( F_{t(1),\ldots,t(m)}^{x} f \) is continuous on compact subsets \( K \) of \((S,d)\), relative to the metric \( d \). This proves Assertion 2.

5. By Theorem \[11.7.3\] the a.u. càdlàg Markov process \( X \) is strongly Markov. To be precise, the following two conditions hold.

(i) \( \tau \) be an arbitrary stopping time with values in \([0,\infty)\), relative to the filtration \( \mathcal{L} \). Then the function \( X_{\tau} \) is a r.v. relative to \( L^{(\tau)} \), and

(ii). The process \( X \) is strongly Markov relative to filtration \( \mathcal{L} \). Specifically, let \( \tau \) be an arbitrary stopping time with values in \([0,\infty)\), relative to the filtration \( \mathcal{L} \). Let \( 0 \equiv r_{0} \leq r_{1} \leq \cdots \leq r_{n} \) be an arbitrary nondecreasing sequence in \([0,\infty)\), and let \( f \in C(S^{m+1},d^{m+1}) \) be arbitrary. Then

\[
I_{0}(f(X_{\tau + r_{0}},X_{\tau + r_{1}},\ldots,X_{\tau + r_{m}})|L^{(\tau)}) = I_{0}(f(X_{\tau + r_{0}},X_{\tau + r_{1}},\ldots,X_{\tau + r_{m}})|X_{\tau}) = F_{r_{0},\ldots,r_{m}}^{X_{\tau}}(f) \quad (11.9.24)
\]

as r.v.'s. By Corollary \[11.9.4\] we have \( X_{\tau + r_{i}} = X_{\tau + r_{i+1}} \) on some full set, for each \( i = 1,\ldots,m \). Hence equality \(11.9.24\) implies that

\[
I_{0}(f(X_{\tau + r_{0}},X_{\tau + r_{1}},\ldots,X_{\tau + r_{m}})|L^{(\tau)}) = I_{0}(f(X_{\tau + r_{0}},X_{\tau + r_{1}},\ldots,X_{\tau + r_{m}})|X_{\tau}) = F_{r_{0},\ldots,r_{m}}^{X_{\tau}}(f) = F_{r_{0},\ldots,r_{m}}^{X_{\tau}}(f) \quad (11.9.25)
\]

Assertion 3 has been proved. This shows that the process \( X \) is also strongly Markov.

6. To complete the proof, we need to show that the process \( X \) is a.u. càdlàg relative to the metric \( d \), as in Definition \[10.10.4\]. In other words, we need to prove that it is continuous in probability on each interval \([0,N]\), and that the shifted process \( Y \equiv X^{N} : [0,1] \times (\Omega,L,E) \rightarrow (S,d) \) is a.u. càdlàg, for each \( N \geq 0 \). Definition \[10.10.4\] also defines the shifted processes. We will give the proof only for the case where \( N = 0 \). The other cases are similar.

7. To that end, let \( Y \equiv X^{0} \equiv X|[0,1] \). Let \( Z \equiv Y|Q_{\infty} = X|Q_{\infty} \). Then, thanks to the strong continuity of the Feller semigroup \( V \) and to the strong Markov property of the process \( X \), the process \( Z \) is strongly right continuous in probability, in the sense of Definition \[10.7.3\] We will prove that, in addition, the process \( Z \) is also a.u. bounded, in the sense of Definition \[10.7.2\]

To that end, let \( \varepsilon_{0} \equiv 0 \) be arbitrary. Let \( \varepsilon \equiv 2^{-1} \varepsilon_{0} \). Write \( n \equiv \kappa_{V}(\varepsilon) \). Take any \( b_{1} \in (n+1,n+2) \). Let

\[
\beta_{aub}(\varepsilon_{0}) \equiv 2b_{1} + d(x_{0},x).
\]

Now consider each \( k \geq 0 \) and each \( \gamma' > \beta_{aub}(\varepsilon) \). For abbreviation, write \( \gamma \equiv \gamma' - d(x_{0},x) \). Then \( \gamma > 2b_{1} \).

Let \( \eta \equiv \eta_{\gamma|Q(\varepsilon)} \) be the simple first exit time in the sense of Definition \[8.2.7\]. Then

\[
P(\bigvee_{r \in Q(\varepsilon)} \mathbf{d}(x,Z_{r}) > \gamma, d(x,Z_{1}) \leq b_{1}) \leq P(\mathbf{d}(x,Z_{\eta}) > \gamma; d(x,Z_{1}) \leq b_{1})
\]

\[
\leq P(d(Z_{\eta},Z_{1}) > \gamma - b_{1}) \leq P(d(Z_{\eta},Z_{1}) > b_{1})
\]
\[ \leq P(d(X_\eta, X_1) > b_1) \leq E(\tilde{h}_{X(\eta), r}(X_1)) \]
\[ = \int V_\eta^r(dy) \int V_{1-\eta}^r(dz) \tilde{h}_{r, n}(z) = \int V_\eta^r(dy) V_{1-\eta}^r d\tilde{h}_{r, n} \]
\[ \leq \int V_\eta^r(dy) \varepsilon = \varepsilon. \]
Therefore
\[ P(\bigvee_{r \in Q(h)} d(x, Z_r) > \gamma) \]
\[ \leq P(\bigvee_{r \in Q(h)} d(x, Z_r) > \gamma; d(x, Z_t) \leq b_1) + P(d(x, Z_t) > b_1) \leq \varepsilon + \varepsilon = 2\varepsilon. \]
Hence
\[ P(\bigvee_{r \in Q(h)} d(x_0, Z_r) > \gamma') \equiv P(\bigvee_{r \in Q(h)} d(x_0, Z_r) > d(x_0, x) + \gamma) \]
\[ \leq P(\bigvee_{r \in Q(h)} d(x, Z_r) > \gamma) \leq 2\varepsilon. \]

Summing up, we have proved that the process \( Z = X|Q_\infty \) is a.u. bounded, with a modulus of a.u. boundlessness \( \beta_{\text{aub}} \). Since it is also strongly right continuous, Theorem \[10.7.8\] is applicable to \( Z \), and implies that right-limit extension \( \tilde{X} = \Phi_{r, \text{Lim}}(Z) : [0, 1] \times \Omega \rightarrow S \) relative to the metric \( d \), is an a.u. càdlàg process relative to the metric \( d \). At the same time \( X \) is a.u. càdlàg relative to the metric \( d \). Therefore \( X|[0, 1] = \Phi_{r, \text{Lim}}(Z) \) relative to the metric \( d \). Since sequential convergence relative to \( d \) is equivalent to sequential convergence relative to \( \tilde{d} \), we have \( X|[0, 1] = \tilde{X} \). Therefore \( X|[0, 1] \) is an a.u. càdlàg process relative to the metric \( d \).

Similarly we can prove that, for each \( N \geq 0 \), the shifted process \( X^N : [0, 1] \times (\Omega, L, E) \rightarrow (S, d) \) defined by \( X^N = X_{N+t} \), for each \( t \in [0, 1] \) is a.u. càdlàg. Summing up, the process is a.u. càdlàg in the sense of Definition \[10.10.4\].

The theorem is proved. \( \square \)

**Corollary 11.9.6. (Modulus of a.u. boundlessness on finite intervals).** The process \( X = X^{X_N} \) constructed in Theorem \[11.9.3\] is a.u. bounded in the following sense. Let \( \varepsilon_0 > 0 \) be arbitrary. Let \( M > N \geq 0 \) be arbitrary integers. Then there exists \( \beta \equiv \beta_{\text{aub}}(\xi_0, N, M) > 0 \) so large that, for some measurable set \( \omega \) with \( P(A^c) < \varepsilon_0 \), we have
\[ d(x_0, X(t, \omega)) \leq \beta \]
for each \( t \in [N, M] \cap \text{domain}(X(\cdot, \omega)) \), for each \( \omega \in \Omega \). The operation is then called a modulus of a.u. boundlessness of the Feller process \( X \).

**Proof.** 1. We will prove only that the process \( X^0 = X|[0, 1] \) is a.u. bounded, with a modulus \( \beta_{\text{aub}}(\cdot, 0, 1) \). The proof for the shifted processes \( X^N \) with \( N \geq 1 \) is similar with modulus \( \beta_{\text{aub}}(\cdot, N, N + 1) \). Then the a.u. boundlessness of the shifted processes \( X^0, X^1, \ldots, X^{N-1} \) together imply the a.u. boundlessness of the process \( X \) on \([0, M]\). The moduli \( \beta_{\text{aub}}(\cdot, N, N + 1), \ldots, \beta_{\text{aub}}(\cdot, M - 1, M) \) will together yield the modulus \( \beta_{\text{aub}}(\cdot, N, M) \).
CHAPTER 11. MARKOV PROCESS

To proceed, let \( Y \equiv X | [0, 1] \). Let \( Z \equiv Y | Q_m = X | Q_m \). In Step 7 of the proof of Theorem [11.9.5] we saw that the process \( Z \) is a.u. bounded in the sense of Definition [10.7.2] with some modulus of a.u. boundlessness \( \beta_{\text{auB}} \). We also saw that the process \( Y \equiv X | [0, 1] \) is a.u. càdlàg, and that \( Y = \Phi_{\text{Lim}}(Z) \) relative to the metric \( d \).

Now let \( \varepsilon_0 > 0 \) be arbitrary. Write \( \varepsilon \equiv 2^{-1} \varepsilon_0 \). Take any \( \gamma \geq \langle \beta_{\text{auB}}(\varepsilon) \rangle \). Define

\( \tilde{\beta}_{\text{auB}}(\varepsilon_0, 0, 1) \equiv \gamma + 2 \varepsilon \).

2. By Condition 3 in Definition [10.3.2] for a.u. càdlàg processes on \([0, 1]\), there exists (i) \( \delta_{\text{aucl}}(\varepsilon) > 0 \), (ii) a measurable set \( A_1 \) with \( P(A'_1) < \varepsilon \), (iii) an integer \( h \geq 1 \), and (iv) a sequence of r.r.v.'s

\[
0 = \tau_0 < \tau_1 < \cdots < \tau_{h-1} < \tau_h = 1,
\]

such that, for each \( i = 0, \cdots, h - 1 \), the function \( X_{\tau(i)} \) is a r.v., and such that, (v) for each \( \omega \in A_1 \), we have

\[
\bigwedge_{i=0}^{h-1} (\tau_{i+1}(\omega) - \tau_i(\omega)) \geq \delta_{\text{aucl}}(\varepsilon),
\]

with

\[
d(X(\tau_i(\omega), \omega), X(\cdot, \omega)) \leq \varepsilon,
\]

on the interval \( \theta_i(\omega) \equiv [\tau_i(\omega), \tau_{i+1}(\omega)) \) or \( \theta_i(\omega) \equiv [\tau_i(\omega), \tau_{i+1}(\omega)] \) according as \( 0 \leq i < h - 2 \) or \( i = h - 1 \).

3. Now take \( k \geq 0 \) so large that \( 2^{-k} < \delta_{\text{aucl}}(\varepsilon) \). Then, because \( \gamma \geq \beta_{\text{auB}}(\varepsilon) \), we have

\[
P(A_0^c) < \varepsilon,
\]

where

\[
A_0 \equiv \left( \bigvee_{r \in Q_k} d(x_0, Z_r) \leq \gamma \right)
\]

4. Consider each \( \omega \in A \equiv A_0 A_1 \) and each \( i = 0, \cdots, h - 1 \). Then, inequality [11.9.27] implies that the interval \( \theta_i(\omega) \) contains some point \( r \in Q_k \equiv \{0, 2^{-k}, 2 \cdot 2^{-k}, \cdots, 1\} \). Hence inequality [11.9.27] implies that, for each \( r \in \theta_i(\omega) \), we have

\[
d(x_0, X(t, \omega)) \leq d(x_0, X(r, \omega)) + d(X(r, \omega), X(\tau_i(\omega), \omega)) + d(X(\tau_i(\omega), \omega), X(t, \omega))
\]

\[
\leq d(x_0, Z(r, \omega)) + d(X(r, \omega), X(\tau_i(\omega), \omega)) + d(X(\tau_i(\omega), \omega), X(t, \omega))
\]

\[
\leq \gamma + \varepsilon + \varepsilon.
\]

Combining, we see that \( d(x_0, X(t, \omega)) \leq \gamma + 2 \varepsilon \) for each \( t \in \theta_0(\omega) \cup \cdots \cup \theta_{h-1}(\omega) \). Since this last union of intervals is dense in \([0, 1]\), and since the function \( X(\cdot, \omega) \) is right continuous, it follows that \( d(x_0, X(t, \omega)) \leq \gamma + 2 \varepsilon \equiv \tilde{\beta}_{\text{auB}}(\varepsilon_0, 0, 1) \) for each \( t \in [0, 1] \cap \text{domain}(X(\cdot, \omega)) \), for each \( \omega \in A \). Note that \( P(A') = P(A_0 A_1)^c < 2 \varepsilon \equiv \varepsilon_0 \). We have verified that the operation \( \tilde{\beta}_{\text{auB}}(\cdot, 0, 1) \) is a modulus of a.u. boundlessness of the process \( X | [0, 1] \).

\[ \square \]

Yuen-Kwok Chan 482 Constructive Probability
11.9. FELLER SEMIGROUP AND FELLER PROCESS

**Definition 11.9.7. (Feller process).** Let \( V \equiv \{ V_t : t \in [0, \infty) \} \) be an arbitrary Feller semigroup on the locally compact metric space \((S, d)\). Let \( x \in (S, d) \) be arbitrary. Let \( X \) be an arbitrary a.u. càdlàg process whose marginal distributions are given by the family \( F^{x, V} \), and which is adapted to some right continuous filtration \( \mathcal{L} \), and which is strongly Markov relative to the filtration \( \mathcal{L} \) and the Feller semigroup \( V \), in the sense of Conditions 3 in Theorem 11.9.5. Then \( X \) is called a Feller process generated by the initial state \( x \) and Feller semigroup \( V \).

**Theorem 11.9.8. (Abundance of first exit times for Feller process over finite intervals).** Let \( V \equiv \{ V_t : t \in [0, \infty) \} \) be an arbitrary Feller semigroup on the locally compact metric space \((S, d)\). Let \( x \in (S, d) \) be arbitrary. Let

\[
X : [0, \infty) \times (\Omega, \mathcal{L}, \mathbb{P}) \rightarrow (S, d),
\]

be the Feller process generated by the initial state \( x \) and Feller semigroup \( V \), in the sense of Theorem 11.9.5. Let \( \mathcal{L}^0 \equiv \{ L^0_t : t \in [0, \infty) \} \) be an arbitrary right continuous filtration relative to which the process \( X \) is adapted. Let \( f : (S, d) \rightarrow \mathbb{R} \) be an arbitrary nonnegative function which is continuous on compact subsets of \((S, d)\), such that \( f(X_0) \leq a_0 \) for some \( a_0 \in \mathbb{R} \). Let \( a \in (a_0, \infty) \) and be arbitrary.

Then there exists a countable subset \( G \) of \( \mathbb{R} \) such that, for each \( a \in (a_0, \infty) \), for each \( M \geq 1 \), the first exit time \( \tau_{f,a,M}(X) \) of the open subset \( (f < a) \) exists, in the sense of Definition 11.8.1. Here \( G_c \) denotes the metric complement of \( G \) in \( \mathbb{R} \).

Note that, in general, there is no requirement that the process actually exits \( (f < a) \) ever. It is stopped at time \( M \) if it does not exit by then.

**Proof.** Let \( x \in (S, d) \) and the continuous function \( f \) be as given in the hypothesis. Thus \( f(X_0) = f(x) \leq a_0 \) for some \( a_0 \in \mathbb{R} \). Let \( b \geq 0 \) be such that \( |f| \leq b \). Let \( M \geq 1 \) be arbitrary.

1. Use the terminology and the notations in the proof of Theorem 11.9.5. There is no loss of generality in assuming that \( X = X^{x, V} \) is the process constructed in the proof of Theorem 11.9.5, where we saw that, on a full set, we have \( X^{x, V} = X^{x, T} \), where \( T \) is the one-point compactification of the Feller semigroup \( V \), and where the process \( X^{x, T} \) is constructed in Step 2 of said proof.

2. Let \( k \geq 0 \) be arbitrary. Then Corollary 11.9.6 says that there exists \( \beta_k \equiv \tilde{\beta} \) such that, for some measurable set \( A_k \) with \( P(A_k^c) < 2^{-k} \), we have

\[
d(x_0, X(t, \omega)) \leq \beta_k
\]

for each \( t \in [0, M] \cap \text{domain}(X(\cdot, \omega)) \), for each \( \omega \in A_k \). Define the measurable set

\[
A_{k+} \equiv \bigcap_{i=k}^{\infty} A_i.
\]

Then \( P(A_{k+}^c) < 2^{-k+1} \).

3. Let \( (n_k)_{k=0,1,\ldots} \) be an increasing sequence such that \( n_k > k \equiv \tilde{\beta} \). Let \( k \geq 0 \) be arbitrary. Define \( f_k \equiv f_{h_{n(k)}(\cdot)}(\cdot, n(k)) \in C(S, d) \). Then \( |f_k| \leq b \), and \( f_k \) has the same
compact support as \( h_{x(0),n(k)} \). Hence \( f_k \in C(S,d) \subset C(\overline{S},d) \), with the understanding that \( f_k(\Delta) \equiv 0 \). Let \( y \in S \) be arbitrary such that \( h_{x(0),n(k)}(y) = 1 \). Then

\[
f_k(y) = f(y).
\]

Note that, since \( f \geq 0 \), we have \( f_k \uparrow f \).

4. First consider the process

\[
X = \mathcal{X} \equiv \mathcal{X}^{\mathcal{F}}, [0, \infty) \times (\Theta_0, L_0, I_0) \to (\mathcal{F}, \mathcal{F}). \tag{11.9.31}
\]

By Theorem 11.8.4 there exists a countable subset \( G \) of \( R \) such that, for each \( n \in (a_0, \infty) \), the first exit time \( \tau_k \equiv \tau_{(k),n,M} \) exists. By Definition 11.8.1 \( \tau_k \) is a stopping time relative to \( \mathcal{L} \), with values in \([0, M]\), such that the function \( X_{(k)}(\omega) \) is a well-defined r.v relative to \( L(\tau_k) \), with values in \( \mathcal{F} \), and such that, for each \( \omega \in \text{domain}(X_{(k)}) \), we have

(i). \( f_k(X(\cdot, \omega)) < a \) on the interval \([0, \tau_k(\omega)]\), and

(ii). \( f_k(X_{(k)}(\omega)) \geq a \) if \( \tau_k(\omega) < M \).

5. We will verify that the sequence \( \{\tau_k\}_{k=0,1,\ldots} \) is nonincreasing. Suppose \( \tau_k(\omega) < \tau_{k+1}(\omega) \) for some \( \omega \in \Omega \). Then, according to Condition (i), applied to \( f_{k+1} \), we have

\[
f_{k+1}(X(\tau_k(\omega), \omega)) < a.
\]

Moreover, \( \tau_k(\omega) < M \) because \( \tau_{k+1}(\omega) \leq M \). Hence \( f_k(X_{(k)}(\omega)) \geq a \) according to Condition (ii). This is a contradiction because \( f_k \leq f_{k+1} \). We conclude that \( \tau_k \geq \tau_{k+1} \).

6. Next, let \( i > k \geq 0 \) be arbitrary. Consider each \( \omega \in \Omega \) such that \( \tau_i(\omega) > \tau_k(\omega) \). Then, according to Condition (i), we have \( f_k(X(\tau_i(\omega), \omega)) < a \). Moreover, \( \tau_i(\omega) < M \), whence, \( f_i(X_{(i)}(\omega)) \geq a \), according to Condition (ii) applied to \( f_i \). Combining,

\[
f_k(X_{(i)}(\omega)) < f_i(X_{(i)}(\omega)).
\]

In other words,

\[
f(X_{(i)}(\omega))h_{x(0),n(k)}(X_{(i)}(\omega)) < f(X_{(i)}(\omega))h_{x(0),n(i)}(X_{(i)}(\omega)).
\]

Cancelling the common factor, we obtain

\[
h_{x(0),n(k)}(X_{(i)}(\omega)) < h_{x(0),n(i)}(X_{(i)}(\omega)) \leq 1
\]

The strict inequality implies that \( d(x_0, X_{(i)}(\omega)) \geq n_k > \beta_k \). Therefore, according to Step 2, we have \( \omega \in A^{F_k} \subset A_k^{+} \). Summing up, \( (\tau_i > \tau_k) \subset A_k^{+} \). Hence \( \tau_i = \tau_k \) on \( A_k^{+} \). Since \( P(A_k^{+}) \leq 2^{-k+1} \) is arbitrarily small for sufficiently large \( k \geq 0 \), it follows that \( \tau_k \downarrow \tau \) a.s. for some r.v. \( \tau \) with values in \([0, M]\). Moreover,

\[
\tau = \tau_k \tag{11.9.32}
\]

on \( A_k^{+} \), for each \( k \geq 0 \).

7. Next we will verify that \( \tau \) is a stopping time relative to the right continuous filtration \( \mathcal{L} \equiv \{ L^{(i)} : t \in [0, \infty) \} \). To that end, consider each regular point \( t \in [0, M] \) of \( \tau \).

Yuen-Kwok Chan 484 Constructive Probability
11.10. THE BROWNIAN MOTION IN $\mathbb{R}^m$

Let $s \in (t, \infty)$ be arbitrary. Let $(s_k)_{k=0,1,\ldots}$ be a sequence such that $s_k \in (t, s \wedge (t + 2^{-k}))$ is a regular point of the r.v.'s $\tau$ and $\tau_k$, for each $k \geq 0$. Then

$$1_{(\tau(k) \leq s(k))} \geq 1_{(\tau \leq s)} \geq 1_{(\tau \leq t)}$$

for each $k \geq 0$. Moreover, for each $k \geq 0$, we have $\tau = \tau_k$ on the set $A_{k+}$. Hence

$$E1_{(\tau(k) \leq s(k))} = E1_{(\tau(k) \leq s(k))}1_{A(k+)} + E1_{(\tau(k) \leq s(k))}1_{A(k+)^c}$$

$$\leq E1_{(\tau \leq s)}1_{A(k+)} + 2^{-k+1}$$

$$\leq E1_{(\tau \leq s)} + 2^{-k+1} \downarrow E1_{(\tau \leq t)}.$$  

At the same time, $1_{(\tau(k) \leq s(k))} \in L^{(s(k))} \subset L^{(t)}$ because $\tau_k$ is a stopping time relative to the filtration $\mathcal{L}$, for each $k \geq 0$, according to Step 4. Therefore the Monotone Convergence Theorem implies that $1_{(\tau \leq t)} \in L^{(t)}$, where $s \in (t, \infty)$ is arbitrary. We conclude that

$$1_{(\tau \leq t)} \in L^{(t+)} = L^{(t)}.$$  

where the equality is thanks to the right continuity of the filtration $\mathcal{L}$. Thus we have verified that $\tau$ is a stopping time relative to the filtration $\mathcal{L}$.

8. Observe that, for each $i \geq k \geq 0$, we have $(X_{\tau(k)} = X_{\tau})$ on $A_{k+}$, thanks to equality (11.9.32). Hence, trivially, $X_{\tau(k)} \to X_{\tau}$ a.e. Since $X_{\tau(k)}$ is a r.v. with values in $(\mathcal{S}, \mathcal{D})$, so is $X_{\tau}$.

Because there exists a full set on which $X_{\tau} = X_{\tau}$ for each $t \in [0, 1]$, the r.v. $X_{\tau}$ has values in $(\mathcal{S}, \mathcal{D})$. Since the identity mapping $i : (\mathcal{S}, \mathcal{D}) \to (\mathcal{S}, \mathcal{D})$ is continuous according to Condition 3 of Definition (11.9.1) the function $X_{\tau}$ is actually a r.v. with values in $(\mathcal{S}, \mathcal{D})$. By restricting the r.v. $X_{\tau}$ to the full set $D = \cap_{\kappa=0}^\infty \cup_{k=0}^\infty A_{k+}$, we may assume that $\text{domain}(X_{\tau}) \subset D$.

9. Now consider each $\omega \in \text{domain}(X_{\tau})$. Let $t \in [0, \tau(\omega))$ be arbitrary. Take $\kappa \geq 0$ be so large that

$$h_{i(\sigma),\sigma(\kappa)}(X_{\tau}(\omega)) = 1 = h_{i(\sigma),\sigma(\kappa)}(X_{\tau}(\omega)),$$

which leads to $f_k(X_{\tau}(\omega)) = f(X_{\tau}(\omega))$ and $f_k(X_{\tau}(\omega)) = f(X_{\tau}(\omega))$, for each $k \geq \kappa$.

Separately, because $\omega \in D$, there exists $k \geq \kappa$ such that $\omega \in A_{k+}$. Hence $\tau(\omega) = \tau_k(\omega)$ and $X_{\tau(k)}(\omega) = X_{\tau}(\omega)$. Consequently, $t \in [0, \tau_k(\omega))$. Conditions (i) and (ii) in Step 4 therefore implies

(i'). $f(X(t, \omega)) < a$ , and

(ii'). $f(X_{\tau}(\omega)) \geq a$ if $\tau(\omega) < M$.

We have thus verified all the conditions in Definition (11.8.1) for $\tau$ to be the first exit time in $[0, M]$ of the open subset $(f < a)$ by the process $X$. In symbols, $\tau_{f,a,M} \equiv \tau_{f,a,M}(X) \equiv \tau$. The theorem is proved.

11.10 The Brownian motion in $\mathbb{R}^m$

In the remainder of this chapter, let $m \geq 1$ be arbitrary, but fixed, and let $(\mathbb{R}^m, d^m)$ denote the $m$-dimensional Euclidean metric space. Thus $d^m(x,y) = |x - y|$ for each $x,y \in \mathbb{R}^m$. 

Yuen-Kwok Chan 485 Constructive Probability

\textbf{Definition 11.10.1. (Notations for matrices and vectors).} We will use the notations of matrices and vectors in Section 5.7 with one exception: for the transpose of an arbitrary matrix \(A\), we will write \(A^t\), rather than the symbol \(A^T\) used in Section 5.7, so that we can reserve the symbol \(T\) for transition distributions. We will regard each point 
\[
x \equiv (x_1, \cdots, x_m) \in \mathbb{R}^m
\]
as a column vector, i.e. a \(m \times 1\) matrix 
\[
\begin{bmatrix}
x_1 \\
\vdots \\
x_m
\end{bmatrix}
\]. Then \(x^t x\) is a \(1 \times 1\) matrix which we identify with its sole entry \(\sum_{i=1}^{m} x_i^2\), the inner product of the vector \(x\). At the risk of some confusion, we will write \(0 \equiv (0, \cdots, 0) \in \mathbb{R}^m\), and write \(I\) for the the \(m \times m\) identity matrix.

\[\blacksquare\]

\textbf{Definition 11.10.2. (Notations for normal distributions and normal p.d.f.'s on \(\mathbb{R}^m\)).} We will use the notations and results for normal distributions in Section 5.7. In particular, for each \(t \geq 0\), recall, from Definition 5.7.7, the normal distribution \(\Phi_{x,t}\) on \(\mathbb{R}^m\) with mean vector \(x \equiv (x_1, \cdots, x_m) \in \mathbb{R}^m\) and covariance matrix \(I t\). If \(t > 0\), then \(\Phi_{x,t}\) has the p.d.f. \(\varphi_{x,t} \equiv \varphi_{x,t,t}\) defined by
\[
\varphi_{x,t}(y) \equiv (2\pi)^{-m/2} t^{-m/2} \exp\left(-\frac{1}{2t} (y-x)^t (y-x)\right)
\]
\[
= (2\pi)^{-m/2} t^{-m/2} \exp\left(-\frac{1}{2t} \sum_{i=1}^{m} (y_i - x_i)^2\right) \quad (11.10.1)
\]
for each \(y \equiv (y_1, \cdots, y_m) \in \mathbb{R}^m\). A r.v. \(U\) with values in \(\mathbb{R}^m\) is said to be standard normal if it has the normal distribution \(\Phi_{0,1}\).

In the remainder of this chapter, let \(U, W, V, U_1, U_2, \cdots\) be an arbitrary independent sequence of standard normal r.v.'s with values in \(\mathbb{R}^m\), on some probability space \((\Omega, \mathcal{L}, \mathbb{P})\). These r.v.'s are used only for the compact notations for their joint distributions; the sample space \((\Omega, \mathcal{L}, \mathbb{P})\) is immaterial. For example,
\[
\mathbb{E} f(x + \sqrt{t} U) = \int_{\mathbb{R}^m} \Phi_{x,t}(du) f(u) = \int_{\mathbb{R}^m} \Phi_{0,t}(du) f(x + u),
\]
where the expectation on the left-hand side gives a compact notation of two integrals on the right.

\[\blacksquare\]

We next generalize the definition of Brownian motion introduced in Definition 9.4.1.

\textbf{Definition 11.10.3. (Brownian motion in \(\mathbb{R}^m\)).} An a.u. continuous process \(B : [0, \infty) \times (\Omega, \mathcal{L}, \mathbb{P}) \to \mathbb{R}^m\) is called a Brownian Motion in \(\mathbb{R}^m\) if (i) \(B_0 = 0\), (ii) for each sequence \(0 \equiv t_0 \leq t_1 \leq \cdots \leq t_{n-1} \leq t_n \in [0, \infty)\), the r.v.'s \(B_{t_1} - B_{t_0}, \cdots, B_{t_n} - B_{t_{n-1}}\) are independent, and (iii) for each \(s, t \in [0, \infty)\), the r.v. \(B_t - B_s\) is normal with mean 0 and covariance matrix \(|t - s| I\).
Let $k = 1, \ldots, m$ be arbitrary. We will write $B_{k,t}$ for the $k$-th coordinate of the r.v. $B_t$, for each $t \in [0, \infty)$. Thus $B_t \equiv (B_{1,t}, \ldots, B_{m,t})$, for each $t \in [0, \infty)$. The process $B_k : [0, \infty) \times (\Omega, \mathcal{L}, E) \to \mathbb{R}$ defined by

$$(B_{k,t})_t = B_{k,t}$$

for each $t \in [0, \infty)$, is called the $k$-th coordinate process of $B$. It is easily verified that if $B$ is a Brownian Motion in $\mathbb{R}^m$, then $B_k$ is a Brownian motion in $\mathbb{R}$.

