Hence their coefficients must be equal in Equation (1) and (6). Since, we obtain $q$ defining the generalized momentum conjugate to $L$

The relation of Lagrangian function $L(q, \dot{q}, t)$ with Hamilton’s function is defined by the following equation

$$H = p\dot{q} - L(q, \dot{q}, t) = p\dot{q} - \left[W(q, \dot{q}, t) + jZ(q, \dot{q}, t)\right]$$

Taking total differentiation of equation (2), we obtain

$$dH = pd\dot{q} + qdp - \frac{\partial L}{\partial \dot{q}}dq - i\frac{\partial L}{\partial q}dq - \frac{\partial L}{\partial t}dt$$

Defining the generalized momentum conjugate to $q$ as

$$p = \frac{\partial L}{\partial \dot{q}}$$

and using

$$\frac{\partial L}{\partial q}dq = \frac{d}{dt}\frac{\partial L}{\partial \dot{q}}dq = \dot{p}dq$$

we obtain

$$dH = \dot{p}dq - \dot{q}dp - (\frac{\partial L}{\partial t}dt)$$

Since, $q$ and $p$ are independent variables, the variations of $dq$, $dp$ and $dt$ are mutually independent. As a result their coefficients must be equal in Equation (1) and (6). Hence

$$\dot{q} = \frac{\partial U}{\partial p} + j\frac{\partial V}{\partial p}$$

$$\dot{p} = -\frac{\partial U}{\partial q} - j\frac{\partial V}{\partial q}$$

and

$$\frac{\partial H}{\partial t} = -\frac{\partial L}{\partial t}$$

These first-order differential equations are called as Hamilton’s canonical equation of motion. By considering a complex Hamilton function of the form $H(q, p, t) = U(q, p, t) + jV(q, p, t)$, we obtained the Hamilton’s canonical equation of motion for the Hamilton’s function $H(q, p, t)$ defined on complex phase space. In order to understand the Hamilton dynamics in complex phase-space, we consider an example of simple harmonic motion defined by the following Hamilton’s function $H(q, p, t)$ with imaginary part equal to zero,

$$H(q, p, t) = U(q, p, t) + jV(q, p, t) = \frac{P^2}{2m} + \frac{k}{2}q^2$$

From equation (7,8,9), we have

$$\dot{q} = \frac{\partial H}{\partial p} = \frac{p}{m}$$

$$\dot{p} = -\frac{\partial H}{\partial q} = -kq$$

Figure (1(a)) shown the phase space trajectory of simple harmonic motion.

Consider an example of simple harmonic motion defined by the following complex Hamilton’s function $H(q, p, t)$ with non-zero imaginary part,

$$H(q, p, t) = U(q, p, t) + jV(q, p, t) = \frac{P^2}{2m} + j\frac{k}{2}q^2$$

The corresponding equation of motion can be written as

$$\dot{q} = \frac{\partial H}{\partial p} = \frac{p}{m}$$

$$\dot{p} = -\frac{\partial H}{\partial q} = -jkq$$

$$\frac{\partial H}{\partial t} = 0$$

Figure (1(b),1(c)) shown the trajectory of simple harmonic motion on complex phase space.

Let $F(q, p)$ and $H(q, p)$, with $H(q, p) = U(q, p) + jV(q, p)$, be two functions on phase space. Then the Poisson bracket is given by

$$[F, H] = [F, U] + j[F, V]$$

In particular, $[q, q] = [q, q] + j[\dot{q}, p_k] = j\delta_{ik}$ and $[\dot{q}, jp_k] = [\dot{q}, \dot{q}] + j[\dot{q}, \dot{p}_k] = j\delta_{ik}$. With the help of Hamilton’s equations (7,8,9), we have

$$\frac{dF}{dt} = [F, H] + \frac{\partial F}{\partial t} = [F, U] + j[F, V] + \frac{\partial F}{\partial t}$$
Consider a bivariate Hamilton function \( H'(q, p) \) associated to the univariate Hamilton function \( H(z) \) via \( H'(x, y) = U(x, y) + jV(x, y) = H(z)|_{z=x+jy} \). The total differential is defined as
\[
dH' = \frac{\partial H'(q, p)}{\partial q} dq + \frac{\partial H'(q, p)}{\partial p} dp
\]

