(Communicated by the associate editor name)

Abstract. We study the robust output regulation of linear boundary control systems by constructing extended systems. The extended systems are established based on solving static differential equations under two new conditions. We first consider the abstract setting and present finite-dimensional reduced order controllers. The controller design is then used for particular PDE models: high-dimensional parabolic equations and beam equations with Kelvin-Voigt damping. Numerical examples will be presented using Finite Element Method.

1. Introduction

We consider linear boundary control systems of the form [17, Chapter 10]
\[
\dot{w}(t) = \mathcal{A}w(t), \quad w(0) = w_0,
\]
\[
\mathcal{B}w(t) = u(t),
\]
\[
y(t) = C_0w(t)
\]
on a Hilbert space $X_0$ where $C_0$ is a bounded linear operator. The main aim of robust output regulation problem for boundary control systems is to design a dynamic error feedback controller so that the output $y(t)$ of the linear infinite-dimensional boundary control system converges to a given reference signal $y_{\text{ref}}(t)$, i.e.
\[
\|y(t) - y_{\text{ref}}(t)\| \to 0, \quad \text{as } t \to \infty.
\]
In addition, the control is required to be robust in the sense that the designed controller achieves the output tracking and disturbance rejection even under uncertainties and perturbations in the parameters of the system.

The robust output regulation and internal model based controller design for linear infinite-dimensional systems and PDEs — with both distributed and boundary control — has been considered in several articles, see [5–7, 9, 11, 13] and references therein. In [10], two finite-dimensional low-order robust controllers for parabolic control systems with distributed inputs and outputs was constructed. The main aim of this paper is to extend this design for linear boundary control systems. However, the main challenge is that the boundary input generally corresponds to an unbounded input operator. To tackle this issue, we construct an extended system with a new state variable $x = (v, u)^T = (w - Eu, u)^T$ where $E$ is an extension operator in such a way that the input operator of the new system is bounded.

The construction of extension operator $E$ is one of key points of this paper. In the literature (for example [3, Section 3.3]), the operator $E$ is chosen to be a right inverse operator of $B$. However, finding an arbitrary right inverse operator is not easy. In this paper, we propose the additional conditions to construct the operator $E$. The construction of $E$ is completed by solving static differential equations. The idea comes from recent works on boundary stabilization for PDEs (for example [1, 12, 14]) or boundary control systems in abstract form (see [15–17]). Under our approach, the theory of partial differential equations guarantees the existence of the extension operator $E$. For simple cases (such as the heat equation with Neumann boundary control in Section 4.2), the construction of $E$ by the new conditions does not give significant advantages compared to the choice of a right arbitrary inverse operator. Nevertheless, the advantage of our new approach can see clearly in more complicated partial differential equations (for example general linear parabolic equations on multi-dimensional domains, see the numerical example in Section 4.3). For these cases, the construction of right inverse operators by hand is not possible. In our approach we can approximate the operator $E$ by solving differential equations numerically and use the approximation in the controller design.

For the reference signals, we assume that $y_{ref} : \mathbb{R} \to \mathbb{C}^p$ can be written in the form

$$y_{ref}(t) = a_0(t) + \sum_{k=1}^{q} (a_k(t) \cos(w_k t) + b_k(t) \sin(w_k t))$$ (1)

where all frequencies $\{w_k\}_{k=0}^{q} \subset \mathbb{R}$ with $0 = w_0 < w_1 < \cdots < w_q$ are known, but the coefficient polynomials vectors $\{a_k(t)\}_k$ and $\{b_k(t)\}_k$ with real or complex coefficients (any of the polynomials are allowed to be zero) are unknown. We assume the maximum degrees of the coefficient polynomial vectors are known, so that $a_k(t) \in \mathbb{C}^p$ are polynomial of order at most $n_k - 1$ for each $k \in \{0, \ldots, q\}$. The class of signals having the form (1) is diverse. In Section 4.3, we present a numerical example with non-smooth reference signals. To track non-smooth signals, we approximate them by truncated Fourier series. In another numerical example, we track a signal where the coefficients are not constants.
Under certain standing assumptions, we present an algorithm to design a robust controller for boundary control system by employing the finite-dimensional controllers in [10]. To apply the finite-dimensional controllers design for boundary control systems, we need some checkable assumptions to obtain the stabilizability and detectability of the extended systems. The assumptions can be influenced by free choices of some parameters in the construction of the extended systems. The next step is to utilize the controller design for two particular partial differential equations, namely linear diffusion-convection-reaction equations and linear beam equations with Kelvin-Voigt damping. For the case of beam equations, we present two different extended systems which work well both in theoretical and numerical aspects.

The numerical computation is another contribution of this paper. Actually there are several numerical schemes satisfying the approximation assumption $A1$ below. We also use Finite Element Method (FEM) as in [10] to simulate the controlled solution. We will present two numerical examples: a 2D diffusion-reaction-convection equation and a 1D beam equation with Kelvin-Voigt damping. In both examples, by choosing a suitable family of test functions, we approximate all operators and construct the extension operators $E$ numerically (in case we do not know $E$ explicitly). Then our finite-dimensional controllers can be computed through matrix computations. Another advantage of Finite Element Method is that this method can deal with various types of multi-dimensional domains (see the example in Section 4.3).

The paper is organised as follows. In Section 2, we construct extended system from boundary control system with two additional assumptions on abstract boundary control systems, propose a collection of assumptions on the system, formulate the robust output regulation problem, and recall the Galerkin approximation. In Section 3.1, we present the algorithm to design the robust controller for boundary control system and clarify that the controller solves the robust output regulation problem in Theorem 3.1. Section 4 deals with general parabolic PDE models. Section 5 concentrates on beam equations with Kelvin-Voigt damping. Two numerical examples will follow in each section by using Finite Element method.

**Notation.** For a linear operator $A : X \to Y$ we denote by $D(A), \mathcal{N}(A), \mathcal{R}(A)$ the domain, kernel, and range of $A$, respectively. $\rho(A)$ denotes the resolvent set of operator $A$, $\sigma(A) = \mathbb{C} \setminus \rho(A)$ denotes the spectrum of operator $A$. The space of bounded linear operators from $X$ to $Y$ is denoted by $\mathcal{L}(X,Y)$.
2.1. Boundary control system. We start with the abstract boundary control system

\[ \dot{w}(t) = A w(t), \quad w(0) = w_0, \]  
\[ B w(t) = u(t), \]  
\[ y(t) = C_0 w(t). \]

with \( A : D(A) \subset X_0 \to X_0 \) and \( B : D(A) \subset X_0 \to X_0 \).

Assumption 2.1. There exist two operators \( A_d \) and \( A_{rc} \) satisfying \( D(A_d) = D(A) \subseteq D(A_{rc}) \) and the decomposition \( A = A_d + A_{rc} \), and \( A_{rc} \) is relatively bounded with respect to \( A_d \).

\( A_{rc} \) is relatively bounded to \( A_d \) if \( D(A_d) \in D(A_{rc}) \) and there are non-negative constants \( \alpha \) and \( \beta \) so that

\[ \|A_{rc}x\| \leq \alpha\|x\| + \beta\|A_d x\| \quad \text{for all } x \in D(A_d). \]

The notations \( A_d \) and \( A_{rc} \) are motivated by linear parabolic equations where we usually choose \( A_d \) as the diffusion term and \( A_{rc} \) as the reaction-convection term. We assume that the system (2) is a “boundary control system” in the sense of [15,17].

Definition 2.2. The control system (2) is a boundary control system if the followings hold:

a. The operator \( A_0 : D(A_0) \to X_0 \) with \( D(A_0) = D(A) \cap \mathcal{N}(B) \) and \( A_0 x = Ax \) for \( x \in D(A_0) \) is the infinitesimal generator of a strongly continuous semigroup on \( X_0 \).

b. \( \mathcal{R}(B) = U \).

The condition (b) implies that there exist an operator \( E \in \mathcal{L}(U,X_0) \) such that \( BE = I \). However, finding an arbitrary right inverse operator of \( B \) is not easy especially in the cases of multi-dimensional PDEs. Thus we propose the following additional assumption to construct the operator \( E \).

Assumption 2.3. There exists a constant \( \eta \geq 0 \) such that \( \eta \in \rho(A_0) \) and \( E \in \mathcal{L}(U,X_0) \) such that \( \mathcal{R}(E) \subset D(A) \) and

\[ A_d Eu = \eta Eu, \]  
\[ BEu = u, \]

for all \( u \in U \).

Under Assumptions 2.1 and 2.3, \( A_{rc} E \) is a bounded linear operator since \( U \) is finite-dimensional and \( \|A_{rc} Eu\| \leq \alpha\|Eu\| + \beta\|A_d Eu\| \leq (\alpha + \beta\eta)\|E\||u||_U \).

Remark 2.4. Comparing with the definition 3.3.2 in [3], the condition (3a) is new. For particular PDEs, the construction of extension \( E \) based on (3a) and (3b) leads to solve an ODE or an elliptic PDE. We call \( E \) as “an extension” since its role is to transfer the boundary control into the whole domain. Note that the operator \( E \) depends on the choice of \( \eta \geq 0 \). The
We next introduce two assumptions on the system.