Suppose $B : [0, \infty) \times (\Omega, \mathcal{L}, E) \to \mathbb{R}^m$ is a Brownian Motion in $\mathbb{R}^m$. Let $x \equiv (x_1, \ldots, x_m) \in \mathbb{R}^m$ be arbitrary. Then we will write $B^x$ for the process $x + B : [0, \infty) \times (\Omega, \mathcal{L}, E) \to \mathbb{R}^m$, and call $B^x$ a Brownian motion in $\mathbb{R}^m$ starting at the point $x$. Thus, for each $k = 1, \ldots, m$, the process $B^x_{k,t}$ is a Brownian motion in $\mathbb{R}$ starting at the point $x_k$.

To construct a Brownian motion, we will define a certain Feller semigroup $T$ on $[0, \infty)$ with state space $(\mathbb{R}^m, d^m)$, and then prove that any a.u. càdlàg Feller process with initial state 0 and with this Feller semigroup $T$ is a Brownian motion. This way, we can use the theorems in the preceding sections for a.u. càdlàg Feller processes, to infer strong Markov property, and abundance of first exit times.

**Lemma 11.10.4. (Semigroup for the Brownian motion).** Let $t \geq 0$ be arbitrary. Define the function $T_t : C_{ub}(\mathbb{R}^m, d^m) \to C_{ub}(\mathbb{R}^m, d^m)$ by

$$T_t(f)(x) \equiv T^x_t(f) \equiv \mathbb{E}f(x + \sqrt{t}U) = \int_{\mathbb{R}^m} \Phi_{0,t}(du)f(x + u)$$  \hspace{1cm} (11.10.2)

for each $x \in \mathbb{R}^m$, for each $f \in C_{ub}(\mathbb{R}^m, d^m)$. Then the family $T \equiv \{T_t : t \in [0, \infty)\}$ is a Feller semigroup in the sense of Definition [11.9.2]. We will call $T$ the $m$-dimensional Brownian semigroup.

**Proof.** We need to verify the conditions in Definition [11.9.2] for the family $T$ to be a Feller semigroup. It is trivial to verify that, for each $t \in [0, \infty)$ and for each $y \in S$, the function $T_t^y$ is a distribution on $(\mathbb{R}^m, d^m)$.

1. Let $N \geq 1$, $t \in [0, N]$, and $f \in C_{ub}(\mathbb{R}^m, d^m)$ be arbitrary with a modulus of continuity $\delta_f$ and with $|f| \leq 1$. Consider the function $T_t^y f$ defined in equality [11.10.2]. Let $\varepsilon > 0$ be arbitrary. Let $x, y \in \mathbb{R}^m$ be arbitrary with $|x - y| < \delta_f(\varepsilon)$. Then $|(x + u) - (y + u)| = |x - y| < \delta_f(\varepsilon)$. Hence

$$|T_t^y(f)(x) - T_t^y(f)(y)| \equiv \int_{\mathbb{R}^m} \Phi_{0,t}(du)f(x + u) - \int_{\mathbb{R}^m} \Phi_{0,t}(du)f(y + u)$$

$$\leq \int_{\mathbb{R}^m} \Phi_{0,t}(du)|f(x + u) - f(y + u)| < \varepsilon.$$
CHAPTER 11. MARKOV PROCESS

Hence $T_t(f)$ has the same modulus of continuity $\alpha_N(\delta_f) \equiv \delta_f$ as the function $f$. Thus the family $T$ has a modulus of smoothness $\alpha_T \equiv (1, t, \cdots)$ where $t$ is the identity operation. The smoothness condition, Condition 1 of Definition 11.9.2 has been verified for the family $T$. In particular, we have a function $T_t : C_{ub}(R^m, d^m) \rightarrow C_{ub}(R^m, d^m)$.

2. We will next prove that $T_t^*(f)$ is continuous in $t$. To that end, let $\varepsilon > 0$, $x \in R^m$ be arbitrary. Note that the standard normal r.v. $U$ is a r.v. Hence there exists $a_\varepsilon > 0$ so large that $E(\{U > a(\varepsilon)\}) < 2^{-1} \varepsilon$. Note also that $\sqrt{t}$ is a uniformly continuous function of $t \in [0, \infty)$, with some modulus of continuity $\delta_{s\varepsilon}$. Let $t, s \geq 0$ be such that

$$|t - s| \leq \delta_t(\varepsilon, \delta_f) \equiv \delta_{s\varepsilon}(a_\varepsilon^{-1} \delta_f(2^{-1} \varepsilon)). \tag{11.10.3}$$

Then $\sqrt{t} - \sqrt{s} < a_\varepsilon^{-1} \delta_f(2^{-1} \varepsilon)$. Hence

$$|(x + \sqrt{t}u) - (x + \sqrt{su})| = |\sqrt{tu} - \sqrt{su}| < \delta_f(2^{-1} \varepsilon)$$

for each $u \in R^m$ with $|u| \leq a_\varepsilon$. Therefore the defining equality $t^{(s)}$ leads to

$$|T_t^*(f) - T_s^*(f)| \leq \tilde{E}|f(x + \sqrt{t}U) - f(x + \sqrt{s}U)|$$

$$\leq \tilde{E}|f(x + \sqrt{t}U) - f(x + \sqrt{s}U)| 1_{\{|U| \leq a(\varepsilon)\}} + \tilde{E}1_{\{|U| > a(\varepsilon)\}}$$

$$\leq \tilde{E}2^{-1}1_{\{|U| \leq a(\varepsilon)\}} + \tilde{E}1_{\{|U| > a(\varepsilon)\}}$$

$$\leq 2^{-1} \varepsilon + 2^{-1} \varepsilon = \varepsilon. \tag{11.10.4}$$

Thus the function $T_t^* f$ is uniformly continuous in $t \in [0, \infty)$, with a modulus of continuity independent of $x$. In the special case where $s = 0$, we have equality $T_t^*(f) = \tilde{E}f(x + \sqrt{t}U) = f(x)$, whence inequality $t^{(s)}$ yields

$$|T_t(f) - f| \leq \varepsilon$$

for each $t \in [0, \delta_t(\varepsilon, \delta_f))$. The strong-continuity condition, Condition 3 in Definition 11.9.2 is also verified for the family $T$, with $\delta_t$ being the modulus of strong continuity.

3. Next let $t, s \geq 0$ be arbitrary. First assume that $s > 0$. Then $(t + s)^{-\frac{1}{2}}(\sqrt{tW} + \sqrt{sV})$ is a standard normal r.v. with values in $R^m$. Hence, for each $x \in R^m$, we have

$$T_{t+s}(f) = \tilde{E}f(x + \sqrt{t+s}U) = \tilde{E}f(x + \sqrt{tW} + \sqrt{sV})$$

$$= \int_{w \in R^m} \int_{v \in R^m} \phi_{t,s}(w) \phi_{0,s}(v) f(x + w + v) dw dv$$

$$= \int_{v \in R^m} \left( \int_{w \in R^m} \phi_{t,s}(w) f(x + w + v) dw \right) \phi_{0,s}(v) dv$$

$$= \int_{v \in R^m} ((T_{t}(f)(x + v)) \phi_{0,s}(v) dv$$

$$= T_s^*(T_t f), \tag{11.10.5}$$

provided that $s \in (0, \infty)$. At the same time, inequality $11.10.4$ shows that both ends of equality $11.10.5$ are continuous functions of $s \in [0, \infty)$. Hence equality $11.10.5$ can be extended, by continuity, to

$$T_{t+s}^*(f) = T_s^*(T_t f)$$

Yuen-Kwok Chan 488 Constructive Probability
for each \( s \in [0, \infty) \). It follows that \( T_{s+t} = T_s T_t \) for each \( t, s \in [0, \infty) \). Thus the semigroup property, Condition 2 in Definition \([11.9.2]\) is proved for the family \( T \).

4. The non-explosion condition, Condition 4 in Definition \([11.9.2]\) is also straightforward, and is left as an exercise.

5. Summing up, all the conditions in Definition \([11.9.2]\) hold for the family \( T \) to be a Feller semigroup with state space \((R^m, \mathcal{m})\).

**Theorem 11.10.5. (Construction of Brownian motion in \( R^m \)).** A Brownian motion in \( R^m \) exists which is an a.u. continuous Feller process generated by the initial state \( x = 0 \) and the Brownian semigroup \( T \equiv \{T_t : t \geq 0 \} \) constructed in Lemma \([11.10.4]\).

**Proof.** 1. By Theorem \([11.9.5]\) there exists a a time-uniformly a.u. càdlàg, strongly Markov, Feller process

\[
B : [0, \infty) \times (\Omega, \mathcal{L}, \mathbb{P}) \rightarrow (R^m, \mathcal{m})
\]

with initial state \( 0 \in R^m \) and the given Feller semigroup \( T \). In particular, the family \( F^{0,T} \) of marginal distributions of the process \( B \) is generated by the initial state \( 0 \in R^m \) and the Feller semigroup \( T \), in the sense of equality \([11.9.19]\) in Theorem \([11.9.5]\). Furthermore, the process \( B \) has a modulus of continuity in probability \( \delta_{C_p, \delta(T)} \) where \( \delta_T \) is the modulus of strong continuity of \( T \) defined in equality \([11.10.3]\) in Lemma \([11.10.4]\). We will prove that the process \( B \) is a Brownian motion.

2. Since the process \( B \) has initial state \( 0 \in R^m \), we have trivially \( B_0 = 0 \).

3. Let \( \mathcal{F} = \{L^t : t \in [0, \infty) \} \) be a right continuous filtration to which the process \( B \) is adapted. Let \( 0 \equiv t_0 \leq t_1 \leq \cdots \leq t_{n-1} \leq t_n \in [0, \infty) \). Let \( f_1, \cdots, f_n \in C_{ub}(R^m, \mathcal{m}) \) be arbitrary. We will prove, inductively on \( k = 0, 1, \cdots, n \), that

\[
E \left[ \prod_{i=1}^k f_i(B_{t(i)} - B_{t(i-1)}) \right] = \prod_{i=1}^k \int_{R^m} \Phi_{0, (i-1)} (du) f_i(u).
\]

(11.10.6)

To start, with \( k = 0 \), equality \([11.10.6]\) is trivially valid because, by convention, the empty product on each side of the equality \([11.10.6]\) is equal to 1. Inductively, suppose equality \([11.10.6]\) has been proved for \( k-1 \), where \( 1 \leq k \leq n \). For abbreviation, define the function \( g_k \in C_{ub}(R^m \times R^m, \mathcal{m} \otimes \mathcal{m}) \) by

\[
g_k(y_1, y_2) \equiv f_k(y_2 - y_1)
\]

for each \((y_1, y_2) \in R^m \times R^m\). Then, by the Markov property of the a.u. càdlàg Feller process \( B \), proved in Theorem \([11.9.5]\) we have

\[
E(g_k(B_{t(k-1)} - B_{t(k)})) = F^{(t(k-1)), T}_{0, (k-1)}(g_k)
\]

(11.10.7)

as r.v.'s, where \( F^{(t(k)), T}_{0, (k-1)} \) is the function defined in Assertion 2 of Theorem \([11.9.5]\).

Note that

\[
F^{(t(k-1)), T}_{0, (k-1)} g_k \equiv \int_{R^m} \Phi_{0, (k-1)} (du) g_k(x_1)
\]

(11.10.8)

Yuen-Kwok Chan 489 Constructive Probability
CHAPTER 11. MARKOV PROCESS

where the second equality is from the defining equality \(11.10.2\) and where the last equality is from the definition of the function \(g_k\).

At the same time, Since the function \(\prod_{i=1}^{k-1} f_i(B_{t(i)} - B_{t(i-1)})\) is a member of \(L^{[k(k-1)]}\) and is bounded, equality \(11.10.7\) implies, according to basic properties of conditional expectations in Assertion 4 of Proposition \(5.6.6\) that

\[
E \left( \prod_{i=1}^{k-1} f_i(B_{t(i)} - B_{t(i-1)}) \right) g_k(B(t(k-1)), B(t(k))) = E \left( \prod_{i=1}^{k-1} f_i(B_{t(i)} - B_{t(i-1)}) \right) E_{B(t(k-1))}^0 f_{0,t(k)-t(k-1)} g_k
\]

\[
= E \left( \prod_{i=1}^{k-1} f_i(B_{t(i)} - B_{t(i-1)}) \right) \int_{\mathbb{R}^n} \Phi_{0,t(k)-t(k-1)}(du) f_k(u)
\]

\[
= \left( \prod_{i=1}^{k-1} \int_{\mathbb{R}^n} \Phi_{0,t(i)-t(i-1)}(du) f_i(u) \right) \int_{\mathbb{R}^n} \Phi_{0,t(k)-t(k-1)}(du) f_k(u)
\]

\[
= \prod_{i=1}^{k} \int_{\mathbb{R}^n} \Phi_{0,t(i)-t(i-1)}(du) f_i(u),
\]

where the second equality is from equality \(11.10.8\) and where the third equality is from the induction hypothesis that equality \(11.10.6\) has been proved for \(k-1\). Thus equality \(11.10.6\) is proved for \(k\). The induction is completed, resulting in

\[
E \prod_{i=1}^{n} f_i(B_{t(i)} - B_{t(i-1)}) = \prod_{i=1}^{n} \int_{\mathbb{R}^n} \Phi_{0,t(i)-t(i-1)}(du) f_i(u). \tag{11.10.9}
\]

4. Let \(j = 1, \ldots, n\) be arbitrary. In the special case where \(f_i \equiv 1\) for each \(i = 1, \ldots, n\) with \(i \neq j\), equality \(11.10.9\) reduces to

\[
E f_j(B_{t(j)} - B_{t(j-1)}) = \int_{\mathbb{R}^n} \Phi_{0,t(j)-t(j-1)}(du) f_j(u). \tag{11.10.10}
\]

Hence the r.v. \(B_{t(j)} - B_{t(j-1)}\) has the normal distribution \(\Phi_{0,t(j)-t(j-1)}\) where \(j \geq 1\), and \(t_{j-1}, t_j \in [0, \infty)\) are arbitrary with \(t_{j-1} \leq t_j\).

5. In the general case, substituting equality \(11.10.10\) back into equality \(11.10.9\) yields

\[
E \prod_{i=1}^{n} f_i(B_{t(i)} - B_{t(i-1)}) = \prod_{i=1}^{n} E f_j(B_{t(i)} - B_{t(i-1)}),
\]

where the functions \(f_1, \ldots, f_n \in C_{ub}(\mathbb{R}^n, d^m)\) are arbitrary. It follows that the r.v.’s \(B_{t(1)} - B_{t(0)}, \ldots, B_{t(n)} - B_{t(n-1)}\) are independent.

6. Let \(f \in C_{ub}(\mathbb{R}^n, d^m)\) be arbitrary. Equality \(11.10.10\) implies that

\[
E f(B_t - B_s) = \int_{\mathbb{R}^n} \Phi_{0,t-s}(du) f(u). \tag{11.10.11}
\]
for each
\[(t, s) \in C \equiv \{(r, v) \in [0, \infty)^2 : r \leq v\}\]

Similarly,
\[E f(B_t - B_s) = E f(-(B_t - B_t)) = \int_{\mathbb{R}^m} \Phi_{0,|t-s|}(du) f(-u) = \int_{\mathbb{R}^m} \Phi_{0,|t-s|}(du) f(u).\]  \hspace{1cm} (11.10.12)

for each \((t, s) \in C' \equiv \{(r, v) \in [0, \infty)^2 : r \geq v\}\)

Since both ends of equality [11.10.11] are continuous in \((t, s)\), and since \(C \cup C'\) is dense in \([0, \infty)^2\), we obtain
\[E f(B_t - B_s) = \int_{\mathbb{R}^m} \Phi_{0,|t-s|}(du) f(u)\]  \hspace{1cm} (11.10.13)

for each \((t, s) \in [0, \infty)^2\). Summing up, Conditions (i-iii) in Definition [11.10.3] have been proved for the process \(B\). It remains to prove a.u. continuity in Definition for \(B\) to be a Brownian motion in \(\mathbb{R}^m\).

7. To that end, let \(k = 1, \cdots, m\) be arbitrary. As in Definition [11.10.3] write \(B_{k,t}\) for the \(k\)-th coordinate of the r.v. \(B_t\), for each \(t \in [0, \infty)\). Thus \(B_t \equiv (B_{1,t}, \cdots, B_{m,t})\), for each \(t \in [0, \infty)\). The process \(B_{k,\cdot} : [0, \infty) \times (\Omega, \mathcal{L}, E) \to \mathbb{R}\) defined by
\[(B_{k,\cdot})_t \equiv B_{k,t}\]

for each \(t \in [0, \infty)\), is called the \(k\)-th coordinate process of \(B\).

8. Consider the first-coordinate process \(X \equiv B_{1,\cdot}\). Note that the process \(X\) inherits continuity in probability from the from the process \(B\). Since \((B_{1,0}, \cdots, B_{m,0}) \equiv B_0 = (0, \cdots, 0) \in \mathbb{R}^m\), we have \(B_{1,0} = 0 \in \mathbb{R}\). Let \(t, \tau \geq 0\) and \(g \in C_{\text{ub}}(\mathbb{R}^1, d^1)\) be arbitrary. Define \(f \in C_{\text{ub}}(\mathbb{R}^m, d^m)\) by \(f(x_1, \cdots, x_m) \equiv g(x_1)\) for each \((x_1, \cdots, x_m) \in \mathbb{R}^m\). Then equality [11.10.13] implies that
\[E g(X_t - X_s) = E g(B_{1,t} - B_{1,s}) = E f(B_t - B_s) = \int_{\mathbb{R}^m} \Phi_{0,|t-s|}(du) f(u)\]
\[= \int \cdots \int \Phi_{0,|t-s|}(du_1) \cdots \Phi_{0,|t-s|}(du_m) f(u_1, \cdots, u_m)\]
\[= \int \cdots \int \Phi_{0,|t-s|}(du_1) \cdots \Phi_{0,|t-s|}(du_m) g(u_1)\]
\[= \int \Phi_{0,|t-s|}(du_1) g(u_1).\]  \hspace{1cm} (11.10.14)

where \(\Phi_{0,|t-s|}\) stands for the normal distribution on \((\mathbb{R}^1, d^1)\) with mean 0 and variance \(|t - s|\), and where \(g \in C_{\text{ub}}(\mathbb{R}^1, d^1)\) is arbitrary. Thus we see that \(X_t - X_s\) is normally distributed r.r.v. with mean 0 and variance \(|t - s|\).
9. Next, let the sequence $0 \equiv t_0 \leq t_1 \leq \cdots \leq t_n \leq t_n$ in $[0, \infty)$ be arbitrary. For each $i = 1, \cdots, m$, let $g_i \in C_{ab}(\mathbb{R}^i, \mathbb{R})$ be arbitrary, and define $f_i \in C_{ab}(\mathbb{R}^m, \mathbb{R})$ by $f_i(x_1, \cdots, x_m) \equiv g_i(x_1)$ for each $(x_1, \cdots, x_m) \in \mathbb{R}^m$. Then
\[
E \prod_{i=1}^n g_i(X_{t(i)} - X_{t(i-1)}) = E \prod_{i=1}^n f_i(B_{t(i)} - B_{t(i-1)})
= \prod_{i=1}^n E \prod_{j=1}^n (B_{t(2j)}(B_{t(j)i} - B_{t(j-1)i})) = \prod_{i=1}^n E g_i(X_{t(i)} - X_{t(i-1)})
\]
Consequently, the r.r.v.’s $X_{t(1)} - X_{t(0)}, \cdots, X_{t(n)} - X_{t(n-1)}$ are independent, and normally distributed with mean 0 and variance $t_1 - t_0, \cdots, t_n - t_{n-1}$ respectively.

10. It follows that the restricted process
\[
Z \equiv X_{\mathcal{O}_x} : \mathcal{O}_x \times (\Omega, L, E) \to \mathbb{R}
\]
has the property that (i) $Z_0 = 0$, (ii) for each sequence $0 \equiv t_0 \leq t_1 \leq \cdots \leq t_n \leq t_n$ in $\mathcal{O}_x$, the r.r.v.’s $Z_{t(1)} - Z_{t(0)}, \cdots, Z_{t(n)} - Z_{t(n-1)}$ are independent, and (iii) for each $s, t \in \mathcal{O}_x$, the r.r.v. $Z_t - Z_s$ is normal with mean 0 and variance $|t - s|$. In other words, the process $Z$ satisfies all the conditions in Assertion 1 of 9.4.2. Accordingly, the extension-by-limit
\[
\overline{X}_1 \equiv \Phi_{lim}(Z) : [0, \infty) \times \Omega \to \mathbb{R}
\]
is a Brownian motion in $\mathbb{R}^1$. In particular the process $\overline{X}$ is a.u. continuous. Hence there exists a full subset $H_1$ of $(\Omega, L, E)$ such that
\[
\overline{X}_1(t, \omega) = \lim_{r \to t, r \in \mathcal{O}_x} Z(r, \omega) = \lim_{r \to t, r \in \mathcal{O}_x} X(r, \omega) \equiv \lim_{r \to t, r \in \mathcal{O}_x} B_1(r, \omega).
\]
for each $t \in [0, \infty)$, for each $\omega \in H_1$.

11. For each $k = 2, \cdots, m$, repeating the arguments in Steps 8-10 with the process $B_k$, in the place of $B_1$, we see that there exists a full subset $H_k$ of $(\Omega, L, E)$ such that
\[
\overline{X}_k(t, \omega) = \lim_{r \to t, r \in \mathcal{O}_x} B_k(r, \omega)
\]
for each $t \in [0, \infty)$, for each $\omega \in H_k$. Combining, we see that, on the full set $H = H_1 \cap \cdots \cap H_m$, we have
\[
(\overline{X}_1(t, \omega), \cdots, \overline{X}_m(t, \omega)) = \lim_{r \to t, r \in \mathcal{O}_x} (B_1(r, \omega), \cdots, B_m(r, \omega)) \equiv \lim_{r \to t, r \in \mathcal{O}_x} B(r, \omega).
\]
Consequently, the right limit $\lim_{r \to t, r \in \mathcal{O}_x} B(r, \omega)$ exists and
\[
(\overline{X}_1(t, \omega), \cdots, \overline{X}_m(t, \omega)) = \lim_{r \to t, r \in \mathcal{O}_x} B(r, \omega).
\]
for each $t \in [0, \infty)$, for each $\omega \in H$. At the same time, since $B$ is a.u. càdlàg, there exists a full subset $G \subset \bigcap_{t \in \mathcal{O}_x} domain(B_t)$ of $(\Omega, L, E)$ such that if the right limit $\lim_{r \to t, r \in \mathcal{O}_x} B(r, \omega)$ exists, then $t \in domain(B(\cdot, \omega))$ and
\[
B(t, \omega) = \lim_{r \to t, r \in \mathcal{O}_x} B(r, \omega).
\]
Combining, we see that, for each \( \omega \in H \cap G \), we have \( \text{domain}(B(\cdot, \omega)) = [0, \infty) \) and

\[
B(\cdot, \omega) = (\tilde{X}_1(\cdot, \omega), \cdots, \tilde{X}_m(\cdot, \omega)).
\]

Since the process \((\tilde{X}_1, \cdots, \tilde{X}_m) : [0, \infty) \times \Omega \rightarrow \mathbb{R}^m\) is a.u. continuous, it follows that the process \( B \) is a.u. continuous.

Summing up, all the conditions in Definition 11.10.3 are verified for the process \( B \) to be a Brownian motion in \( \mathbb{R}^m \). \( \square \)

**Corollary 11.10.6. (Basic properties of Brownian Motion in \( \mathbb{R}^m \)).** Let \( B : [0, \infty) \times (\Omega, \mathcal{L}, E) \rightarrow \mathbb{R}^m \) be an arbitrary Brownian motion in \( \mathbb{R}^m \). Let \( \mathcal{L} \) be an arbitrary right continuous filtration to which the Brownian motion \( B \) is adapted. Then the following holds.

1. \( B \) is equivalent to the Brownian motion constructed in Theorem 11.10.5 and is an a.u. continuous Feller process with Feller semigroup \( \mathcal{T} \) defined in Lemma 11.10.4.

2. The Brownian motion \( B \) is strongly Markov relative to \( \mathcal{L} \). Specifically, given any stopping time \( \tau \) values in \([0, \infty)\) relative to \( \mathcal{L} \), equality 11.9.20 in Theorem 11.9.5 holds for the process \( B \) and the stopping time \( \tau \).

3. Let \( A \) be an arbitrary orthogonal \( k \times m \) matrix. Thus \( AA^t = I \) is the \( k \times k \) identity matrix. Then the process \( AB : [0, \infty) \times (\Omega, \mathcal{L}, E) \rightarrow \mathbb{R}^k \) is a Brownian Motion.

4. Let \( b \) be an arbitrary unit vector. Then the process \( b^tB : [0, \infty) \times (\Omega, \mathcal{L}, E) \rightarrow \mathbb{R} \) is a Brownian Motion in \( \mathbb{R} \).

5. Let \( \gamma > 0 \) be arbitrary. Define the process \( \tilde{B} : [0, \infty) \times (\Omega, \mathcal{L}, E) \rightarrow \mathbb{R}^m \) by \( \tilde{B}_t \equiv \gamma^{-1/2}B_{\gamma t} \) for each \( t \in [0, \infty) \). Then \( \tilde{B} \) is a Brownian Motion adapted to the right continuous filtration \( \mathcal{L}^\gamma \equiv \{L^{(\gamma)} : t \in [0, \infty)\} \).

**Proof.** 1. Let \( \hat{B} : [0, \infty) \times (\hat{\Omega}, \hat{\mathcal{L}}, \hat{E}) \rightarrow \mathbb{R}^m \) denote the Brownian motion constructed in Theorem 11.10.5. Thus \( \hat{B} \) is an a.u. continuous Feller process. Hence it has marginal f.j.d.'s given by the family \( F^{0,\mathcal{T}} \) generated by the Feller semigroup \( \mathcal{T} \). Define the processes \( Z \equiv B|_{\Omega_{\omega}} \) and \( \hat{Z} \equiv \hat{B}|_{\Omega_{\omega}} \). Let \( m \geq 0 \) and the sequence \( 0 = r_0 \leq r_1 \leq \cdots \leq r_m \) in \( \Omega_{\omega} \), and \( f \in C(\mathbb{R}^{m+1}) \) be arbitrary. Then

\[
E f(Z_0, Z_{r_1}, \cdots, Z_{r_m}) = E f(B_0, B_{r_1}, \cdots, B_{r_m})
\]

\[
= E f(0, B_{r_1} - B_{r_0}, (B_{r_1} - B_{r_0}) + (B_{r_2} - B_{r_1}) + \cdots + (B_{r_m} - B_{r_{m-1}}))
\]

\[
= \hat{E} f(0, \hat{B}_{r_1} - \hat{B}_{r_0}, (\hat{B}_{r_1} - \hat{B}_{r_0}) + (\hat{B}_{r_2} - \hat{B}_{r_1}) + \cdots + (\hat{B}_{r_m} - \hat{B}_{r_{m-1}}))
\]

\[
= \hat{E} f(\hat{Z}_0, \hat{Z}_{r_1}, \cdots, \hat{Z}_{r_m}) = F^{0,\mathcal{T}}_{r_0,\cdots,r_m} f,
\]

where the third equality follows from Conditions (i) and (ii) of Definition 11.10.3. In other words, the marginal f.j.d.'s of \( B|_{\Omega_{\omega}} \) and \( \hat{B}|_{\Omega_{\omega}} \) are equal. Since the Brownian motions \( B \) and \( \hat{B} \) are a.u. continuous, it follows that the marginal f.j.d.'s of \( B, \hat{B} \) are equal, and given by the family \( F^{0,\mathcal{T}} \). Thus the Brownian motion \( \hat{B} \) is also generated by the initial state 0 and Feller semigroup \( \mathcal{T} \). Assertion 1 is proved.
CHAPTER 11. MARKOV PROCESS

2. Consequently, Assertion 2 then follows from Definition 11.9.7.

3. Let $A$ be an arbitrary orthogonal $k \times m$ matrix. Then trivially $AB_0 = A0 = 0 \in R^k$. Thus Condition (i) of Definition 11.10.3 holds for the process $AB$. Next, let the sequence $0 \equiv t_0 \leq t_1 \leq \cdots \leq t_n \leq t_{n+1}$ be arbitrary. Then the r.v.'s $B(t_1) - B(t_0), \ldots, B(t_n) - B(t_{n-1})$ are independent. Hence the r.v.'s $A(B(t_1) - B(t_0)), \ldots, A(B(t_n) - B(t_{n-1}))$ are independent, establishing Condition (ii) for the process $AB$. Now let $s, t \in [0, \infty)$ be arbitrary. Then the r.v. $B_t - B_s$ is normal with mean 0 and covariance matrix $|t - s|I$, where $I$ stands for the $k \times k$ identity matrix. Hence $A(B_t - B_s)$ is normal with mean 0, with covariance matrix

$$E(A(B_t - B_s)(B_t - B_s)^t A') = A(E(B_t - B_s)(B_t - B_s)^t)A' = A[(t - s)|A^t] = |t - s|I.$$

This proves Condition (iii) for the process $AB$. Assertion 3 is proved.

4. Let $b$ be an arbitrary unit vector. Then $u'\beta$ is a $1 \times m$ matrix. Hence, according to Assertion 3, the process $u'\beta : [0, \infty) \times (\Omega, L, E) \to R$ is a Brownian Motion in $R$.

5. Define the process $B : [0, \infty) \times (\Omega, L, E) \to R^m$ by $B_t \equiv \gamma^{-1}2\beta_t$ for each $t \in [0, \infty)$. Trivially, Conditions (i) and (ii) of Definition 11.10.3 hold for the process $B$. Let $s, t \in [0, \infty)$ be arbitrary. Then the r.v. $B_t - B_s$ is normal with mean 0 and covariance matrix $|t - s|I$. Hence the r.v. $B_t - B_s \equiv \gamma^{-1}2\beta_t - \gamma^{-1}2\beta_s$ has covariance matrix

$$(\gamma^{-1/2})^2 |\beta_t - \beta_s| = |t - s|I.$$

Thus Conditions (iii) of Definition 11.10.3 is also verified for the process $B$ to be a Brownian motion. Moreover, for each $t \in [0, \infty)$, we have $B_t \equiv \gamma^{-1/2}2\beta_t \in L[|\beta|^t]$. Hence the process $B$ is adapted to the filtration $\mathcal{L}_t \equiv \{L[|\beta|^t] : t \in [0, \infty)\}$. Assertion 4 and the corollary are proved.

11.11 First Exit Times from Spheres by the Brownian Motion in $R^m$

In this section, let $m \geq 1$ be arbitrary, but fixed. We will use the terminology and notations in the previous section.

