We show that the supersymmetric algebra of Witten’s quantum mechanics is invariant under a given point canonical transformation. It is shown that Witten’s supersymmetric quantum mechanics can be isospectral or not to the seed Hamiltonian depending on the space coordinate you work on. We illustrate our results by generating a new class of exactly solvable supersymmetric partner Hamiltonians which are not isospectral to the seed Hamiltonian.

Keywords: Supersymmetric quantum mechanics, Point canonical transformations, Hamiltonian
If we add and subtract to equation (3) the term \(d[W(\tilde{x})\phi_n^{-}(\tilde{x})]/d\tilde{x}\) we have

\[
\frac{d}{d\tilde{x}} \left[ \phi_n^{-}(\tilde{x}) \right] + W \phi_n^{-}(\tilde{x}) + \left( 2g' + \frac{q'}{q} - \frac{W}{g} \right) \frac{d\phi_n^{-}(\tilde{x})}{d\tilde{x}} + \left[ \left( \frac{q''}{q'} \frac{g'}{g} - \frac{dW}{d\tilde{x}} \right) - 2m(q')^2 U(q(\tilde{x})) - \varepsilon_n \right] \phi_n^{-}(\tilde{x}) = 0. \tag{4}
\]

Adding and subtracting \(2m\varepsilon_0\) in equation (10) we have

\[
- \frac{dW}{d\tilde{x}} - 2m \left( (U(q(\tilde{x})) - \varepsilon_n) \right) = E_n - W^2. \tag{11}
\]

Since the superpotential has to be independent of the index \(n\) we have to choose \(E_n = 2m(\varepsilon_n - \varepsilon_0)\). Note that we have set the energy of the ground state of \(\hat{H}_-\) to zero. The energy spectra of the two partner Hamiltonians \(\hat{H}_\pm\) are the same, the only exception is the ground state of \(\hat{H}_-\), which lacks a counter part in \(\hat{H}_+\). The superpotential is obtained by solving the following Ricatti differential equation

\[
- \frac{dW}{d\tilde{x}} - 2mU_-(q(\tilde{x})) = -W^2. \tag{12}
\]

where \(U_-(q(\tilde{x})) = U(q(\tilde{x})) - \varepsilon_0\). One can easily verify that a particular solution of equation (12) is given in terms of the ground state wave function by

\[
W(\tilde{x}) = -\frac{1}{\psi_0(q)} \frac{dq}{dq} q'. \tag{13}
\]

Therefore, the solutions of the two partner Hamiltonians with potentials \(U_\pm(q(x)) = W^2 \pm dW/d\tilde{x}\) are related by \(\phi_n^-(\tilde{x}) = \psi_n(x)\) and \(\phi_n^+(\tilde{x}) = \hat{A}\phi_n^-(\tilde{x})/\sqrt{E_n}\) for \(n = 0, 1, 2, \ldots\). Thus, the corresponding zero energy is missing from the spectrum of \(\hat{H}_+\). At this stage, it is natural to ask whether it is possible to find another point canonical transformation that will result in a constant term on the left hand side of equation (5), which will be identified with the energy \(E_n\). We find that this is indeed the case if we set

\[
\left( \frac{dq}{dq} \right)^2 U(q) = \frac{m}{\sigma^2}. \tag{14}
\]

where \(\sigma^2\) is an adjustable parameter. If we substitute equation (14) into equation (5) we have

\[
\frac{g''}{q'} - \frac{q'' g'}{q'^2} - \frac{dW}{d\tilde{x}} - 2m \left( \frac{m}{\sigma^2} - (q')^2 \varepsilon_n \right) = E_n - W^2. \tag{15}
\]

If we choose \(W = g'/g + \xi(\tilde{x})\) in equation (15) we have

\[
- \frac{d\xi}{d\tilde{x}} - 2m \left( \frac{m}{\sigma^2} - \frac{m\varepsilon_n}{\sigma^2 U(q)} \right) = E_n - \frac{q''}{q'^2} \xi - \xi^2. \tag{16}
\]

