THE CONSTANT FACTOR IN THE ASYMPTOTIC FOR PRACTICAL NUMBERS

ANDREAS WEINGARTNER

Abstract. An integer \( n \geq 1 \) is said to be practical if every natural number \( m \leq n \) can be expressed as a sum of distinct positive divisors of \( n \). The number of practical numbers up to \( x \) is asymptotic to \( cx/\log x \), where \( c \) is a constant. In this note we show that \( c = 1.33607 \).

1. Introduction

Following Srinivasan [7], we call an integer \( n \geq 1 \) practical if every natural number \( m \leq n \) can be expressed as a sum of distinct positive divisors of \( n \). Let \( P(x) \) be the number of practical numbers up to \( x \). Margenstern [4] conjectured that \( P(x) \) is asymptotic to \( cx/\log x \) and gave the empirical estimate \( c \approx 1.341 \). This conjecture was confirmed with the estimate [9, Thm. 1.1]

\[
P(x) = \frac{cx}{\log x} \left\{ 1 + O\left( \frac{\log \log x}{\log x} \right) \right\},
\]

(1)

The constant factor \( c \) is given by the sum of an infinite series [11, Thm. 1],

\[
c = \frac{1}{1 - e^{-\gamma}} \sum_{n \in P} \frac{1}{n} \left( \sum_{p \leq \sigma(n)+1} \frac{\log p}{p-1} - \log n \right) \prod_{p \leq \sigma(n)+1} \left( 1 - \frac{1}{p} \right),
\]

(2)

where \( \gamma \) is Euler’s constant, \( P \) is the set of practical numbers, \( p \) runs over primes and \( \sigma(n) \) is the sum of the positive divisors of \( n \). As a consequence, Corollary 1 of [11] states that \( 1.311 < c < 1.693 \). The purpose of this note is to establish a more precise estimate for \( c \).

Theorem 1. We have \( 1.336073 < c < 1.336077 \).

While in [11] we used the extremal behavior of \( \sigma(n) \) to estimate the contribution to (2) from large \( n \), here we apply the new identity in Lemma 2 together with the multiplicativity of \( \sigma(n) \). As a result, the remaining gap in Theorem 1 is almost entirely due to the error term of Lemma 4 when estimating the inner sum over primes in (2).

2010 Mathematics Subject Classification. 11N25, 11N37.
2. Lemmas

As Lemmas 1 and 2 apply to other sets of numbers besides the practical numbers, we recall the general setup from [10].

Let \( \theta \) be an arithmetic function, \( \theta : \mathbb{N} \to \mathbb{R} \cup \{\infty\} \). We write \( B \) to denote the set of positive integers containing \( n \leq B \) if and only if \( \theta \) satisfies the following conditions:

\[
\theta : \mathbb{N} \to \mathbb{R} \cup \{\infty\}, \quad \theta(1) \geq 2, \quad \theta(n) \geq P^+(n) \quad (n \geq 2),
\]

where \( P^+(n) \) denotes the largest prime factor of \( n \). The assumptions in (3) only eliminate the trivial case \( B = \{1\} \). Let \( B(x) \) be the number of positive integers \( n \leq x \) in \( B \). We write \( \chi(n) \) to denote the characteristic function of the set \( B \).

Sierpinski [6] and Stewart [8] found that if \( \theta(n) = \sigma(n) + 1 \), then \( B = \mathcal{P} \).

Lemma 1. Let \( \theta \) satisfy (3). For \( \text{Re}(s) > 1 \) we have

\[
\sum_{n \geq 1} \frac{\chi(n)}{n^s} \prod_{p \leq \theta(n)} \left(1 - \frac{1}{p^s}\right) = 1.
\]

If \( B(x) = o(x) \), the equation also holds at \( s = 1 \).