- Assumption II: The pair \((A_0, E)\) is exponentially stabilizable.
- Assumption I2: There exists \(L_0 \in \mathcal{L}(\mathbb{C}, X_0)\) such that \(A_0 + L_0 C_0\) is exponentially stable and for every \(k \in \{1, \ldots, q\}\) we have \(P_k(iw_k) \neq 0\) where \(P_k(\lambda) = C_0 R(\lambda, A_0 + L_0 C_0) E\).

Let \(V_0\) be a Hilbert space, densely and continuously imbedded in \(X_0\). We denote the inner product on \(X_0\) and \(V_0\) with \(\langle \cdot, \cdot \rangle_{X_0}\) and \(\langle \cdot, \cdot \rangle_{V_0}\), respectively. Analogously denote by \(\| \cdot \|_{X_0}\) and \(\| \cdot \|_{V_0}\) the norms on \(X_0\) and \(V_0\).

**Assumptions on the sesquilinear form.** We assume that operator \(A_0\) corresponds with sesquilinear form \(\sigma_0\) by the formula below

\[
\langle -A_0 w_1, w_2 \rangle = \sigma_0(w_1, w_2), \quad \forall w_1, w_2 \in V_0
\]

where \(D(A_0) = \{ w \in V_0 \mid \sigma_0(w, \cdot) \}\) has an extension to \(X_0\). The sesquilinear form \(\sigma_0: V_0 \times V_0 \to \mathbb{C}\) satisfies two assumptions

- Assumption S1(Boundedness): There exist \(c_1 > 0\) such that for \(w_1, w_2 \in V_0\) we have
  \[
  |\sigma_0(w_1, w_2)| \leq c_1 \|w_1\|_{V_0} \|w_2\|_{V_0}.
  \]
- Assumption S2(Coercivity): There exist \(c_2 > 0\) and some real \(\lambda_0 > 0\) such that for \(w \in V_0\), we have
  \[
  \text{Re} \sigma_0(w, w) + \lambda_0 \|w\|_{X_0}^2 \geq c_2 \|w\|_{V_0}^2.
  \]

Under these assumptions, \(A_0 - \lambda_0 I\) generates an analytic semigroup on \(X_0\) (see [2]).

### 2.2. Construction of the extended system.

By defining a new variable \(v(t) = w(t) - E u(t)\), we rewrite the equation (2) in a new form

\[
\begin{align*}
\dot{v}(t) &= A_0 v(t) - E(\dot{u}(t) - \eta u(t)) + A_{rc} E u(t), \quad (4a) \\
v(0) &= v_0. \quad (4b)
\end{align*}
\]

Since \(A_0\) is the infinitesimal generator of an analytic semigroup, and \(E, A_{rc} E\) are bounded linear operators, Theorem 3.1.3 in [3] implies that the equation (4) has a unique classical solution for \(v_0 \in D(A_0)\) and \(u \in C^2([0, \tau]; U)\) for all \(\tau > 0\). The concept of “classical solution” means that \(v(t)\) and \(\dot{v}(t)\) are elements of \(C((0, \tau), X_0)\) for all \(\tau > 0\), \(v(t) \in D(A_0)\) and \(v(t)\) satisfies (4).

Denoting \(\kappa(t) = \dot{u}(t) - \eta u(t)\), we obtain the extended systems with the new state variable \(x = (v, u)\top = (w - E u, u)\top \in X := X_0 \times U\) and a new control input \(\kappa(t)\) as follows

\[
\dot{x}(t) = \begin{bmatrix} A_0 & A_{rc} E \\ 0 & \eta I \end{bmatrix} x(t) + \begin{bmatrix} -E \\ I \end{bmatrix} \kappa(t), \quad x(0) = \begin{bmatrix} w(0) - E u(0) \\ u(0) \end{bmatrix}. \quad (5)
\]
The observation part can be rewritten with the new variable as follows
\[ y(t) = C_0 w(t) = C_0 (v(t) + Eu(t)) = \begin{bmatrix} C_0 & C_0 E \end{bmatrix} x(t). \] (6)

The theorem below shows the relationship between the solutions of (2), (4), and (5). Its proof is analogous to the proof in [3, Theorem 3.3.4].

**Theorem 2.5.** Consider the boundary control system (2) and the abstract Cauchy equation (4). Assume that \( u \in C^2([0, \tau]; U) \) for all \( \tau > 0 \). Then, if \( v_0 = w_0 - Eu(0) \in D(A_0) \), the classical solutions of (2) and (4) are related by
\[ v(t) = w(t) - Eu(t). \]
Furthermore, the classical solution of (2) is unique.

In addition, if \( v_0 \in D(A_0) \), the extended system (5) with \( (x_0)_1 = v_0, (x_0)_2 = u(0) \) has the unique classical solution \( x(t) = (v(t), u(t))^\top \), where \( v(t) \) is the unique classical solution of (4).

### 2.3. The Robust Output Regulation Problem.

We write the system (5)-(6) in an abstract form on a Hilbert space \( X = X_0 \times U \).
\[ \dot{x}(t) = Ax(t) + B\kappa(t), \]
\[ y(t) = Cx(t) \]

where
\[ A = \begin{bmatrix} A_0 & A\kappa E \\ 0 & \eta I \end{bmatrix}, \quad B = \begin{bmatrix} -E \\ I \end{bmatrix}, \quad C = \begin{bmatrix} C_0 & C_0 E \end{bmatrix}. \] (8)

Note that \( B \) and \( C \) are bounded operators.

We consider the design of internal model based error feedback controllers of the form on \( Z = C^s \)
\[ \dot{z}(t) = G_1 \dot{z}(t) + G_2 e(t), \quad z(0) = z_0 \in Z, \]
\[ \kappa(t) = K \ddot{z}(t), \]
where \( e(t) = y(t) - y_{\text{ref}}(t) \) is the regulation error, \( G_1 \in C^{s \times s}, G_2 \in C^{s \times p} \), and \( K \in C^{m \times s} \). Letting \( x_e(t) = (x(t), z(t))^\top \), the system and the controller can be written together as a closed-loop system on the Hilbert space \( X_e = X \times Z \)
\[ \dot{x}_e(t) = A_e x_e(t) + B_e y_{\text{ref}}(t), \quad x_e(0) = x_{e0} \]
\[ e(t) = C_e x_e(t) + D_e y_{\text{ref}}(t) \]

where \( x_{e0} = (x_0, z_0)^\top \) and
\[ A_e = \begin{bmatrix} A \\ G_2 C \\ G_1 \end{bmatrix}, \quad B_e = \begin{bmatrix} 0 \\ -G_2 \end{bmatrix}, \quad C_e = \begin{bmatrix} C \\ 0 \end{bmatrix}, \quad D_e = -I. \]

The operator \( A_e \) generates a strongly continuous semigroup \( T_e(t) \) on \( X_e \).
The Robust Output Regulation Problem. The matrices \((G_1, G_2, K)\) are to be chosen so that the conditions below are satisfied.

(a) The semigroup \(T_e(t)\) is exponentially stable.
(b) There exists \(M_e, w_e > 0\) such that for all initial states \(x_0 \in X\) and \(z_0 \in Z\) and for all signal \(y_{\text{ref}}(t)\) of the form (1) we have

\[
\|y(t) - y_{\text{ref}}(t)\| \leq M_e e^{-w_e t} (\|x_0\| + \|\Lambda\|),
\]

where \(\Lambda\) is a vector containing the coefficients of the polynomials \(\{a_k(t)\}_k\) and \(\{b_k(t)\}_k\) in (1).
(c) When \((A, B, C)\) are perturbed to \((\tilde{A}, \tilde{B}, \tilde{C})\) in such a way that the perturbed closed-loop system remains exponentially stable, then for all \(x_0 \in X\) and \(z_0 \in Z\) and for all signals \(y_{\text{ref}}(t)\) of the form (1) the regulation error satisfies (9) for some modified constants \(\tilde{M}_e, \tilde{w}_e > 0\).

2.4. Galerkin approximation. Let \(V_0^N \subset V_0\) be a sequence of finite-dimensional subspaces. We define \(A_0^N : V_0^N \rightarrow V_0^N\) by

\[
\langle -A_0^N v_1, v_2 \rangle = \sigma_0(v_1, v_2) \quad \text{for all} \quad v_1, v_2 \in V_0^N,
\]

that is, \(A_0^N\) is defined via restriction of \(\sigma_0\) to \(V_0^N \times V_0^N\). Assume that operator \(A_{rc}\) corresponds with sesquilinear \(\sigma_{rc}\) by the formula

\[
\langle -A_{rc} w_1, w_2 \rangle = \sigma_{rc}(w_1, w_2), \quad \forall w_1, w_2 \in V_0
\]

where \(D(A_{rc}) = \{w \in V_0 \mid \sigma_{rc}(w, \cdot)\) has an extension to \(X_0\}\}. We define \(A_{rc}^N : V_0^N \rightarrow V_0^N\) by

\[
\langle -A_{rc}^N v_1, v_2 \rangle = \sigma_{rc}(v_1, v_2) \quad \text{for all} \quad v_1, v_2 \in V_0^N,
\]

For a given \(E \in \mathcal{L}(U, X_0)\), we define \(E^N \in \mathcal{L}(U, V_0^N)\) by

\[
\langle E^N \kappa, v_2 \rangle = \langle \kappa, E^* v_2 \rangle_{X_0} \quad \text{for all} \quad v_2 \in V_0^N,
\]

and \(C_0^N \in \mathcal{L}(V_0^N, Y)\) denotes the restriction of \(C_0\) onto \(V_0^N\).