Definition 11.11.1. (Notations for a filtered Brownian motion in $R^m$). Let $B : [0, \infty) \times (\Omega, L, E) \to R^m$ be an arbitrary Brownian motion. Let $\mathcal{L}$ be an arbitrary right continuous filtration to which the process $B$ is adapted. Unless otherwise stated, all stopping times are relative to this right continuous filtration $\mathcal{L}$. Let $x \in R^m$ be arbitrary. Recall that the process $B^x \equiv x + B$ is then called a Brownian motion starting at $x$. Trivially, the process $B^x$ is an a.u. càdlàg Feller process with the same Brownian semigroup $T \equiv \{T_t : t \in [0, \infty)\}$, defined in Lemma 11.10.4 and is adapted to the filtration $\mathcal{L}$ like $B$. Corollary 11.10.6 then says that the process $B^x$ is an a.u. continuous Feller process relative to the filtration $\mathcal{L}$ and the Feller semigroup $T$, and therefore that it is strongly Markov relative to the filtration $\mathcal{L}$ and the Feller semigroup $V$, in the sense of Conditions 3 in Theorem 11.9.5.
11.11. FIRST EXIT TIMES FROM SPHERES BY THE BROWNIAN MOTION IN \( \mathbb{R}^m \)

\[\square\]

**Definition 11.11.2. (Notations for spheres and their boundaries).** Let \( x \in \mathbb{R}^m \) and \( r > 0 \) be arbitrary. Define the open sphere \( D_{x,r} \equiv \{ z \in \mathbb{R}^m : |z-x| < r \} \), its closure

\[\overline{D}_{x,r} \equiv \{ z \in \mathbb{R}^m : |z-x| \leq r \},\]

and its boundary

\[\partial D_{x,r} \equiv \{ z \in \mathbb{R}^m : |z-x| = r \} .\]

Define \( D^c_{x,r} \equiv \{ z \in \mathbb{R}^m : |z-x| > r \} \). We will write, for abbreviation, \( D, \partial D, D^c \) for \( D_{0,1}, \partial D_{0,1}, D^c_{0,1} \) respectively.

\[\square\]

**Definition 11.11.3. (First exit times from spheres by Brownian Motion in \( \mathbb{R}^m \)).** Let \( B : [0, \infty) \times (\Omega, L, E) \rightarrow \mathbb{R}^m \) be an arbitrary Brownian motion. Let \( \mathcal{L} \) be an arbitrary right continuous filtration to which the process \( B \) is adapted. Let \( x, y, z \in \mathbb{R}^m \) and \( a, r > 0 \) be arbitrary such that \( |x-y| < r \). Suppose there exists a stopping time \( \tau_{x,y,r} ; B \) with values in \( (0, \infty) \), relative to the right continuous filtration \( \mathcal{L} \), such that, for a.e. \( \omega \in \Omega \), we have (i) \( B^{\tau_{x,y,r}}(\cdot, \omega) \in D_{x,r} \) on the interval \( [0, \tau_{x,y,r} ; (\omega)) \), and (ii) \( B^{\tau_{x,y,r} ; (\omega)}(\omega) \in \partial D_{x,r} \).

Then the stopping time \( \tau_{x,y,r} ; B \) is called the first exit time from the open sphere \( D_{x,r} \) by the Brownian motion \( B^r \) starting at \( x \). Note that, if \( \tau_{x,y,r} ; B \) exists, then, because the Brownian motion \( B \) is an a.u. càdlàg Feller process, Assertion 3 of Theorem 11.9.5 implies that \( B^{\tau_{x,y,r} ; (\omega)}(\omega) = \partial D_{x,r} \) is a r.v. with values in \( \mathbb{R}^m \), and is measurable relative to \( L^{(\tau_{x,y,r} ; B)} \).

Note that, in contrast to the case of a general Feller process, the exit time here is over the infinite interval. The following Theorem 11.11.7 will prove that it exists as a r.r.v.; the Brownian motion exits any open ball in some finite time.

When the Brownian motion \( B \) is understood from context, we will write simply \( \tau_{x,y,r} = \tau_{0,y,r} ; B \).

\[\square\]

**Lemma 11.11.4. (Translation-invariance of certain first exit times).** Let \( B : [0, \infty) \times (\Omega, L, E) \rightarrow \mathbb{R}^m \) be an arbitrary Brownian motion. Let \( \mathcal{L} \) be an arbitrary right continuous filtration to which the process \( B \) is adapted. Let \( x, y, z \in \mathbb{R}^m \) and \( a, r > 0 \) be arbitrary such that \( |x-y| < r \). If the first exit time \( \tau_{x,z} ; B \) exists, then (i) the first exit time \( \tau_{-z,y,-z} ; B \) exists, in which case \( \tau_{-z,y,-z} = \tau_{x,z} \), with \( u + B^{\tau_{-z,y,-z} ; (\omega)} = B^{\tau_{x,z} ; (\omega)} \) for each \( t \in [0, \tau_{x,z} ; (\omega)) \), and (ii) the first exit time \( \tau_{x,ay,ar} ; B \) exists, in which case \( \tau_{x,ay,ar} = \tau_{x,z} \).

**Proof.** Suppose the first exit time \( \tau_{x,z} \) exists. Then, by Definition 11.11.3 for a.e. \( \omega \in \Omega \), we have (i) \( x + B(t, \omega) \equiv B^t(\cdot, \omega) \in D_{x,r} \) on the interval \( [0, \tau_{x,z} ; (\omega)) \), and (ii) \( x + B_{t(\tau_{x,z} ; (\omega))}(\omega) \in \partial D_{x,r} \). Equivalently, (i') \( B^{\tau_{x,z} ; (\omega)} = B^r \) on the interval \( [0, \tau_{x,z} ; (\omega)) \), and (ii') \( B^{\tau_{x,z} ; (\omega)}(\omega) \in \partial D_{x,r} \). Hence, again by Definition 11.11.3, the first exit time \( \tau_{x,-y,-z} ; B \) exists and is equal to \( \tau_{x,z} \). Assertion (i) is proved. The proof of Assertion (ii) is similar.

\[\square\]

**Lemma 11.11.5. (Existence of first exit times from certain open spheres by Brownian motions).** Let \( B : [0, \infty) \times (\Omega, L, E) \rightarrow \mathbb{R}^m \) be an arbitrary Brownian motion. Let \( \mathcal{L} \) be an arbitrary right continuous filtration to which the process \( B \) is adapted. Then there exists a countable subset \( H \) of \( \mathbb{R} \) such that for each \( x \in \mathbb{R}^m \) and \( a \in (|x|, \infty)H_c \), the first exit time \( \tau_{x,0,a} \) exists. Here \( H_c \) denotes the metric complement of \( H \) in \( \mathbb{R} \).

Yuen-Kwok Chan 495 Constructive Probability
CHAPTER 11. MARKOV PROCESS

Proof. 1. Define the function \( f : \mathbb{R}^m \rightarrow \mathbb{R} \) by

\[ f(y) \equiv |y| \quad (11.11.1) \]

for each \( y \in \mathbb{R}^m \). Then \( f \) is a uniformly continuous function on each compact subset of \( \mathbb{R}^m \). Moreover, \( (f < a) = D_{0,a} \) and \( (f = a) = \partial D_{0,a} \) for each \( a > 0 \).

2. For each \( x \in \mathbb{R}^m \), the Brownian motion \( B^x \) is an a.u. càdlàg Feller process, with \( f(B^x_0) \equiv |B^x_0| = |x| \). Theorem [11.9.8] therefore implies that there exists a countable subset \( H \) of \( \mathbb{R} \) such that, for each \( x \in \mathbb{R}^m \), for each \( a \in (|x|, \infty)H \), and \( M \geq 1 \) for each \( x \), the first exit time \( \tau_{f,a,M} \) exists for the process \( B^x \).

3. Consider each \( x \in \mathbb{R}^m \),

\[ a \in (|x|, \infty)H, \]

and \( M \geq 1 \). Then the first exit time \( \tau_{f,a,M} \) exists according to Step 2. Recall that, by Definition [11.8.1], \( \tau_{f,a,M} \) is the first exit time in \([0,M]\) of the open subset \((f < a) = D_{0,a} \) by the process \( B^x \). Moreover, by Definition [11.8.1], the function \( B^x_\tau \) is a well-defined r.v. Furthermore, Lemma [11.8.2] says that, for each \( r \in (0,M) \) and \( N \geq M \), we have

\[ \tau_{f,a,M} \leq \tau_{f,a,N}, \quad (11.11.2) \]

\[ (\tau_{f,a,M} < M) \subset (\tau_{f,a,N} = \tau_{f,a,M}), \quad (11.11.3) \]

and

\[ (\tau_{f,a,N} \leq r) = (\tau_{f,a,M} \leq r). \quad (11.11.4) \]

We will prove that the a.u. limit

\[ \tau_a \equiv \lim_{M \to \infty} \tau_{f,a,M} \]

exists, is a stopping time relative to the filtration \( \mathcal{L} \), and satisfies the conditions in Definition [11.11.3] to be the first exit time \( \tau_{f,a,0} \) from the open sphere \( D_{0,a} \) by the Brownian motion \( B^x \).

Recall that \( B^x_1 : \mathbb{R} \times (\Omega, L, E) \rightarrow \mathbb{R} \) denotes the first component of the Brownian motion \( B \). As such, \( B^x_1 \) is a Brownian motion in \( \mathbb{R} \). Suppose \( M \geq 2 \). Then the r.r.v. \( B^x \mid_{\Omega \sim M} \) has a normal distribution on \( \mathbb{R} \), with mean 0 and variance \( M - 1 \). Since said normal distribution has a p.d.f. \( \phi_{0,M-1} \) which is bounded by \( (2\pi(M-1))^{-1/2} \), the set

\[ A_M \equiv \{ |B^x_{M-1}| < a \} \]

is measurable, with

\[ P(A_M) = \int_{u=-2a}^{2a} \phi_{0,M-1}(du) \leq 4a(2\pi(M-1))^{-1/2} \rightarrow 0 \]

as \( M \to \infty \). At the same time,

\[ A'_M = \{ |B^x_{M-1}| \geq a \} \subset \{ |B^x_{M-1}| \geq a \} \equiv (f(B^x_{M-1}) \geq a). \]

Yuen-Kwok Chan 496 Constructive Probability
Therefore, by Condition (i) of Definition\[11.8.1\] for the first exit time $\tau_{f,a,M}$, we have
\[ A_M^c \subset (f(B_{M-1}^t) \geq a) \subset (M - 1 \geq \tau_{f,a,M}) \]
\[ \subset (\tau_{f,a,M} < M) \subset \bigcap_{N=M}^{\infty} (\tau_{f,a,N} = \tau_{f,a,M}) \]  \hspace{1cm} (11.11.5)

where the next-to-last inclusion relation is thanks to relation \[11.11.3\] and where the last inclusion relation is trivial. Hence, on $A_M^c$, we have $\tau_{f,a,N} \uparrow \tau_a$ uniformly for some function $\tau_a$. Since $P(A_M^a)$ is arbitrarily close to 1 if $M$ is sufficiently large, we conclude that $\tau_{f,a,N} \uparrow \tau_a$ a.u. and therefore that $\tau_a$ is a r.r.v. Note that $\tau_{f,a,1} > 0$. Hence $\tau_a > 0$. In other words, $\tau_a$ is a r.r.v. with values in $(0, \infty)$.

3. To prove that the r.r.v. $\tau_a$ is a stopping time, consider each $t \in (0, \infty)$ be an arbitrary regular point of $\tau_a$. Let $s \in (t, \infty)$ be arbitrary. Let $r \in (t, s)$ be an arbitrary regular point of the r.r.v.’s in the sequence $\tau_a, \tau_{f,a,1}, \tau_{f,a,2}, \ldots$. Take any $M > r$. Then, according to equality \[11.11.4\] we have $(\tau_{f,a,M} \leq r) = (\tau_{f,a,N} \leq r)$ for each $N \geq M$. Letting $N \to \infty$, we obtain $(\tau_{f,a,M} \leq r) = (\tau_a \leq r)$. It follows that
\[ (\tau_a \leq r) = (\tau_{f,a,M} \leq r) \in L^r \subset L^s \]

because $\tau_{f,a,M}$ is a stopping time relative to the right continuous filtration $\mathcal{F}$. Therefore, if we take a sequence $(r_k)_{k=1,2,\ldots}$ of regular points in $(t, s)$ of the r.r.v.’s in the sequence $\tau_a, \tau_{f,a,1}, \tau_{f,a,2}, \ldots$, such that $r_k \downarrow t$, then we obtain
\[ (\tau_a \leq t) = \bigcap_{k=1}^{\infty} (\tau_a \leq r_k) \in L^s. \]

Since $s \in (t, \infty)$ is arbitrary, it follows that
\[ (\tau_a \leq t) \in \bigcap_{s \in (t, \infty)} L^s \equiv L^{(t)} = L^t, \]

where the last equality is because the filtration $\mathcal{F}$ is right continuous by assumption. Thus the r.r.v. $\tau_a$ is a stopping time.

4. It remains to show that $\tau_a$ is the desired first exit time. To that end, first note that, by Assertion 1 of Lemma\[11.7.3\] $B_{\tau(a)}$ is a well defined r.v. and is measurable relative to $L(\tau(a))$. Define the null set
\[ A \equiv \bigcap_{M=2}^{\infty} A_M, \]

Consider each $\omega \in A^c$. Then $\omega \in A_M^c$ for some $M \geq 2$ with
\[ M > u \equiv \tau_a(\omega). \]

Hence relation\[11.11.5\] implies that
\[ \omega \in (\tau_a = \tau_{f,a,M}) \subset (B_{\tau(a)} \cap B_{\tau(f,a,M)}^c) \]
\[ \hspace{1cm} (11.11.6) \]

Yuen-Kwok Chan

497 Constructive Probability
Consequently, $\tau_{f,a,M}(\omega) = u < M$. By Definition [11.8.1] of the first exit time $\tau_{f,a,M}$, we then have (i) $f(B^a(\omega)) < a$ on the interval $[0,u)$, and (ii) $f(B^a(\omega)) \geq a$. Conditions (i) and (ii) can be rewritten as conditions (i') $f(B^a(\omega)) < a$ on the interval $[0,\tau_a(\omega))$, and (ii') $f(B^a(\omega)) \geq a$. Since $B^a(\omega)$ is a continuous function, we obtain (i'') $f(B^a(\omega)) < a$ on the interval $[\tau_a(\omega), a]$, and (ii'') $f(B^a(\omega)) = a$. Therefore, by the observation in Step 1, we have (i'') $B^a(\omega) \in \mathcal{D}_{0,a}$ on the interval $[\tau_a(\omega), \tau_a(\omega))$, and (ii'') $f(B^a(\omega)) \in \partial \mathcal{D}_{0,a}$, where $\omega \in A^c$ is arbitrary. By restricting the domain of the r.r.v. $\tau_a$ to the full set $A^c$, we obtain conditions (i'') and (ii'') for each $\omega \in \text{domain}(\tau_a)$.

We have verified all the conditions in Definition [11.11.3] for the stopping time $\tau_a$ to be the first exit time $\tau_{a,0,a}$ from the open sphere $D_{0,a}$ by the Brownian motion $B^a$, where $a \in (|x|, \infty)$ are arbitrary. The lemma is proved. \hfill $\blacksquare$

**Lemma 11.11.6. (First level-crossing time for Brownian motion in $R^1$, and the Reflection Principle).** Suppose $m = 1$. Let $x \in R^1$ be arbitrary. Then there exists a countable subset $G$ of $R$ with the following properties.

Let $B: [0, \infty) \times (\Omega, \mathcal{L}, \mathbb{P}) \to R^1$ be an arbitrary Brownian motion adapted to some right continuous filtration $\mathcal{F}$. Let $a \in (x, \infty)\mathcal{G}_c$ be arbitrary. Then there exists a stopping time $\tau_{x,a}$ with values in $[0,1]$ relative to $\mathcal{F}$, such that for a.e. $\omega \in \Omega$, we have (i) $\tau_{x,a}(\omega) < a$ on the interval $[0,\tau_{x,a}(\omega))$, and (ii) $\tau_{x,a}(\omega) = a$ if $\tau_{x,a}(\omega) < 1$. Moreover, each $t \in [0,1]$ is a regular point of the r.r.v. $\tau_{x,a}$, with

$$
P(\tau_{x,a} \leq t) = 2P(B_t > a-t) = 2(1 - \Phi_{0,t}(a-x)). \tag{11.11.7}
$$

We will call $\tau_{x,a}$ a level-crossing time by the Brownian motion $B$.

This lemma is sufficient for our immediate application in the next theorem. We note that the lemma can easily be strengthened to have an empty set $G$ of exceptional points.

**Proof.** 1. Define the function $f: R \to R$ by

$$
f(y) \equiv y \tag{11.11.8}
$$

for each $y \in R$. Then, trivially, $f$ is uniformly continuous and bounded on bounded sets. Let $x \in R^1$ be arbitrary. Then the Brownian motion $B^x$ is an a.u. càdlàg Feller process, with $f(B^x_0) \equiv B^x_0 = x$. Therefore Assertion 1 of Theorem [11.9.3] says that there exists a countable subset $G$ of $R$ such that, for each point $a \in (x, \infty)\mathcal{G}_c$, and for $M = 1$, the first exit time $\tau_{x,a} \equiv \tau_{f,a,1}$ exists for the process $B^x$. Consider each

$$
a \in (x, \infty)\mathcal{G}_c.
$$

By Definition [11.8.1] for first exit times, we have, for a.e. $\omega \in \Omega$, the conditions (i') $f(\tau_{x,a}(\omega)) < a$ on the interval $[0,\tau_{x,a}(\omega))$, and (ii') $f(\tau_{x,a}(\omega)) = a$ if $\tau_{x,a}(\omega) < 1$. In view of the defining formula [11.11.3] Conditions (i') and (ii') are equivalent to the desired Conditions (i) and (ii). It remains to verify equality [11.11.7].

2. To that end, let $t \in (0,1]$ be arbitrary. First assume that $t$ is a regular point of the r.r.v. $\tau_{x,a}$, such that $t \neq u$ for each $u \in \mathcal{G}_c$. Write, for abbreviation, $\tau \equiv \tau_{x,a}$. Let $(\eta_h)_{h \in (0,1]}$ be an arbitrary non increasing sequence of stopping times such that, for each $h \geq 0$, the r.r.v. $\eta_h$ has values in $\mathcal{G}_c$, and such that

$$
\tau \leq \eta_h < \tau + 2^{-h+2}. \tag{11.11.9}
$$

Yuen-Kwok Chan 498 Constructive Probability
Note that such a sequence exists by Assertion 1 of Proposition 11.1.1. Then \( \eta_h \to \tau \) a.u. Hence \( \mathcal{B}^h_t \to \mathcal{B}_t \) a.u., as \( h \to \infty \), thanks to the a.u. continuity of the Brownian motion \( \mathcal{B} \). Define the indicator function \( g : R^2 \to R \) by \( g(z, w) = 1_{(w - z > 0)} \) for each \( (z, w) \in R^2 \).

For convenience of notations, let \( \tilde{B} : [0, \infty) \times (\Omega, L, E) \to R^1 \) be a second Brownian motion adapted to some right continuous filtration \( \mathcal{F}_t \), such that each measurable function relative to \( L(\tilde{B}_t : t \geq 0) \) is independent. The reader can easily verify that such an independent copy of \( B \) exists, by replacing \( (\Omega, L, E) \) with the product space \( (\Omega, L, E) \otimes (\Omega, L, E) \), and by identifying \( \mathcal{B} \) with \( \mathcal{B} \otimes 1 \), and identifying \( B \) with \( 1 \). Using basic properties of first exit times and a.u. convergence, we calculate

\[
P(\tau < t; \mathcal{B}^t_t > a) = P(\tau < t; \mathcal{B}^1_t = a; \mathcal{B}^t_t > a) = P(\tau < t; \mathcal{B}^1_t = a; \mathcal{B}^t_t - \mathcal{B}^1_t > 0) = P(\tau < t; \mathcal{B}^t_t - \mathcal{B}^1_t > 0) = \lim_{h \to \infty} P(\eta_h < t; \mathcal{B}_h - \mathcal{B}_h^1 > 0)
\]

\[
= \lim_{h \to \infty} \sum_{u \in Q(h) \mid 0} P(\eta_h = u; \mathcal{B}_u - \mathcal{B}_u^1 > 0) = \lim_{h \to \infty} \sum_{u \in Q(h) \mid 0} E g(\mathcal{B}_u, \mathcal{B}_u^1) \eta(h) = u,
\]

(11.11.10)

where \( T \) is the Brownian semigroup defined in Lemma 11.10.4, and where, for each \( z \in R \), the family \( F^z \) is generated by the initial state \( z \) and the Feller semigroup \( T \), in the sense of Theorem 11.9.5. Thus, for each \( z \in R \) and \( u < t \), we have

\[
F^z_{t-u} g = \int T^z_{t-u} (dw) g(z, w) = \int_{w < z} \Phi_{z,t-u} (dw) 1_{(w - z > 0)} = \int_{w < z} \Phi_{z,t-u} (dw) = \frac{1}{2}.
\]

Hence equality (11.11.10) yields

\[
P(\tau < t; \mathcal{B}^t_t > a) = \lim_{h \to \infty} \sum_{u \in Q(h) \mid 0} E \left[ \frac{1}{2}; \eta_h = u \right] = \frac{1}{2} P(\tau < t),
\]

Note that \( (\mathcal{B}^t_t > a) \subset (\tau_{x,a} < t) \) by the definition of the first level-crossing time \( \tau \equiv \tau_{x,a} \).

Combining,

\[
P(\tau_{x,a} < t) \equiv P(\tau < t) = 2P(\tau < t; \mathcal{B}^t_t > a) = 2P(\mathcal{B}^t_t > a)
\]

\[
= 2P(\mathcal{B}^t_t \geq a - x) = 2(1 - \Phi_{0,t}(a - x)), \tag{11.11.11}
\]

where \( t \in (0, 1] \) is an arbitrary regular point of the r.r.v. \( \tau_{x,a} \), with \( t \neq u \) for each \( u \in \mathcal{Q} \).

Since such points are dense in the interval \( (0, 1) \), the continuity of the right-hand side of equality (11.11.11) as a function of \( t \) implies that each \( t \in [0, 1] \) is a regular point of the r.r.v. \( \tau_{x,a} \), with

\[
P(\tau_{x,a} < t) = 2(1 - \Phi_{0,t}(a - x)),
\]

where \( a \in (x, \infty) \) is arbitrary. The lemma is proved. \( \square \)
By Lemma 11.11.5, there exists a countable subset and prove that the first exit time exists, from any open sphere by a Brownian motion started in the interior. It also estimates some bounds between successive first exit times from two concentric open spheres with approximately equal radii.

**Theorem 11.11.7. (Existence of first exit times from open spheres by Brownian motions).** Let \( B : [0, \infty) \times (\Omega, \mathcal{L}, \mathbb{P}) \rightarrow \mathbb{R}^m \) be an arbitrary Brownian motion. Let \( \mathcal{F} \) be an arbitrary right continuous filtration to which the process \( B \) is adapted. Let \( x \in \mathbb{R}^m \) be arbitrary. Then the following holds.

1. Let \( b > |x| \) be arbitrary. Then the first exit time \( \tau_{x,0,b} \) from the open sphere \( D_{0,b} \) by the Brownian motion \( B^x \) exists.

2. Let \( r > 0 \) be arbitrary. Then the first exit time \( \tau_{x,x,r} \) from the open sphere \( D_{x,r} \) by the Brownian motion \( B^x \) exists, and is equal to \( \tau_{0,r} \). In short \( \tau_{x,x,r} = \tau_{0,r} \).

3. Now let \( k \geq 1 \) and \( b' > b'' \) be arbitrary with \( b' - b'' < 2^{-k} \). Then

\[
\tau_{x,0,b'} - \tau_{x,0,b''} < 2^{-k}
\]

on some measurable set \( A \) with \( P(A^c) < 2^{-k/2} \).

**Proof.** 1. By Lemma 11.11.5 there exists a countable subset \( H \) of \( R \) such that the first exit time \( \tau_{x,a} \) exists for each \( a \in (|x|, \infty) \). By Lemma 11.11.6 there exists a countable subset \( G \) of \( R \), such that for each \( a > 0 \) and \( c \in (a, \infty) G \), we have (i) the first level-crossing time \( \tau_{x,a,c} \) with values in \((0, 1]\) exists relative to \( B \), and (ii) each \( t \in [0, 1] \) is a regular point of \( \tau_{x,a,c} \), with

\[
P(\tau_{a,c} < t) = 2(1 - \Phi(\frac{c-a}{\sqrt{\varepsilon_n}})).
\]

2. To prove Assertion 1, let \( b > |x| \) be arbitrary. Let \( n \geq 1 \) be arbitrary, but fixed till further notice. For abbreviation, write \( \varepsilon_n = \tau_n = 2^{-n} \). Take \( a_n \in (|x|, b) \) such that \( b - a_n < \varepsilon_n \). Take \( c_n \in (b, b + \varepsilon_n) \) for each \( n \). Then \( a_n < b < c_n \), and the first exit times \( \tau_{x,0,a_n} \), \( \tau_{x,0,c_n} \), and the first level-crossing time \( \tau_{x,a_n,c_n} \) exist. In the following, for abbreviation, write \( \tau_{x,0,a} \equiv \tau_{x,0,a_n} \) and \( \tau_{x,0,c} \equiv \tau_{x,0,c_n} \).

3. For later reference, we estimate some normal probability. Note that \( c_n - a_n < 2\varepsilon_n \). Hence

\[
\frac{c_n - a_n}{\sqrt{\varepsilon_n}} < \frac{2\varepsilon_n}{\sqrt{\varepsilon_n}} = 2\sqrt{\varepsilon_n}.
\]

Therefore

\[
\Phi_{x(a_n)}(c_n - a_n) = \frac{1}{2} + \int_{0}^{\frac{c_n - a_n}{\sqrt{\varepsilon_n}}} \phi_{x}(v)dv \leq \frac{1}{2} + \int_{0}^{2\sqrt{\varepsilon_n}} \phi_{x}(v)dv
\]

\[
\leq \frac{1}{2} + \frac{2\sqrt{\varepsilon_n}}{\sqrt{2\pi}} \leq \frac{1}{2} + 2^{-\varepsilon_n}.
\]

4. Recall that each point \( y \in \mathbb{R}^m \) is regarded as a column vector, with transpose denoted by \( y' \). Let \( u \in \mathbb{R}^m \) be arbitrary such that \( |u| = 1 \). In other words, \( u \) is a unit column vector. Define the process

\[
\overline{B} : [0, \infty) \times (\Omega, \mathcal{L}, \mathbb{P}) \rightarrow \mathbb{R}
\]
by
\[ \mathcal{B}_s = a_n^{-1}(B_s^x)^\prime(B_s^x + \tau - B_0^x) \]
for each \( s \in [0, \infty) \). In other words, we reset the clock to 0 at the stopping time \( \tau \), and starts tracking the projection, in the direction \( u \), of the Brownian motion \( B^x \) relative to the new origin \( B_0^x \). Note that
\[ \mathcal{B}_s = a_n^{-1}(B_s^x)^\prime(B_s^x + \tau - B_0^x) \]
for each \( s \in [0, \infty) \).

5. We will next prove that, with \( x \) and \( a_n \) fixed, the process \( \mathcal{B} \) is a Brownian motion in \( \mathbb{R}^1 \). To that end, let \( \mathcal{T} \equiv \{ \mathcal{T}_t : t \geq 0 \} \) denote the 1-dimensional Brownian semigroup in the sense of Lemma 11.10.4. Trivially \( \mathcal{B}_0 = 0 \), and the process \( \mathcal{B} \) inherits a.u. continuity from the process \( B^x \). Write, for abbreviation, \( Y_s \equiv B_{\tau(x,0,a(n))}^x + s \) for each \( s \geq 0 \), and write \( U \equiv a_n^{-1}Y_0 \). Then
\[ UY_0 = a_n^{-1}Y_0 - a_n^{-1}Y_0^2 = a_n^{-1}|B_{\tau(x,0,a(n))}^x|^2 = a_n^{-1}a_n^2 = a_n, \quad (11.11.14) \]
where the fourth equality is because \( B_{\tau(x,0,a(n))}^x \in \partial D_{0,a(n)} \) by the definition of the first exit time \( \tau_{x,0,a(n)} \). Next let \( s_1, \ldots, s_k \) be an arbitrary sequence in \( [0, \infty) \), and let \( f \in C_{ab}(\mathbb{R}^k) \) be arbitrary. Then
\[
E f(B_{\tau(x,0,a(n))}^x) = E(E f(B_{\tau(x,0,a(n))}^x) d\mathcal{T})
\]
\[
= E(E(a_n^{-1}(B_0^x)^\prime(B_0^x + s_1) - B_0^x)^\prime(\tau(x,0,a(n))) d\mathcal{T})
\]
\[
= E(E(a_n^{-1}(B_0^x)^\prime(B_0^x + s_1) - B_0^x)^\prime(\tau(x,0,a(n))) d\mathcal{T})
\]
\[
= E(E(f(U \tilde{B}_1^x) - a_n, U \tilde{B}_2^x - a_n) d\mathcal{T})
\]
\[
= E(E(f(U \tilde{B}_1^x, U \tilde{B}_2^x) d\mathcal{T})
\]
\[
= \int_{u \in \partial D(0,1)} E(M(u) d\mathcal{T})
\]
where the last equality is by Fubini’s Theorem. At the same time, for each unit vector \( u \in \mathbb{R}^n \), we have, according to Assertion 4 of Corollary 11.10.6
\[
E f(u \tilde{B}_1^x, \ldots, u \tilde{B}_k^x) = E f(\tilde{B}_1^x, \ldots, \tilde{B}_k^x)
\]
where \( \tilde{B} \) is some arbitrarily fixed Brownian motion in \( \mathbb{R}^1 \). Hence
\[
E f(B_{\tau(x,0,a(n))}^x) = E f(B_{\tau(x,0,a(n))}^x)
\]
Thus the process \( \mathcal{B} \) has the same marginal f.j.d.'s as the Brownian motion \( \tilde{B} \). We conclude that \( \mathcal{B} \) is a Brownian motion, as alleged.
6. Since \(c_n \in (a_n, \infty)G_{\omega}\), it follows that the first level-crossing time \(\tau_{a(n),c(n)}\) relative to the Brownian motion \(\mathcal{B}^{(n)}\) exists, as remarked in Step 2. Moreover, equalities \[11.11.12\] and \[11.11.13\] together imply that

\[
P(\tau_{a(n),c(n)} < t_n) = 2(1 - \Phi_{0,2}(c_n - a_n)) \geq 2 - (1 + 2^{-n/2}) = 1 - 2^{-n/2}.
\]

Recall from above the r.v.'s \(Y_0 = B^x_{\tau_{x,0,a(n)}}\) and \(U \equiv a_n^{-1}Y\). Then

\[
U'Y = a_n^{-1}Y'Y = a_n^{-1}|Y|^2 = a_n^{-1}|B^x_{\tau_{x,0,a(n)}}|^2 = a_n^{-1}a_n^2 = a_n^2
\]

(11.11.15)

Now consider each \(\omega \in (\tau_{a(n),c(n)} < t_n)\). Then

\[
s \equiv \tau_{a(n),c(n)}(\omega) < t_n \equiv \epsilon_n \equiv 2^{-n}.
\]

Hence \(\mathcal{L}_{(n)}^{(a(n))(\omega)} = c_n\). In other words,

\[
a_n + U'(\omega)(B_{\tau_{x,0,a(n)}}(\omega) - B_{\tau_{x,0,a(n)}}(\omega)) = c_n,
\]

which, in view of equality \[11.11.15\], simplifies to

\[
U'(\omega)B_{\tau_{x,0,a(n)}}(\omega) = c_n.
\]

Since \(U'(\omega)\) is a unit vector, it follows that

\[
|B_{\tau_{x,0,a(n)}}(\omega)| \geq |U'(\omega)B_{\tau_{x,0,a(n)}}(\omega)| = c_n.
\]

Consequently, by the defining properties of the first exit time \(\tau_{x,0,a(n)}\), we obtain

\[
\tau_{x,0,a(n)}(\omega) < \tau_{x,0,c(n)}(\omega) < 2^{-n} + \tau_{x,0,a(n)}(\omega),
\]

(11.11.16)

where \(\omega \in (\tau_{a(n),c(n)} < t_n)\) is arbitrary, where \(P(\tau_{a(n),c(n)} < t_n) \in [2^{-n/2}, 0)\). It follows that \(\tau_{x,0,a(n)} \uparrow \hat{\tau}\) u.a. and \(\tau_{x,0,c(n)} \downarrow \hat{\tau}\) u.a. for some r.r.v. \(\hat{\tau}\).