Proof. The case \( \text{Re}(s) > 1 \) is [11, Lemma 1]. The case \( s = 1 \) is [10, Theorem 1]. When \( s = 1 \), the series actually converges for any \( B \) to a value \( L \in [0, 1] \) (see [10, Lemma 4]), with \( L = 1 \) if and only if \( B(x) = o(x) \) (see [10, Theorem 1]). \( \square \)

Lemma 2. Let \( q \) be prime and \( h \in \mathbb{N} \). For \( \text{Re}(s) > 1 \) we have

\[
\sum_{n \geq 1} \frac{\chi(n)}{n^s} \prod_{p \leq \theta(n)} \left(1 - \frac{1}{p^s}\right) = \frac{1 - 1/q^h}{q^{hs}} \sum_{\theta(n) \geq q} \frac{\chi(n)}{n^s} \prod_{p \leq \theta(n)} \left(1 - \frac{1}{p^s}\right).
\]

If \( B(x) = o(x) \), the equation also holds at \( s = 1 \).

Proof. We first assume \( \text{Re}(s) > 1 \). Each natural number \( m \) with prime factorization \( m = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_k^{\alpha_k}, \ p_1 < p_2 < \ldots < p_k \), factors uniquely as \( m = nr \), where \( n = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_j^{\alpha_j} \in B \) and \( p_{j+1} > \theta(n) \) for some \( j \) with \( 0 \leq j < k \), or \( m = n \in B \) and \( r = 1 \). If \( q^h || m \) then either \( q^h || n \) or \( q^h || r \). Accordingly

\[
\sum_{m \geq 1} \frac{1}{m^s} = \sum_{n \geq 1} \frac{\chi(n)}{n^s} \prod_{p \leq \theta(n)} \left(1 - \frac{1}{p^s}\right)^{-1} + \sum_{n \geq 1} \frac{\chi(n)}{n^s} \frac{1}{q^{hs}} \prod_{p \neq q} \left(1 - \frac{1}{p^s}\right)^{-1}.
\]
On the other hand,

$$\sum_{m \geq 1} \frac{1}{m^s} = \frac{1}{q^h} \prod_{p \neq q} \left(1 - \frac{1}{p^s}\right)^{-1} = \frac{1-1/q^s}{q^h} \prod_{p \geq 2} \left(1 - \frac{1}{p^s}\right)^{-1}. $$

Setting the right-hand sides equal and dividing by $\zeta(s) = \prod_{p \geq 2} \left(1 - \frac{1}{p^s}\right)^{-1}$ yields

$$\frac{1-1/q^s}{q^h} = \sum_{n \geq 1} \chi(n) n^s \prod_{p \leq \theta(n)} \left(1 - \frac{1}{p^s}\right) + \frac{1-1/q^s}{q^h} \sum_{n \geq 1} \chi(n) n^s \prod_{p \leq \theta(n)} \left(1 - \frac{1}{p^s}\right).$$

For $\text{Re}(s) > 1$, the result follows now from Lemma 1. To show that the last equation, and hence Lemma 2, also holds at $s = 1$ if $B(x) = o(x)$, it suffices to show that the last two sums are continuous from the right at $s = 1$. We have

$$\prod_{p \leq \theta(n)} \left(1 - \frac{1}{p^s}\right) \asymp s - 1 + \frac{1}{\log \theta(n)},$$

uniformly for $n \geq 1$ and $1 \leq s \leq 2$, by [11, Eq. (24)]. Thus, uniformly for $1 \leq s \leq 2$,

$$\sum_{n > N} \frac{\chi(n)}{n^s} \prod_{p \leq \theta(n)} \left(1 - \frac{1}{p^s}\right) \ll \sum_{n > N} \frac{\chi(n)}{n^s} (s - 1) + \sum_{n > N} \frac{\chi(n)}{n^s} \frac{1}{\log \theta(n)},$$

say. Since $B(x) = o(x)$, partial summation shows that $G_N(s) = o(1)$ as $N \to \infty$, uniformly for $1 \leq s \leq 2$. We have $H_N(s) \leq H_N(1) = o(1)$ as $N \to \infty$, since the series in Lemma 1 converges when $s = 1$. It follows that $G_N(s) + H_N(s) = o(1)$ as $N \to \infty$, uniformly for $1 \leq s \leq 2$, which concludes the proof. \hfill $\square$