Let \(P^N\) denote the usual orthogonal projection of \(X_0\) onto \(V_0^N\), i.e., for \(v_1 \in V_0\)

\[P^N v_1 \in V_0^N\] and \(\langle P^N v_1, v_2 \rangle = \langle v_1, v_2 \rangle_{X_0}\) for all \(v_2 \in V_0^N\).

We assume an approximation assumption as follows

- Assumption A1: For any \(v \in V_0\), there exists a sequence \(v^N \in V_0^N\) such that \(\|v^N - v\|_{V_0} \rightarrow 0\) as \(N \rightarrow \infty\).

3. Reduced order finite-dimensional controllers

3.1. The controller. In this section, we recall a finite-dimensional controller design, namely “Observer-based finite dimensional controller” presented in [10, Section III.A] to design robust controller for boundary control system (2). Another controller, namely “Dual observer-based finite dimensional controller” presented in [10, Section III.B] can be applied analogously.
The finite-dimensional robust controller is based on an internal model with a reduced order observer of the original system and has the form

$$
\dot{z}_1(t) = G_1 z_1(t) + G_2 e(t) \\
\dot{z}_2(t) = (A^*_L + B^*_L K^*_Y) z_2(t) + B^*_L K^*_Y z_1(t) - L^* e(t) \\
u(t) = K_1^N z_1(t) + K_2^N z_2(t)
$$

with state \((z_1(t), z_2(t)) \in Z := Z_0 \times \mathbb{C}^r\). All matrices \((G_1, G_2, A^*_L, B^*_L, K^*_Y, K^*_2, L^*)\) are chosen based on the four-step algorithm given below. The matrices \(G_1, G_2, K_1^N\) are the internal model in the controller. The remaining matrices \(A^*_K, B^*_L, L^*, K^*_Y\) are computed based on the Galerkin approximation \((A_0^N, A_{rc}^N, E^N, C_0^N)\) and model reduction of this approximation.

**Step 1. The Internal Model:**

We choose \(Z_0 = Y^{n_0} \times Y^{2n_0} \times \cdots \times Y^{n_0}\), \(G_1 = \text{diag}(J^0_Y, \ldots, J^q_Y) \in \mathcal{L}(Z_0)\), and \(G_2 = (G_2^k)_{k=0}^q \in \mathcal{L}(Y, Z_0)\). The components of \(G_1\) and \(G_2\) are chosen as follows. For \(k = 0\) we let

$$
J^0_Y = \begin{bmatrix} 0_p & I_p \\ 0_p & \ddots \\ \vdots & \ddots & I_p \\ 0_p & \end{bmatrix}, \quad G_2^0 = \begin{bmatrix} 0_p \\ \vdots \\ 0_p \\ I_p \end{bmatrix}
$$

where \(0_p\) and \(I_p\) are the \(p \times p\) zero and identity matrices, respectively.

For \(k \in \{1, \ldots, q\}\) we choose

$$
J^k_Y = \begin{bmatrix} \Omega_k & I_{2p} \\ \Omega_k & \ddots \\ \vdots & \ddots & I_{2p} \\ \Omega_k & \end{bmatrix}, \quad G_2^k = \begin{bmatrix} 0_{2p} \\ \vdots \\ 0_{2p} \\ I_p \\ 0_p \end{bmatrix}
$$

where \(\Omega_k = \begin{bmatrix} 0_p & \omega_k I_p \\ -\omega_k I_p & 0_p \end{bmatrix}\).

**Step 2. The Galerkin Approximation:**

For a fixed and sufficiently large \(N \in \mathbb{N}\) we apply the Galerkin approximation described in Section 2.4 in \(V_0\) to operators \((A_0, A_{rc}, E, C_0)\) to get their corresponding approximations \((A_0^N, A_{rc}^N, E^N, C_0^N)\). Then we compute the matrices \((A^N, B^N, C^N)\) as follows

$$
A^N = \begin{bmatrix} A_0^N & A_{rc}^N E^N \\ 0 & \eta I \end{bmatrix}, \quad B^N = \begin{bmatrix} -E^N \\ I \end{bmatrix}, \quad C^N = \begin{bmatrix} C_0^N & C_0^N E^N \end{bmatrix}.
$$

**Step 3. Stabilization:**

Denote the approximation \(V^N := V_0^N \times U\) of the space \(V = V_0 \times U\). Let \(\alpha_1, \alpha_2 \geq 0\). Let \(Q_1 \in \mathcal{L}(X, Y_0)\) and \(Q_2 \in \mathcal{L}(U_0, X)\) with \(U_0, Y_0\) Hilbert be such that \((A + \alpha_2 I, Q_2)\) is exponentially stabilizable and \((Q_1, A + \alpha_1 I)\) is exponentially detectable. Let \(Q_1^N\) and \(Q_2^N\) be the approximations of \(Q_1\) and \(Q_2\).
Define the matrices \((A, Q)\) and \((L, R)\) that the extended system \((A, B, C)\) is stabilizable and detectable. The sufficient conditions to guarantee the stabilizability and detectability of \((A, B, C)\) will be presented in Section 3.2.

**Step 4. The Model Reduction:**
For a fixed and suitably large \(r \in \mathbb{N}\), by using the Balanced Truncation method to the stable finite-dimensional system

\[
(A^N + L^N C^N, [B^N + L^N D, L^N], K^N_2),
\]

we obtain a stable \(r\)-dimensional reduced order system

\[
(A^r, [B^r, L', K^r_2]).
\]

The next theorem claims that the controller above solves Robust Output Regulation Problem for the boundary control systems \((2)\). In Section 3.2, we present sufficient conditions for the stabilizability and detectability of the extended system \((A, B, C)\).

**Theorem 3.1.** Let assumptions S1, S2, I1, I2, and A1 be satisfied. Assume that the extended system \((A, B, C)\) in \((8)\) is stabilizable and detectable. The finite dimensional controller \((10)\) solves the Robust Output Regulation Problem provided that the order \(N\) of the Galerkin approximation and the order \(r\) of the model reduction are sufficiently high.

If \(\alpha_1, \alpha_2 > 0\), the controller achieves a uniform stability margin in the sense that for any fixed \(0 < \alpha < \min\{\alpha_1, \alpha_2\}\) the operator \(A_e + \alpha I\) will generate an exponentially stable semigroup if \(N\) and \(r \leq N\) are sufficiently large.

**Proof.** The proof of this theorem is an application of Theorem III.2 in [10] under three checkable statements.

**Step 1. “Stabilizability and Detectability”**
Recall the abstract system

\[
\dot{x}(t) = Ax(t) + B\kappa(t),
\]

\[
y(t) = Cx(t).
\]

We assume that the extended system \((A, B, C)\) is stabilizable and detectable. The sufficient conditions to guarantee the stabilizability and detectability of \((A, B, C)\) will be presented in Section 3.2.
Step 2. “Boundedness and Coercivity of the sesquilinear form”
Define $V = V_0 \times U$ and $X = X_0 \times U$, the sesquilinear form $\sigma$ is defined by
\[
\sigma(\phi, \phi_2) = \sigma ((v_1, u_1), (v_2, u_2)) = \sigma_0(v_1, v_2) - (A_{rc}E u_1, v_2) x_0 - \eta u_1 u_2^T.
\]
For $\phi = (v, u)^T \in V$, we define $\|\phi\|_X^2 = \|v\|_{X_0}^2 + \|u\|_U^2$ and $\|\phi\|_V^2 = \|v\|_{V_0}^2 + \|u\|_V^2$.