In order to solve equation (16) we need to specify first the potential \(U(q)\) since the potential depends on the parameter.
Therefore, we will solve equation (16) for the case of the harmonic oscillator potential, i.e. $U(q) = m\omega^2 q^2/2$. Using equation (14) we have the following first order differential equation

$$\sqrt{U(q)} dq = \frac{\sqrt{m}}{\sigma} d\tilde{x}$$ \hspace{1cm} (17)

From equation (17) we obtain $x = q(\tilde{x}) = \sqrt{2\sqrt{2}\tilde{x}/\omega}\sigma$. Note that this coordinate transformation is defined only for $0 < \tilde{x} < \infty$. Using the solution of equation (17) we obtain for the potential energy $U(q(\tilde{x})) = 2m\omega\tilde{x}/\sigma$ and the term $q''/q = -1/2\tilde{x}$. Substituting these two terms in equation (16) we have

$$-\frac{d\xi}{d\tilde{x}} - 2m \left( \frac{m^3}{\xi^2} - \frac{\xi_n}{\xi_0^2} - \frac{m^3}{\xi^2} + \frac{m}{2\sqrt{2}\tilde{x}} \right) = E_n \frac{1}{2\tilde{x}} \xi - \xi^2$$ \hspace{1cm} (18)

Since the superpotential has to be independent of the index $n$ we must choose $\sigma = \xi_n/m$. Adding and subtracting $2m^4/\xi_0^2$ into equation (18) we have

$$-\frac{d\xi}{d\tilde{x}} - 2m \left( \frac{m^3}{\xi^2} + \frac{m^3}{\xi_0^2} - \frac{m}{2\sqrt{2}\tilde{x}} \right) = E_n \frac{1}{2\tilde{x}} \xi - \xi^2$$ \hspace{1cm} (19)

Choosing $E_n = 2m^4(\xi_0^{-2} - \xi_n^{-2})$ in equation (19) we get the following Ricatti differential equation for $\xi$

$$-\frac{d\xi}{d\tilde{x}} - 2m \left( \frac{m^3}{\xi_0^2} + \frac{2m^2}{\sqrt{2}\tilde{x}} \right) = \frac{1}{2\tilde{x}} \xi - \xi^2$$ \hspace{1cm} (20)

One can easily verify that a particular solution to equation (20) is given by $\xi(\tilde{x}) = 2\sqrt{2}m^2/\omega$. The general solution of equation (20) might be obtained once we know a particular solution and will give us a family of superpotentials. If we let $\xi(\tilde{x}) = 2\sqrt{2}m^2/\omega + 1/z(\tilde{x})$ and substitute in equation (20) we get the following linear differential equation for $z$, i.e.

$$\frac{dz}{d\tilde{x}} = \left( \frac{1}{2\tilde{x}} - \frac{4\sqrt{2}m^2}{\omega} \right) z - 1.$$ \hspace{1cm} (21)

The general solution of equation (21) is given by

$$z(\tilde{x}) = \frac{1}{2m} \sqrt{\frac{\omega\pi\tilde{x}}{2}} e^{-4\sqrt{2}m^2\tilde{x}/\omega} Erfi \left[ \sqrt{\frac{4\sqrt{2}m^2\tilde{x}}{\omega}} \right] + C\sqrt{\frac{\pi}{2}} e^{-4\sqrt{2}m^2\tilde{x}/\omega}$$ \hspace{1cm} (22)

where $Erfi[\tilde{x}]$ is the imaginary error function and $C$ is an integration constant. We will restrict ourselves to use only the particular solution such that the superpotential for our case is given by $W(\tilde{x}) = q''/2q + \xi = -1/4\tilde{x} + 2\sqrt{2}m^2/\omega$.