**Lemma 3.** Let $\theta(n) = \sigma(n) + 1$. We have

$$\sum_{n \geq 1} \frac{\chi(n)}{n} \log \left(\frac{\sigma(n)}{n}\right) \prod_{p \leq \theta(n)} \left(1 - \frac{1}{p}\right) = \sum_{n \geq 1} \frac{\chi(n)}{n} \sum_{q \leq \theta(n)} W_q \prod_{p \leq \theta(n)} \left(1 - \frac{1}{p}\right),$$

where $p$ and $q$ run over primes and

$$0 < W_q := \sum_{h \geq 1} \frac{1 - 1/q^h}{q^h} \log \left(\frac{1 - 1/q^{h+1}}{1 - 1/q}\right) < \frac{1}{q(q-1)}. $$
Proof. The multiplicativity of \( \sigma(n) \) and Lemma 2 yield

\[
\sum_{n \geq 1} \frac{\chi(n)}{n} \log \left( \frac{\sigma(n)}{n} \right) \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right)
= \sum_{n \geq 1} \frac{\chi(n)}{n} \sum_{q^h \mid n} \log \left( 1 + \frac{1}{q} + \cdots + \frac{1}{q^h} \right) \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right)
= \sum_{h \geq 2} \log \left( \frac{1 - 1/q^{h+1}}{1 - 1/q} \right) \sum_{n \geq 1} \frac{\chi(n)}{n} \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right)
= \sum_{q \geq 2} W_q \left( \sum_{n \geq 1} \frac{\chi(n)}{n} \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right) \right)
= \sum_{n \geq 1} \frac{\chi(n)}{n} \sum_{q \leq \theta(n)} W_q \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right).
\]

The convergence of these series follows from (1). We have

\[
0 < W_q < \sum_{h \geq 1} \frac{1 - 1/q^{h+1}}{q^h} \log \left( \frac{1}{1 - 1/q} \right) = \frac{\log(1 - 1/q)}{q} < \frac{1}{q(q - 1)}.
\]

\[\square\]

Lemma 4. Let

\[
\eta(x) = \sum_{p \leq x} \frac{\log p}{p - 1} - \log x + \gamma \quad (4)
\]

and

\[
\delta(x) = \sum_{p \leq x} \frac{\log p}{p} - \log x + \gamma + \sum_{p \geq 2} \frac{\log p}{p(p - 1)} = \eta(x) + \sum_{p > x} \frac{\log p}{p(p - 1)} \quad (5)
\]

We have

\[|\eta(x)| \leq M_k, \quad |\delta(x)| \leq M_k \quad (x \geq 2^k),\]

where \( M_k \) is given by

\[
\begin{array}{|c|c|c|c|}
\hline
k & M_k \times 10^5 & k & M_k \times 10^5 & k & M_k \times 10^5 \\
\hline
23 & 51.60 & 28 & 8.173 & 33 & 1.654 \\
24 & 36.80 & 29 & 6.377 & 34 & 1.101 \\
25 & 27.65 & 30 & 5.122 & 35 & 0.833 \\
26 & 17.60 & 31 & 3.143 & 36 & 0.569 \\
27 & 13.04 & 32 & 2.174 & 37 & 0.438 \\
\hline
\end{array}
\]

Table 1. The values of \( M_k \) are best possible apart from rounding.
Proof. Let $\vartheta(x) = \sum_{p \leq x} \log p$ and $\psi(x) = \sum_{p^i \leq x} \log p$. By Eq. (4.21) of Rosser and Schoenfeld [5], we have

$$
\delta(y) - \delta(x) = \frac{\vartheta(y) - y}{y} - \frac{\vartheta(x) - x}{x} + \int_x^y \frac{\vartheta(t) - t}{t^2} dt. \quad (6)
$$

Büthe [2, Thm. 2] showed that $-1.95\sqrt{x} \leq \vartheta(x) - x < -0.05\sqrt{x}$ for $1423 \leq x \leq 10^{19}$. Together with (6) we get, for $1423 \leq x \leq y \leq 10^{19}$,

$$
\delta(x) + \frac{x - \vartheta(x)}{x} - \frac{3.9}{\sqrt{x}} \leq \delta(y) \leq \delta(x) + \frac{x - \vartheta(x)}{x} - 0.05. \quad (7)
$$