Since $\sigma_0$ satisfies two assumptions $S1$ and $S2$, there exists constants $c_1 > 0$, $c_2 > 0$ and $\lambda_0 > 0$ such that for $v_1, v_2$, and $v \in V_0$ we have
\[
|\sigma_0(v_1, v_2)| \leq c_1 \|v_1\|_{V_0} \|v_2\|_{V_0},
\]
\[
\text{Re } \sigma_0(v, v) + \lambda_0 \|v\|_{X_0}^2 \geq c_2 \|v\|_{V_0}^2.
\]

To check the boundedness of $\sigma(\phi, \phi_2)$, we have
\[
|\sigma(\phi, \phi_2)| \leq |\sigma_0(v_1, v_2)| + |(A_{rc}E u_1, v_2) x_0| + \eta u_1 u_2^T
\]
\[
\leq (c_1 + k \|A_{rc}E\|_{L(U, X_0)} + \eta) \|\phi_1\|_V \|\phi_2\|_V - \lambda_0 \|v\|_{X_0}^2.
\]

Regarding the coercivity of $\sigma(\phi, \phi)$, let $\phi = (v, u)$, we have
\[
\text{Re } \sigma(\phi, \phi) = \text{Re } \sigma_0(v, v) - \text{Re } (A_{rc}E u, v) x_0 - \eta \|u\|_V^2
\]
\[
\geq c_2 (\|v\|_{V_0}^2 + \|u\|_V^2) - \left(\lambda_0 + \frac{1}{2}\right) \|v\|_{X_0}^2 - \left(\frac{1}{2} \|A_{rc}E\|_{L(U, X_0)}^2 + \eta + c_2\right) \|u\|_V^2.
\]

Define $\lambda_1 = \max \left\{\lambda_0 + \frac{1}{2}, \frac{1}{2} \|A_{rc}E\|_{L(U, X_0)}^2 + \eta + c_2\right\}$, we finally obtain $\text{Re } \sigma(\phi, \phi) + \lambda_1 \|\phi\|_X^2 \geq c_2 \|\phi\|_V^2$.

In conclusion the sesquilinear form $\sigma$ satisfies two assumptions $S1$ and $S2$ in the suitable spaces $X$ and $V$.

Step 3. “Approximation assumption”
Denote analogously $V^n = V_0^n \times U$. Under assumption $A1$, for any $v \in V_0$, there exists a sequence $v^n \in V_0^n$ such that $\|v^n - v\|_{V_0} \to 0$ as $n \to \infty$. Then for $x = (v, u) \in V$, define the sequence $x^n = (v^n, u) \in V^n$ satisfying $\|x^n - x\|_V \to 0$ as $n \to \infty$.

3.2. Stabilizability and detectability of the extended systems. In this section, we use three Theorems 5.2.6, 5.2.7, and 5.2.11 in [3]. We introduce new notations as follows. The spectrum of $A_0$ is decomposed into two distinct parts of the complex plane
\[
\sigma^+(A_0) = \sigma(A_0) \cap \overline{C_0^+}, \quad C_0^+ = \{\lambda \in \mathbb{C} | \text{Re } \lambda > 0\},
\]
\[
\sigma^-(A_0) = \sigma(A_0) \cap \overline{C_0^-}, \quad C_0^- = \{\lambda \in \mathbb{C} | \text{Re } \lambda < 0\}.
\]

Under the detectability of $(A_0, C_0)$ or the stabilizability of $(A_0, E)$, Theorems 5.2.6 or 5.2.7 in [3] guarantees that $A_0$ satisfies the spectrum decomposition assumption at 0. The decomposition of the spectrum induces a corresponding decomposition of the state space $X_0$, and of the operator $A$. We follow the definition of $T_0(t)$ as in [3, Equation 5.33].
Lemma 3.2. Assume that \((A_0, C_0)\) is exponentially detectable.

(i.) If \(A_{rc}E = 0\) and \(C_0E\) is injective, the extended system \((A, C)\) is also exponentially detectable.

(ii.) If \(A_{rc}E \neq 0\), assume further that
\[
\mathcal{N}(\eta I - A) \cap \mathcal{N}(C) = \{0\}
\]
then the extended system \((A, C)\) is exponentially detectable.

Proof. Since \((A_0, C_0)\) is exponentially detectable, Theorem 5.2.7 in \([3]\) implies that \(A_0\) satisfies the spectrum decomposition at 0, \(T_0^+(t)\) is exponentially stable, and \(\sigma^+(A_0)\) is finite. Then we can apply Theorem 5.2.11 in \([3]\) for the detectable pair \((A_0, C_0)\) to obtain that
\[
\mathcal{N}(sI - A_0) \cap \mathcal{N}(C_0) = \{0\} \quad \text{for all} \ s \in \mathbb{C}_0^+.
\]
Under our choice \(\eta \in \rho(A_0)\), the extended operator \(A\) satisfies all conditions of Theorem 5.2.11. To prove the detectability of the extended system \((A, C)\), we will verify that
\[
\mathcal{N}(sI - A) \cap \mathcal{N}(C) = \{0\} \quad \text{for all} \ s \in \mathbb{C}_0^+.
\]
Take \((v, u)^\top \in \mathcal{N}(sI - A) \cap \mathcal{N}(C)\), for any \(s \in \mathbb{C}_0^+\) we have
\[
\begin{cases}
(sI - A_0)v - A_{rc}Eu = 0, \\
(s - \eta)u = 0, \\
C_0v + C_0Eu = 0.
\end{cases}
\]
(i.) If \(A_{rc}E = 0\), we rewrite the conditions (13) as \((sI - A_0)v = 0\), \((s - \eta)u = 0\), and \(C_0v + C_0Eu = 0\). For \(s \in \mathbb{C}_0^+ \setminus \eta\), we have that \(u = 0\), \((sI - A_0)v = 0\), and \(C_0v = 0\). This implies that \(v \in \mathcal{N}(sI - A_0) \cap \mathcal{N}(C_0) = \{0\}\), and thus \(v = 0\).

For \(s = \eta \in \rho(A_0)\), we get that \(v = 0\) and \(C_0Eu = 0\). Under the condition that \(C_0E\) is injective, this implies that \(u = 0\).

Finally for all \(s \in \mathbb{C}_0^+\), we obtain that \(\mathcal{N}(sI - A) \cap \mathcal{N}(C) = \{0\}\). It follows that the extended pair \((A, C)\) is exponentially detectable.

(ii.) If \(A_{rc}E \neq 0\), we first consider \(s \in \mathbb{C}_0^+ \setminus \eta\). Analogously as in the first case, we get that \(u = 0\), \((sI - A_0)v = 0\), and \(C_0v = 0\). This implies that \(v = 0\) due to the detectability of the pair \((A_0, C_0)\).

In the case \(s = \eta\), we rewrite the condition as \((\eta I - A_0)v - A_{rc}Eu = 0\) and \(C_0v + C_0Eu = 0\). Under the additional assumption (12), we get that \((v, u) = 0\).

Since \(\mathcal{N}(sI - A) \cap \mathcal{N}(C) = \{0\}\) for all \(s \in \mathbb{C}_0^+\), we conclude that the extended pair \((A, C)\) is exponentially detectable.

\[\square\]

Lemma 3.3. Assume that \((A_0, E)\) is exponentially stabilizable.

(i.) If \(A_{rc}E = 0\), the extended system \((A, B)\) is also exponentially stabilizable.
Thus the extended system $(A, B)$ is exponentially detectable. Analogously as in Lemma 3.2 we get that

$$\mathcal{N}(sI - A_0^*) \cap \mathcal{N}(E^*) = \{0\} \quad \text{for } s \in \sigma^+(A_0), \quad (14)$$

the extended system $(A, B)$ is exponentially stabilizable.

Proof. The pair $(A_0, E)$ is exponentially stabilizable if and only if $(A_0^*, E^*)$ is exponentially detectable. Analogously as in Lemma 3.2 we get that

$$\mathcal{N}(sI - A_0^*) \cap \mathcal{N}(E^*) = \{0\} \quad \text{for } s \in \mathbb{C}_0^+.$$  

Since the pair $(A_0, E)$ is exponentially stabilizable, by Theorem 5.2.6 in [3] the extended operator $A$ satisfies all conditions of Theorem 5.2.11 in [3]. To prove the stabilizability of the extended system $(A, B)$, we will check that

$$\mathcal{N}(sI - A^*) \cap \mathcal{N}(B^*) = \{0\} \quad \text{for } s \in \mathbb{C}_0^+.$$  

If $(v, u) \in \mathcal{N}(sI - A^*) \cap \mathcal{N}(B^*)$, for $s \in \mathbb{C}_0^+$ then

$$\begin{cases}
(sI - A_0^*)v = 0, \\
(-A_{rc}E)^*v + (s - \eta)u = 0, \\
-E^*v + u = 0.
\end{cases} \quad (15)$$

(i.) If $A_{rc}E = 0$, the conditions (15) are rewritten as $(sI - A_0^*)v = 0$, $(s - \eta)u = 0$, $-E^*v + u = 0$. For $s \in \mathbb{C}_0^+ \setminus \eta$, it follows that $u = 0$ and $(sI - A_0^*)v = 0$ and $E^*v = 0$. It is equivalent that $v \in \mathcal{N}(sI - A^*) \cap \mathcal{N}(E^*)$. Thus $v = 0$. For $s = \eta$, since $\eta \in \rho(A_0)$, we get that $v = 0$. It follows that $u = 0$.

Finally, for all $s \in \mathbb{C}_0^+$, we get that $\mathcal{N}(sI - A^*) \cap \mathcal{N}(B^*) = \{0\}$. Therefore we conclude that the extended system $(A, B)$ is stabilizable.