We are now ready to obtain the supersymmetric partner Hamiltonians for the harmonic oscillator with their energy spectra and eigenfunction using the standard rules of supersymmetric quantum mechanics. We will set $m = \omega = 1$ for simplicity. The results of using the point canonical transformation given by equation (17) are as follows:

$$E_n = 8 \left( 1 - \frac{1}{(2n + 1)^2} \right)$$ \hspace{1cm} (23)

$$U_-(\tilde{x}) = 8 - \frac{3}{16\tilde{x}^2} - \frac{\sqrt{2}}{\tilde{x}}$$ \hspace{1cm} (24)

$$U_+(\tilde{x}) = 8 + \frac{5}{16\tilde{x}^2} - \frac{\sqrt{2}}{\tilde{x}}$$ \hspace{1cm} (25)

$$\phi_n^{(-)}(\tilde{x}) = \left( \frac{2^{9/2} \tilde{x}}{(2n + 1)^{5/2}} \right)^{1/4} H_n \left( \frac{4\sqrt{2}\tilde{x}}{\sqrt{2n+1}} \right) e^{-2\sqrt{2}\tilde{x}/(2n+1)}$$ \hspace{1cm} (26)

$$\phi_n^{(+)}(\tilde{x}) = \frac{n + 3/2}{2\sqrt{2}(n + 3/2)^{2 - 1/4}} A\phi_n^{(-)}$$ \hspace{1cm} (27)

where $H_n(q)$ are the Hermite polynomial. Again, the corresponding zero energy is missing from the spectrum of $H_+$. Interestingly, we see from equation (23) that the energy spectra of the partner Hamiltonians $H_\pm$ is not isospectral to the reference Hamiltonian, i.e. $\xi_n = n + 1/2$.

Figure (1) shows the graph of $|\phi_n^{(-)}|^2$ as a function of $\tilde{x}$. We see that all the eigenfunctions for the partner Hamiltonian $H_-$ are well behaved at the origin, i.e. $\lim_{\tilde{x} \to 0} \phi_n^{(-)} \to 0$.

In figures (2) and (3) we show the graphs of $|\phi_n^{(+)}|^2$ as a function of $\tilde{x}$ for $n$ even and $n$ odd, respectively. From the figures we see that half of the eigenfunctions for the partner Hamiltonian $H_+$ are well behaved at the origin, i.e. $\lim_{\tilde{x} \to 0} \phi_n^{(+)} \to 0$.

Note also that the supersymmetric partner Hamiltonian $H_+$ has exactly the same structure as the radial equation (20). For this case, only the solutions given by $\phi_n^{(+)}$ satisfy the correct boundary conditions for a Hydrogen like potential.
FIG. 2: The graph shows the probability distributions for \( n = 0, 2, 4, 6 \) for the stationary states of the partner Hamiltonian \( \hat{H}_1 \). Note how the \(|\phi_2n|^2\) blows up as \( \tilde{x} \to 0 \). Nevertheless, the eigenfunctions \( \phi_2n^{(+)\ } \) are normalizable functions.

FIG. 3: The graph shows the probability distributions for \( n = 1, 3, 5, 7 \) for the stationary states of the partner Hamiltonian \( \hat{H}_1 \). Note how the \(|\phi_2n+1|^2\) goes to zero at the origin.

In conclusion, we have demonstrated that for a given potential \( U(x) \) and energy spectra \( E_n \) the algebra of unbroken supersymmetric quantum mechanics can be obtained through a coordinate transformation given by \( x = q(\tilde{x}) \) where \( q(\tilde{x}) = S^{-1}(\sqrt{m\tilde{x}/\sigma}) \) where \( S(y) = \int \sqrt{U(y)} \, dy \).

This coordinate transformation is used to generate a new class of supersymmetric partner Hamiltonians which are not isospectral to the seed Hamiltonian, in contrast to standard supersymmetric quantum mechanics. This results provide a new way to obtain exactly solvable potentials in one dimensional quantum mechanics.

We should point out that there might be other point canonical transformations that could result in a constant term in the left hand side of equation (5) that could be interpreted as the energy \( E_n \) and that will result in other classes of supersymmetric partner Hamiltonians.