Rosser and Schoenfeld [5, Thm. 13] found that $|\psi(x) - \vartheta(x)| < 1.4262\sqrt{x}$ for all $x > 0$. Dusart [3, Prop. 3.2] gives inequalities of the form $|\psi(x) - x| \leq \epsilon_i x$ for $x \geq e^{b_i}$. Hence

$$
\left| \frac{\vartheta(y) - y}{y} - \frac{\vartheta(x) - x}{x} \right| \leq \frac{1.4262}{\sqrt{e^{b_i/2}}} + \epsilon_i \quad (x \geq e^{b_i}),
$$

where the pairs $(b_i, \epsilon_i)$ take the values $(\log(10^{19}), 1.161 \times 10^{-7}), (45, 1.225 \times 10^{-8}), \ldots, (500, 1.215 \times 10^{-11})$, according to [3, Table 1]. Together with (6), we find that

$$
|\delta(y) - \delta(x)| \leq 2.630 \times 10^{-7} \quad (10^{19} = x \leq y \leq e^{600}). \quad (8)
$$

Finally, for $y \geq e^{600}$ we use Proposition 8 from Axler [1]:

$$
|\delta(y)| \leq \frac{3}{40 \log^2 y} + \frac{3}{20 \log^3 y} \leq 2.091 \times 10^{-7}, \quad (y \geq e^{600}). \quad (9)
$$

We now show how these inequalities give rise to Table 1. We only need to verify the case $k = 37$. The other values of $M_k$ in Table 1 follow by computer calculation. With the computer we verify that $0 < \eta(x) < \delta(x) < M_{37} = 4.38 \times 10^{-6}$ for $2^{37} \leq x \leq 2^{38}$. For $x = 2^{38}$, we calculate $\delta(x)$ and $\vartheta(x)$ and use (7) to obtain

$$
|\delta(y)| \leq 3.759 \times 10^{-6} \quad (2^{38} \leq y \leq 10^{19}).
$$

With (8) this implies

$$
|\delta(y)| \leq 3.759 \times 10^{-6} + 0.263 \times 10^{-6} = 4.022 \times 10^{-6} \quad (2^{37} \leq y \leq e^{600}).
$$

Together with (9) this shows that $|\delta(x)| \leq M_{37}$ for $x \geq 2^{37}$. To show that $\eta(x)$ satisfies the same inequality, note that

$$
0 < \delta(x) - \eta(x) = \sum_{p > x} \frac{\log p}{p(p-1)} < \int_x^\infty \frac{\log t}{t^2} dt = \frac{1 + \log x}{x} < 10^{-10}
$$

for $x \geq 2^{38}$. \qed
3. Proof of Theorem 1

Throughout this section we assume that \( \theta(n) = \sigma(n) + 1 \), so that \( B = P \) and \( \chi(n) \) is the characteristic function of the set of practical numbers. We need to estimate \( \alpha = (1 - e^{-\gamma}) c = \lim_{N \to \infty} \alpha_N \), where

\[
\alpha_N = \sum_{n \leq N} \frac{\chi(n)}{n} \left( \sum_{p \leq \theta(n)} \frac{\log p}{p - 1} \right) \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right). \tag{10}
\]

We write \( \alpha = \alpha_N + \beta_N \), with \( \alpha_N \) being computable by (10). To estimate \( \beta_N \), note that (4) implies

\[
\beta_N = \sum_{n > N} \frac{\chi(n)}{n} \left( \eta(\theta(n)) + \log(\theta(n)/n) - \gamma \right) \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right). \tag{11}
\]

Let

\[
\varepsilon_N = \sum_{n > N} \frac{\chi(n)}{n} \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right) = 1 - \sum_{n \leq N} \frac{\chi(n)}{n} \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right),
\]

by Lemma 1. The last equation allows us to calculate \( \varepsilon_N \) on a computer. The contribution from \( -\gamma \) to (11) is \( -\gamma \varepsilon_N \). If \( n \) is practical, then \( n - 1 \) can be written as the sum of some proper divisors of \( n \), so \( \sigma(n) - n \geq n - 1 \) and \( \theta(n) = \sigma(n) + 1 \geq 2n \). The contribution from \( \eta(\theta(n)) \) to (11) in absolute value is therefore at most

\[
\sum_{n > N} \frac{\chi(n)}{n} \eta(\theta(n)) \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right) \leq E(2N) \varepsilon_N,
\]

where

\[
E(x) := \sup_{y \geq x} |\eta(y)|.
\]