(ii.) We consider the case as $A_{rc}E \neq 0$. For $s \in \mathbb{C}_0^+ \cap \rho(A_0^*)$, we get that $v = 0$ and then $u = 0$.

For $s \in \sigma^+(A_0^*)$, we rewrite $u = E^*v$ and

$$0 = (A_{rc}E)^*v - (s - \eta)u = (A_{rc}E)^*v + (s - \eta)E^*v = (A_{rc}E + (\eta - \bar{\eta})E^*)v$$

It follows that $v \in \mathcal{N}((A_{rc}E + (\eta - \bar{\eta})E^*))$. Moreover $v \in \mathcal{N}((sI - A_0^*)^*)$. Under the additional assumption (14), we get that $v = 0$, and then $u = 0$.

In conclusion for all $s \in \mathbb{C}_0^+$, we have that $\mathcal{N}(sI - A^*) \cap \mathcal{N}(B^*) = \{0\}$ and thus the extended system $(A, B)$ is stabilizable. \&

Remark 3.4. Comparing with the approach in [3], to prove the detectability and stabilizability of the extended systems, the first standing assumption is $0 \in \rho(A_0)$ (see Exercise 5.25 in [3]). In our approach, we instead require $\eta \in \rho(A_0)$. This condition is less restrictive since we can freely choose $\eta > 0$.

Remark 3.5. The additional conditions (12) and (14) to guarantee the detectability and stabilizability of the extended system in Lemmas 3.2 and 3.3 are checkable. We need to check (12) for only $\eta$ and (14) for finite $s \in \sigma^+(A_0)$. Under the Galerkin approximation, we can easily verify these.
conditions (12) and (14) by using the approximations of all operators. We then check these conditions below

\[ N(\eta I - A_N) \cap N(C_N) = \{0\}, \]
\[ N\left((sI - A_0^N)^s\right) \cap N\left((A_{\infty c}E_N + (\eta - s)E_N)^s\right) = \{0\} \quad \text{for } s \in \sigma^+(A_0^N). \]

4. Boundary control of parabolic partial differential equations

We consider controlled parabolic equations with Dirichlet boundary controls, for time \( t > 0 \), in a \( C^\infty \)-smooth domain \( \Omega \subset \mathbb{R}^d \) with \( d \) a positive integer, located locally on one side of its boundary \( \partial \Omega = \Gamma_c \cup \Gamma_u \), \( \Gamma_c \cap \Gamma_u = \emptyset \) as follows

\[
\frac{\partial w}{\partial t}(\xi,t) - \nu \Delta w(\xi,t) + \alpha(\xi)w(\xi,t) + \nabla \cdot (\beta(\xi)w(\xi,t)) = 0, \quad w(x,0) = w_0(\xi),
\]

(16a)

\[
w(\bar{\xi},t) = \sum_{i=1}^{m} u_i(t)\psi_i(\bar{\xi}) \text{ for } \bar{\xi} \in \Gamma_c, \quad w(\bar{\xi},t) = 0 \text{ for } \bar{\xi} \in \Gamma_u.
\]

(16b)

In the variable \((\xi,\bar{\xi},t) \in \Omega \times \Gamma \times (0, +\infty)\), the unknown in the equation is the function \( w = w(\xi,t) \in \mathbb{R} \). The diffusion coefficient \( \nu \) is a positive constant. The functions \( \alpha : \mathbb{R} \to \mathbb{R} \) and \( \beta : \mathbb{R}^d \to \mathbb{R} \) are fixed and depend only on \( \xi \). Function \( w_0 \) is known. We also assume that \( \alpha \in L^\infty(\Omega, \mathbb{R}) \) and \( \beta \in L^\infty(\Omega, \mathbb{R}^d) \).

The functions \( \psi_i(\bar{\xi}) \) are fixed and will play the role of boundary actuators. The control input is \( u(t) = (u_i(t))_{i=1}^{m} \in U = \mathbb{C}^{m} \) (see [12] and example below).

Analogously we assume the system has \( p \) measured outputs so that

\[
y(t) = (y_k(t))_{k=1}^{p} \in Y = \mathbb{R}^p \text{ and }
\]

\[
y_k(t) = \int_{\Omega} w(\xi,t)c_k(\xi)d\xi,
\]

for some fixed \( c_k(\cdot) \in L^2(\Omega, \mathbb{R}) \). The output operator \( C_0 \in \mathcal{L}(X_0, Y) \) is such that \( C_0w = (\langle w, c_k \rangle_{L^2(\Omega)})_{k=1}^{p} \) for all \( w \in X_0 \).

4.1. Constructing the extended system. We choose \( X_0 = L^2(\Omega, \mathbb{R}) \), \( V_0 = H^1_0(\Omega, \mathbb{R}) \) and denote \( X = X_0 \times U \), \( V = V_0 \times U \). Denote \( v = w - Eu \), \( A_d w := \nu \Delta w \) and \( A_{rc} w := -\alpha w - \nabla \cdot (\beta w) \).

For each actuator \( \psi_i \in H^2(\Gamma) \), we choose the extension \( \Psi_i \in H^2(\Omega) \) which solves the elliptic equations

\[
\nu \Delta \Psi_i = \eta \Psi_i, \quad \Psi_i|_{\Gamma_c} = \psi_i, \quad \Psi_i|_{\Gamma_u} = 0.
\]

(17)
We then set the operator $E : U \to S_{\Psi}$ with $S_{\Psi} := \text{span}\{\Psi_i \mid i \in \{1, 2, \ldots, m\}\}$ as

$$Eu := \sum_{i=1}^{m} u_i \Psi_i.$$ 

We rewrite the boundary control problem with the new state variable $x = (v, u)^\top = (w - Eu, u)^\top$. The new dynamic control variable $\kappa(t) \in U$ is defined as $\kappa_i(t) = \dot{u}_i(t) - \eta u_i(t)$ for all $i \in \{1, \ldots, m\}$. The new input operator $B \in \mathcal{L}(U, X)$ is such that $B\kappa = \begin{bmatrix} -E \\ I \end{bmatrix} \kappa = \begin{bmatrix} -\sum_{i=1}^{m} \kappa_i \Psi_i \end{bmatrix}$ for all $\kappa \in U$. The new output operator $C \in \mathcal{L}(X, Y)$ is such that

$$Cx = \left( \int_{\Omega} v(\xi) c_k(\xi) d\xi + \sum_{i=1}^{m} u_i \int_{\Omega} \Psi_i(\xi) c_k(\xi) d\xi \right)_{k=1}^{p}$$

for all $x \in X$. We get an extended system with $(A, B, C)$ as in (8).

As shown in [10, Section V. B.], the sesquilinear $\sigma_0$ corresponding with operator $A_0$ is bounded and coercive. Thus the sesquilinear form $\sigma$ corresponding with the extended operator $A$ here has the same properties (as shown in the proof of (3.1)).

4.2. A 1D heat equation with Neumann boundary control. In this section we consider a 1D heat equation with Neumann boundary control and construct the extended system by our approach. Reformulating this control system as an extended system was also considered in [3, Example 3.3.5] with the choice of right inverse operator. We first introduce the PDE model

$$\frac{\partial w}{\partial t}(\xi, t) = \frac{\partial^2 w}{\partial \xi^2}(\xi, t), \quad \frac{\partial w}{\partial t}(0, t) = 0, \quad \frac{\partial w}{\partial t}(1, t) = u(t),$$

$$w(\xi, 0) = w_0(\xi).$$

To construct the extended system, we define $X_0 = L^2(0, 1)$, $U = \mathbb{C}$. The operator $A = \frac{\partial^2}{\partial \xi^2}$ is with domain $D(A) = \{ h \in H^2(0, 1) \mid \frac{dh}{d\xi}(0) = 0 \}$ and the boundary operator $Bh = \frac{dh}{d\xi}(1)$ with $D(B) = D(A)$.

We define operator $A_0 = \frac{\partial^2}{\partial \xi^2}$ with domain $D(A_0) = D(A) \cap N(B) = \{ h \in H^2(0, 1) \mid \frac{dh}{d\xi}(0) = \frac{dh}{d\xi}(1) = 0 \}$.

By choosing $A_0 = A_0$, we define $Eu(t) = g(\xi) u(t)$ where $g(\xi)$ solves the following second order ODE

$$g''(\xi) = g(\xi), \quad g'(0) = 0, \quad g'(1) = 1.$$ 

By solving this ODE, we get $g(\xi) = \frac{2\pi}{\sqrt{\xi^2 + 1}} \cosh \xi$. By denoting an extended variable $x = (v, u)^\top$, we get an abstract system $\dot{x}(t) = Ax(t) + B\kappa(t)$ where

$$A = \begin{bmatrix} \frac{\partial^2}{\partial \xi^2} & 0 \\ 0 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} -E \\ 1 \end{bmatrix}.$$
In [3], the function \( g(\xi) = \frac{1}{2} \xi^2 \) was chosen and also defined \( Eu(t) = g(\xi)u(t) \).