Using \( H'(q, p) = U(q, p) + jV(q, p) \), we obtain
\[
dH' = \frac{\partial U(q, p)}{\partial q} dq + j \frac{\partial V(q, p)}{\partial q} dq + \frac{\partial U(q, p)}{\partial p} dp + j \frac{\partial U(q, p)}{\partial p} dp
\]

Since, \( z = q + jp \) and \( z^* = q - jp \), we have
\[
dz = dq + j dp

dz^* = dq - j dp
\]
and
\[
dq = \frac{1}{2}(dz + dz^*)
dp = \frac{1}{2j}(dz - dz^*)
\]

The total differential \( dH \) of a complex valued Hamilton function \( H(z) \) can be expressed as
\[
dH = \frac{\partial H(z)}{\partial z} dz + \frac{\partial H(z)}{\partial z^*} dz^* \tag{11}
\]
where the Wirtinger derivatives are defined by
\[
\frac{\partial}{\partial z} = \frac{1}{2} \left[ \frac{\partial}{\partial q} - j \frac{\partial}{\partial p} \right] \tag{12}
\]
\[
\frac{\partial}{\partial z^*} = \frac{1}{2} \left[ \frac{\partial}{\partial q} + j \frac{\partial}{\partial p} \right] \tag{13}
\]

Using \( H = pq - L \), we have
\[
dH = pdq + \dot{q} dp - \frac{\partial L}{\partial z} dz^1 - \frac{\partial L}{\partial z^*} dz^{1*} \tag{14}
\]
where
\[
z^1 = (q + jq)
z^{1*} = (q - jq)
dq = \frac{1}{2}(dz^1 + dz^{1*})
d\dot{q} = \frac{1}{2j}(dz^1 - dz^{1*})
\]

Equation (14) becomes
\[
dH = pdq + \dot{q} dp - \frac{1}{2} \left( \frac{\partial}{\partial q} - j \frac{\partial}{\partial q} \right) L(dq + j\dot{q}) - \frac{1}{2} \left( \frac{\partial}{\partial q} + j \frac{\partial}{\partial q} \right) L(dq - j\dot{q}) \tag{15}
\]

FIG. 1: Trajectories of simple harmonic motion on phase space \((q, p)\), \((jq, p)\) and \((q, jp)\).
Using equation (4) and (5), equation (15) can be rewritten as

\[ dH = \dot{q}dp - \dot{p}dq \]  

(16)

Using \( dq = (dz + dz^*)/2 \), and \( dp = (dz - dz^*)/2j \), we have

\[ dH = \frac{\dot{q}}{2j}(dz - dz^*) - \frac{\dot{p}}{2}(dz + dz^*) \]  

(17)

or

\[ dH = \left( \frac{\dot{q}}{2j} - \frac{\dot{p}}{2} \right)dz - \left( \frac{\dot{q}}{2j} + \frac{\dot{p}}{2} \right)dz^* \]  

(18)

Comparing the coefficient of \( dz \) and \( dz^* \) in equation (18) with equation (11), we obtain

\[ \dot{q} = j \left( \frac{\partial}{\partial z} - \frac{\partial}{\partial z^*} \right)H \]  

(19)

\[ \dot{p} = - \left( \frac{\partial}{\partial z} + \frac{\partial}{\partial z^*} \right)H \]  

(20)

Equation (19-20) are Hamilton equation of motion in complex phase space. Substituting back the Wirtinger derivatives (equation (12,13)) in equation (19-20), we obtain Hamilton equation of motion in real phase space;

\[ \dot{q} = \frac{\partial H}{\partial p} \]  

(21)

\[ \dot{p} = - \frac{\partial H}{\partial q} \]  

(22)

Equation (19-20) are basic Hamilton’s canonical equation of motion which can be used to understand the dynamics of particles in complex phase space.