6. We will prove that \(\hat{\tau}\) satisfies the conditions in Definition \[11.11.3\] for the first exit time \(\tau_{x,0,b}\) to exist and be equal to \(\hat{\tau}\).

To that end, Let \(t \in (0, \infty)\) be an arbitrary regular point of the r.r.v. \(\hat{\tau}\). Let \((t_j)_{j=0} \in \infty\) be a decreasing sequence in \(t, \infty)\) such that \(t_j \downarrow t\) and such that \(t_j\) is a regular point of the stopping times \(\tau_{x,0,a(n)}, \tau_{x,0,c(n)}\), for each \(n, j \geq 0\). Then

\[
(\hat{\tau} < t_j) = \bigcup_{n=0}^{\infty} \bigcap_{k=n}^{\infty} (\tau_{x,0,c(n)} \leq t_j) \in L^{(t)}
\]

for each \(j \geq 0\). Consequently

\[
(\hat{\tau} \leq t) = \bigcap_{j=0}^{\infty} (\hat{\tau} < t_j) \in L^{(t)} = L^{(t)},
\]

where the last equality is due to the right continuity of the filtration \(\mathcal{L}\). Thus we see that the r.r.v. \(\hat{\tau}\) is a stopping time relative to the filtration \(\mathcal{L}\).
11.11. FIRST EXIT TIMES FROM SPHERES BY THE BROWNIAN MOTION IN \( \mathbb{R}^m \)

7. Because \( \tau_{x_0,c(n)} \downarrow \widehat{\tau} \) and \( \tau_{x_0,a(n)} \uparrow \widehat{\tau} \) a.u., as proved in Step 5, and because the process \( B^x \) is a.u. continuous, we see that \( B^x_{\tau_{x_0,o,c(k)}} \) is a well defined r.v. and that \( B^x_{\tau_{x_0,o,c(k)}} \to B^x_{\widehat{\tau}} \) a.u. as \( k \to \infty \). Since \( B^x_{\tau_{x_0,o,c(k)}} \in D_{x_0,c(k)} \) and \( c_k \downarrow b \), the distance \( d(B^x_{\tau_{x_0,o,c(k)}}, \partial D_{0,b}) \to 0 \) a.u. as \( k \to \infty \). Consequently, \( B^x_{\widehat{\tau}} \) has values in \( \partial D_{0,b} \). Now consider each \( \omega \in \text{domain}(B^x_{\widehat{\tau}}) \) and consider each \( t \in [0, \widehat{\tau}(\omega)) \). Then \( t \in [0, \tau_{x_0,a(n)}(\omega)) \) for some sufficiently large \( k \geq 0 \). Hence \( B^x_t \in D_{0,a(k)} \subset D_{0,b} \).

Thus we have verified the conditions in Definition 11.11.3 for the first exit time \( \tau_{x_0,b} \) to exist and be equal to \( \widehat{\tau} \). Since \( b \in (|x|, \infty) \) is arbitrary, Assertion 1 of the theorem is proved.

8. Proceed to prove Assertion 2. To that end, let \( r > 0 \) be arbitrary. By the just-established Assertion 1 of this theorem, applied to the case where \( x = 0 \) and \( b = r > 0 \), we see that the first exit time \( \tau_{0,r} \) exists. Therefore Lemma 11.11.4 says that the stopping time \( \tau_{x,x,r} \) exists and is equal to \( \tau_{0,0,r} \). Assertion 2 of this theorem is also proved.

9. It remains to prove Assertion 3. To that end, let \( k \geq 1 \) and \( b' > b'' \) be arbitrary, with \( b' - b'' < 2^{-k} \). Then there exist \( d'' < b'' \) and \( c' > b' \) such that \( d'', c' \in H_c G_c \) and such that \( c' - d'' < 2^{-k} \). Repeating the above Steps 3-6, with \( d'', c' \) in the place of \( a_n, c_n \) respectively, we obtain, in analogy to inequality 11.11.16, some measurable set \( A \) with \( P(A^c) < 2^{-k/2} \) such that, on \( A \), we have

\[
\tau_{x_0,d''} < \tau_{x_0,c'} < 2^{-k} + \tau_{x_0,d''},
\]

whence

\[
0 < \tau_{x_0,c'} - \tau_{x_0,d''} < 2^{-k}.
\]

Therefore

\[
\tau_{x_0,b'} - \tau_{x_0,b''} < \tau_{x_0,c'} - \tau_{x_0,a''} < 2^{-k}
\]

on the measurable set \( A \) with \( P(A^c) < 2^{-k/2} \). Assertion 3 and the theorem are proved.  

\( \Box \)
Part IV

Appendix
For completeness and for ease of reference, we include in this Appendix some theorems in the subject of Several Real Variables, especially the Theorem for the Change of Integration Variables, which we use many times in this book. For the proofs of these theorems, we assume no knowledge of axiomatic Euclidean Geometry. For example, in the proof of the Theorem for the change of Integration Variables, we do not assume any prior knowledge that a rotation of the plane preserves the area of a triangle, because we consider this a special case of the theorem we are proving.

The reader who is familiar with the subject as presented in Chapters 9 and 10 of [Rudin 2013], can safely skip this Appendix.
Chapter 12

The Inverse Function Theorem

Before proceeding, recall some notations and facts about vectors and matrices.

Let \( x \in \mathbb{R}^n \) be arbitrary. Unless otherwise specified, \( x_i \) will denote the \( i \)-th component of \( x \). Thus \( x = (x_1, \cdots, x_n) \). Similarly, if \( f : A \to \mathbb{R}^n \) is a function, then, unless otherwise specified, \( f_i : A \to \mathbb{R} \) will denote the \( i \)-th component of \( f \). Thus \( f_i(u) \equiv (f(u))_i \) for each \( i = 1, \cdots, n \) and for each \( u \in A \). Let \( G \) be an \( m \times n \) matrix with entries in \( \mathbb{R} \), and let \( x = (x_1, \cdots, x_n) \in \mathbb{R}^n \). Then we will regard \( x \) as a column vector, i.e. an \( n \times 1 \) matrix, and write \( Gx \) for the matrix product of \( G \) and \( x \). Thus \( Gx \) is a column vector in \( \mathbb{R}^m \). Consider the Euclidean space \( \mathbb{R}^n \). Let \( u \in \mathbb{R}^n \) be arbitrary. We will write \( u_k \) for the \( k \)-th coordinate of \( u \), and define \( \|u\| \equiv \sqrt{u_1^2 + \cdots + u_n^2} \). Then \( \frac{1}{n} \sum_{j=1}^{n} |v_j| \leq \left( \frac{1}{n} \sum_{j=1}^{n} v_j^2 \right)^{1/2} = \frac{1}{\sqrt{n}} \|v\| \) by Lyapunov’s inequality. Suppose \( G = [G_{i,j}] \) is an \( n \times n \) matrix. The determinant of \( G \) is defined as

\[
\det G \equiv \sum_{\pi \in \Pi} \text{sign}(\pi)G_{1,\pi(1)}G_{2,\pi(2)}\cdots G_{n,\pi(n)},
\]

where \( \Pi \) is the set of all permutations on \( \{1, \cdots, n\} \) and where \( \text{sign}(\pi) \) is +1 or −1 according as \( \pi \) is an even or odd permutation. If \( n > 1 \), for each \( i, j = 1, \cdots, n \) let \( G'_{i,j} \) be the \( (n-1) \times (n-1) \) matrix obtained by deleting the \( i \)-th row and \( j \)-th column from \( G \). If \( n = 1 \), define \( G'_{1,1} \equiv [1] \) so that \( \det G'_{1,1} = 1 \). For later reference, the next lemma collects some convenient bounds for matrices, and lists some basic facts from Matrix Algebra without giving the proofs.

**Lemma 12.0.1.** (Matrix Basics). Suppose the \( m \times n \) matrices \( G = [G_{i,j}] \) and \( \bar{G} = [\bar{G}_{i,j}] \) are such that \(|G_{i,j}| \leq b \) and \(|\bar{G}_{i,j}| \leq b \) for each \( i = 1, \cdots, m \), and for each \( j = 1, \cdots, n \), where \( b > 0 \). Then the following holds.

1. \( \|Gw\| \leq \sqrt{mnb} \|w\| \) for each \( w \in \mathbb{R}^n \).
2. Suppose \( m = n \). Then \( |\det G| \leq n!b^n \). If, in addition, \( |\det G| \geq c \) where \( c > 0 \), then, for each \( i = 1, \cdots, n \), there exists \( j = 1, \cdots, n \) with \( |G_{i,j}| \geq (n!b^{n-1})^{-1}c \).
3. Suppose \( m = n \) and \( |\det G| \geq c \) where \( c > 0 \). Then \( G \) has an inverse \( G^{-1} = F = [F_{i,j}] \) where \( F_{i,j} \equiv (\det G)^{-1}(-1)^{i+j}/\det G'_{i,j} \). Furthermore, for each \( w \in \mathbb{R}^n \), we
CHAPTER 12. THE INVERSE FUNCTION THEOREM

have

\[ \|G^{-1}w\| \leq \beta \|w\|. \] (12.0.1)

where \( \beta \equiv n!e^{-1}b^{n-1} \).

4. Suppose \( m = n \). Let \( i = 1, \ldots, n \) be arbitrary. Then

\[ \det G = \sum_{j=1}^{n} (-1)^{i+j} G_{i,j} \det G'_{i,j} = \sum_{j=1}^{n} (-1)^{i+j} G_{j,i} \det G'_{j,i}. \]

In particular, if there exists \( k = 1, \ldots, n \) such that \( G_{i,j} = 0 \) for each \( j = 1, \ldots, n \) with \( j \neq k \), then \( \det G = (-1)^{i+k} G_{i,k} \det G'_{i,k} \). Similarly, if there exists \( k = 1, \ldots, n \) such that \( G'_{j,i} = 0 \) for each \( j = 1, \ldots, n \) with \( j \neq k \), then \( \det G = (-1)^{i+k} G_{k,i} \det G'_{k,j} \).

5. Suppose \( m = n \) and \( G \) and \( F \) are \( n \times n \) matrices. Then \( \det(GF) = \det(G) \det(F) \).

Proof.

1. For each \( w \in \mathbb{R}^n \), we have

\[ \|Gw\| \equiv \sqrt{\sum_{i=1}^{m} \left( \sum_{j=1}^{n} G_{i,j}w_j \right)^2} \leq b \sqrt{\sum_{i=1}^{m} \left( \sum_{j=1}^{n} |w_j| \right)^2} \]

\[ \leq b \sqrt{\sum_{i=1}^{m} (\sqrt{n} \|w\|)^2} = \sqrt{mn}b \|w\|. \] (12.0.2)

2. Let \( \Pi \) be the set of all permutations on \( \{1, \ldots, n\} \). Since the set \( \Pi \) has \( n! \) elements, we obtain, from the definition of the determinant,

\[ |\det G| \leq \sum_{\pi \in \Pi} |G_{1,\pi(1)}G_{2,\pi(2)} \cdots G_{n,\pi(n)}| \leq n!b^n. \]

Suppose, in addition, that \( |\det G| \geq c \). Then there exists \( \pi \in \Pi \) such that

\[ |G_{1,\pi(1)}G_{2,\pi(2)} \cdots G_{n,\pi(n)}| \geq (n!)^{-1}c. \]

Hence \( |G_{i,\pi(i)}| \geq (n!)^{-1}c/n! \) for each \( i = 1, \ldots, n \).

3. Cramer’s Rule, whose straightforward proof using the definition of the determinant is omitted, says that \( F \) is the inverse of \( G \). If \( n = 1 \), then \( |F_{1,1}| = |(\det G)^{-1}| \leq c^{-1}. \)

If \( n > 1 \), then \( |\det G'_{j,i}| \leq (n-1)!b^{n-1} \) for each \( i, j = 1, \ldots, n \), according to Assertion 2, and so

\[ |F_{i,j}| = |(\det G)^{-1} \det G'_{j,i}| \leq c^{-1}(n-1)!b^{n-1}. \]

Hence, by Assertion 1, \( \|G^{-1}w\| \equiv \|Fw\| \leq n(n-1)!c^{-1}b^{n-1} \|w\| \) for each \( w \in \mathbb{R}^n \) if \( n > 1 \). Combining, \( \|G^{-1}w\| \leq \beta \|w\| \) for each \( w \in \mathbb{R}^n \) and for each \( n \geq 1 \), where \( \beta \equiv n!e^{-1}b^{n-1} \).

4,5. Proof omitted. \( \square \)

Yuen-Kwok Chan 510 Constructive Probability
Let $d$ denote the Euclidean metric defined by $d(u, v) \equiv \|u - v\|$ for all $u, v \in \mathbb{R}^n$. Let $u \in \mathbb{R}^n$, and let $r \geq 0$. For each compact subset $K$ of $\mathbb{R}^n$, let $d(u, K)$ denote the distance from $u$ to $K$. Define $B(u, r) \equiv \{v: \|v - u\| \leq r\}$, $B^c(u, r) \equiv \{v: \|v - u\| < r\}$, and $\partial B(u, r) \equiv \{v: \|v - u\| = r\}$. Suppose $K$ is a compact subset of $\mathbb{R}^n$. Since the function $d(\cdot, K)$ is continuous on $\mathbb{R}^n$, the closed $r$-neighborhood $(d(\cdot, K) \leq r) \equiv \{u \in \mathbb{R}^n : d(u, K) \leq r\}$ is compact for all but countably many $r > 0$.

A compact subset $K$ is said to be well contained in a subset $A$ of $\mathbb{R}^n$ if $K \subset A$ for some $r > 0$. In that case, we write $K \Subset A$. More generally, a subset $B$ is said to be well contained in $A$ if $B \subset K \Subset A$ for some compact subset $K$.

Suppose $K \Subset A$. Let $r > 0$ be such that $K_r \subset A$. Let $t \in (0, r)$ be arbitrary such that $K_t$ is compact. Let $s \in (0, r - t)$ be arbitrary such that $(K_s)_t$ is compact. Then $(K_s)_t \subset K_r \subset A$. Hence $K_r \Subset A$. In words, if a compact $K$ is well contained in the set $A \subset \mathbb{R}^n$, then some compact neighborhood of $K$ is well contained in $A$.

**Definition 12.0.2. (Derivative and Jacobian).** Let $n, m \geq 1$ and let $M$ be the linear space of $m \times n$ matrices with real number components. Let $A$ be any open subset of $\mathbb{R}^n$. A function $g: A \to \mathbb{R}^m$ is said to be differentiable on $A$ if there exists a function $G: A \to M$ such that, for each compact subset $K$ with $K \subset A$, there exists an operation $\delta_K: (0, \infty) \to (0, \infty)$ such that

$$\|g(v) - g(u) - G(u)(v - u)\| \leq \delta_K(\varepsilon) \|v - u\|$$

for each $u, v \in K$ with $\|u - v\| \leq \delta_K(\varepsilon)$. Here $v - u$ is regarded as a column vector with $n$ rows, and $G(u)(v - u) \in \mathbb{R}^m$ is the matrix-vector product. The matrix valued function $G$ on $A$ is then called a derivative of $g$ on $A$, and, for each compact subset $K$ with $K \subset A$, the operation $\delta_K$ is called the modulus of differentiability of $g$ on $K$. If $\delta: (0, \infty) \to (0, \infty)$ is an operation such that $\delta$ is a modulus of differentiability of $g$ on each compact subset well contained in $A$, then we say that $\delta$ is a modulus of differentiability of $g$ on the open set $A$. To emphasize that $\delta_K$ is independent of $u \in K$, we sometimes say that $g$ is uniformly differentiable on $K$. For each $u \in A$ and each $i = 1, \cdots, m$ and $j = 1, \cdots, n$, the component of $G(u)$ at the $i$-th row and $j$-th column is called the first order partial derivative of $g_i$ relative to the $j$-th component variable, and is denoted by $G_{i,j}(u) \equiv G(u)_{i,j} \equiv \frac{\partial g_i}{\partial v_j}(u)$. In the case where $n = m$, for each $u \in A$, the determinant $\det G(u) \equiv \det \left[ \frac{\partial g_i}{\partial v_j}(u) \right]$ is called the Jacobian of $g$ at $u$.

Note that we write $G_i(u), G(u)_{i,j},$ and $\frac{\partial g_i}{\partial v_j}(u)$ interchangeably. In the last expression, $v_j$ is a dummy variable. For example, the expressions $\frac{\partial g_i}{\partial v_j}(u), \frac{\partial g_i}{\partial v_j}(u)$ or $\frac{\partial g_i}{\partial v_j}(u)$, with different dummy variables, all have the same value as $G(u)_{i,j}$.

**Proposition 12.0.3. (Uniqueness of derivative).** Suppose $g: A \to \mathbb{R}^m$ is differentiable on the open subset $A$ of $\mathbb{R}^n$. Then the derivative of $g$ on $A$ is unique.

**Proof.** Suppose $G$ and $H$ are both derivatives of $g$ on $A$. Consider any $u \in A$. Let $r > 0$ be such that $B(u, 2r) \subset A$ and let $K \equiv B(u, r)$. Then $K_r \subset A$ and so $K \subset A$. Let $\varepsilon > 0$ be arbitrary. There exists $\delta_0 \in (0, r)$ such that $\|g(v) - g(u) - G(u)(v - u)\| \leq \frac{\varepsilon}{2} \|v - u\|$ and $\|g(v) - g(u) - H(u)(v - u)\| \leq \frac{\varepsilon}{2} \|v - u\|$ for each $v \in B(u, \delta_0)$. Write $Q \equiv G(u) - H(u)$. Then we have

$$\|Q(v - u)\| \leq \varepsilon \|v - u\|$$

(12.0.3)
for each \( v \in B(u, \delta_0) \). Consider any \( j = 1, \ldots, n \). Let
\[
v \equiv (u_1, \ldots, u_{j-1}, u_j + \delta_0, u_{j+1}, \ldots, u_n).
\]
Then \( v - u = (0, \ldots, 0, \delta_0, 0, \ldots, 0) \) has entries 0 except that the \( j \)-th entry is \( \delta_0 \), whence
\[
Q(v - u) = \delta_0 (Q_{1,j}, \ldots, Q_{m,j}.
\]
Therefore inequality [12.0.3] yields
\[
\delta_0 \| (Q_{1,j}, \ldots, Q_{m,j}) \| \leq \varepsilon \delta_0.
\]
Canceling, we see that \( \| (Q_{1,j}, \ldots, Q_{m,j}) \| \leq \varepsilon \) for arbitrary \( \varepsilon > 0 \). Consequently
\[
\| (Q_{1,j}, \ldots, Q_{m,j}) \| = 0
\]
and so \( Q_{i,j} = 0 \) for each \( i = 1, \ldots, m \). Equivalently \( G(u) = H(u) \) for any \( u \in A \).

**Proposition 12.0.4.** (Differentiability and uniform continuity). Suppose \( g : A \to \mathbb{R}^m \)
is differentiable on the open subset \( A \) of \( \mathbb{R}^n \). Then the derivative \( G \) of \( g \) is uniformly continuous on every compact subset \( K \) with \( K \subseteq A \). More specifically, if \( K_i \subseteq A \) for some \( i \geq 0 \) and if \( \delta \) is a modulus of differentiability of \( g \) on \( K_i \), then the operation \( \delta_i : (0, \infty) \to (0, \infty) \) defined by \( \delta_i(\varepsilon) \equiv \frac{1}{2} \delta(\frac{\varepsilon}{t}) \) for each \( \varepsilon > 0 \) is a modulus of continuity of \( G_i \) on \( K \) for each \( i = 1, \ldots, n \).

**Proof.** Let \( K \) be a compact subset of \( A \) with \( K \subseteq A \). Let \( t > 0 \) be such that \( K_i \subseteq A \). Let \( \delta \) be a modulus of differentiability of \( g \) on \( K_i \). Let \( u \in K \) be arbitrary but fixed. Define a function \( f : A \to \mathbb{R}^m \) by \( f(v) \equiv g(v) - g(u) - G(u)(v - u) \) for each \( v \in A \). Define \( F(v) \equiv G(v) - G(u) \) for each \( v \in A \). Then, for arbitrary \( \varepsilon > 0 \) and for each \( w, v \in K_i \) with \( \| w - v \| \leq \delta(\varepsilon) \), we have
\[
\| f(w) - f(v) - F(v)(w - v) \| \equiv \| f(w) - f(v) - (G(v) - G(u))(w - v) \|
\]
\[
\equiv \| g(w) - g(u) - G(u)(w - u) - g(v) + g(u) + G(u)(v - u) - (G(v) - G(u))(w - v) \|
\]
\[
= \| g(w) - g(v) - G(v)(w - v) \| \leq \varepsilon \| w - v \|. \tag{12.0.4}
\]
Clearly \( f(u) = 0 \), and \( F(u) = 0 \), the \( m \times n \) matrix whose entries are zeros. By setting \( v = u \) in inequality [12.0.4] we have
\[
\| F(w) \| \leq \varepsilon \| w - u \| \tag{12.0.5}
\]
for each \( w \in K_i \) with \( \| w - u \| \leq \delta(\varepsilon) \) and for each \( \varepsilon > 0 \).

Now let \( \varepsilon > 0 \) be arbitrary and let \( a \equiv \frac{1}{4} \delta(\varepsilon) \). Let \( v \in K \) be arbitrary such that \( \| v - u \| \leq a \). Fix any \( i = 1, \ldots, m \) and \( j = 1, \ldots, n \). Define \( w \equiv (v_1, \ldots, v_{j-1}, v_j + \varepsilon, v_{j+1}, \ldots, v_n) \). Note that \( w - v \equiv (0, \ldots, 0, a, 0, \ldots, 0) \) has all components equal to 0 except the \( j \)-th. Hence \( \| w - v \| = a \) and so \( w \in K_i \). Moreover \( \| w - u \| \leq \| w - v \| + \| v - u \| \leq 2a \leq \delta(\varepsilon) \) and so \( \| f(w) \| \leq \varepsilon \| w - u \| \) by inequality [12.0.5]. Therefore
\[
|F(v)_{i,j}| = \left| \sum_{k=1}^{n} F(v)_{i,k} (w - v)_k \right| = |(F(v)(w - v))_i|
\]
\[
\leq \| F(v)(w - v) \| \leq \| f(w) - f(v) - F(v)(w - v) \| + \| f(w) \| + \| f(v) \|
\]
that consideration yields, we see that
\[ |F(v)_{i,j} - G(u)_{i,j}| \leq 4\epsilon. \]
Equivalently, \([G(v)]_{i,j} - G(u)_{i,j}\) \leq 4\epsilon. The proposition is proved.

**Proposition 12.0.5. (Differentiability and Lipschitz continuity).** Suppose \(g : A \rightarrow \mathbb{R}^m\) is a differentiable function on the open subset \(A\) of \(\mathbb{R}^n\). Let \(K\) be any compact subset with \(K \in A\). Then \(g\) is Lipschitz continuous on \(K\).

**Proof.** Let \(K\) be a compact subset of \(A\) with \(K \in A\). Let \(t > 0\) be such that \(K_t \in A\). Let \(\delta\) be a modulus of differentiability of \(g\) on \(K_t\). By Proposition 12.0.1, there exists \(\epsilon > 0\) such that \(\epsilon a \leq 4\epsilon a\). Let \(u, v \in K\) be such that \(|u - v| < a\). Either (i) \(|v - u| < 3a\) or (ii) \(|v - u| > 2a\). In case (i), we have \(|v - u| < 3a \leq \delta(1)\) whence \(|g(u) - g(v) - G(u)(v - u)| \leq |u - v|\).

**Proposition 12.0.6. (Chain Rule)** Let \(f : A \rightarrow \mathbb{R}^m\) and \(g : B \rightarrow \mathbb{R}^n\) be differentiable functions on the open subsets \(A\) and \(B\) of \(\mathbb{R}^n\) and \(\mathbb{R}^m\) respectively, such that for each compact subset \(K\) of \(A\) with \(K \subset A\) we have \(f(K) \subset K' \subset B\) for some compact subset \(K'\) of \(B\). Let \(F\) and \(G\) denote the derivatives of \(f\) and \(g\) respectively. Then the composite function \(g(f) : A \rightarrow \mathbb{R}^n\) is differentiable on \(A\), with derivative \(G(f)\).

**Proof.** Let \(K\) be any compact subset of \(A\) with \(K \subset A\). By hypothesis there exists a compact subset \(K'\) of \(B\) with \(f(K) \subset K' \subset B\). Let \(\delta\) and \(\delta'\) denote the moduli of differentiability of \(f\) and \(g\) on \(K\) and \(K'\) respectively. By Proposition 12.0.1, \(f\) is Lipschitz continuous on \(K\), with a Lipschitz constant \(c > 0\). By Proposition 12.0.4, the partial derivatives \(G_{i,j}\) are uniformly continuous, hence bounded in absolute value, on \(K'\) for each \(i = 1, \ldots, n\) and each \(j = 1, \ldots, m\). Let \(b > 0\) be such that \(|G_{i,j}| \leq b\) on \(K'\) for each \(i = 1, \ldots, n\) and each \(j = 1, \ldots, m\).

Let \(\epsilon > 0\) be arbitrary. Let \(x, y \in K\) be arbitrary with \(|x - y| < \delta(\epsilon) \equiv \delta'\epsilon\). Let \(y = f(x)\) and \(v = f(y)\). Then \(u, v \in K'\), and \(|v - u| \equiv |f(y) - f(x)| \leq c|x - y| \leq \delta'(\epsilon)\), whence
\[
|g(v) - g(u) - G(u)(v - u)| \leq \epsilon |v - u| \leq c\epsilon |y - x|.
\]
At the same time,
\[
|f(y) - f(x) - F(x)(y - x)| \leq \epsilon |y - x|.
\]
Combining, we obtain
\[ \|G(u)(f(y) - f(x) - F(x)(y - x))\| \leq \sqrt{mn} \|f(y) - f(x) - F(x)(y - x)\| \leq \sqrt{mn}\varepsilon \|y - x\|. \]

Hence, according to Lemma 12.0.1,
\[ \|G(u)(f(y) - f(x)) - G(f(x))F(x)(y - x)\| \leq \sqrt{mn}\varepsilon \|y - x\|. \]
Combining, we obtain
\[ \|g(f(y)) - g(f(x)) - G(f(x))F(x)(y - x)\| \leq \sqrt{mn}\varepsilon \|y - x\|. \]

Since \( \varepsilon > 0 \) is arbitrary with the operation \( \delta_2 : (0, \infty) \to (0, \infty) \) defined by \( \delta_2(\varepsilon) \equiv \delta_1((c + \sqrt{mn})^{-1}\varepsilon) \) for each \( \varepsilon > 0 \) as a modulus of differentiability on \( K \). Since \( K \in A \) is arbitrary, we see from inequality (12.0.6) that \( G(f)F \) is the derivative of \( g(f) \) on \( A \).}

The proof below for the Inverse Function Theorem is by the method of contraction mapping.

**Theorem 12.0.7. (Inverse Function Theorem)** Let \( g : B \to \mathbb{R}^n \) be a differentiable function on an open subset \( B \) of \( \mathbb{R}^n \), with derivative \( G \). Define the Jacobian \( J(v) \equiv \det G(v) \) for each \( v \in B \). Suppose \( K \) is a compact subset of \( B \) with \( K \subseteq B \) for some \( r > 0 \), and suppose \( |J| \geq c \) on \( K \), for some \( c > 0 \). Let \( \delta \) be a modulus of differentiability of \( g \) on \( K \), and let \( b > 0 \) be such that \( |G_{ij}| \leq b \) on \( K \), for each \( i, j = 1, \ldots, n \). Then there exists \( k = s(n, r, b, c, \delta) \) > 0 such that for each \( u \in K \) we have (i) there exists a function \( f : C \equiv B^\ast(g(u), s) \to B(u, r) \) such that \( g(f(y)) = y \) for each \( y \in C \), and (ii) the inverse function \( f \) is differentiable on \( C \), with derivative \( F \equiv G(f)^{-1} \), and with a modulus of differentiability \( \delta' \equiv \delta'(n, r, b, c, \delta) \) on the open set \( C \). Note that we write \( s = s(n, r, b, c, \delta) \) to emphasize that \( s \) depends only on \( n, r, b, c, \delta \).