This choice leads to another extended system with \( A = \begin{bmatrix} \frac{d^2}{dx^2} & 1 \\ 0 & 0 \end{bmatrix} \) and the same \( B \). We emphasize that the corresponding operator \( A \) does not coincide with the choice of \( \eta = 0 \) in our approach. We then apply the controller design in Section 3.1 for the extended systems.

For simple PDE models, the construction of extension \( E \) using our approach does not yet give significant advantages over the method presented in [3]. We will next present a two-dimensional PDE model where the construction of \( E \) would not be possible by hand.

### 4.3. A 2D diffusion-reaction-convection model

In this example, we consider the equation (16) on a domain \( \Omega = \left( \bigcup_{i=1}^{6} \Omega_i \right) \setminus \Omega_7 \) (plotted in (1)) where

\[
\begin{align*}
\Omega_1 &= \{ (\xi_1, \xi_2) \in \mathbb{R}^2 | -2 < \xi_1 < 0, -1 < \xi_2 \leq 1 \}, \\
\Omega_2 &= \{ (\xi_1, \xi_2) \in \mathbb{R}^2 | \xi_1^2 + \xi_2^2 < 1, \xi_1 \geq 0, \xi_2 \leq 0 \}, \\
\Omega_3 &= \{ (\xi_1, \xi_2) \in \mathbb{R}^2 | -1 \leq \xi_1 \leq 1, 0 < \xi_2 < 2 \}, \\
\Omega_4 &= \{ (\xi_1, \xi_2) \in \mathbb{R}^2 | \xi_1^2 + (\xi_2 - 2)^2 < 1, \xi_2 \geq 2 \}, \\
\Omega_5 &= \{ (\xi_1, \xi_2) \in \mathbb{R}^2 | (\xi_1 + 2)^2 + (\xi_2 - 2)^2 > 1, -2 < \xi_1 \leq -1, 1 \leq \xi_2 < 2 \}, \\
\Omega_6 &= \{ (\xi_1, \xi_2) \in \mathbb{R}^2 | (\xi_1 + 2)^2 + \xi_2^2 < 1, \xi_1 \leq -2 \}, \\
\Omega_7 &= \left\{ (\xi_1, \xi_2) \in \mathbb{R}^2 | \left( \xi_1 + \frac{3}{2} \right)^2 + \left( \xi_2 - \frac{1}{4} \right)^2 \leq \frac{4}{25} \right\}.
\end{align*}
\]

The boundary \( \Gamma \) can be described as seven segments

\[
\begin{align*}
\Gamma_1 &= \{ (\xi_1, -1) \in \mathbb{R}^2 | -2 < \xi_1 < 0 \}, \\
\Gamma_2 &= \{ (\xi_1, \xi_2) \in \mathbb{R}^2 | \xi_1^2 + \xi_2^2 = 1, \xi_1 \geq 0, \xi_2 \leq 0 \}, \\
\Gamma_3 &= \{ (1, \xi_2) \in \mathbb{R}^2 | 0 < \xi_2 < 2 \}, \\
\Gamma_4 &= \{ (\xi_1, \xi_2) \in \mathbb{R}^2 | \xi_1^2 + (\xi_2 - 2)^2 = 1, \xi_2 \geq 2 \}, \\
\Gamma_5 &= \{ (\xi_1, \xi_2) \in \mathbb{R}^2 | (\xi_1 + 2)^2 + (\xi_2 - 2)^2 = 1, \xi_1 \geq -2, \xi_2 < 2 \}, \\
\Gamma_6 &= \{ (\xi_1, \xi_2) \in \mathbb{R}^2 | (\xi_1 + 2)^2 + \xi_2^2 = 1, \xi_1 \leq -2 \}, \\
\Gamma_7 &= \left\{ (\xi_1, \xi_2) \in \mathbb{R}^2 | \left( \xi_1 + \frac{3}{2} \right)^2 + \left( \xi_2 - \frac{1}{4} \right)^2 = \frac{4}{25} \right\}.
\end{align*}
\]

We take \( \nu = 0.5 \), \( \alpha(\xi) = 3(\xi_1 + \xi_2) \), \( \beta_1(\xi) = \cos(\xi_1) - \sin(2\xi_2) - 2 \), \( \beta_2(\xi) = \sin(3\xi_1) + \cos(4\xi_2) \), \( \beta = (\beta_1, \beta_2) \) in (16).

We consider (16) with two boundary inputs located in two distinct segments \( \Gamma_3 \) and \( \Gamma_6 \) (see red segments of boundary in Figure 1), i.e. \( \Gamma_c = \Gamma_3 \cup \Gamma_6 \) and \( \Gamma_c = \Gamma_1 \cup \Gamma_2 \cup \Gamma_4 \cup \Gamma_5 \cup \Gamma_7 \). On these segments, for \( \xi = (\xi_1, \xi_2) \in \Gamma \), we
take $ψ_1(ξ) = \sin \left( \frac{πξ_2}{2} \right) \chi_{Γ_3}(ξ)$ and $ψ_2(ξ) = \sin \left( 3 \left( θ(ξ) - \frac{π}{2} \right) \right) \chi_{Γ_6}(ξ)$ where $θ(ξ) = \arctan \left( \frac{ξ_1 + 2ξ_2}{ξ_2} \right)$. Next we define two extensions of boundary controls by solving elliptic equations with $η = ν = 0.5$

$$ν \Delta Ψ_i = ηΨ_i, \quad Ψ_i |_{Γ_e} = ψ_i, \quad Ψ_i |_{Γ_u} = 0 \quad i \in \{1, 2\}. \quad (18)$$

Two corresponding solutions $Ψ_1$ and $Ψ_2$ are plotted in (2).

**Remark 4.1.** In the theoretical results, we have asked the boundary actuators to be in $H^{\frac{3}{2}}(Γ)$. Two actuators $ψ_1(ξ)$ and $ψ_2(ξ)$ above are actually in $H^s(Γ)$ with $s < \frac{3}{2}$, but not necessarily in $H^{\frac{3}{2}}(Γ)$. This lack of regularity will be neglected in simulation.
Two measurements act on blue rectangular subdomains of $\Omega$ (see Figure 1). The rectangular $\Omega_{m1}$ has four corners

$$(-1, -0.75), (-0.5, -0.75), (-0.5, -0.25), (-1, -0.25),$$

and the rectangular $\Omega_{m2}$ has four corners

$$(-3, 1.9464), (0.0536, 2.3), (-3, 2.6536), (0.6536, 2.3).$$

More precisely, we choose $c_1(\cdot) = \chi_{\Omega_{m1}}(\cdot), c_2(\cdot) = \chi_{\Omega_{m2}}(\cdot)$. Our aim is to track a non-smooth periodic reference signal $y_{\text{ref}}(t + 2) = y_{\text{ref}}(t) = (y_1(t), y_2(t)), \forall t \geq 0$ where

$$y_1(t) = \begin{cases} 1 & \text{if } 0 \leq t < \frac{1}{2}, \\ -2t + 2 & \text{if } \frac{1}{2} \leq t < 1, \\ 0 & \text{if } 1 \leq t < \frac{3}{2}, \\ 2t - 3 & \text{if } \frac{3}{2} \leq t < 2, \end{cases}$$

and

$$y_2(t) = \begin{cases} -t & \text{if } 0 \leq t < 1, \\ t - 2 & \text{if } 1 \leq t < 2. \end{cases}$$

This type of signals is approximated by truncated Fourier series

$$y_{\text{ref}}(t) \approx a_0(t) + \sum_{k=1}^{q} (a_k(t) \cos(k\pi t) + b_k(t) \sin(k\pi t)).$$

Here we use $q = 10$ and the corresponding set of frequencies is $\{k\pi \mid k \in \{0,1,\ldots,10\}\}$ and $n_k = 1$ for all $k \in \{0,1,\ldots,10\}$. The domain $\Omega$ is approximated by a polygonal domain $\Omega_D$ and we consider a partition of $\Omega_D$ into non-overlapping triangles to discretize the extended system using Finite Element Method. We construct the observer-based controller using a Galerkin approximation with order $n = 1956$ and subsequent Balanced Truncation with order $r = 30$. The internal model has dimension $\dim Z_0 = 2 \times 2 \times 10 + 2 \times 1 \times 1 = 42$. The parameters of the stabilization are chosen as

$$\alpha_1 = 0.65, \ \alpha_2 = 0.95, \ R_1 = I_2, \ R_2 = 10^{-2} I_2.$$  

The operators $Q_0$, $Q_1$, and $Q_2$ are freely chosen such that $Q_2Q_0^* = I_X$ and $C^*_c C_c = I_{Z_0 \times X}$. Another Finite Element approximation with $N = 2688$ is constructed to simulate the original system. The initial states to solve the controlled system are $v_0(\xi) = 0.25 \sin(\xi_1)$ and $u_0 = 0 \in \mathbb{R}^{12+30}$. The tracking signals are plotted in Figure 3. In Figure 4, the first Hankel singular values of the Galerkin approximation are plotted.
5. Boundary control of a beam equation with Kelvin-Voigt damping