It remains to estimate the contribution from \( \log(\theta(n)/n) \) to (11), that is

\[
\sum_{n > N} \frac{\chi(n)}{n} \log \left( \frac{\sigma(n) + 1}{n} \right) \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right) = T_N + D_N,
\]

where

\[
T_N := \sum_{n > N} \frac{\chi(n)}{n} \log(\sigma(n)/n) \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right)
\]

and

\[
0 < D_N = \sum_{n > N} \frac{\chi(n)}{n} \log(1 + 1/\sigma(n)) \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right) < \frac{\varepsilon_N}{2N}.
\]

since \( 0 < \log(1 + 1/\sigma(n)) < 1/\sigma(n) \leq 1/(2n - 1) < 1/(2N) \). Combining these estimates, we have

\[
\alpha_N + T_N + \varepsilon_N(-\gamma - E(2N)) < \alpha < \alpha_N + T_N + \varepsilon_N(-\gamma + 1/(2N) + E(2N)). \tag{12}
\]
To compute $T_N$ we write $T_N = A - U_N$, where

$$U_N = \sum_{n \leq N} \frac{\chi(n)}{n} \log(\sigma(n)/n) \prod_{p \leq \theta(n)} \left(1 - \frac{1}{p}\right),$$

can be calculated on a computer and

$$A = \sum_{n \geq 1} \frac{\chi(n)}{n} \sum_{q \leq \theta(n)} W_q \prod_{p \leq \theta(n)} \left(1 - \frac{1}{p}\right),$$

by Lemma 3. We write

$$A = \sum_{1 \leq n \leq N} + \sum_{n > N} = A_N + V_N,$$

say. For practical $n > N$ we have $\theta(n) > 2N$, so

$$\sum_{q \leq 2N} W_q \leq \sum_{q \leq \theta(n)} W_q < \sum_{q \geq 2} W_q < \sum_{q \leq 2N} W_q + \sum_{q > 2N} \frac{1}{q(q-1)} < \sum_{q \leq 2N} W_q + \frac{1}{2N},$$

by Lemma 3. Thus

$$\varepsilon_N \sum_{q \leq 2N} W_q < V_N < \varepsilon_N \left( \sum_{q \leq 2N} W_q + \frac{1}{2N} \right). \quad (13)$$

To calculate $W_q$ efficiently, we write

$$W_q = -\log(1 - 1/q) + (q - 1) \sum_{h \geq 1} \log(1 - 1/q^{h+1})$$

$$= -\log(1 - 1/q) - (q - 1) \sum_{h \geq 1} \frac{1}{q^{h+1}} \sum_{j \geq 1} \frac{1}{j} \left(\frac{1}{q^{h+1}}\right)^j$$

$$= -\log(1 - 1/q) - \sum_{j \geq 1} \frac{q - 1}{jq^{j+1}(q^{j+1} - 1)}$$

$$= -\log(1 - 1/q) - \sum_{1 \leq j \leq J} \frac{q - 1}{jq^{j+1}(q^{j+1} - 1)} - R_{q,J} = W_{q,J} - R_{q,J},$$

say, where

$$0 < R_{q,J} < \frac{1}{J+1} \sum_{j > J} \frac{q - 1}{q^{j+1}(q^{j+1} - 1)} < \frac{1}{J} \sum_{j > J} \frac{q - 1}{q^{2j+2}} = \frac{1}{Jq^{2J+2}(q + 1)},$$

Thus

$$\sum_{q \geq 2} R_{q,J} < \sum_{q \geq 2} \frac{1}{Jq^{2J+2}(q + 1)} < \frac{1}{3J} \left( \frac{1}{22J+2} + \int_2^\infty x^{-2J-2}dx \right) < \frac{1}{J2^{2J+3}},$$

for $J \geq 2$. Replacing $W_q$ by $W_{q,J} > W_q$ in (13) yields

$$\varepsilon_N \left( Y_{2N,J} - \frac{1}{J2^{2J+3}} \right) < V_N < \varepsilon_N \left( Y_{2N,J} + \frac{1}{2N} \right), \quad (14)$$