**Proof.** Note that by Proposition 12.0.4 \( G_{ij} \) is uniformly continuous on \( K \) for each \( i, j = 1, \ldots, n \), with a modulus of continuity \( \delta_1 \) defined by \( \delta_1(\varepsilon) \equiv \frac{1}{4}\delta_2(\varepsilon) \) for each \( \varepsilon > 0 \). By the same token, there exists \( b > 0 \) be such that \( |G_{ij}| \leq b \) on \( K \), for each \( i, j = 1, \ldots, n \). Define the operation \( \delta_2 : (0, \infty) \to (0, \infty) \) by \( \delta_2(\varepsilon) \equiv \delta_1\left(\frac{|G_{ij}|}{n}\right) \) for each \( \varepsilon > 0 \). Let \( \beta \equiv n^c \beta^{n-1} \varepsilon_0 \equiv (4\beta)^{-1} \). Let \( a \equiv \frac{1}{2}\delta_2(\varepsilon_0) \) and \( s \equiv \frac{\pi}{2\beta} \). We will show that \( s \) has the desired properties.

To that end, consider any \( u \in K \). Let \( v = g(u) \). Consider any \( v, w \in B(u, a) \). Then \( v, w \in K \). Moreover \( \|v - w\| \leq 2a \leq \delta_2(\varepsilon_0) \).

Let \( \varepsilon > 0 \) be arbitrary. Suppose \( \|v - w\| \leq \delta_2(\varepsilon) \equiv \frac{1}{4}\delta_1\left(\frac{|G_{ij}|}{n}\right) \) for each \( \varepsilon > 0 \). Then, since \( \delta \) is a modulus of differentiability of \( g \), we have
\[ \|g(w) - g(v) - G(v)(w - v)\| \leq \frac{\varepsilon}{4n} \|w - v\| \leq \varepsilon \|w - v\|. \]
Therefore we see, by Lemma 12.0.1, that the inverse matrix \( G \) follows that, for arbitrary \( \Phi \in B(u,a) \), we have

\[
\| \Phi(w) - \Phi(v) \| = \| w - v - G^{-1}(u)(g(w) - g(v)) \| \\
= \| G^{-1}(u)(G(u)(w - v) - g(w) + g(v)) \| \\
\leq \beta \| G(u)(w - v) - g(w) + g(v) \| \\
\leq \beta \| G(v)(w - v) - g(w) + g(v) \| + \beta \| (G(u) - G(v))(w - v) \| \\
\leq \beta \varepsilon_0 \| w - v \| + \beta \varepsilon_0 \| w - v \| = 2\beta \varepsilon_0 \| w - v \| \equiv \frac{1}{2} \| w - v \| \quad (12.0.11)
\]

where the first inequality follows from inequality [12.0.10] applied to \( u \), and where the third inequality follows from inequalities [12.0.7] and [12.0.9] with \( \varepsilon \) replaced by \( \varepsilon_0 \). It follows that, for arbitrary \( \Phi \in B(u,a) \),

\[
\| \Phi(v) - u \| \leq \| \Phi(v) - \Phi(u) \| + \| \Phi(u) - u \| \leq \frac{1}{2} \| v - u \| + \frac{a}{2} \leq \frac{a}{2} + \frac{a}{2} = a,
\]

and so \( \Phi(v) \in B(u,a) \). Thus we see that \( \Phi \) is a function mapping \( B(u,a) \) into \( B(u,a) \).

Now define \( u(0) = u \), and inductively define \( u(k) = \Phi(\Phi(\cdots(\Phi(u(0)))) \) for each \( k \geq 1 \). Then, according to inequality [12.0.11]

\[
\| u(k) - u^{(k-1)} \| \equiv \| \Phi(u^{(k-1)}) - \Phi(u^{(k-2)}) \| \\
\leq \frac{1}{2} \| u^{(k-2)} - u^{(k-1)} \| \leq \cdots \leq 2^{-k+1} \| u^{(1)} - u^{(0)} \|
\]

for each \( k \geq 1 \). Therefore \( u(k) \to v \) for some \( v \in B(u,a) \). By the Lipschitz continuity of \( \Phi \) displayed in inequality [12.0.11] we have \( \Phi(u(k)) \to \Phi(v) \). Equivalently \( u^{(k+1)} \to \Phi(u(k)) \to \Phi(v) \). Therefore \( v = v + G^{-1}(u)(y - g(v)) \) and so \( G^{-1}(u)(y - g(v)) = 0 \). Multiplying the last equality from the left by the matrix \( G(u) \), we obtain \( y - g(v) = 0 \), or
In other words, we will show that $v$ is unique. Suppose $y = g(w)$ for some other $w \in B(u, a)$. Then $g(w) = g(v)$, and so

$$\|G(v)(w - v)\| = \|g(w) - g(v) + G(v)(w - v)\| \leq \varepsilon_0 \|w - v\|$$

according to inequality $\text{[12.0.7]}$ with $\varepsilon$ replaced by $\varepsilon_0$. Hence

$$\|w - v\| = \|G(v)^{-1}G(v)(w - v)\| \leq \beta \|G(v)(w - v)\| \leq \beta \varepsilon_0 \|w - v\|.$$  

Consequently $\|w - v\| = 0$ and $w = v$. Summing up, for each $y \in B(g(u), s)$, there exists a unique $v \in B(u, a)$ such that $y = g(v)$. Hence $B(g(u), s) \subset g(B(u, a)) \subset g(B(u, r))$. We can therefore define a function $f$ on $B(g(u), s)$ by $f(y) = v$ where $v \in B(u, a)$ is such that $y = g(v)$, for each $y \in B(g(u), s)$. By definition, $g(f(y)) = y$ for each $y \in B(g(u), s)$.

In other words, $f$ is the inverse of $g$ on $B(x, s)$, with values in $B(u, a)$.

Next, we will prove the differentiability of $f$ on $C \equiv B'(x, s)$. Consider any $y, z \in B(x, s)$. Let $v \equiv f(y)$ and $w \equiv f(z)$. Then $y = g(v)$ and $z = g(w)$ by the definition of the inverse function $f$. Using inequality $\text{[12.0.7]}$ we estimate

$$\|v - w - G(w)^{-1}(y - z)\| = \|G(w)^{-1}(G(w)(v - w) - g(v) + g(w))\|$$

$$\leq \beta \|G(w)(v - w) - g(v) + g(w)\| \leq \beta \varepsilon_0 \|v - w\|.$$  

Hence

$$\|v - w\| \leq \|G(w)^{-1}(y - z)\| + \beta \varepsilon_0 \|v - w\|.$$  

It follows that

$$\|v - w\| \leq \frac{\beta}{1 - \beta \varepsilon_0} \|G(w)^{-1}(y - z)\|$$

$$\leq \frac{\beta}{1 - \beta \varepsilon_0} \|y - z\| = \frac{4}{3} \beta \|y - z\|.$$  

Thus $\|f(y) - f(z)\| \leq \frac{4}{3} \beta \|y - z\|$ for each $y, z \in B(x, s)$. In other words, $f$ is Lipschitz continuous on $B(x, s)$, with Lipschitz constant $\frac{4}{3} \beta$.

Now let $\varepsilon > 0$ be arbitrary, and let $y, z \in B(x, s)$ be such that $\|y - z\| \leq \delta'(\varepsilon) \equiv \frac{3}{4} \beta^{-1} \delta(\frac{4}{3} \beta^{-2} \varepsilon)$. Then inequality $\text{[12.0.13]}$ implies that $\|v - w\| \leq \delta(\frac{4}{3} \beta^{-2} \varepsilon)$. Therefore inequalities $\text{[12.0.7]}$ through $\text{[12.0.10]}$ hold for $v, w$. Using inequality $\text{[12.0.7]}$ we now obtain

$$\|v - w - G(w)^{-1}(y - z)\| = \|G(w)^{-1}(G(w)(v - w) - g(v) + g(w))\|$$

$$\leq \beta \|G(w)(v - w) - g(v) + g(w)\| \leq \frac{3}{4} \beta^{-1} \|v - w\| \leq \frac{3}{4} \beta^{-1} \frac{4}{3} \beta \|y - z\|.$$  

In other words,

$$\|f(y) - f(z) - G(f(z))^{-1}(y - z)\| \leq \varepsilon \|y - z\|.$$  

Yuen-Kwok Chan 516 Constructive Probability
for arbitrary $y, z \in B(x, s)$ with $\|y - z\| \leq \delta'(\epsilon)$. In particular, inequality \[12.0.14\] holds for each $y, z \in C \equiv B^0(x, s)$ with $\|y - z\| \leq \delta'(\epsilon)$. We have thus proved that $f$ is differentiable on $C$, with derivative $F = G(h)^{-1}$, and with modulus of differentiability $\delta'$ for each compact subset well contained in $C$. The Reader can trace the definitions of $s$ and $\delta'$ to verify that they depend only on $n, r, b, c$, and $\delta$. The theorem is proved. $\Box$

**Corollary 12.0.8. (Condition for inverse function to be differentiable).** Let $A, B$ be open subsets of $\mathbb{R}^n$. Let $g : B \to A$ be a differentiable function on $B$, with derivative $G$. Define the Jacobian $J(\nu) \equiv \det G(\nu)$ for each $\nu \in B$. Suppose $|J| \geq c$ for some $c > 0$ on each compact subset $K$ with $K \subset B$. Suppose the inverse function $f : A \to B$ of $g$ exists, such that for each compact subset $H$ of $A$ with $H \subset A$ we have $f(H) \subset B$. Then the inverse function $f$ is differentiable on $A$, with derivative $F \equiv G(f)^{-1}$. In particular, $f$ is uniformly continuous on compact subsets well contained in $A$.

Proof. Let $H$ be an arbitrary compact subset of $A$ with $H \subset A$. Then $H_a \subset A$ for some $a > 0$. Define $K \equiv f(H)$. By hypothesis $K_a \subset B$ for some $r > 0$. Hence $|J| \geq c$ for some $c > 0$ on $K_{r'}$. Let $\delta$ be a modulus of differentiability of $g$ on $K_{r'}$, and let $b > 0$ be such that $|G_{ij}| \leq b$ on $K_{r'}$, for each $i,j = 1, \ldots, n$. Let $\delta_b$ be a modulus of continuity of $g$ on $K_{r'}$, and let $r > 0$ be such that $r < r' \wedge \delta_b(a)$. Then $g(K_a) \subset H_a$. By the Inverse Function Theorem \[12.0.7\] there exists $s = s(n, r, b, c, \delta) > 0$ such that for each $u \in K$ we have (i) there exists a function $\tilde{f} : C \equiv B'(g(u), s) \to B(u, r)$ such that $g(\tilde{f}(y)) = y$ for each $y \in C$, and (ii) the inverse function $\tilde{f}$ is differentiable on $C$, with derivative $F \equiv G(\tilde{f})^{-1}$, and with a modulus of differentiability $\delta' = \delta'(n, r, b, c, \delta)$ on the open set $C$. Consider any $u \in K$ and let $\tilde{f}, C$ be as in conditions (i) and (ii). Then, for each $y \in C$, we have $\tilde{f}(y) \in B(u, r) \subset K_{r'}$. Hence $y = g(\tilde{f}(y)) \in g(K_{r'}) \subset H_a$. Moreover $f(y) = f(g(\tilde{f}(y))) = \tilde{f}(y)$ for each $y \in C$. Consequently, condition (ii) implies that $f$ is differentiable on $C$, with derivative $F \equiv G(f)^{-1}$, and with $\delta'$ as a modulus of differentiability on $C$. Now, let $x_1, \ldots, x_m$ be an $\frac{1}{r}$-approximation of $H$. For each $i = 1, \ldots, m$ define $u_i \equiv f(x_i)$ and $C_i \equiv B'(g(u_i), s) \equiv B'(x_i, s)$. Let $\varepsilon > 0$ be arbitrary. Let $x, y \in H$ be such that $\|x - y\| < \delta'(\varepsilon) \wedge \frac{1}{r}$. Then $\|x - x_i\| < \frac{1}{r}$ for some $i = 1, \ldots, m$, whence $x, y \in C_i$. Since $\delta'$ is a modulus of differentiability of $\tilde{f}$ on $C_i$, and since $\|x - y\| < \delta'(\varepsilon) \wedge \frac{1}{r}$, we have $\|f(y) - f(x) - F(x)(y - x)\| \leq \varepsilon \|y - x\|$. Thus the operation $\delta'(\cdot) \wedge \frac{1}{r}$ is a modulus of differentiability of $f$ on $H$. Since the compact subset $H \subset A$ is arbitrary, we see that $f$ is differentiable on $A$. $\Box$
CHAPTER 12. THE INVERSE FUNCTION THEOREM
Chapter 13

Change of Integration Variables

In this section let $n \geq 1$ be a fixed integer. Let $\mu_1$ and $\mu$ denote the the measures with respect to the Lebesgue integrations $\int \cdot \, dx$ and $\int \cdots \int \cdot \, dx_1 \cdots dx_n$ respectively. All measure-theoretic terms will be with respect to the Lebesgue integrations.

First an easy lemma, classically trivial, gives a sufficient condition for a subset of $R$ to be an open interval. Note that a non-empty set that is the intersection of two open intervals $(a, b)$ and $(a', b')$ is again an open interval, because $(a, b) \cap (a', b') = (a \vee a', b \wedge b')$.

**Lemma 13.0.1.** *(Condition of a nonempty subset of $R$ to be an interval).* Let $n \geq 2$ be arbitrary. Let $z_k, z'_k, c_k, a_k \in R$ for $k = 1, \cdots, n$. Suppose the set $\Gamma \equiv \{ x \in R : z_k < c_k + a_k x < z'_k \}$ for $k = 1, \cdots, n-1 \} \cap (z_n, z'_n)$ is non-empty. Then $\Gamma$ is an open interval in $R$.

*Proof.* Since $\Gamma = \bigcap_{k=1}^{n-1} \{ x \in R : z_k < c_k + a_k x < z'_k \} \cap (z_n, z'_n)$, it suffices, in view of the remark preceding this lemma, to prove the lemma for the case $n = 2$. By hypothesis, there exists $y \in R$ such that $z_1 < c_1 + a_1 y < z'_1$ and $z_2 < y < z'_2$. Let $\varepsilon > 0$ be so small that $z_1 + \varepsilon < c_1 + a_1 y < z'_1 - \varepsilon$. Then either (i) $|a_1 y| < \frac{\varepsilon}{2}$ and $|a_1|(|z_2| \vee |z'_2|) < \frac{\varepsilon}{2}$, or (ii) $|a_1 y| > 0$ or $|a_1|(|z_2| \vee |z'_2|) > 0$. Suppose condition (i) holds. Then, for each $x \in (z_2, z'_2)$, we have

$$|c_1 + a_1 x - (c_1 + a_1 y)| \leq |a_1 y| + |a_1 x| < |a_1 y| + |a_1|(|z_2| \vee |z'_2|) < \varepsilon$$

whence $z_1 < c_1 + a_1 x < z'_1$. It follows that $(z_2, z'_2) \subseteq \{ x \in R : z_1 < c_1 + a_1 x < z'_1 \}$ and so $\Gamma \equiv \{ x \in R : z_1 < c_1 + a_1 x < z'_1 \} \cap (z_2, z'_2) = (z_2, z'_2)$. On the other hand, suppose condition (ii) holds. Then $|a_1| > 0$. Hence either $a_1 > 0$ or $a_1 < 0$. In the first case $\Gamma = (a_1^{-1}(z_1 - c_1), a_1^{-1}(z'_1 - c_1)) \cap (z_2, z'_2)$. In the second case $\Gamma = (a_1^{-1}(z'_1 - c_1), a_1^{-1}(z_1 - c_1)) \cap (z_2, z'_2)$. Thus we see that $\Gamma$ is an open interval under either of the conditions (i) and (ii). \qed

In the following, an interval $\Delta$ in $R$ will mean a non-empty subset of $R$ that is equal to one of $(a, b)$, $(a, b]$, $[a, b)$, or $[a, b]$ for some $a, b \in R$ with $a \leq b$, and the length of $\Delta$ is defined to be $|\Delta| \equiv b - a$. More generally, the Cartesian product $\Delta \equiv \Delta_1 \times \cdots \times \Delta_n$, where $\Delta_i$ is an interval in $R$ for each $i = 1, \cdots, n$, is called an $n$-interval, and the length
of $\Delta$ is defined to be $|\Delta| \equiv \sqrt[n]{\prod_{i=1}^{n} |\Delta_i|}$ while the diameter of $\Delta$ is defined to be $||\Delta|| \equiv \sqrt{\sum_{i=1}^{n} |\Delta_i|^2}$. The intervals $\Delta_1, \cdots, \Delta_n$ in $\mathbb{R}^n$ are then called the factors of the $n$-interval $\Delta$. If each of the factors of $\Delta$ is an open interval, then $\Delta$ is called an open $n$-interval. If all the factors of $\Delta$ are of the same length, then $\Delta$ is called an $n$-cube. The center $x$ of $\Delta$ is defined to be $x = (x_1, \cdots, x_n)$ where $x_i$ is the mid-point of $\Delta_i$ for each $i = 1, \cdots, n$. By Fubini’s Theorem, we have $\mu(\Delta) = \prod_{i=1}^{n} \mu_1(\Delta_i)$.

The next lemma is the formula for the change of integration variables in the special case of a linear transformation.

**Lemma 13.0.2. (Volume of a parallelepiped).** Let $a \in \mathbb{R}^n$ be arbitrary. Let $F$ be an $n \times n$ matrix with $|\det F| > 0$. Let $f : \mathbb{R}^n \to \mathbb{R}^n$ be the linear function defined by $f(y) = a + Fy$ for each $y \in \mathbb{R}^n$. Let $\Delta \equiv \Delta_1 \times \cdots \times \Delta_n$ be any $n$-interval in $\mathbb{R}^n$. Then $f(\Delta)$ is an integrable set, and $\mu(f(\Delta)) = |\det F| \mu(\Delta)$.

**Proof.** Since $|\det F| > 0$, the matrix $F$ has an inverse $G \equiv F^{-1}$, with $|\det G| = |\det F|^{-1}$. Define the linear function $g : \mathbb{R}^n \to \mathbb{R}^n$ by $g(v) = b + Gv$ for each $v \in \mathbb{R}^n$, where $b \equiv -Ga$. Then $g$ is the inverse of $f$ on $\mathbb{R}^n$. Note that the desired equality is equivalent to

$$\mu(\Delta) = |\det F|^{-1} \mu(g^{-1}(\Delta)),$$

or

$$\mu(\Delta) = |\det G| \int_{\mathbb{R}^n} \cdots \int_{\mathbb{R}^n} 1_{\prod_{i=1}^{n} |(v_1, \cdots, v_n)|} dv_1 \cdots dv_n. \quad (13.0.1)$$

First assume that the lemma holds for each open $n$-interval. Let $\Delta \equiv \Delta_1 \times \cdots \times \Delta_n$ be an arbitrary $n$-interval. For each $i = 1, \cdots, n$ and $k \geq 1$ define the open interval $\Delta_i^{(k)} \equiv (r,s), (r - \frac{1}{k}, s), \cdots, \Delta_i = (r, s)$. Then for each $k \geq 1$, the open $n$-interval $\Delta^{(k)} \equiv \prod_{i=1}^{n} \Delta_i^{(k)}$. Then (i) $\Delta^{(k)} \supset \Delta^{(k+1)}$ for each $k \geq 1$, (ii) $\bigcap_{k=1}^{n} \Delta^{(k)} = \Delta$ and (iii) $\mu(\Delta^{(k)}) \downarrow \mu(\Delta)$. Here condition (iii) follows from Proposition 4.9.9 which says that every interval in $\mathbb{R}$ is Lebesgue integrable and has measure equal to its length. By assumption, the lemma holds for $\Delta^{(k)}$ for each $k \geq 1$. Hence $f(\Delta^{(k)})$ is an integrable set, and $\mu(f(\Delta^{(k)})) = |\det F| \mu(\Delta^{(k)})$ for each $k \geq 1$. This implies that $\mu(f(\Delta^{(k)})) \downarrow |\det F| \mu(\Delta)$ while $\bigcap_{k=1}^{n} f(\Delta^{(k)}) = f(\Delta)$. Hence $f(\Delta)$ is an integrable set, with

$$\mu(f(\Delta)) = \lim_{k \to \infty} \mu(f(\Delta^{(k)})) = |\det F| \mu(\Delta).$$

Thus the lemma holds also for the arbitrary $n$-interval $\Delta$. We see that we need only prove the lemma for open $n$-intervals.

To that end, let $\Delta \equiv (z_1, z_1') \times \cdots \times (z_n, z_n')$ be an arbitrary open $n$-interval. Proceed by induction.

First assume that $n = 1$. The $1 \times 1$ matrix $F$ can be regarded as a real number. By hypothesis $|F| = |\det F| > 0$. We will assume $F < 0$, the positive case being similar. Then $f(\Delta) = (a + Fz_1', a + Fz_1)$, an interval. Therefore, by Proposition 4.9.9, we have

$$\mu(f(\Delta)) = a + Fz_1 - a - Fz_1' = F(z_1 - z_1') = |F| \mu(\Delta),$$

establishing the lemma for $n = 1$.

Yuen-Kwok Chan 520 Constructive Probability
Suppose the lemma has been proved for \( n = 1, \ldots, m - 1 \) for some \( m > 1 \). We will give the proof for \( n = m \). Since \( |\det G| = |\det F| > 0 \), there exists, by Lemma [12.0.1] some \( f = 1, \ldots, n \) such that \( |G_{n,f}| > 0 \). Without loss of generality, and for ease of notations, we assume that \( f = n \) and that \( G_{n,n} > 0 \).

Let \((v_1, \ldots, v_{n-1}) \in R^{n-1}\) be arbitrary. Define the function \( \varphi \equiv \varphi(v_1, \ldots, v_{n-1}) : R \rightarrow R \) by

\[
\varphi(v_n) \equiv \varphi(v_1, \ldots, v_{n-1})(v_n) \equiv g_n(v_1, \ldots, v_n) = b_n + \sum_{i=1}^{n-1} G_{n,i}v_i + G_{n,n}v_n
\]

for each \( v_n \in R \). Since \( G_{n,n} > 0 \), a direct substitution shows that \( \varphi \) has an inverse \( \psi \equiv \psi(v_1, \ldots, v_{n-1}) : R \rightarrow R \) given by

\[
\psi(x_n) \equiv \psi(v_1, \ldots, v_{n-1})(x_n) \equiv -G^{-1}_{n,n}b_n - \sum_{i=1}^{n-1} G_{n,i}G_{i,n}v_i + G_{n,n}^{-1}v_n
\]

(13.0.2)

for each \( x_n \in R \). Define the linear function

\[
\lambda_k(v_1, \ldots, v_{n-1}, x_n) \equiv g_k(v_1, \ldots, v_{n-1}, \psi(v_1, \ldots, v_{n-1})(x_n))
\]

\[
= b_k + \sum_{i=1}^{n-1} G_{k,i}v_i + G_{k,n}(-G^{-1}_{n,n}(b_n + \sum_{i=1}^{n-1} G_{n,i}v_i) + G_{n,n}^{-1}v_n)
\]

\[
= c_k + \sum_{i=1}^{n-1} \lambda_{k,i}v_i + \lambda_{k,n}x_n
\]

(13.0.3)

for each \( k = 1, \ldots, n \), and for each \((v_1, \ldots, v_{n-1}, x_n) \in R^n\), where \( c_k \equiv b_k - G^{-1}_{n,n}G_{k,n}b_n \), \( \lambda_{k,i} \equiv G_{k,i} - G^{-1}_{n,i}G_{k,n}G_{n,i} \), and \( \lambda_{k,n} \equiv G_{k,n}G_{n,n}^{-1} \) for each \( k = 1, \ldots, n \) and for each \( i = 1, \ldots, n - 1 \). Now define an \( n \times n \) matrix \( \Psi \) by \((i') \Psi_{k,i} \equiv 1 \) or \( \Psi_{k,i} = 0 \) according as \( k = i \) or \( k \neq i \), for \( k, i = 1, \ldots, n - 1 \), \((ii') \Psi_{n,i} \equiv -G^{-1}_{n,i}G_{i,n} \), and \( \Psi_{i,n} = 0 \) for \( i = 1, \ldots, n - 1 \), \((iii') \Psi_{n,n} \equiv G_{n,n}^{-1} \). Then \( \psi(v_1, \ldots, v_{n-1}, x_n) \equiv -G^{-1}_{n,n}b_n + \sum_{i=1}^{n-1} \Psi_{n,i}v_i + \Psi_{n,n}x_n \). Note that \( \Psi \) is a triangular matrix, with each entry above the diagonal equal to 0. Hence \( \det \Psi = \prod_{i=1}^{n} \Psi_{n,i} = G_{n,n}^{-1} \). Moreover, a direct matrix multiplication verifies that \( \Lambda \equiv G\Psi \). Consequently \( \det \Lambda = \det G \cdot \det \Psi = G_{n,n}^{-1} \det G \). Hence \( |\det \Lambda| > 0 \).

Note from their definition that \( \Lambda_{n,i} = 0 \) for \( i = 1, \ldots, n - 1 \), and that \( \Lambda_{n,n} = 1 \). By Lemma [12.0.1] it follows that \( \det \Lambda = \det \Lambda' \) where \( \Lambda' \) is the \((n - 1) \times (n - 1)\) matrix obtained by deleting the \( n \)-th row and \( n \)-th column in \( \Lambda \).

Let \( \Lambda \) be an arbitrary subset of \( R \) which is dense in \( \Lambda \). Assume that the lemma holds for each open \( n \)-interval each of whose factors has endpoints in \( \Lambda \). Now let \( \Lambda \) be an arbitrary open \( n \)-interval. Let \((\Delta^{(k)})_{k=1,2,\ldots} \) be a sequence of open \( n \)-intervals whose factors have endpoints in \( \Lambda \), such that \((i'') \Delta^{(k)} \subset \Delta^{(k+1)} \) for each \( k \geq 1 \), \((ii'') \bigcup_{k=1}^{n} \Delta^{(k)} = \Delta \) and \((iii'') \mu(\Delta^{(k)}) \uparrow \mu(\Delta) \). By assumption, the lemma holds for \( \Delta^{(k)} \) for each \( k \geq 1 \). Hence \( \mu(\bigcup_{k=1}^{n} \Delta^{(k)}) \) is an integrable set, and \( \mu(\bigcup_{k=1}^{n} \Delta^{(k)}) = |\det F|\mu(\Delta) \) for each \( k \geq 1 \). This implies that \( \mu(\bigcup_{k=1}^{n} \Delta^{(k)}) \uparrow |\det F|\mu(\Delta) \). Hence \( \mu(\Delta) \) is integrable with

\[
\mu(\Delta) = \lim_{k \to \infty} \mu(\bigcup_{k=1}^{n} \Delta^{(k)}) = |\det F|\mu(\Delta).
\]
Thus the lemma holds also for the arbitrary \( n \)-interval \( \Delta \). We see that we need only prove the lemma for open \( n \)-intervals with endpoints in \( A \). In the remainder of this proof, we will let \( A \) be the set of continuity points of the measurable functions \( g_k \) and \( \lambda_k \) for each \( k = 1, \ldots, n \). By Proposition 4.8.1, the set \( A \) is the metric complement of a countable subset of \( R \), whence \( A \) is dense in \( R \). We will prove the lemma for an arbitrary open \( n \)-interval whose factors have endpoints in \( A \), thereby completing the proof.