Consider a one-dimensional Euler-Bernoulli beam model on $\Omega = (0, l)$

\[
\frac{\partial^2 w}{\partial t^2}(\xi, t) + \frac{\partial^2}{\partial \xi^2} \left( \alpha \frac{\partial^2 w}{\partial \xi^2}(\xi, t) + \beta \frac{\partial^3 w}{\partial \xi^2 \partial t}(\xi, t) \right) + \gamma \frac{\partial w}{\partial t}(\xi, t) = 0, \quad (19a)
\]

\[
w(\xi, 0) = w_0(\xi), \quad \frac{\partial w}{\partial t}(\xi, 0) = w_1(\xi), \quad (19b)
\]

\[
y(t) = C_1 w(\cdot, t) + C_2 \dot{w}(\cdot, t), \quad (19c)
\]

where $\alpha, \beta, \gamma$ are constants so that $\alpha, \beta > 0$ and $\gamma \geq 0$. The measurement operators for the deflection $w(\cdot, t)$ and the velocity $\dot{w}(\cdot, t)$ are such that
functions $c_k(\cdot) \in L^2(0, l)$. We consider boundary conditions
\[
w(0, t) = \frac{\partial w}{\partial \xi}(0, t) = \frac{\partial^3 w}{\partial \xi^3}(l, t) = 0, \quad \frac{\partial^2 w}{\partial \xi^2}(l, t) = u(t),
\]
where $u(t)$ is the boundary input at $\xi = l$. This type of boundary controls was considered in [17, Section 10.4] and [4] (with boundary disturbance signals).

Let $W_0 = \left\{ w \in H^2(0, l) \mid w(0) = \frac{\partial w}{\partial \xi}(0) = 0 \right\}$ and define the inner product on $W_0$ by
\[
\langle w_1, w_2 \rangle_{W_0} = \int_0^l w_1(\xi)w_2(\xi)d\xi, \quad \forall w_1, w_2 \in W_0.
\]

We define the spaces $X_0 = W_0 \times L^2(0, l)$, $V_0 = W_0 \times W_0$ and the operator
\[
A = \begin{bmatrix}
0 & I \\
-\alpha \frac{\partial^4}{\partial \xi^4} & -\beta \frac{\partial^4}{\partial \xi^4} - \gamma
\end{bmatrix},
\]
with $D(A) = \left\{ (w_1, w_2) \in V_0 \mid \alpha \frac{\partial^2 w_1}{\partial \xi^2} + \beta \frac{\partial^2 w_2}{\partial \xi^2} \in H^2(0, l), \frac{\partial^3 w_1}{\partial \xi^3}(l) = 0 \right\}$.

The boundary operator $B : X_0 \to \mathbb{C}$ denotes by $B \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} = \frac{\partial w_2}{\partial \xi}(l)$.

The operator $A_0$ is given by $A_0 = \begin{bmatrix}
0 & I \\
-\alpha \frac{\partial^4}{\partial \xi^4} & -\beta \frac{\partial^4}{\partial \xi^4} - \gamma
\end{bmatrix}$ with the domain
\[
D(A_0) = D(A) \cap \mathcal{N}(B) = \left\{ (v_1, v_2) \in V_0 \mid \alpha \frac{\partial^2 v_1}{\partial \xi^2} + \beta \frac{\partial^2 v_2}{\partial \xi^2} \in H^2(0, l), \frac{\partial^3 v_1}{\partial \xi^3}(l) = \frac{\partial^3 v_1}{\partial \xi^3}v_1(l) = 0 \right\}.
\]

**5.1. The extended system.** Choose $A_d = \begin{bmatrix}
0 & I \\
-\alpha \frac{\partial^4}{\partial \xi^4} & -\beta \frac{\partial^4}{\partial \xi^4}
\end{bmatrix}$ and

\[
A_{rc} = \begin{bmatrix}
0 & 0 \\
0 & -\gamma
\end{bmatrix}
\]
with $D(A_d) = D(A)$ and $D(A_{rc}) = X_0$. We construct

\[
E(u(t)) = \begin{bmatrix} g_1(\xi) \\ g_2(\xi) \end{bmatrix} u(t) \text{ satisfying both conditions } 3a \text{ and } 3b \text{ as follows}
\]

\[
\begin{bmatrix}
0 & I \\
-\alpha \frac{\partial^4}{\partial \xi^4} & -\beta \frac{\partial^4}{\partial \xi^4}
\end{bmatrix} \begin{bmatrix} g_1(\xi) \\ g_2(\xi) \end{bmatrix} = \eta \begin{bmatrix} g_1(\xi) \\ g_2(\xi) \end{bmatrix}, \quad B \begin{bmatrix} g_1(\xi) \\ g_2(\xi) \end{bmatrix} = 1.
\]

$g_1(0) = g_1'(0) = g_1'''(l) = 0$, $g_2(0) = g_2'(0) = 0.$
We need to solve a system of ODEs as follows

\[ g_2(\xi) = \eta g_1(\xi), \]  

\[ g_1^{(m)}(\xi) = -\eta^2 \frac{\partial^4}{\partial \xi^4} g_1(\xi), \]  

\[ g_1(0) = g'(0) = g''(l) = 0, \quad g''(l) = 1, \]  

\[ g_2(0) = g_2'(0) = 0. \]  

We have freedom of choices on boundary conditions of \( g_2 \). Here we choose \( g_2''(l) = 0 \) and \( g_2''(l) = \eta \). The condition \( \alpha g_2'' + \beta g_2'' \in H^2(0, l) \) can be verified after solving the system.

Define the change of variable \( \begin{bmatrix} v \\ \tilde{v} \end{bmatrix} = \begin{bmatrix} w \\ \dot{w} \end{bmatrix} - Eu(t) \), and the new control \( \kappa(t) = \dot{u}(t) - \eta u(t) \). The extended system can be rewritten in terms of the new state \( x = (v, \dot{v}, u) \) in the abstract form \( \dot{r}(t) = Ax(t) + Bu(t) \), where

\[
A = \begin{bmatrix}
0 & -\alpha & 0 \\
-\beta & 0 & -\gamma \\
0 & 0 & \eta
\end{bmatrix}, \quad B = \begin{bmatrix}
-g_1(\xi) \\
-g_2(\xi) \\
1
\end{bmatrix}.
\]

The sesquilinear associated to the operator \( A_0 \) is bounded and coercive (see [8] and [10, Section V.C.]). Thus the sesquilinear generated by operator \( A \) in (21) is also bounded and coercive as shown in the proof of 3.1.

The observation part can be rewritten in the new state

\[ y(t) = C_1 v(\cdot, t) + C_2 \dot{v}(\cdot, t) = C_1 (w(\cdot, t) + g_1(\cdot) u(t)) + C_2 (\dot{w}(\cdot, t) + g_2(\cdot) u(t)) \]

which implies that \( C = [C_1 \quad C_2 \quad C_1 g_1 + C_2 g_2] \). Under this setting, the extended system \( (A, B, C) \) can be rewritten in the abstract form as in (5)-(6).

5.2. An alternative extended system. For second-order (in time) PDE models, we can use an alternative approach to construct the extended system. For this class of system, this approach here is more natural than the first one. However it still has some disadvantages that we will discuss below.

Let us define \( v(\xi, t) = w(\xi, t) - g(\xi) u(t) \) where \( g(\xi) \) solves the ODE

\[ g'''(\xi) - \eta g(\xi) = 0, \]  

\[ g(0) = g'(0) = g''(l) = 0, \]  

\[ g''(l) = 1 \]  

where \( \eta \) is a positive constant. Then we can rewrite the equation (19) as follows

\[ \frac{\partial^2 v}{\partial t^2}(\xi, t) + \alpha \frac{\partial^4 v}{\partial \xi^4}(\xi, t) + \left( \beta \frac{\partial^4}{\partial \xi^4} + \gamma \right) \frac{\partial v}{\partial t}(\xi, t) \]

\[ = - (u''(t) + (\beta n + \gamma) u(t) + \alpha \eta u(t)) \) \( g(\xi), \]

\[ v(0, t) = \frac{\partial v}{\partial \xi}(0, t) = \frac{\partial^2 v}{\partial \xi^2}(l, t) = \frac{\partial^3 v}{\partial \xi^3}(l, t) = 0. \]
Defining $\kappa(t) = u''(t) + (\beta \eta + \gamma)u'(t) + \alpha \eta u(t)$, we get an alternative extended system $\dot{x}(t) = Ax(t) + B\kappa(t)$ where

$$A = \begin{bmatrix} \alpha \beta^4 & \frac{1}{\beta} \\
\frac{1}{\beta} & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}, \quad B = \begin{bmatrix} 0 \\
0 \\
0 & 0 & -\alpha \eta & -\beta \eta - \gamma
\end{bmatrix}. \quad (24)$$

The observation part can be rewritten in the new state as

$$y(t) = C_1 v(\cdot, t) + C_2 \dot{v}(\cdot, t) = C_1(w(\cdot, t) + g(\cdot)u(t)) + C_2(\ddot{w}(\cdot, t) + g(\cdot)u'(t)),$$

which leads to the output operator $C = [C_1 C_2 C_1g C_2g]$.