where
\[ Y_{2N,J} = \sum_{q \leq 2N} W_{q,J}. \]
Replacing \( W_q \) by \( W_{q,J} \) in \( A_N \) gives
\[
A_{N,J} - \frac{1 - \varepsilon_N}{J^{2J+3}} < A_N < A_{N,J},
\]
where
\[ A_{N,J} = \sum_{n \leq N} \chi(n) \sum_{q \leq \theta(n)} W_{q,J} \prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right). \]
Since \( T_N = A - U_N = A_N + V_N - U_N \), combining (14) and (15) with (12) yields the lower bound
\[
\alpha > \alpha_N + A_{N,J} - U_N - \frac{1}{J^{2J+3}} + \varepsilon_N \left( Y_{2N,J} - \gamma - E(2N) \right)
\]
and the upper bound
\[
\alpha < \alpha_N + A_{N,J} - U_N + \varepsilon_N \left( Y_{2N,J} + \frac{1}{N} - \gamma + E(2N) \right). \]
We let \( J = 13 \) and \( N = 2^{31} \), so that \( E(2N) \leq M_{32} = 2.174 \times 10^{-5} \) by Lemma 4. Dividing both bounds for \( \alpha \) by \( 1 - e^{-\gamma} \), we get
\[ 1.33607322 < c < 1.33607654. \]

4. Discussion
Without precomputing the products and sums over primes, calculating \( \alpha_N, \varepsilon_N, A_{N,J} \) and \( U_N \) would take \( N^{2+o(1)} \) steps. To avoid this, we make a table with the practical numbers \( n \leq N \) in the first column and the values of \( \theta(n) = \sigma(n) + 1 \) in the second column. We then sort the table according to \( \theta(n) \). Next, we compute the three quantities
\[
\prod_{p \leq \theta(n)} \left( 1 - \frac{1}{p} \right), \quad \sum_{p \leq \theta(n)} \log p \quad p - 1, \quad \sum_{q \leq \theta(n)} W_{q,J},
\]
recursively, for increasing values of \( \theta(n) \), and store these values in columns 3 through 5 of our table. Finally, we sort the entire table according to \( n \) in the first column. Creating this table takes \( N^{1+o(1)} \) steps and \( N^{1+o(1)} \) bytes of memory. Calculating \( \alpha_N, \varepsilon_N, A_{N,J} \), and \( U_N \), with the use of this table, requires \( N^{1+o(1)} \) steps.

With \( J = 13 \) and \( N = 2^{31} \), the calculations took just over thirteen hours on a computer with sixteen gigabytes of RAM. Increasing \( N \) further would require more memory, because of the large table.

Note that the gap between the upper and lower bound for \( \alpha \) is
\[
2\varepsilon_N E(2N) + \frac{\varepsilon_N}{N} + \frac{1}{J^{2J+3}} = 2\varepsilon_N E(2N) + O(1/N),
\]
if $2^{J+3} \geq N$. It follows from (1) that $\varepsilon_N \sim ce^{-\gamma}/\log N$. After dividing by $1 - e^{-\gamma}$, the gap for $c$ is asymptotic to

$$\frac{2ce^{-\gamma}E(2N)}{(1 - e^{-\gamma})\log N}. \quad (17)$$

The width of the interval in (16) is $3.32 \times 10^{-6}$. If we increase $N$ from $2^{31}$ to $2^{36}$, Lemma 4 would allow us to replace $M_{32} = 2.174 \times 10^{-5}$ by $M_{37} = 0.438 \times 10^{-5}$ as an upper bound for $E(2N)$. With (17), we expect the width of the interval for $c$ to be about $0.6 \times 10^{-6}$ when $N = 2^{36}$, while our algorithm would require about $2^5 = 32$ times as much memory and computing time compared to $N = 2^{31}$.

Assuming the Riemann hypothesis, we have [11, Lemma 13]

$$E(x) = \sup_{y \geq x} |\eta(y)| \leq \frac{\log^2 x}{T\sqrt{x}} \quad (x \geq 25), \quad (18)$$

so that the expression in (17) is $O(\log N/\sqrt{N})$. However, the upper bounds listed in Table 1, which are best possible, are significantly better than (18).