To that end, let \( \Delta \equiv (z_1, z'_1) \times \cdots \times (z_n, z'_n) \) be an open \( n \)-interval with \( z_1, \ldots, z_n, z'_1, \ldots, z'_n \in A \). Then the set \( g^{-1}(\Delta) = \bigcap_{k=1}^{n} (z_k < g_k < z'_k) \) is a measurable subset in \( R^n \). Since \( g^{-1} \equiv f \) is continuous, \( g^{-1}(\Delta) \) is also bounded. Hence \( g^{-1}(\Delta) \) is an integrable set. Similarly \( \lambda^{-1}(\Delta) \) is an integrable set. By Fubini’s Theorem, there exists a full subset \( D \) of \( R^{n-1} \) such that \( 1_{\lambda^{-1}(\Delta)}(v_1, \ldots, v_{n-1}) \) is an integrable indicator on \( R \) for each \( (v_1, \ldots, v_{n-1}) \in D \). In other words, in terms of equality (13.0.3), the set

\[
\Gamma_{v_1, \ldots, v_{n-1}} \equiv \bigcap_{k=1}^{n} \{ x_n : c_k + \sum_{i=1}^{n-1} \Lambda_{k,i}v_i + \Lambda_{k,n}x_n \in \Delta_k \} \quad (13.0.4)
\]

is an integrable subset of \( R \) for each \( (v_1, \ldots, v_{n-1}) \in D \). In view of equality (13.0.3) we have

\[
\Gamma_{v_1, \ldots, v_{n-1}} = \{ x_n : g(v_1, \ldots, v_{n-1}, \psi(x_n)) \in \Delta \}. \quad (13.0.5)
\]

Moreover, since \( \Lambda_{n,i} = 0 \) for \( i = 1, \ldots, n-1 \), and \( \Lambda_{n,n} = 1 \) while \( c_n = 0 \), equality (13.0.4) reduces to

\[
\Gamma_{v_1, \ldots, v_{n-1}} = \bigcap_{k=1}^{n-1} \{ x_n : c_k + \sum_{i=1}^{n-1} \Lambda_{k,i}v_i + \Lambda_{k,n}x_n \in \Delta_k \} \cap (z_n, z'_n). \quad (13.0.6)
\]

Define \( \Delta' \equiv A_1 \times \cdots \times A_{n-1} \). Using Fubini’s Theorem, and applying the induction hypothesis, in the form of equality (13.0.1) to the \( (n-1) \)-interval \( \Delta' \), we obtain

\[
\int \cdots \int_{\Delta} \, dx_1 \cdots dx_n = \int \int_{\Gamma_{v_1, \ldots, v_{n-1}}} 1_{(z_n, z'_n)}(x_n) \mu'(\Delta') \, dx_n \\
= \int \int_{\Gamma_{v_1, \ldots, v_{n-1}}} 1_{(z_n, z'_n)}(x_n) \mu'(\Delta') \, dx_n \\
= \int \int_{\Gamma_{v_1, \ldots, v_{n-1}}} \mu(\Gamma_{v_1, \ldots, v_{n-1}}) \, dv_1 \cdots dv_{n-1}, \quad (13.0.7)
\]

where \( \Lambda' \) is the \( (n-1) \times (n-1) \) submatrix of \( \Lambda \) defined previously, and where \( \mu' \) is the Lebesgue measure on \( R^{n-1} \).
Let \((v_1, \cdots, v_{n-1}) \in D\) be arbitrary. Write \(\Gamma \equiv \Gamma_{v_1, \cdots, v_{n-1}}, \varphi \equiv \varphi_{v_1, \cdots, v_{n-1}}, \) and \(\psi \equiv \psi_{v_1, \cdots, v_{n-1}}\) for short. Define
\[
\Theta \equiv \Theta_{v_1, \cdots, v_{n-1}} \equiv \{v_n : g(v_1, \cdots, v_{n-1}, v_n) \in \Delta\}.
\]
Since \(\psi\) has an inverse function \(\varphi\), it follows from equality \((13.0.5)\) that
\[
\psi(\Gamma) = \{v_n : g(v_1, \cdots, v_{n-1}, v_n) \in \Delta\} \equiv \Theta. \tag{13.0.8}
\]
Let \(\varepsilon > 0\) be arbitrary. At lease one of the three following conditions must hold: (a) \(\mu_1(\Gamma) < \varepsilon\) and \(\mu_1(\Theta) < \varepsilon\), (b) \(\mu_1(\Gamma) > 0\), or (c) \(\mu_1(\Theta) > 0\). If condition (a) holds, then
\[
|\mu_1(\Gamma) - |G_{n,n}|\mu_1(\Theta)| < \varepsilon (1 + |G_{n,n}|). \tag{13.0.9}
\]
Suppose condition (b) holds. Then \(\Gamma\) is non-empty. Suppose condition (c) holds. Then \(\Theta\) is non-empty, whence \(\Gamma\) is also non-empty, thanks to equality \((13.0.8)\). Therefore, if either of conditions (b) and (c) holds, then \(\Gamma\) is non-empty, and Lemma \((13.0.1)\) together with equality \((13.0.6)\) implies that \(\Gamma\) is an open interval. The induction hypothesis therefore applies, in either case, to the interval \(\Gamma\) and the linear function \(\psi\), yielding
\[
\mu_1(\Gamma) = |G_{n,n}|\mu_1(\psi(\Gamma)) \equiv |G_{n,n}|\mu_1(\Theta). \tag{13.0.10}
\]
Inequality \((13.0.9)\) is thus established under each of conditions (a-c). Since \(\varepsilon > 0\) is arbitrary, we conclude therefore that \(\mu_1(\Gamma) = |G_{n,n}|\mu_1(\Theta)\) for each \((v_1, \cdots, v_{n-1})\) in the full set \(D \subset R^{n-1}\). Combining with equality \((13.0.7)\) and recalling that \(\det \Lambda = G_{n,n}^{-1} \det G\), we obtain
\[
\int \cdots \int_{\Delta} dx_1 \cdots dx_n = |\det \Lambda| \int \cdots \int_{\Gamma} \mu_1(\Gamma_{v_1, \cdots, v_{n-1}}) dv_1 \cdots dv_{n-1}
\]
\[
= |\det \Lambda| \cdot |G_{n,n}| \int \cdots \int_{\Theta} \mu_1(\Theta) dv_1 \cdots dv_{n-1}
\]
\[
= |\det G| \int \cdots \int \{1_{\Theta_{v_1, \cdots, v_{n-1}}}(v_n)dv_n\} dv_1 \cdots dv_{n-1}
\]
\[
\equiv |\det G| \int \cdots \int \{1_{\{v_n : g(v_1, \cdots, v_n) \in \Delta\}} dv_n\} dv_1 \cdots dv_{n-1}
\]
\[
= |\det G| \int \cdots \int \{1_{\{v_1, \cdots, v_n \in \Delta\}} dv_1 \cdots dv_n\}
\]
\[
\equiv |\det G| \int \cdots \int 1_{g^{-1}(\Delta)} dv_1 \cdots dv_n = |\det G| \mu(\Delta).
\]
Induction is completed. \(\square\)

In the following, if \(\Delta \equiv [a_1, a_1 + t] \times \cdots \times [a_n, a_n + t]\) is any closed \(n\)-cube with length \(|\Delta| = t\), then for each \(r \in (-1, 1)\) we define \(\Delta' \equiv [a_1 - \frac{r}{2}t, a_1 + t + \frac{r}{2}t] \times \cdots \times [a_n - \frac{r}{2}t, a_n + t + \frac{r}{2}t]\). Similar notations are used for half-open \(n\)-cubes. Thus \(\Delta'\) has the same center as \(\Delta\) and is similar to \(\Delta\) with a scale of \(1 + r\). In particular \(|\Delta'| = (1 + r)|\Delta|\) and \(\Delta^0 = \Delta\).

Recall that a subset \(H\) of an open set \(A\) is said to be well contained in \(A\), or \(H \subseteq A\) in symbols, if \(H \subset K \subset K_a \subset A\) for some compact subset \(K\) and some \(a > 0\). Recall that \(K_a\) stands for the compact \(a\)-neighborhood of \(K\).

Yuen-Kwok Chan 523 Constructive Probability
Lemma 13.0.3. (Parallelepiped sandwich). Let \(A, B\) be open subsets of \(\mathbb{R}^n\). Let \(f : A \to B\) be a differentiable function on \(A\), with derivative \(F\). Suppose \(f\) has an inverse function \(g : B \to A\) which is differentiable on \(B\), with derivative \(G\), and which is Lipschitz continuous on \(B\). Suppose \(b, c > 0\) are such that \(|\det G| \geq c\) and \(|G_{i,j}| \leq b\) for \(i, j = 1, \ldots, n\) on \(B\). Let \(\delta : (0, \infty) \to (0, \infty)\) be an operation. Then for each \(\varepsilon > 0\) there exists \(\tau = \tau(\varepsilon, n, b, c, \delta) > 0\) with the following properties. Let \(t \in (0, \tau)\) be arbitrary. Let \(\Delta \equiv (x_1-t, x_1+t) \times \cdots \times (x_n-t, x_n+t)\) be any half open \(n\)-cube with center \(x \equiv (x_1, \ldots, x_n)\), such that (i) \(\Delta \subset A\), (ii) \(f(\Delta)\) and \(f(\overline{\Delta})\) are integrable sets with \(\mu(f(\Delta)) = \mu(f(\overline{\Delta}))\), where \(\overline{\Delta} \equiv [x_1-t, x_1+t] \times \cdots \times [x_n-t, x_n+t]\), (iii) \(f(\overline{\Delta}) \subset B\), and (iv) \(\delta\) is a modulus of differentiability of \(f\) on \(\Delta\). Then

\[
|\mu(f(\Delta)) \cdot |\det F(x)|^{-1} - \mu(\Delta)| \leq n(2^{n-1} + 1)\varepsilon \mu(\Delta) . \tag{13.0.11}
\]

**Proof.** By hypothesis \(g\) is Lipschitz continuous on \(B\) with some Lipschitz constant \(c_g > 0\).

Let \(x \in A\) be arbitrary, and let \(u \equiv f(x)\). Define the linear function \(\tilde{f} : \mathbb{R}^n \to \mathbb{R}^n\) by \(\tilde{f}(y) \equiv f(x) + F(x)(y-x)\) for each \(y \in \mathbb{R}^n\). By the Chain Rule, we have \(F(x) = G(u)^{-1}\). By hypothesis \(|\det G(u)| \geq c\) and \(|G_{i,j}(x)| \leq b\) for each \(i, j = 1, \ldots, n\). By Lemma 12.0.1

\[
\|F(x)w\| = \|G(u)^{-1}w\| \leq \beta \|w\| \tag{13.0.12}
\]

and \(\|F(x)^{-1}w\| = \|G(u)w\| \leq nb \|w\|\) for each \(w \in \mathbb{R}^n\), where \(\beta \equiv n!c^{-1}b^{n-1}\). Replacing \(w\) by \(F(x)w\) in the last inequality, we obtain \(\|F(x)w\| \geq n^{-1}b^{-1} \|w\|\) for each \(w \in \mathbb{R}^n\). Let \(\varepsilon \in (0, 1)\) be arbitrary. Define \(\tau \equiv n^{-\frac{1}{2}} \delta(\frac{1}{n} - \frac{1}{2}b^{-1}\varepsilon)\). We will show that \(\tau\) has the desired properties.

To that end, let \(t \in (0, \tau)\) be arbitrary. Let \(\Delta \equiv (x_1-t, x_1+t) \times \cdots \times (x_n-t, x_n+t)\) be any half open \(n\)-cube with center \(x \equiv (x_1, \ldots, x_n)\), such that conditions (i-iii) hold. We will prove inequality 13.0.25. First note that since \(\Delta \subset A\), and \(f(\overline{\Delta}) \subset B\), the functions \(f\) and \(g\) are uniformly continuous on \(\Delta\) and \(f(\overline{\Delta})\) respectively. Consequently \(f(\overline{\Delta})\) is a compact set.

Consider any \(y \in \Delta\). We have \(\|y-x\| \leq \sqrt{nt} < \sqrt{n}\tau \leq \delta(\frac{1}{n} - \frac{1}{2}b^{-1}\varepsilon)\), whence

\[
\|f(y) - \tilde{f}(y)\| \equiv \|f(y) - f(x) - F(x)(y-x)\| \leq \frac{1}{2}n^{-\frac{1}{2}}b^{-1}\varepsilon \|y-x\|
\]

\[
\leq \frac{1}{2}n^{-\frac{1}{2}}b^{-1}\varepsilon \sqrt{nt} = \frac{1}{2}n^{-1}b^{-1}\varepsilon t . \tag{13.0.13}
\]

Write \(z \equiv f(y) - f(x) - F(x)(y-x)\) and \(v \equiv F(x)^{-1}z\). Then \(\|v\| \leq nb \|z\| \leq \frac{1}{2}nbn^{-1}b^{-1}\varepsilon t < \varepsilon t\). Hence \(y_k + v_k \in [x_k-t(1+\varepsilon), x_k+t(1+\varepsilon)]\) for each \(k = 1, \ldots, n\). Thus \(y + v \in \Delta^c\), in the notations introduced before this lemma. Moreover

\[
f(y) = f(x) + F(x)(y-x) + z
\]

\[
eq f(x) + F(x)(y-x + v) \equiv \tilde{f}(y+v) \in \tilde{f}(\Delta^c).
\]

Since \(y \in \Delta\) is arbitrary, we see that \(f(\Delta) \subset \tilde{f}(\Delta^c)\) and so \(\mu(f(\Delta)) \leq \mu(\tilde{f}(\Delta^c))\). On the other hand, by Lemma 13.0.2 we have \(\mu(\tilde{f}(\Delta^c)) = \mu(\Delta^c)\) \(\det F(x)\). Combining, we obtain

\[
\mu(f(\Delta)) \leq \mu(\Delta^c) \cdot |\det F(x)| = (1 + e)^n \mu(\Delta) \cdot |\det F(x)| . \tag{13.0.14}
\]
At the same time, since $\varepsilon \in [0, 1]$, we have $|n(1+\varepsilon)^n - n| \leq n2^{n-1}$. Taylor’s Theorem therefore yields the bound $|(1+\varepsilon)^n - (1+ne)| \leq n2^{n-1}\varepsilon$ whence $|(1+\varepsilon)^n - 1| \leq n(2^{n-1}+1)\varepsilon$. Therefore inequality 13.0.14 implies

$$
\mu(f(\Delta)) \leq n(2^{n-1}+1)n\mu(\Delta).
$$

Next consider any $y \in \Delta^{-\varepsilon}$. We will prove that $\tilde{f}(y) \in f(\Delta)$. For the sake of a contradiction, suppose $a \equiv d(\tilde{f}(y), f(\Delta)) > 0$. Write $u \equiv f(x)$. Since $f(\Delta) \subset B$, there exists $r > 0$ such that $f(\Delta) \subset B$. Let $\varepsilon' > 0$ be so small that $3\varepsilon' < r$ and $\varepsilon' + \beta c\varepsilon' < \frac{1}{2}n^{-1}b^{-1}\varepsilon t$. Let $\varepsilon > 0$ be so large that $\frac{1}{2}e^{\sqrt{\varepsilon}} \leq \varepsilon'$. For each $k = 0, \ldots, p$ define $y_k \equiv (1 - \frac{k}{p})x + \frac{k}{p}y$ and define $\nu_k \equiv \tilde{f}(y_k) = u + \frac{k}{p}F(x)(y-x)$. Then $y_k \in \Delta^{-\varepsilon'}$ for each $k = 0, \ldots, p$ because, being an $n$-interval, $\Delta^{-\varepsilon'}$ is convex. Moreover, $d(v_0, f(\Delta)) = d(f(x), f(\Delta)) = 0$, and $d(v_p, f(\Delta)) = d(f(y), f(\Delta)) = a > 0$ by assumption. Hence there exists $j = 1, \ldots, p$ such that $d(y_j, f(\Delta)) < 2\varepsilon' < r$ and $d(v_j, f(\Delta)) > \varepsilon'$. Since $|v_j - v_{j-1}| = \frac{1}{p}||F(x)(y-x)|| \leq \frac{1}{p}||y-x|| \leq \frac{1}{p}\varepsilon^{\sqrt{\varepsilon}} \leq \varepsilon'$, it follows that $d(v_j, f(\Delta)) < 2\varepsilon'$ holds. Consequently $y_j, v_j \in f(\Delta), r \subset B$. Define $\varepsilon' \equiv g(v_{j-1})$ and $\varepsilon'' \equiv g(v_j)$. Then $v_{j-1} = f(\varepsilon')$ and $v_j = f(\varepsilon'')$. Since $d(v_j, f(\Delta)) > \varepsilon'$, we have $d(\varepsilon', \Delta) > 0$, thanks to the continuity of $f$. On the other hand, since $d(v_{j-1}, f(\Delta)) < 2\varepsilon'$, there exists $z \in \Delta$ such that $|v_{j-1} - f(z)| < 2\varepsilon'$. Since the function $g$ is Lipschitz continuous on $B$ with Lipschitz constant $c_g$, the last inequality yields $||g(v_{j-1}) - g(f(z))|| < 2c_g\varepsilon'$, or equivalently, $|\varepsilon' - z| < 2c_g\varepsilon'$. Similarly, from $|v_{j-1} - f(z)| \leq \varepsilon'$ we deduce $|\varepsilon'' - z| \leq c_g\varepsilon'$. Combining, we have $|\varepsilon'' - z| < 3c_g\varepsilon'$. Since $y_j \in \Delta^{1-\varepsilon}$, and since $d(\varepsilon', \Delta) > 0$, we have $|y_j - z''| > \varepsilon t$. Hence

$$
\|\tilde{f}(y_j) - \tilde{f}(z'')\| = \|F(x)(y_j - z'')\| 
\geq n^{-1}b^{-1}\|y_j - z''\| > n^{-1}b^{-1}\varepsilon t.
$$

On the other hand,

$$
\|\tilde{f}(y_j) - \tilde{f}(z'')\| \equiv \|v_j - \tilde{f}(z'')\| 
\leq \|v_j - v_{j-1}\| + \|v_{j-1} - f(z)\| + \|f(z) - \tilde{f}(z)\| \|\tilde{f}(z) - \tilde{f}(z'')\| 
\leq \varepsilon' + 2\varepsilon' \|f(z) - \tilde{f}(z)\| \|F(x)(z - z'')\|.
$$

In view of inequalities 13.0.13 and 13.0.12, the last expression is bounded by

$$
3\varepsilon' + \frac{1}{2}n^{-1}b^{-1}\varepsilon t + \beta \|z - z''\| 
\leq 3\varepsilon' + \frac{1}{2}n^{-1}b^{-1}\varepsilon t + 3\beta c_g\varepsilon' 
< \frac{1}{2}n^{-1}b^{-1}\varepsilon t + \frac{1}{2}n^{-1}b^{-1}\varepsilon t = n^{-1}b^{-1}\varepsilon t,
$$

which contradicts inequality 13.0.16. Thus we see that $d(\tilde{f}(y), f(\Delta)) = 0$. We conclude that $\tilde{f}(y) \in f(\Delta)$. Since $y \in \Delta^{-\varepsilon}$ is arbitrary, we have $\tilde{f}(\Delta^{-\varepsilon}) \subset f(\Delta)$. On the other

Yuen-Kwok Chan
525
Constructive Probability
hand, by Lemma 13.0.2 we have $\mu(f(\Delta^{-\varepsilon})) = \mu(\Delta^{-\varepsilon})|\det F(x)|$. Combining, we obtain

$$
(1 - \varepsilon)^n\mu(\Delta)|\det F(x)| = \mu(\Delta^{-\varepsilon})|\det F(x)| = \mu(f(\Delta^{-\varepsilon})) \leq \mu(f(\Delta)) = \mu(f(\Delta)).
$$

(13.0.17)

At the same time, since $\varepsilon \in [0,1]$, we have $n(1 - \varepsilon)^{n-1} - n \leq n2^{n-1} = n^{2^{n-1}-1}$. Taylor’s Theorem yields $|n(1 - \varepsilon)^n - (1 - n\varepsilon)| \leq n2^{n-1}\varepsilon$ whence $|(1 - \varepsilon)^n - 1| \leq n(2^{n-1} + 1)\varepsilon$. Inequality [13.0.17] therefore yields

$$
\mu(f(\Delta))|\det F(x)|^{-1} - \mu(\Delta) \geq ((1 - \varepsilon)^n - 1)\mu(\Delta)
$$

(13.0.18)

Combining inequalities [13.0.15] and [13.0.18], we obtain the desired inequality [13.0.11]. The lemma is proved.

Let $K$ be an arbitrary compact subset of $\mathbb{R}^n$. The closed $r$-neighborhood $\{d(\cdot, K) \leq r\} \equiv \{u \in \mathbb{R}^n : d(u, K) \leq r\}$ is compact for all but countably many $r > 0$. At the same time, all but countably many $r > 0$ are regular points of the measurable function $d(\cdot, K)$. For the remainder of this section, we will write $K_r$ for $d(\cdot, K) \leq r$ only with the implicit assumption that $d(\cdot, K) \leq r$ is compact and that $r > 0$ is a regular point of $d(\cdot, K)$. Thus $K_r$ is compact and measurable, hence integrable. Furthermore $K_r^c \equiv (d(\cdot, K) > r)$ according to Corollary 4.8.16.

Lemma 13.0.4. (Special half open $n$-interval). Let $A, B$ be an open subset of $\mathbb{R}^n$. Let $f : A \to B$ be a function which is uniformly continuous on compact subsets well contained in $A$. Suppose $g : B \to A$ is an inverse function of $f$ and is uniformly continuous on compact subsets well contained in $B$. Let $H, K$ be compact subsets of $\mathbb{R}^n$ with $H \subseteq A$ and $K \subseteq B$. Then there exists $\alpha \in \mathbb{R}$ with the following properties. Suppose $\Delta$ is a closed $n$-interval with $\Delta = [\alpha + q_1, \alpha + q_1'] \times \cdots \times [\alpha + q_n, \alpha + q_n']$ where $q_i, q_i'$ are arbitrary rational numbers with $q_i < q_i'$ for each $i = 1, \ldots, n$. Suppose $\Delta \subset H$ and $f(\Delta) \subset K$. Let $\Delta = (\alpha + q_1, \alpha + q_1') \times \cdots \times (\alpha + q_n, \alpha + q_n')$. Then $f(\Delta)$ and $f(\Delta)^c$ are integrable sets with $\mu(f(\Delta)) = \mu(f(\Delta)^c)$. Moreover $f(\Delta)^c = (d(\cdot, f(\Delta)) > 0) a.e.$ In other words, the measure theoretic complement of $f(\Delta)$ is equal to its metric complement.

Proof. Since $f(\Delta) = g^{-1}(\Delta)$, the measurability of $f(\Delta)$ for all rational numbers $q_i, q_i'$ and for all but countably many $\alpha \in \mathbb{R}$ would follow if $g$ is a measurable function on $\mathbb{R}^n$. However, $g$ is not necessarily defined a.e. on $\mathbb{R}^n$. Hence we introduce a function $\bar{g}$ which is measurable on $\mathbb{R}^n$ and which is equal to $g$ on a neighborhood of $K$.

Since $K \subseteq B$, there exists $\rho > 0$ such that $K_\rho \subseteq B$. Write $M \equiv K_\rho$. Then $M \subseteq M_r \subseteq B$ for some $r > 0$. Moreover $M$ is a compact and integrable set, and $M_r^c \equiv (d(\cdot, M) > r)$, according to the remarks preceding this lemma. Let $i = 1, \ldots, n$ be arbitrary. Define a function $\bar{g}_i : M_r \cup M_r^c \to \mathbb{R}$ by (i) $\bar{g}_i(u) \equiv g_i(u)(1 - r^{-1}d(u, M)^+)$ if $u \in M_r$, and (ii) $\bar{g}_i(u) \equiv 0$ if $u \in M_r^c$. We will show that $\bar{g}_i$ is uniformly continuous on $M_r \cup M_r^c$. In view of conditions (i) and (ii), the function $\bar{g}_i$ is uniformly continuous on each of $M_r$ and $M_r^c$. Let $\varepsilon > 0$ be arbitrary. It suffices to show that $|\bar{g}_i(u) - \bar{g}_i(v)| < \varepsilon$ if $u \in M_r$ and $v \in M_r^c$ are such that $|u - v| < \eta$ for sufficiently small $\eta > 0$. Let $\eta \in (0, r)$ be so small that $|g|\eta \leq \varepsilon r$ on $M_r$. Consider $u \in M_r$ and $v \in M_r^c$ with $|u - v| < \eta$. Since $v \in M_r^c$,
we have \( d(v, M) > r \). Consequently \( d(u, M) > r - \eta \). It follows from the defining condition (i) that \( \|g_i(u)\| = \|g_i(u)\| \leq \varepsilon \). Since \( v \in M^c \), we have \( \|g_i(v)\| = 0 \). Combining, we obtain \( \|g_i(u) - g_i(v)\| < \varepsilon \). Thus we see that \( g_i \) is uniformly continuous on \( M \cup M^c \). Since \( M \cup M^c \) is dense in \( R^n \), the function \( g_i \) can be extended to a continuous function \( g_i : R^n \to R \). In view of condition (i), we have \( g_i = g \) on \( M \). Being continuous on \( R^n \), the function \( g_i \) is measurable. Therefore \( g_i - q \) is a measurable function on \( R^n \) for each \( i = 1, \ldots, n \) and each rational number \( q \). Because \( R^n \) is \( \sigma \)-finite, there exists, according to Proposition [4.8.14], a real number \( \alpha \) which is a continuity point of \( g_i - q \) for each \( i = 1, \ldots, n \) and each rational number \( q \). Let \( i = 1, \ldots, n \) be arbitrary, and let \( q \) be an arbitrary rational number. Then \( (g_i - q \leq \alpha)M \cup (g_i - q > \alpha)M \cup (\bar{g}_i - q \geq \alpha)php.M \) are integrable sets, with \( \mu((g_i - q > \alpha)M) = \mu((\bar{g}_i - q \geq \alpha)M) \). Hence \( (g_i - q \geq \alpha)M \cup (\bar{g}_i - q \leq \alpha)M \) a.e. In other words \( M(\bar{g}_i \leq \alpha + q), M(\bar{g}_i > \alpha + q) \), and \( M(\bar{g}_i \geq \alpha + q) \) are integrable sets, with \( \mu(M(\bar{g}_i \geq \alpha + q)) = M(\bar{g}_i > \alpha + q) \) a.e.

Now suppose \( \Delta \) is a half open \( n \)-interval with \( \Delta = (\alpha + q_1 \alpha + q_1^1) \times \cdots \times (\alpha + q_n, \alpha + q_n^1) \). Then, according to equality [4.8.19], we have \( u \in (M(x_1 \leq \bar{g}_i)M(\bar{g}_i \leq x_1^i))' \) for some \( i = 1, \ldots, n \). In view of Corollary [4.8.16], we therefore have \( u \in M^c \cup \bar{g}_i < x_1 \cup (x_1^i < \bar{g}_i) \). Since \( u \in M \) and so \( g(u) = g(u) \), it follows that \( u \in \{g_1 < x_1 \} \cup \{x_1^i < \bar{g}_i \} \). Thus \( g_1 < x_1 - \varepsilon \) or \( x_1^i + \varepsilon < g(u) \) for some \( \varepsilon > 0 \). Suppose \( d(u, g^{-1}(\Delta)) < \delta_\varepsilon(\varepsilon) \), where \( \delta_\varepsilon \) is a modulus of continuity of \( g \) on \( M \). Then \( d(g(u), \bar{\Delta}) < \varepsilon \). Consequently \( g(u) \in [x_1 - \varepsilon, x_1^i + \varepsilon] \), a contradiction. Hence \( d(u, g^{-1}(\Delta)) \geq \delta_\varepsilon(\varepsilon) \). We conclude that \( M \) is measurable in \( (\Delta, g^{-1}(\Delta)) \geq 0 \). Next consider any \( u \in M^c = (d(\cdot, M) > 0) \). Since \( g^{-1}(\Delta) \subset M \), we have \( d(u, g^{-1}(\Delta)) > 0 \). We conclude that \( M^c \cdot g^{-1}(\Delta) \subset (d(\cdot, g^{-1}(\Delta)) > 0) \). Combining, we obtain

\[
(M \cup M^c)g^{-1}(\Delta) \subset (M \cup M^c)(d(\cdot, g^{-1}(\Delta)) > 0).
\]

Conversely, consider any \( u \in M \). Let \( y = g(u) \) and so \( u = f(y) \). Suppose \( u \in (d(\cdot, g^{-1}(\Delta)) > 0) \). In other words \( d(u, f(\Delta)) > 0 \), or

\[
d(f(y), f(\Delta)) \geq \varepsilon > 0
\]
for some $\varepsilon > 0$. By hypothesis, $\bar{\Delta} \subset H \subset H_0 \subset A$ for some $a > 0$, and $f$ is uniformly continuous on $H_0$ with some modulus of continuity $\delta_f$. Suppose $d(y, \bar{\Delta}) < a$. Then $d(y, H) \leq d(y, \bar{\Delta}) < a$. It follows that $y \in H_0$ and so $d(y, \bar{\Delta}) \geq \delta_f(\varepsilon) > 0$, in view of inequality [13.0.21]. Combining, we see that in any case $d(y, \bar{\Delta}) \geq a \land \delta_f(\varepsilon) > 0$. Therefore there exists $i = 1, \ldots, n$ such that $y_i < x_i$ or $x'_i < y_i$. In other words, $g_i(u) < x_i$ or $x'_i < g_i(u)$. Since $u \in M$ and $g = \bar{g}$ on $M$, this implies that

$$u \in M(\bar{g}_i < x_i) \cup M(x'_i < \bar{g}_i) = M(M(x_i \leq \bar{g}_i \leq x'_i))^c$$

$$\subset M \cap \{u \in M : x_i \leq \bar{g}_i(u) \leq x'_i \text{ for each } i = 1, \cdots, n\}^c = Mg^{-1}(\bar{\Delta})^c,$$

in view of equality [13.0.19]. Thus we see that

$$M(d(.; g^{-1}(\bar{\Delta})) > 0) \subset Mg^{-1}(\bar{\Delta})^c \subset (M \cup M^c)g^{-1}(\bar{\Delta})^c$$

At the same time, since $M \supset g^{-1}(\bar{\Delta})$, we have $M^c \subset g^{-1}(\bar{\Delta})^c$

$$M^c(d(.; g^{-1}(\bar{\Delta})) > 0) \subset M^c = M^c g^{-1}(\bar{\Delta})^c \subset (M \cup M^c) g^{-1}(\bar{\Delta})^c.$$

Combining, we obtain

$$\langle M \cup M^c \rangle (d(.; g^{-1}(\bar{\Delta})) > 0) \subset (M \cup M^c) g^{-1}(\bar{\Delta})^c. \quad (13.0.22)$$

Expressions [13.0.20] and [13.0.22] together show that $(M \cup M^c)(d(.; g^{-1}(\bar{\Delta})) > 0) = (M \cup M^c) g^{-1}(\bar{\Delta})^c$. Since $M \cup M^c$ is a full set, it follows that $(d(.; g^{-1}(\bar{\Delta})) > 0) = g^{-1}(\bar{\Delta})^c$ a.e., as desired.  

**Lemma 13.0.5. (Partition of $n$-cube).** Let $\Delta = \prod_{i=1}^n [a_j, a_j + t]$ be an arbitrary $n$-cube. Let $p \geq 1$. For each $j = 1, \cdots, n$ and $k = 0, \cdots, p$ define $a_{j,k} \equiv a_j + \frac{k}{p}t$. For each $\kappa \in \{1, \cdots, p\}^n$ define $\Delta_\kappa \equiv \prod_{j=1}^n [a_{j,\kappa_j-1}, a_{j,\kappa_j}]$. Then

$$\Delta^{\eta/p} = \bigcup_{\kappa \in \{1, \cdots, p\}^n} \Delta_\kappa^{\eta}$$

for arbitrary $\eta > 0$.

**Proof.** Let $\eta > 0$ be arbitrary. Then, for each $j = 1, \cdots, n$, we have

$$[a_j, a_j + t]^{\eta/p} \equiv [a_j - \frac{\eta}{2p}t, a_j + t + \frac{\eta}{2p}t]$$

$$= \bigcup_{k=1}^p [a_{j,k-1} - \frac{\eta}{2p}t, a_{j,k} + \frac{\eta}{2p}t] \equiv \bigcup_{k=1}^p [a_{j,k-1}, a_{j,k}]^{\eta}.$$

Hence

$$\Delta^{\eta/p} = \prod_{j=1}^n [a_j, a_j + t]^{\eta/p} = \prod_{j=1}^n \bigcup_{k=1}^p [a_{j,k-1}, a_{j,k}]^{\eta}$$

$$= \bigcup_{\kappa \in \{1, \cdots, p\}^n} \prod_{j=1}^n [a_{j,\kappa_j-1}, a_{j,\kappa_j}]^{\eta} = \bigcup_{\kappa \in \{1, \cdots, p\}^n} \Delta_\kappa^{\eta}. \quad \square$$
Lemma 13.0.6. (Sufficient condition for image of compact set to be compact). Let $A$ and $B$ be open subsets of $\mathbb{R}^n$. Suppose the following two conditions hold.

1. $g : B \rightarrow A$ is a function which is differentiable on $B$, such that for each compact subset $K \Subset B$ we have $|J| \equiv |\det G| \geq c$ on $K$ for some $c > 0$, where $G$ is the derivative of $g$.

2. There exists a function $f : A \rightarrow B$ which is the inverse of $g$, such that for each compact subset $H$ of $A$ with $H \Subset A$ we have $f(H) \Subset B$.