**Lemma 5.1.** Consider the abstract differential equation $\dot{x}(t) = Ax(t) + B\kappa(t)$ where $A$ and $B$ are defined in (24). Assume that $u \in C^3([0, \tau]; \mathbb{R})$ for all $\tau > 0$ and $(v_0, v_1) = (w_0 - gu(0), w_1 - gu'(0)) \in D(A_0)$. The extended system with $(x_0)_1 = v_0, (x_0)_2 = v_1, (x_0)_3 = u(0), (x_0)_4 = u'(0)$ has a unique solution $x(t) = (v(t), \dot{v}(t), u(t), u'(t))^\top$.

**Proof.** By denoting $A_1 = \begin{bmatrix} 0 & \frac{1}{\beta} \\
-\alpha \beta^4 & -\beta \frac{1}{\beta} - \gamma
\end{bmatrix}$ and $A_2 = \begin{bmatrix} 0 & 1 \\
-\alpha \eta & -\beta \eta - \gamma
\end{bmatrix}$, we rewrite $A = \begin{bmatrix} A_1 & 0 \\
0 & A_2
\end{bmatrix}$. Then we analogously apply Lemma 3.2.2 in [3] and the procedure of Theorem 2.5 to get the result. □

**Remark 5.2.** Comparing with the case of parabolic equations in Section 4, the difference is that we can find the extension $Eu(t)$ explicitly by solving ODE (20) or (22).

Considering the system of ODE (20), the characteristic equation is $\lambda + \frac{\beta^2}{\alpha + \beta \eta} = 0$. By denoting $\tilde{\eta} = \sqrt{\frac{\beta^2}{\alpha + \beta \eta}}$, the solution of characteristic equation is $\lambda = \pm \tilde{\eta} \pm i\tilde{\eta}$. Thus the general solution is

$$g_1(\xi) = m_1 e^{\tilde{\eta} \xi} \cos(\tilde{\eta} \xi) + m_2 e^{\tilde{\eta} \xi} \sin(\tilde{\eta} \xi) + m_3 e^{-\tilde{\eta} \xi} \cos(\tilde{\eta} \xi) + m_4 e^{-\tilde{\eta} \xi} \sin(\tilde{\eta} \xi)$$

and $g_2(\xi) = \eta g_1(\xi)$. Obviously $g_1(\xi)$ and $g_2(\xi)$ belong to $H^2(0, l)$. On the other hand, for the ODE (22), the corresponding characteristic equation is $\lambda^4 - \eta = 0$ whose solutions are $\lambda = \pm \psi \sqrt{\eta}$ and $\lambda = \pm i \psi \sqrt{\eta}$. The general solution is

$$g(\xi) = m_1 e^{\psi \sqrt{\eta} \xi} + m_2 e^{-\psi \sqrt{\eta} \xi} + m_3 \cos(\psi \sqrt{\eta} \xi) + m_4 \sin(\psi \sqrt{\eta} \xi).$$

All unknown parameters $m_1, m_2, m_3, m_4$ can be determined from the boundary conditions by solving a corresponding linear algebraic system.

### 5.3. Two approaches with other types of boundary control

The type of boundary condition below was presented before in some works [8, Section 3] or [10, Section V.C]. Here we design a boundary control. The
construction of extension operator \( Eu(t) \) in section 5.1 can be modified to adapt with this type of boundary condition

\[
\begin{align*}
\alpha \frac{\partial^2 w}{\partial \xi^2}(l, t) + \beta \frac{\partial^3 w}{\partial \xi^2 \partial t}(l, t) &= u(t), \\
\alpha \frac{\partial^2 w}{\partial \xi^2}(l, t) + \beta \frac{\partial^3 w}{\partial \xi^2 \partial t}(l, t) &= 0,
\end{align*}
\]

By denoting \( M(\xi, t) = \alpha \frac{\partial^2 w}{\partial \xi^2}(\xi, t) + \beta \frac{\partial^3 w}{\partial \xi^2 \partial t}(\xi, t) \), we modify the domain of \( A \) as

\[
D(A) = \left\{ (w_1, w_2) \in V \mid \alpha \frac{d^2 w_1}{d\xi^2} + \beta \frac{d^2 w_2}{d\xi^2} \in H^2(0, l), \frac{dM}{d\xi}(l, \cdot) = 0 \right\}.
\]

The boundary operator \( B : X_0 \to \mathbb{C} \) denotes by \( B \left[ \begin{array}{c} w_1 \\ w_2 \end{array} \right] = \alpha \frac{d^2 w_1}{d\xi^2}(l) + \beta \frac{d^2 w_2}{d\xi^2}(l) \) with \( D(B) = D(A) \).

The domain of operator \( A_0 \) is denoted by

\[
D(A_0) = \left\{ (v_1, v_2) \in V \mid \alpha \frac{d^2 v_1}{d\xi^2} + \beta \frac{d^2 v_2}{d\xi^2} \in H^2(0, l), M(l, \cdot) = \frac{dM}{d\xi}(l, \cdot) = 0 \right\}.
\]

With the same choice of \( A_d \) and \( A_{rc} \), we get the system of ODEs as follows

\[
\begin{align*}
g_2(\xi) &= \eta g_1(\xi), \\
g_1^{(m)}(\xi) &= \frac{-\eta^2}{\alpha + \beta \eta} g_1(\xi)
\end{align*}
\]

whose boundary conditions are modified as

\[
\begin{align*}
g_1(0) &= g_1'(0) = g_1''(l) = 0, \\
g_2'(0) &= g_2'(0) = 0.
\end{align*}
\]

Again, we can choose \( g_2''(l) = 0 \) and \( g_2'(l) = \frac{\eta}{\alpha + \beta \eta} \).

However the approach in section 5.2 does not work with this type of boundary conditions.

5.4. **A numerical example.** In this example, we consider the system (19) with \( l = 7, \alpha = 10, \beta = 0.01, \) and \( \gamma = 10^{-5} \). The observation is

\[
y(t) = \int_{1/2}^4 w(\xi, t) + \frac{\partial w}{\partial t}(\xi, t)d\xi, \quad \text{i.e.} \quad C_1 = C_2 = \chi_{(2,4)}(\cdot).
\]

With the choice of parameters, the stability margin of the system is very small (approximately \( 10^{-3} \)). In this example, we use the boundary control to improve the stability of the original system and obtain an acceptable closed-loop stability margin.

We want to track the reference signal \( y_{\text{ref}}(t) = \frac{1}{10}(t^2 - t) \sin(3t) \). The set of frequency has only one element \( \{3\} \) with \( n_k = 3 \).

We also used two different meshes. Again, we use Finite Element Method with cubic Hermit shape functions as in [10, Section V.C.]. We construct
the observer-based finite-dimensional controller based on the algorithm in Section 3.1 using a coarse mesh with \( n = 34 \) (the corresponding size of the matrix \( A^n \) is 138) and subsequent Balanced Truncation with order \( r = 50 \). The internal model has dimension \( \dim Z_0 = 2 \times 3 = 6 \).

For the controller in Section 5.1, we choose \( \eta = 0.12 \) in system (20). The corresponding solutions \( g_1 \) and \( g_2 \) are plotted in Figure 5a. The parameters of the stabilization are chosen as

\[
\alpha_1 = 0.65, \quad \alpha_2 = 0.5, \quad R_1 = 0.1, \quad R_2 = 1.
\]

For the alternative extended system in Section 5.2, we choose \( \eta = 10 \) in (22). The solution \( g \) of (22) with \( \eta = 10 \) is plotted in Figure 5b. We choose other parameters of stabilization to improve the stability margin as

\[
\alpha_1 = 0.75, \quad \alpha_2 = 0.5, \quad R_1 = 1, \quad R_2 = 10^{-3}.
\]

![Figure 5. Solutions of ODEs.](image)

For the simulation of the original system (19), we use another Finite Element approximation with \( N = 86 \). The corresponding size of matrix \( A^N \) is 346. The initial state of the original systems \( v_0(\xi) = 0.25(\cos(5\xi) - 2) \), \( v_1(\xi) = 0.25 \sin(5\xi) \), and \( z_0 = \{v \in \mathbb{R}^{6+40} \mid v_i = -0.3\} \).

The tracking controlled signals under two different extensions are plotted in Figure 6 where the blue line corresponds with the extension (21) and the green one corresponds with the extension (24).

6. Conclusions

We have presented new methods for design finite-dimensional reduced order controllers for robust output regulation problems of boundary control systems. The controllers are constructed based on an extended system. Theorem 3.1 shows that the controllers solve the robust output regulation problem. The construction of extended system is completed by two additional assumptions. Comparing with the choice of arbitrary right inverse operators in the literature, our construction is efficient in PDE models with
multi-dimensional domains. Concerning with the boundary disturbance signals, some examples was also introduced before in [10, Section V. A.] or [4]. We remark that the method can be analogously applied to construct a new bounded disturbance operator. We can then extend the control design here for the case with boundary disturbance signals.