Then, for each compact subset $H \Subset A$, the set $K \equiv f(H)$ is a compact subset of $B$.

Proof. Let $H$ be a compact subset $H \Subset A$. Conditions 1 and 2, in view of Corollary [12.0.8] implies that $f$ is differentiable on $A$. Consequently $f$ is uniformly continuous on $A$. It follows that $K$ is totally bounded. It remains to show that $K$ is compact. By condition 2, the set $K \equiv f(H)$ is such that $K \Subset B$. In other words $K \subset K' \subset B$ for some compact subset $K'$ of $B$. Hence it suffices to show that $K$ is closed. Suppose $(u_k)_1^\infty$ is a sequence in $K$ such that $u_k \rightarrow u$ for some $u \in K'$. By Proposition [12.0.5] $g$ is Lipschitz continuous on any compact subset well contained in $B$. In particular $g$ is uniformly continuous on $K'$. Therefore $g(u_k) \rightarrow g(u)$ in $A$. Since $g(u_k) \in H$ for each $k \geq 1$ and since $H$ is closed, we have $g(u) \in H$. Therefore $u = f(g(u)) \in f(H) = K$. Thus $K$ is closed.

Lemma 13.0.7. (Change of integration variables, special case). Let $A$ and $B$ be open subsets of $\mathbb{R}^n$. Suppose the following four conditions hold.

1. $g : B \rightarrow A$ is a function which is differentiable on $B$, such that for each compact subset $K \Subset B$ we have $|J| \equiv |\det G| \geq c$ on $K$ for some $c > 0$, where $G$ is the derivative of $g$.

2. There exists a function $f : A \rightarrow B$ which is the inverse of $g$, such that for each compact subset $H$ of $A$ with $H \Subset A$ we have $f(H) \Subset B$.

3. $H$ is a given compact integrable subset of $A$ with $H \Subset A$, such that $\mu(H) < \infty$ as $\lambda$ a $\# 0$.

Then $f(H)$ is an integrable set. Moreover, for each $X \in C(\mathbb{R}^n)$, the function $1_{f(H)}X(g)|J|$ is integrable, with

$$\int \cdots \int_H^X(x)dx_1 \cdots dx_n = \int \cdots \int_{f(H)} X(g(u))|J(u)|du_1 \cdots du_n \quad (13.0.23)$$

where the functions $g$ and $J$ have been extended to $\mathbb{R}^n$ by $g = 0 = J$ on $B^c$.

Proof. For abbreviation, we will write $\int dx$ for $\int dx_1 \cdots dx_n$, and similarly write $\int du$ for $\int du_1 \cdots du_n$.

Let $H$ be as given in Condition 3. Conditions 1 and 2, in view of Corollary [12.0.8] imply that $f$ is differentiable on $A$. Therefore $f$ is Lipschitz continuous on compact subsets well contained in $A$, by Proposition [12.0.5]. At the same time, Lemma [13.0.6]
implies that $K \equiv f(H)$ is compact. Let $X \in C(R^m)$ be arbitrary. In the following proof, we may assume that $X \geq 0$. The general case of $X \in C(R)$ follows from $X = 2X_+ - |X|$ and from linearity.

Since $K \in B$ by Condition 3, we have $K_\rho \in B$ for some $\rho > 0$. By Proposition [12.0.3], $g$ is Lipschitz continuous on $K_\rho$. By Condition 1, $|\rho| \geq c$ on $K_\rho$ for some $c > 0$. By Proposition [12.0.4], the partial derivative $G_{i,j}$ of $g$ is uniformly continuous on $K_\rho$ for each $i, j = 1, \ldots, n$. Hence the Jacobian $J$ is uniformly continuous on $K_\rho$, as is the product $X(g)J$. Let $\delta_\chi$ denote a modulus of continuity of $X$ on $R^n$, and let $\delta_{X_{i,j}}$ denote a modulus of continuity of $X(g)J$ on $K_\rho$. Let $\beta > 0$ be such that $|\chi| \leq \beta$ on $R^n$. Let $b > 0$ be such that $|G_{i,j}| \leq b$ on $K_\rho$ for each $i, j = 1, \ldots, n$.

Since $H \in A$, we have $H_\rho \in A$ for some $a > 0$. By Lemma [13.0.4], there exists $\alpha \in R$ with the following properties. Suppose $\overline{\Delta}$ is a closed $n$-interval with $\overline{\Delta} \equiv [\alpha + q_1, \alpha + q'_1] \times \cdots \times [\alpha + q_n, \alpha + q'_n]$, where $q_i, q'_i$ are rational numbers for each $i = 1, \ldots, n$. Suppose $\overline{\Delta} \subset H_\rho$ and suppose $f(\overline{\Delta}) \subset K_\rho$. Let $\Delta \equiv (\alpha + q_1, \alpha + q'_1) \times \cdots \times (\alpha + q_n, \alpha + q'_n)$. Then $f(\Delta)$ and $f(\overline{\Delta})$ are integrable sets with $\mu(f(\Delta)) = \mu(f(\overline{\Delta}))$, and

$$f(\overline{\Delta}) = (d(\cdot, f(\overline{\Delta})) > 0) \quad \text{a.e.}$$  \hspace{1cm} \text{(13.0.24)}

In the remainder of this proof, $\rho$ and $\alpha$ will be fixed. We will call a number $\alpha' \in R$ special if $\alpha' = \alpha + q$ for some rational number $q$. We will call a half open $n$-interval $\Delta$ a special $n$-interval if $\Delta = (x_1, x'_1] \times \cdots \times (x_n, x'_n]$ where $x_i, x'_i$ are special numbers for each $i = 1, \ldots, n$. A special $n$-interval which is an $n$-cube will be called a special $n$-cube. Suppose $\Delta$ is a special $n$-interval. If, in addition, $\overline{\Delta} \subset H_\rho$ and $f(\overline{\Delta}) \subset K_\rho$, then, according to the preceding paragraph, the sets $f(\Delta)$ and $f(\overline{\Delta})$ are integrable sets with $\mu(f(\Delta)) = \mu(f(\overline{\Delta}))$, and equality $$f(\overline{\Delta}) = (d(\cdot, f(\overline{\Delta})) > 0) \quad \text{a.e.}$$ \hspace{1cm} \text{(13.0.24)}

holds. Let $p \geq 1$ be any integer. Then, for each $\kappa \in \{1, \ldots, p\}^n$, the subinterval

$$\Delta_\kappa \equiv \prod_{i=1}^n (x_i + (\kappa_i - 1)p^{-1}(x'_i - x_i), x_i + \kappa_ip^{-1}(x'_i - x_i)]$$

is again special, because $\kappa_ip^{-1}(x'_i - x_i)$ is a rational number for each $i = 1, \ldots, n$. Thus we see that each special $n$-interval $\Delta$ can be subdivided into arbitrarily small special subintervals, by taking sufficiently large $p \geq 1$.

As remarked at the opening of this proof, the function $f$ is differentiable on $A$, and is therefore uniformly continuous on $H_\rho$. Hence $H \subset H_{a_0} \subset A$ and $f(H_{a_0}) \subset K_\rho \subset B$ for some sufficiently small $a_0 \in (0, a)$. Recall that, by convention, $a_0$ is so chosen that $H_{a_0}$ is an integrable and compact subset of $R^m$. Lemma [13.0.6] implies that $f(H_{a_0})$ is compact. Let $\delta$ denote a modulus of differentiability of $f$ on $H_{a_0}$, and let $\delta_f$ denote a modulus of continuity of $f$ on $H_{a_0}$.

Now let $\Delta_0$ be a fixed special $n$-cube such that $H_{a_0} \subset \Delta_0$. Set $\Phi_0 \equiv \{\Delta_0\}$. Then, trivially, $H_{a_0} \subset \cup_{\Delta \in \Phi_0} \overline{\Delta}$ for arbitrary $\eta > 0$.

For abbreviation, write $e_k \equiv \frac{1}{k}$ for each $k \geq 1$. We will construct, inductively for each $k \geq 0$, a real number $a_k > 0$ and a set $\Phi_k$ of special $n$-cubes of equal size, with $a_k \downarrow 0$, and with the following properties: (I) if $k \geq 1$ then each member of $\Phi_k$ is a subset of some member of $\Phi_{k-1}$, (II) $f(H_{a_k})$ is compact, (III) if $k \geq 1$ then $\mu(H_{a_k}) - \mu(H) < e_k$.}

Yuen-Kwok Chan

Constructive Probability
and (IV) \( H_{a_1} \subset \bigcup_{a \in \Phi_0} \Delta_0 \) for arbitrary \( \eta > 0 \). For the case \( k = 0 \), the objects \( a_0 \) and \( \Phi_0 \) have been constructed which trivially satisfy the Conditions (I-IV).

Suppose \( k \geq 1 \) is such that \( a_j \) and \( \Phi_j \) have been constructed for \( j = 0, \cdots, k-1 \) satisfying Conditions (I-IV). Since \( f \) is uniformly continuous on \( H_{a_{k-1}} \subset H_{a_k} \), and since \( f(H) = K \), there exists \( a_k \in (0, \frac{1}{2} a_{k-1}) \) so small that \( H_{a_k} \subset H_{a_{k-1}} \subset A \) and \( f(H_{a_k}) \subset K \). Moreover, by Condition 3 in the hypothesis, we can choose \( a_k \) so small that \( \mu(H_{a_k}) - \mu(H) < \epsilon_k \). Recall that, by convention, \( a_k \) is so chosen that \( H_{a_k} \) is an integrable and compact subset of \( \mathbb{R}^n \). Lemma 13.0.6 implies that \( f(H_{a_k}) \) is compact. Thus \( H_{a_k} \) satisfies Condition (II) and (III). We proceed to establish also Conditions (I) and (IV) for \( k \).

By Lemma 13.0.3 applied to the function \( f \), there exists \( \tau_k = \tau(\epsilon_k, n, b, c, \delta) > 0 \) with the following properties. Let \( t \in (0, \tau_k) \) be arbitrary. Let \( \Delta \equiv (x_1 - t, x_1 + t) \times \cdots \times (x_n - t, x_n + t) \) be any half open \( n \)-cube with center \( x \equiv (x_1, \cdots, x_n) \), such that (i), (ii) \( f(\Delta) \) and \( f(\Delta) \) are integrable sets with \( \mu(f(\Delta)) = \mu(f(\Delta)) \), where \( \Delta \equiv [x_1 - t, x_1 + t] \times \cdots \times [x_n - t, x_n + t] \), (iii), and (iv) \( \delta \) is a modulus of differentiability of \( f \) on \( \Delta \). Then

\[
|\mu(f(\Delta)) - \mu(\Delta)| \leq n(2^{n-1} + 1)\epsilon \mu(\Delta). \tag{13.0.25}
\]

Continue with the induction process for the construction of \( a_k \) and \( \Phi_k \). By the induction hypothesis, the special \( n \)-cubes in \( \Phi_{k-1} \) are of equal diameter, which we denote by \( t \). Thus \( \| \Delta \| = t \) for each \( \Delta \in \Phi_{k-1} \). Let \( s_k \equiv (0, \frac{1}{2} (a_{k-1} - a_k)) \) be arbitrary. Let \( p = p_k \geq 1 \) be so large that

\[
p^{-1} t < \tau_k \wedge s_k \wedge \delta_k(\epsilon_k) \wedge \delta_f(\delta_X, f(\epsilon_k)). \tag{13.0.26}
\]

Consider an arbitrary special \( n \)-cube \( \Delta \in \Phi_{k-1} \). Write \( \Delta \equiv (\alpha, \alpha + t] \times \cdots \times (\alpha, \alpha + t] \), and, for each \( \kappa \in \{1, \cdots, p\} \), define the special \( n \)-cube

\[
\Delta_\kappa \equiv \prod_{i=1}^{n} (\alpha_i + (\kappa_i - 1)p^{-1} t, \alpha_i + \kappa_i p^{-1} t].
\]

Define the set \( \Psi_k \equiv \{ \Delta_\kappa : \Delta \in \Phi_{k-1} ; \kappa \in \{1, \cdots, p\}^n \} \). Thus \( \Psi_k \) is a set of special \( n \)-cubes each of which is a subcube of some member of \( \Phi_{k-1} \). Moreover, according to Lemma 13.0.5, we have \( \Delta_\kappa \subset \bigcup_{\kappa \in \{1, \cdots, p\}^n} \Delta_\kappa \) for each \( \Delta \in \Phi_{k-1} \) and for arbitrary \( \eta > 0 \). Hence

\[
\bigcup_{\Delta \in \Phi_{k-1}} \Delta_\kappa^{\eta/p} \subset \bigcup_{\Delta \in \Phi_{k-1}} \bigcup_{\kappa \in \{1, \cdots, p\}^n} \Delta_\kappa^{\eta/p} = \bigcup_{\Gamma \in \Psi_k} \Gamma^{\eta/p} \tag{13.0.27}
\]

for arbitrary \( \eta > 0 \). Furthermore, \( \| \Gamma \| = p^{-1} t \) for each \( \Gamma \in \Psi_k \). We can partition the set \( \Psi_k \) into two subsets \( \Phi_k \) and \( \Phi'_k \) such that

\[
\text{if } \Gamma \in \Phi_k \text{ then } d(\Gamma, H_{a_k}) < s_k, \tag{13.0.28}
\]

and

\[
\text{if } \Gamma \in \Phi'_k \text{ then } d(\Gamma, H_{a_k}) > \frac{s_k}{2}. \tag{13.0.29}
\]

The set \( \Phi_k \), being a subset of \( \Psi_k \), automatically satisfies Condition (I).

Yuen-Kwok Chan

531

Constructive Probability
Let $\eta > 0$ be arbitrary. We will show that $H_{a_k} \subset \bigcup_{\Gamma \in \Phi_k} \mathcal{P}$. Consider an arbitrary $x \in H_{a_k}$. Let $\zeta \equiv \eta \wedge \frac{1}{\sqrt[3]{n}}$. By the induction hypothesis, we have $H_{a_k} \subset H_{a_{k-1}} \subset \bigcup_{\Delta \in \Phi_{k-1}} \Delta^{3/p}$. Thus $x \in \Delta^{3/p}$ for some $\Delta \in \Phi_{k-1}$. Therefore, according to expression $[13.0.27]$ we have $x \in \bigcup_{\Gamma \in \Psi_k} \mathcal{P}$. Consequently, $x \in \mathcal{P}$ for some $\Gamma \in \Psi_k$. Hence $d(x, \mathcal{P}) \leq \sqrt[3]{n} \zeta \leq \eta$. Inequality $[13.0.29]$ therefore implies that $\Gamma \notin \Phi_k$. Hence $\Gamma \in \Phi_k$. Consequently $x \in \bigcup_{\Gamma \in \Phi_k} \mathcal{P}$. We conclude that $H_{a_k} \subset \bigcup_{\Gamma \in \Phi_k} \mathcal{P} \subset \bigcup_{\Gamma \in \Phi_k} \mathcal{P}^0$, thereby establishing Condition (IV) for $k$. Induction is completed.

Next let $k \geq 1$ be arbitrary. Consider any $\Gamma \in \Phi_k$. We have, on the one hand, $||\mathcal{P}|| = p^{-1}t < s_k$, and, on the other hand, $d(\mathcal{P}, H_{a_k}) < s_k$ in view of inequality $[13.0.28]$. Since $2s_k < a_{k-1} - a_k$, we obtain

$$\mathcal{P} \subset (H_{a_k})_{2s_k} \subset H_{a_{k-1}} \subset H_{a_k} \subset H_a.$$ 

It follows that

$$f(\mathcal{P}) \subset f(H_{a_{k-1}}).$$ 

(13.0.30)

Consequently $f(\mathcal{P}) \subset K_P$. Hence, since $\Gamma$ is a special $n$-cube, the sets $f(\Gamma)$ and $f(\mathcal{P})$ are integrable, with $\mu(f(\Gamma)) = \mu(f(\mathcal{P}))$. Moreover $f(\mathcal{P}) = (d(\cdot, f(\mathcal{P}))) > 0$ on some full set $D_0$, according to equality $[13.0.24]$. Define $M_k \equiv \bigcup_{\Gamma \in \Phi_k} f(\mathcal{P})$. Then $f(M_k) = \bigcup_{\Gamma \in \Phi_k} f(\mathcal{P})$. From relation $[13.0.30]$, we see that $f(M_k) \subset f(H_{a_k})$.

We will next show, in the other direction, that $f(H_{a_k}) \subset f(M_k)$ a.e. Consider an arbitrary $v \in D \cap f(H_{a_k})$ where $D$ is the full set

$$D \equiv D_0 \cap \bigcap_{\Gamma \in \Phi_k} (f(\mathcal{P}) \cup (d(\cdot, f(\mathcal{P}))) > 0).$$ 

(13.0.31)

Then $v = f(y)$ for some $y \in H_{a_k}$. In view of equality $[13.0.31]$ we have either $v \in f(\mathcal{P})$ for some $\Gamma \in \Phi_k$, or $v \in (d(\cdot, f(\mathcal{P}))) > 0$ for each $\Gamma \in \Phi_k$. In other words either $v \in f(M_k)$, or $v \in (d(\cdot, f(\mathcal{P}))) > 0$ for each $\Gamma \in \Phi_k$. We will show that $v \in f(M_k)$. Suppose, for the sake of a contradiction, that $d(v, f(\mathcal{P})) > 0$ for each $\Gamma \in \Phi_k$. Then $d(f(y), f(\mathcal{P})) = d(v, f(\mathcal{P})) > \zeta$ for each $\Gamma \in \Phi_k$, for some $\zeta > 0$. Define $\eta \equiv \frac{\zeta}{\sqrt[3]{n}} \wedge \frac{1}{\sqrt[3]{n}} \delta(\zeta)$, where $\delta$ is the previously defined modulus of continuity of $f$ on the compact set $M_a$. Then, for each $\Gamma \in \Phi_k$, the assumption that $d(y, \mathcal{P}) < 2\sqrt[3]{n}\eta$ would imply $d(y, \mathcal{P}) < \delta(\zeta)$ and so $d(f(y), f(\mathcal{P})) < \zeta$, a contradiction. Hence

$$d(y, \mathcal{P}) \geq 2\sqrt[3]{n}\eta \quad \text{for each } \Gamma \in \Phi_k.$$ 

(13.0.32)

On the other hand, by Condition (IV), we have $y \in H_{a_k} \subset \bigcup_{\Gamma \in \Phi_k} \mathcal{P}$. Consequently there exists $\Gamma \in \Phi_k$ such that $y \in \mathcal{P}$. Hence $d(y, \mathcal{P}) \leq \sqrt[3]{n}\eta$, contradicting inequality $[13.0.32]$. We conclude that $v \in f(M_k)$. Since $v \in D \cap f(H_{a_k})$ is arbitrary, we have established that $D \cap f(H_{a_k}) \subset f(M_k)$. Consequently $f(H_{a_k}) \subset f(M_k)$ a.e.

Summing up, we have proved that

$$f(H_{a_k}) \subset f(M_k) \subset f(H_{a_{k-1}}) \text{ a.e.}$$ 

(13.0.33)

Since $H = \bigcap_{k=1}^\infty H_{a_k}$, and since $f$ is a bijection, we have $f(H) = \bigcap_{k=1}^\infty f(H_{a_k})$. It follows that

$$f(H) = \bigcap_{k=1}^\infty f(H_{a_k}) \subset \bigcap_{k=1}^\infty f(M_k) \subset \bigcap_{k=1}^\infty f(H_{a_{k-1}}) = f(H) \text{ a.e.}$$
Hence \( f(H) = \bigcap_{k=1}^{\infty} f(M_k) \) a.e.

As a special case, when we apply the arguments in the previous paragraphs with \( f \) replaced by the identity function on \( R^n \), expression \([13.0.33]\) yields \( H_{a_k} \subset M_k \subset H_{a_{k-1}} \) a.e.

Consider any \( \Gamma \in \Phi_0 \). Then \( d(\overline{\Gamma}, \xi) < s_k \) by Condition \([13.0.28]\). Let \( x_\Gamma \) be the center of \( \Gamma \), and let \( u_\Gamma = f(x_\Gamma) \). By expression \([13.0.30]\) we have \( f(\overline{\Gamma}) \subset f(\xi) \subset B \), and so \( \delta \) is a modulus of differentiability of \( f \) on \( \overline{\Gamma} \). We saw earlier that \( f(\overline{\Gamma}) \) is an integrable set. Since \( |\Gamma| = p^{-1}t \leq \xi \), all the conditions are satisfied for inequality \([13.0.25]\) to hold for the \( n \)-cube \( \Gamma \), yielding

\[
|\mu(f(\Gamma))(|\det F(x_\Gamma)|^{-1}) - \mu(\Gamma)| \leq n(2^{n-1} + 1)\varepsilon_k \mu(\Gamma),
\]

where \( F(x_\Gamma) \) is the derivative of \( f \) at \( x_\Gamma \). Since , it follows that

\[
|\mu(\Gamma) - \mu(f(\Gamma))(|\det G(u_\Gamma)|)| \leq n(2^{n-1} + 1)\varepsilon_k \mu(\Gamma).
\]

Equivalently

\[
|\int_{\Gamma} dx - \int_{u_\Gamma} |J(u_\Gamma)| du| \leq n(2^{n-1} + 1)\varepsilon_k \mu(\Gamma).
\]

Multiplying by \( X(x_\Gamma) \equiv X(g(u_\Gamma)) \), and noting that \( |X| \leq \beta \), we obtain

\[
|\int_{\Gamma} X(x_\Gamma)dx - \int_{u_\Gamma} X(x_\Gamma)|J(u_\Gamma)| du| \leq \beta n(2^{n-1} + 1)\varepsilon_k \mu(\Gamma).
\]

At the same time \( ||\overline{\Gamma}|| = p^{-1}t < \delta_k(\varepsilon_k) \land \delta_f(\delta_k(\varepsilon_k)) \) by inequality \([13.0.26]\). Hence \( |X(x) - X(x_\Gamma)| < \varepsilon_k \) and \( \|f(x) - f(x_\Gamma)\| < \delta_k(\varepsilon_k) \) for each \( x \in \Gamma \). Consequently, \( \|u_\Gamma - u\| < \delta_k(\varepsilon_k) \) for each \( u \in f(\Gamma) \), and so \( |X(g(u_\Gamma))|J(u_\Gamma)| - X(g(u))|J(u)|| \leq \varepsilon_k \) for each \( u \in f(\Gamma) \). Combining with inequality \([13.0.34]\) we obtain

\[
|\int_{\Gamma} X(x)dx - \int_{f(\Gamma)} X(g(u))|J(u)| du|
\]

\[
\leq \beta n(2^{n-1} + 1)\varepsilon_k \mu(\Gamma) + \varepsilon_k \mu(\Gamma) + \varepsilon_k \mu(f(\Gamma)).
\]

Summation over all \( \Gamma \in \Phi_0 \) yields

\[
|\int_{M_k} X(x)dx - \int_{f(M_k)} X(g(u))|J(u)| du|
\]

\[
\leq \beta n(2^{n-1} + 1)\varepsilon_k \mu(M_k) + \varepsilon_k \mu(M_k) + \varepsilon_k \mu(f(M_k))
\]

\[
\leq \beta n(2^{n-1} + 1)\varepsilon_k \mu(H_{a_k}) + \varepsilon_k \mu(H_{a_k}) + \varepsilon_k \mu(K_p).
\]

On the other hand, recalling that \( H \subset M_k \subset H_{a_{k-1}} \) a.e. and that \( |X| \leq \beta \), we have

\[
|\int_{M_k} X(x)dx - \int_H X(x)dx|
\]

\[
\leq \beta(\mu(M_k) - \mu(H)) \leq \beta(\mu(H_{a_{k-1}}) - \mu(H)) \leq \beta \varepsilon_{k-1}.
\]
CHAPTER 13. CHANGE OF INTEGRATION VARIABLES

Hence inequality [13.0.35] yields
\[ |\int_X X(x)dx - \int_{f(M_k)} X(g(u))|J(u)|du| \]
\[ \leq \beta n(2^n - 1)\varepsilon_k \mu(H_{0k}) + \varepsilon_k \mu(H_{0k}) + \varepsilon_k \mu(K_p) + \beta \varepsilon_{k-1}. \]
Since \( \varepsilon_k \to 0 \), it follows that
\[ \int_{f(M_k)} X(g(u))|J(u)|du \to \int \chi_{H} X(x)dx \]
(13.0.36) as \( k \to \infty \). At the same time, we have \( M_k \subset M_{k-1} \), and so \( 1_{f(M_k)} \leq 1_{f(M_{k-1})} \) for each \( k \geq 1 \).

Recall the assumption that \( X \geq 0 \). The sequence \( \{1_{f(M_k)}X(g)|J\}_k \) is nonincreasing. By the Monotone Convergence Theorem, expression [13.0.36] implies that
\[ Z \equiv \lim_{k \to \infty} 1_{f(M_k)}X(g)|J| \]
is an integrable function, with
\[ \int Z(u)du = \int X(x)dx. \]

Now let \( U \in C(R^n) \) be such that \( U = 1 \) on \( H_{0k} \). For each \( u \in f(M_k) \) we then have \( g(u) \in M_k \subset H_{0k} \) and so \( U(g(u)) = 1 \). Thus \( U(g) = 1 \) on \( f(M_k) \) for each \( k \geq 1 \).

Define a measurable function \( V \) on \( R^n \) by \( V \equiv |J|^{-1}1_B + 1_{\overline{B}} \). By the arguments in the previous paragraphs, \( Y \equiv \lim_{k \to \infty} f(M_k)|U(g)|J \) is an integrable function. Therefore \( VY \equiv \lim_{k \to \infty} f(M_k)U(g)|J| = \lim_{k \to \infty} f(M_k) \) is a measurable function. We have seen earlier that \( f(H) = \bigcap_{k=1}^{\infty} f(M_k) \) a.e. Combining, we have \( f(H) = VY \) a.e. and so \( f(H) \) is a measurable function, with \( f(H) = \lim_{k \to \infty} 1_{f(M_k)} \) a.e. Since \( f(H) \leq 1_{f(M_k)} \), it follows that \( f(H) \) is an integrable function. In other words, \( f(H) \) is an integrable set.

Moreover, \( Z = 1_{f(H)}X(g)|J| \). Thus
\[ \int f(H) X(g(u))|J(u)|du = \int Z(u)du = \int X(x)dx. \]
The lemma is proved.

Lemma 13.0.8. (Change of integration variables for continuous integrands). Let \( A \) and \( B \) be measurable open subsets of \( R^n \). Suppose the following four conditions hold.
1. \( g : B \to A \) is a function which is differentiable on \( B \), such that for each compact subset \( K \subset B \) we have \( |J| \equiv |\det G| \geq c \) on \( K \) for some \( c > 0 \), where \( G \) is the derivative of \( g \).
2. There exists a function \( f : A \to B \) which is the inverse of \( g \).
3. For each compact subset \( H \) of \( A \) with \( H \subset A \) we have \( f(H) \subset B \).
4. There exists a sequence \( \{H_k\}_{k=1}^{\infty} \) of compact integrable subsets of \( A \) such that \( i \) \( H_k \subset H_{k+1} \subset A \) for each \( k \geq 1 \), \( ii \) \( A = \bigcup_{k=1}^{\infty} H_k \) and \( 1_{H_k} \uparrow 1_A \) in measure.

Then, for each \( X \in C(R^n) \), the function \( 1_B X(g)|J| \) is integrable, and
\[ \int_A X(x)dx_1 \cdots dx_n = \int_B X(g(u))|J(u)|du_1 \cdots du_n, \]
(13.0.37) where the functions \( g \) and \( J \) have been extended to the set \( B^c \) by setting \( g = 0 = J \) on \( B^c \).

Yuen-Kwok Chan 534 Constructive Probability
Proof. For abbreviation, we will write \( \int dx \) for \( \int \cdots \int dx_1 \cdots dx_n \), and similarly \( \int du \) for \( \int \cdots \int du_1 \cdots du_n \).

Since \( H_1 \in A \), there exists \( a_1 > 0 \) such that \( H_1' \equiv (H_1)_{a_1} \in A \). Inductively, suppose \( H'_1, \ldots, H'_k \) have been constructed with \( H'_1 \in \cdots \in H'_k \in A \) for some \( k \geq 1 \). Define \( M_{k+1} \equiv (H'_1 \cup H_{k+1})^c \), the closure of \( H'_1 \cup H_{k+1} \). Then \( M_{k+1} \) is compact. Since \( H'_k \in A \) and \( H_{k+1} \in A \), we also have \( M_{k+1} \in A \). Hence \( H_{k+1}' \equiv (M_{k+1})_{a_{k+1}} \in A \) for some \( a_{k+1} > 0 \). We have constructed inductively the sequence \( (H_k')_{k=1,2,\ldots} \) such that \( H_k' \subset H_{k+1}' \in A \) for each \( k \geq 1 \). Moreover, for each \( k \geq 1 \) we have \( H_k' \equiv (M_k)_{a_k} \) for some compact set \( M_k \) and for some \( a_k \) which, by convention, is chosen to be a regular point of \( d(\cdot,M_k) \). It follows that \( \mu((H_k')_{a_k} \downarrow \mu(H_k') \) as \( a \downarrow 0 \), for each \( k \geq 1 \).

At the same time, since \( H_k \subset H_k' \subset A \) for each \( k \geq 1 \), we have \( A = \bigcup_{k=1}^\infty H_k \subset \bigcup_{k=1}^\infty H_k' \subset A \) and \( 1_{H_k} \uparrow 1_A \) in measure. Thus the sequence \( (H_k')_{k=1,2,\ldots} \) satisfies conditions 4(i) and 4(ii) in the hypothesis. Therefore, we can replace the given sequence \( (H_k)_{k=1,2,\ldots} \) with \( (H_k')_{k=1,2,\ldots} \) and assume that, in addition to conditions 4(i) and 4(ii), we have

\[
\mu((H_k')_{a_k} \downarrow \mu(H_k') \) as \( a \downarrow 0 \)

for each \( k \geq 1 \).

Let \( X \in C(R^n) \) be arbitrary. First suppose \( X \geq 0 \). For each \( k \geq 1 \), the conditions in the hypothesis of Lemma \ref{lem:dominated_convergence}, are satisfied by \( H_k \). Accordingly, \( f(H_k) \) is integrable, and

\[
\int 1_{H_k}(x)X(x)\,dx = \int 1_f(H_k)(u)(g(u))|J(u)|\,du \tag{13.0.38}
\]

for each \( k \geq 1 \). Since \( 1_{H_k} \uparrow 1_A \) in measure, we have \( 1_{H_k}X \uparrow 1_AX \) in measure. Since \( X \) is integrable, the Dominated Convergence Theorem implies that

\[
\int 1_{H_k}(x)X(x)\,dx \uparrow \int 1_A(x)X(x)\,dx. \tag{13.0.39}
\]

It follows from equalities \ref{eq:13.0.38} and \ref{eq:13.0.39} that \( \int 1_f(H_k)(u)(g(u))|J(u)|\,du \) also converges to \( \alpha \equiv 1_A(x)X(x)\,dx \). Hence, according to the Monotone Convergence Theorem, the function \( Z \equiv \lim_{k \to \infty} 1_f(H_k)(g)|J| \) is integrable, with integral \( \alpha \). On the other hand, because \( B = f(A) = \bigcup_{k=1}^\infty f(H_k) \), we have \( 1_f(H_k) \uparrow 1_B \) a.e. and so \( 1_f(H_k)X(g)|J| \uparrow 1_BX(g)|J| \) a.e. Combining, we obtain \( 1_BX(g)|J| = Z \) a.e. Accordingly \( 1_BX(g)|J| \) is integrable, with integral \( \alpha \). The desired equality \ref{eq:13.0.37} is thus proved for the case of a non-negative \( X \in C(R) \). The general case of \( X \in C(R) \) follows from \( X = 2X_+ - |X| \) and from linearity.

The following proposition generalizes the change of integration variables for continuous integrand \( X \) in Lemma \ref{lem:change_of_variables} to allow for a general integrable \( X \).

**Theorem 13.0.9. (Change of integration variables).** Let \( A \) and \( B \) be measurable open subsets of \( R^n \). Suppose the following four conditions hold.

1. \( g : B \to A \) is a function which is differentiable on \( B \), such that for each compact subset \( K \subset B \) we have \( |J| \equiv |\det G| \geq c > 0 \), where \( G \) is the derivative of \( g \).
2. There exists a function \( f : A \to B \) which is the inverse of \( g \).
3. For each compact subset \( H \subset A \) we have \( f(H) \in B \).

Yuen-Kwok Chan 535 Constructive Probability
4. There exists a sequence \((H_k)_{k=1,2,...}\) of compact integrable subsets of \(A\) such that (i) \(H_k \subset H_{k+1} \subset A\) for each \(k \geq 1\), (ii) \(A = \bigcup_{k=1}^{\infty} H_k\) and \(1_{H_k} \uparrow 1_A\) in measure.

Then, for each Lebesgue integrable function \(X\) on \(R^n\) such that the function \(1_{B}X(g)|J|\) is integrable, we have

\[
\int \cdots \int_A X(x)dx_1 \cdots dx_n = \int \cdots \int_B X(g(u))|J(u)|du_1 \cdots du_n, \quad (13.0.40)
\]

where the functions \(g\) and \(J\) have been extended to the set \(B^c\) by setting \(g = 0 = J\) on \(B^c\).

**Proof.** By hypothesis, the functions \(g\) and \(J\) are defined on some full subset \(D_0\) of \(R^n\). Let \(D = D_0 \cap (B \cup B^c)\). Then \(D\) is a full set. Let \(X\) be an arbitrary integrable function on \(R^n\). By Proposition 13.10.12 there exists a sequence \((X_j)_{j=1,2,...}\) in \(C(R^n)\) which is a representation of \(X\) relative to the Lebesgue integration on \(R^n\). In other words, (i) \(\sum_{j=1}^{\infty} |X_j(x)|dx < \infty\), and (ii) if \(x \in R^n\) is such that \(\sum_{j=1}^{\infty} |X_j(x)| < \infty\) then \(x \in \text{domain}(X)\) and \(X(x) = \sum_{j=1}^{\infty} X_j(x)\). By hypothesis, for each \(j \geq 1\), the function \(1_{B}X_j(g)|J|\) is integrable, and equality [13.0.37] in Lemma [13.0.8] holds for each \(|X_j|\). Hence

\[
\sum_{j=1}^{\infty} \int_{A} 1_{B}(u)|X_j(g(u))|J(u)|du = \int_{A} X(x)dx < \infty. \quad (13.0.41)
\]

Define a function \(Y\) on \(R^n\) by

\[
\text{domain}(Y) \equiv \{ u \in D : \sum_{j=1}^{\infty} 1_{B}(u)|X_j(g(u))|J(u)| < \infty \}
\]

and \(Y(u) = \sum_{j=1}^{\infty} 1_{B}(u)X_j(g(u))|J(u)|\) for each \(u \in \text{domain}(Y)\). Then, in view of inequality [13.0.41] the function \(Y\) is integrable, the sequence \((1_{B}X_j(g)|J|)_{j=1,2,...}\) being a representation. Moreover

\[
\int Y(u)du = \sum_{j=1}^{\infty} \int_{A} 1_{B}(u)X_j(g(u))|J(u)|du = \sum_{j=1}^{\infty} \int_{A} X_j(x)dx = \int_{A} X(x)dx.
\]

Consider an arbitrary \(u \in DB\). Then

\[
\sum_{j=1}^{\infty} |X_j(g(u))|J(u)| = \sum_{j=1}^{\infty} 1_{B}(u)|X_j(g(u))|J(u)| < \infty.
\]

Since by hypothesis, we see that \(\sum_{j=1}^{\infty} |X_j(g(u))| < \infty\). It follows from condition (ii) above that \(g(u) \in \text{domain}(X)\) and \(X(g(u)) = \sum_{j=1}^{\infty} X_j(g(u))\). Consequently

\[
1_{B}(u)X(g(u))|J(u)| = \sum_{j=1}^{\infty} 1_{B}(u)X_j(g(u))|J(u)| = Y(u).
\]

We conclude that \(DB \subset \text{domain}(X(g))\) and that \(1_{B}X(g)|J| = Y\) on \(DB\). On the other hand, for each \(u \in DB^c\), we have. Combining, we see that \(1_{B}X(g)|J| = Y\) on the full set \(D(B \cup B^c)\). It follows that \(1_{B}X(g)|J|\) is integrable, which integral equal to \(\int Y(u)du = \int_{A} X(x)dx\). The proposition is thus proved. \(\square\)
The next corollary is a formula for changing integration variables from rectangular coordinates in $R^2$ to polar coordinates. It is all we needed in the text. First an elementary lemma.

**Lemma 13.0.10. (bijection of an arc to an interval).** Let $C \equiv \{(u,v) \in R^2 : u^2 + v^2 = 1 \text{ and } (u,v) \not= (1,0)\}$, where the inequality signifies a positive Euclidean distance. Then the function $h : (0,2\pi) \to C$ defined by $h(\theta) = (\cos \theta, \sin \theta)$ is a bijection. More specifically, for arbitrarily small $\theta_0 \in (0, \frac{\pi}{2})$, the function is a bijection.

**Proof.** Take arbitrary $\theta_0, \theta_1 \in (0, \frac{\pi}{2})$ such that $\theta_0 < \theta_1$. Define $\delta_0 = \sin \theta_0$ and $\delta_1 = \sin \theta_1$. Then $0 < \delta_0 < \delta_1$. Let $(u,v) \in C_{\theta_0}$ be arbitrary. Then $u^2 + v^2 = 1$ and $(u-1)^2 + v^2 \geq \delta_0^2 \equiv \sin^2 \theta_0$. Either $v^2 \geq \delta_0^2$ or $v^2 \leq \delta_1^2$. In the first case, we have in turn $v \geq \delta_0$ or $v \leq -\delta_0$. Suppose $v \geq \delta_0$. Then $u^2 \leq 1 - \delta_0^2 = \cos^2 \theta_0$, and so $u \in [-\cos \theta_0, \cos \theta_0] \subset (-1,1)$. At the same time, the function $\cos : [\theta_0, \pi - \theta_0] \to [-\cos \theta_0, \cos \theta_0]$ has a strictly negative derivative. Hence there exists a unique $\theta \in [\theta_0, \pi - \theta_0] \subset (0, \pi)$ such that $u = \cos \theta$ and $v = \sqrt{1 - u^2} = \sqrt{1 - \cos^2 \theta} = \sin \theta$, the last equality holding because $\sin \theta \geq 0$ on $(0, \pi)$. Next, suppose $v \leq -\delta_0$. Then, again, $u^2 \leq 1 - \delta_0^2$, and so $u \in [-\cos \theta_0, \cos \theta_0] \subset (-1,1)$. At the same time, the function $\cos : [\pi + \theta_0, 2\pi - \theta_0] \to [-\cos \theta_0, \cos \theta_0]$ has a strictly positive derivative. Hence there exists a unique $\theta \in [\pi + \theta_0, 2\pi - \theta_0] \subset (\pi, 2\pi)$ such that $u = \cos \theta$ and $v = -\sqrt{1 - u^2} = -\sqrt{1 - \cos^2 \theta} = \sin \theta$, the last equality holding because $\sin \theta \leq 0$ on $(\pi, 2\pi)$. Now consider the second case, where $v^2 \leq \delta_1^2 \equiv \sin^2 \theta_1$. Thus $v \in [-\sin \theta_1, \sin \theta_1] \subset (-1,1)$. At the same time, the function $\sin : [\pi - \theta_1, \pi + \theta_1] \to [-\sin \theta_1, \sin \theta_1]$ has a strictly negative derivative. Hence there exists a unique $\theta \in [\pi - \theta_1, \pi + \theta_1] \subset (\frac{\pi}{2}, \frac{3\pi}{2})$ such that $v = \sin \theta$. Then $u = -\sqrt{1 - v^2} = -\sqrt{1 - \sin^2 \theta} = \cos \theta$, the last equality holding because $\cos \theta \leq 0$ on $(\frac{\pi}{2}, \frac{3\pi}{2})$. Summing up, we see that for each $(u,v) \in C_{\theta_0}$ there exists $\theta \in [\theta_0, 2\pi - \theta_0]$ such that $(u,v) = (\cos \theta, \sin \theta) \equiv h(\theta)$. Since each $(u,v) \in C$ belongs to $C_{\theta_0}$ for sufficiently small $\theta_0 \in (0, \frac{\pi}{2})$, we have $(u,v) = h(\theta)$ for some $\theta \in (0, 2\pi)$.

Suppose $\theta, \theta' \in (0, 2\pi)$ are such that $(\cos \theta, \sin \theta) = (\cos \theta', \sin \theta')$. Suppose $\theta \neq \theta'$. There are three possibilities: (i) $\theta \in (0, \pi)$, (ii) $\theta \in (\frac{\pi}{2}, \frac{3\pi}{2})$, and (iii) $\theta \in (\pi, 2\pi)$. Consider case (i). Then $\theta' \in (\pi, 2\pi)$ and so $\sin \theta' < 0 < \sin \theta$, a contradiction. Similarly case (iii) would lead to a contradiction. Now consider case (ii). Then $\theta' \in (0, \frac{\pi}{2}) \cup [\frac{3\pi}{2}, 2\pi)$ and we have $\cos \theta' \geq 0 > \cos \theta$, again a contradiction. Hence $\theta = \theta'$. Thus we conclude that $h$ is one-to-one. 

**Corollary 13.0.11. (Change of integration variables from rectangular coordinates to polar coordinates).** For each integrable function $X$ on $R^2$, the function

$$X(r \cos \theta, r \sin \theta)$$

is integrable on $R^2$, with

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} X(x,y) dx dy = \int_{0}^{2\pi} \int_{0}^{\infty} X(r \cos \theta, r \sin \theta) r dr d\theta.$$ 

**Proof.** Let $B \equiv (0, \infty) \times (0, 2\pi)$. Define $g : B \to R^2$ by $g(r, \theta) \equiv (r \cos \theta, r \sin \theta)$ for each $(r, \theta) \in B$. Then $g$ is differentiable on the open set $B$, with derivative $G \equiv$

CHAPTER 13. CHANGE OF INTEGRATION VARIABLES

\[
\begin{bmatrix}
\cos \theta & \sin \theta \\
-r\sin \theta & r\cos \theta
\end{bmatrix}
\text{ and Jacobian } \det G = r. \text{ Let } R_+ \equiv [0,\infty) \times \{0\} \subset \mathbb{R}^2. \text{ Define } \\
A \equiv \{(x,y) \in \mathbb{R}^2 : d((x,y), R_+) > 0\}, \text{ the metric complement of } R_+. \text{ It is easily verified that } A \text{ is an open set. We proceed to verify the conditions in the hypothesis of Lemma } 13.0.8.
\]

We will first prove that \(g(B) \subset A\). Let \(\delta \in (0,\frac{\pi}{2})\) and \(0 < a < b\) be arbitrary. Consider any \((r,\theta) \in [a,b] \times [\delta, 2\pi - \delta]\). Let \((x,y) \equiv g(r, \theta)\). Consider any \((z,0) \in \mathbb{R}^2\). Write \(\alpha \equiv d((x,y),(z,0))\). Then \(\alpha^2 = \|r \cos \theta, r \sin \theta - (z,0)\|^2 = r^2 - 2rr \cos \theta + z^2\). If \(\theta \in [\frac{\pi}{2}, \frac{\pi}{2}]\) then \(\cos \theta \leq 0\) and so \(\alpha^2 \geq r^2 \geq a^2\). If \(\theta \in [\delta, \frac{\pi}{2}] \cup [\frac{3\pi}{2}, 2\pi - \delta]\) then \(\alpha \geq |y| = r \sin \theta \geq a \sin \delta\). Hence \(\alpha \geq a \sin \delta\) if \(\theta \in [\delta, \frac{\pi}{2}] \cup [\frac{3\pi}{2}, 2\pi - \delta]\). By continuity, we therefore have \(\alpha \geq a \sin \delta\) for the given \((r,\theta) \in [a,b] \times [\delta, 2\pi - \delta]\). Since \((z,0) \in \mathbb{R}^+\) is arbitrary, we have \(d((x,y), R_+) \geq a \sin \delta > 0\) and so \(g(r, \theta) \in A\). It follows that

\[g([a,b] \times [\delta, 2\pi - \delta]) \subset \{(x,y) \in \mathbb{R}^2 : d((x,y), R_+) \geq a \sin \delta\} \subset A. \quad (13.0.42)\]

Since \(a > 0\) and \(\delta > 0\) are arbitrarily small, and \(b\) is arbitrarily large, it follows that \(g(B) \equiv g([0,\infty) \times (0,2\pi)) \subset A\).

Next, we will show that the function \(g : B \to A\) has an inverse. Let \(C \equiv \{(u,v) \in R^2 : u^2 + v^2 = 1\ \text{and} \ (u,v) \neq (1,0)\}\). Let \(h : (0,2\pi) \to C\) be the bijection defined by \(h(\theta) \equiv (\cos \theta, \sin \theta)\) as in Lemma 13.0.10 and let \(h^{-1} : C \to (0,2\pi)\) denote its inverse. Let \((x,y) \in A\) be arbitrary. Then \(r \equiv \sqrt{x^2 + y^2} > 0\). Define \(u \equiv \frac{x}{r}\) and \(v \equiv \frac{y}{r}\). Then \(d((u,v),(1,0)) = \frac{1}{r}d((x,y),(0,0)) \geq \frac{1}{r}d((x,y), R_+) > 0\). Hence \((u,v) \in C\). Define \(\theta \equiv h^{-1}(u,v) \in (0,2\pi)\) and define \(f(x,y) \equiv (r,\theta) \in (0,\infty) \times (0,2\pi)\). Then \((u,v) = h(\theta) \equiv (\cos \theta, \sin \theta)\), and so \(g(f(x,y)) \equiv g(r,\theta) = (ru,rv) = (x,y)\). In other words, \(g(f)\) is the identity function on \(A\), and \(f : A \to B\) is the inverse of \(g\).

Let \((a_k),(b_k),(\theta_k)\) be strictly monotone sequences in \(R\) such that \(0 < a_k < b_k < \theta_k < \frac{\pi}{2}\) for each \(k \geq 1\), and such that \(a_k \downarrow 0, b_k \uparrow \infty, \theta_k \downarrow 0\). For each \(k \geq 1\) define \(K_k \equiv [a_k,b_k] \times [\theta_k, 2\pi - \theta_k] \subset B\) and \(H_k \equiv g(K_k)\). Being the product of two closed intervals, \(K_k\) is compact and integrable for each \(k \geq 1\). Moreover \(B = \bigcup_{k=1}^{\infty} K_k\) and so \(A \equiv g(B) = \bigcup_{k=1}^{\infty} g(K_k) \equiv \bigcup_{k=1}^{\infty} H_k\).

Next let \(H\) be an arbitrary compact subset with \(H \subset A\). Since \(H \subset A\), there exists \(a > 0\) such that \(H_a \subset A\). We will show that \(f(H) \subset B\) by proving that \(f(H) \subset K_k\) for sufficiently large \(k\). Let \(j \geq 1\) be so large that \(a_k < a\) and \(H \subset (d(\cdot, (0,0)) \leq b_k)\) for each \(k \geq j\). Consider an arbitrary \((x,y) \in H\). Let \((r,\theta) \equiv f(x,y)\) and \((u,v) \equiv (\frac{x}{r}, \frac{y}{r})\). Then \(r \leq b_j\). Moreover, the assumption that \(r < a\) would imply that \(d((0,0),H) \leq d((0,0),(x,y)) < a\), and so \((0,0) \in H_a \subset A\), whence \(0 = d((0,0), R_+) > 0\), a contradiction. Therefore \(r \geq a \geq a_j\). Next, we have \((u,v) = (\cos \theta, \sin \theta)\). Let \(k \geq j\) be so large that \(\sin^2 \theta_k \leq b_j^2 a^2\). Then

\[(u-1)^2 + v^2 = r^{-2}d((x,y),(r,0))^2 \geq r^{-2}a^2 \geq b_j^2 a^2 \geq \sin^2 \theta_k. \quad (13.0.43)\]

Hence \((u,v) \in C_{\theta_k} \equiv \{(u,v) \in C : (u-1)^2 + v^2 \geq \sin^2 \theta_k\}\). By Lemma 13.0.10 the function \(h : [\theta_k, 2\pi - \theta_k] \to C_{\theta_k}\) is a bijection. Therefore we have \(\theta = h^{-1}(u,v) \in [\theta_k, 2\pi - \theta_k]\). Accordingly

\[f(x,y) \equiv (r,\theta) \in [a_j,b_j] \times [\theta_k, 2\pi - \theta_k] \subset [a_k,b_k] \times [\theta_k, 2\pi - \theta_k] \equiv K_k.\]
Since \((x, y) \in H\) is arbitrary, it follows that \(f(H) \subset K_k\). On the other hand \((K_k)_b \subset K_{k+1}\) where \(b = (a_k - a_{k+1}) \land (b_k + b_{k+1}) \land (\theta_k - \theta_{k+1})\). Hence \(K_k \subset K_{k+1} \subset B\). This proves that \(f(H) \Subset B\).

We next prove that \(H_k \Subset A\) for each \(k \geq 1\). Let \(k \geq 1\) and \(a \in (0, a_k \sin \theta_k)\) be arbitrary. From expression 13.0.42 we see that \(d((x, y), R_+^+) \geq a_k \sin \theta_k\) for each \((x, y) \in H_k \equiv g(K_k)\). Thus \(d((H_k)_a, R_+^+) \geq a_k \sin \theta_k\). Therefore \(d((H_k)_a, R_+^+) \geq a_k \sin \theta_k - a > 0\). Hence \((H_k)_a \subset A\) follows that \(H_k \Subset A\).

We will now prove that \(1_{H_k} \uparrow 1_A\) in measure. To that end, let \(M\) be any integrable subset of \(R^2\). Let \(\epsilon > 0\) be arbitrary. Then there exists \(q \geq 1\) so large that \(\mu(MB_q^e) < \epsilon\), where \(B_q \equiv [-q, q]^2\). Let \(k \geq 1\) be so large that \(4q_a_k \sin \theta_k < \epsilon\). From the previous paragraph we see that \(H_k \subset (d(\cdot, R_+^+) \geq a_k \sin \theta_k)\). Therefore \(\mu(B_q H_k^e) \leq \mu([-q, q] \times [-a_k \sin \theta_k, a_k \sin \theta_k]) = 4q_a_k \sin \theta_k < \epsilon\). Hence

\[
\mu((A - H_k)M) \leq \mu(MH_k^e) \leq \mu(MB_q^e) + \mu(B_q H_k^e) \leq \epsilon + \epsilon = 2\epsilon.
\]

Consequently \(\mu(|1_A - 1_{H_k}|) < \epsilon)M < 2\epsilon\). Since \(\epsilon > 0\) and the integrable set \(M\) is arbitrary, we have \(1_{H_k} \uparrow 1_A\) in measure.

All the conditions in the hypothesis of Lemma 13.0.8 have thus been verified. Accordingly, for each \(X \subset C(R^2)\), the function \(1_B X(g)|J|\) is integrable, with

\[
\int \int_A X(x, y) dx dy = \int \int_B X(r \cos \theta, r \sin \theta) rdr d\theta.
\]  \hfill (13.0.44)

Since \(A\) and \(B\) are full sets of \(R^2\) and \([0, \infty) \times [0, 2\pi]\) respectively, equality \(13.0.44\) yields

\[
\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} X(x, y) dx dy = \int_0^{2\pi} \int_0^{\infty} X(r \cos \theta, r \sin \theta) rdr d\theta
\]  \hfill (13.0.45)

for each \(X \subset C(R^2)\). By Theorem 13.0.9 equality \(13.0.45\) therefore holds also for each integrable function \(X\) on \(H^n\). \(\square\)

**Corollary 13.0.12.** (Integrability of convolution of two integrable functions). Let \(X, Y\) be integrable functions on \(R^n\). Define the function \(Z : R^{2n} \rightarrow R\) by \(Z(u, v) \equiv X(u - v)Y(v)\) where

\[
\text{domain}(Z) \equiv \{(u, v) \in R^{2n} : u - v \in \text{domain}(X) \text{ and } v \in \text{domain}(Y)\}.
\]

Then \(Z\) is an integrable function on \(R^{2n}\). Hence \(X \ast Y \equiv \int X(\cdot - v)Y(v)dv\) is an integrable function on \(R^n\) by Fubini’s Theorem.

**Proof.** Define the function \(W : R^{2n} \rightarrow R\) by \(W(x, y) \equiv X(x)Y(y)\) for each \((x, y)\) in the full set \(\text{domain}(W) \equiv \text{domain}(X) \times \text{domain}(Y)\). By Proposition 4.10.7 the function \(W\) is integrable on \(R^{2n}\). Now define the function \(g : R^{2n} \rightarrow R^{2n}\) by \(g(u, v) \equiv (u - v, v)\). In particular \(g\) has the Jacobian \(J \equiv 1\) on \(R^{2n}\) and has an inverse function \(f\) defined by \(f(x, y) = (x + y, y)\). The conditions in Lemma 13.0.8 are routinely verified. Accordingly \(W(g) \equiv W \circ g\) is an integrable function on \(R^{2n}\), where

\[
\text{domain}(W(g)) \equiv \{(u, v) \in R^{2n} : g(u, v) \in \text{domain}(W)\}
\]
= \{ (u,v) \in \mathbb{R}^2 : (u-v,v) \in \text{domain}(X) \times \text{domain}(Y) \} = \text{domain}(Z)

Moreover, for each \((u,v) \in \text{domain}(W(g))\), we have \(W(g(u,v)) \equiv W(u-v,v) \equiv X(u-v)v \cdot Y(v) \equiv Z(u,v)\). Thus \(Z = W(g)\) and so \(Z\) is integrable. The corollary is proved. \(\square\)
Chapter 14

Taylor’s Theorem

We present the proof of Taylor’s Theorem from [Bishop and Bridges 1985], which is then extended to higher dimension in the next corollary.

Theorem 14.0.1. (Taylor’s Theorem) Let $D$ be a non-empty open interval in $\mathbb{R}$. Let $f$ be a complex-valued function on $D$. Let $n \geq 0$ be arbitrary. Suppose $f$ has continuous derivatives up to order $n$ on $D$. For $k = 1, \ldots, n$ write $f^{(k)}$ for the $k$-th derivative of $f$.

Let $t_0 \in D$ be arbitrary, and define

$$r_n(t) \equiv f(t) - \sum_{k=0}^{n} f^{(k)}(t_0)(t - t_0)^k / k!$$

for each $t \in D$. Then the following holds.

1. If $|f^{(n)}(t) - f^{(n)}(t_0)| \leq M$ on $D$ for some $M > 0$, then $|r_n(t)| \leq M|t - t_0|^n / n!$

2. $r_n(t) = o(|t - t_0|^n)$ as $t \to t_0$. More precisely, suppose $\delta_{f,n}$ is a modulus of continuity of $f^{(n)}$ at the point $t_0$. Let $\epsilon > 0$ be arbitrary. Then $|r_n(t)| < \epsilon|t - t_0|^n$ for each $t \in R$ with $|t - t_0| < \delta_{f,n}(n!\epsilon)$.

3. If $f^{(n+1)}$ exists on $D$ and $|f^{(n+1)}| \leq M$ for some $M > 0$, then $|r_n(t)| \leq M|t - t_0|^n / (n+1)!$.

Proof. 1. Let $t \in D$ be arbitrary. Integrating repeatedly, we obtain

$$|r_n(t)| = \left| \int_{t_0}^{t} \int_{t_0}^{t_1} \cdots \int_{t_0}^{t_{n-1}} (f^{(n)}(t_n) - f^{(n)}(t_0)) dt_n \cdots dt_2 dt_1 \right|$$

$$\leq \left| \int_{t_0}^{t} \int_{t_0}^{t_1} \cdots \int_{t_0}^{t_{n-1}} M dt_n \cdots dt_2 dt_1 \right| = M|t - t_0|^n / n!,$$

where we note that all the integration variables $t_1, \ldots, t_n$ are in the interval $D$.

2. Let $\epsilon > 0$ be arbitrary. Consider each $t \in R$ with $|t - t_0| < \delta_{f,n}(n!\epsilon)$. Then $|f^{(n)}(t) - f^{(n)}(t_0)| \leq n!\epsilon$ for each $t \in D \equiv (t_0 - \delta_{f,n}(n!\epsilon), t_0 + \delta_{f,n}(n!\epsilon))$. By Assertion 1, we then have $|r_n(t)| \leq \epsilon|t - t_0|^n$ for $t \in D$.
3. Integrating repeatedly, we obtain
\[
 r_n(t) = \left| \int_0^t f^{(n+1)}(t) \, dt \right| \\
 \leq \left| \int_0^t \cdots \int_0^t M \, dt \right| = M|t - t_0|^{n+1}/(n+1)!
\]

\[\Box\]

**Corollary 14.0.2.** (Taylor’s Theorem for functions with \(m\) variables which have continuous partial derivatives up to second order). For ease of notations, we state and prove the corollary only for degree \(n = 2\); in other words, only for a twice continuously differentiable, real-valued, function \(f\). Let \(D\) be a non-empty convex open subset in \(\mathbb{R}^m\). Let \(f\) be a real-valued function on \(D\). Suppose \(f\) has continuous partial derivatives up to order 2 on \(D\). In other words, the partial derivatives

\[ f_i \equiv \frac{\partial f}{\partial x_i} \]

and

\[ f_{i,j} \equiv \frac{\partial^2 f}{\partial x_i \partial x_j} \]

are continuous functions on \(D\), for arbitrary \(i, j \in \{1, \cdots, m\}\). Let \(\delta_{f,2}\) be a common modulus of the these second order partial derivatives \(f_{i,j}\). Let \(\bar{x} \equiv (x_1, \cdots, x_m) \in D\) and \(\bar{y} \equiv (y_1, \cdots, y_m) \in D\) be arbitrary, and define

\[ r_{f,2}(\bar{y}) \equiv f(\bar{y}) - \left\{ f(\bar{x}) + \sum_{i=1}^m f_i(\bar{x})(y_i - x_i) \right\} + \frac{1}{2} \sum_{j=1}^m \sum_{i=1}^m f_{i,j}(\bar{x})(y_j - x_j)(y_i - x_i) \]

Let \(\varepsilon > 0\). Suppose

\[ |\bar{y} - \bar{x}| < \delta_{f,2}(m^{-2}\varepsilon). \]

Then

\[ |r_{f,2}(\bar{y})| \leq 2^{\varepsilon} |\bar{y} - \bar{x}|^2. \]

**Proof.** Define the function

\[ g(t) \equiv f(t(\bar{y} - \bar{x}) + \bar{x}) \]

for each \(t \in [0, 1]\). Then the Chain Rule yields

\[ g'(t) = \sum_{i=1}^m f_i(t(\bar{y} - \bar{x}) + \bar{x})(y_i - x_i) \]

and

\[ g''(t) = \sum_{j=1}^m \sum_{i=1}^m f_{i,j}(t(\bar{y} - \bar{x}) + \bar{x})(y_j - x_j)(y_i - x_i). \]

By hypothesis, the partial derivatives \(f_{i,j}\) have a common modulus of continuity \(\delta_{f,2}\) at the point \(\bar{x}\), for each \(i, j = 1, \cdots, m\). Let \(\varepsilon > 0\) be arbitrary.

\[ |\bar{y} - \bar{x}| < \delta_{f,2}(m^{-2}\varepsilon). \]
Hence
\[ |g''(1) - g''(0)| = \left| \sum_{j=1}^{m} \sum_{i=1}^{m} (f_{j,i}(y) - f_{j,i}(x))(y_j - x_j)(y_i - x_i) \right| \]
\[ \leq \left| \sum_{j=1}^{m} \sum_{i=1}^{m} m^{-2} \epsilon (y_j - x_j)(y_i - x_i) \right|. \]
\[ \leq m^{-2} \epsilon m^2 |y - x|^2 = \epsilon |y - x|^2. \]

Therefore
\[ |r_{f,2}(\bar{y})| \equiv |f(\bar{y}) - f(\bar{x}) - \sum_{i=1}^{m} f_i(\bar{x})(y_i - x_i) - \sum_{j=1}^{m} \sum_{i=1}^{m} f_{j,i}(\bar{x})(y_j - x_j)(y_i - x_i) | \]
\[ = |g(1) - g(0) - g'(0) - 2^{-1} g''(0)| = \left| \int_{s=0}^{1} (g'(s) - g'(0) - g''(0)s)ds \right| \]
\[ = \left| \int_{s=0}^{1} \int_{u=0}^{s} (g''(u) - g''(0))du \right| ds \leq \epsilon |\bar{y} - \bar{x}|^2 \int_{s=0}^{1} \int_{u=0}^{s} ds \]
\[ = 2^{-1} \epsilon |\bar{y} - \bar{x}|^2, \]

as alleged. \qed
