We calculate the electromagnetic self-force of a uniformly charged spherical ball moving on a rectilinear trajectory, neglecting the Lorentz contraction.

1. Introduction

In this paper, we calculate the electromagnetic self-force of a uniformly charged spherical ball, moving on a rectilinear trajectory, with a time-dependent velocity. To this end, we use the ansatz from [1], Eq. (4)

\[ \vec{F}_s = -\frac{d\vec{G}_s(t)}{dt}, \]

where \( \vec{F}_s \) is the self-force and \( \vec{G}_s(t) = (1/4\pi c) \int d\vec{r} \vec{E}(\vec{r}, t) \times \vec{B}(\vec{r}, t) \) is the self-field momentum of the charge distribution.

The charge density of a uniformly charged ball of total charge \( e \) and radius \( a \), in the proper frame, is

\[ \rho(\vec{r}) = \frac{3e}{4\pi a^3} \theta(a - r), \]

where \( \theta \) is the Heaviside function. We start our calculation from its multipole expansion

\[ \rho(\vec{r}) = 3e \sum_{n=0}^{\infty} \frac{a^{2n}}{2^n n!(2n + 3)!!} \Delta^n \delta(\vec{r}), \]  

1

where \( \delta \) is the Dirac delta function. Eq. [1] can be justified, for example, as in [2]. We consider that the charge distribution is spherical in the laboratory frame, so our results are valid for small velocities. To obtain the charge density in the laboratory frame, we replace in the right hand side of [1] \( \vec{r} \) with \( \vec{r} - \vec{i} \dot{w}(t) \), where we supposed that the ball is moving along the \( x \)-axis, with the velocity \( \dot{w}(t) \).
2. The calculation of the self-force

Starting from Eq. (1) we can calculate easily the electromagnetic potentials

\[ \phi(\vec{r}, t) = \int d\vec{r}' \frac{\rho(\vec{r}', t - |\vec{r} - \vec{r}'|/c)}{|\vec{r} - \vec{r}'|}, \quad \vec{A}(\vec{r}, t) = \frac{1}{c} \int d\vec{r}' \frac{\vec{J}(\vec{r}', t - |\vec{r} - \vec{r}'|/c)}{|\vec{r} - \vec{r}'|}, \]

and the fields

\[ \vec{E}(\vec{r}, t) = -\nabla \phi(\vec{r}, t) - \frac{1}{c} \frac{\partial}{\partial t} \vec{A}(\vec{r}, t), \quad \vec{B}(\vec{r}, t) = \nabla \times \vec{A}(\vec{r}, t). \]

We write below only the \( y \)- and \( z \)- components of the fields.

\[ E_{y,z}(\vec{r}, t) = 3e \sum_{n=0}^{\infty} \sum_{p=0}^{\infty} \frac{a^{2n} (-1)^{p+1}}{2^n n!(2n+3)!! p!} \Delta^n \partial_{y,z} \frac{w^p (t - \frac{r}{c})}{r}, \quad (2) \]

\[ B_{y,z}(\vec{r}, t) = 3e \sum_{n=0}^{\infty} \sum_{p=0}^{\infty} \frac{a^{2n} (-1)^p}{2^n n!(2n+3)!! p!} \Delta^n \tilde{\partial}_{y,z} \frac{\dot{w} (t - \frac{r}{c}) w^p (t - \frac{r}{c})}{r}, \quad (3) \]

where \( \tilde{\partial}_z = \partial_z \) and \( \tilde{\partial}_y = -\partial_y \). The Fourier transforms of the above fields are

\[ E_{y,z}(\vec{\kappa}, t) = 12\pi e \sum_{p=0}^{\infty} \frac{i^{p+1} \kappa_{y,z} \kappa_x}{k p!} \frac{j_1(ka)}{ka} \int_{0}^{\infty} dr \sin(kr) w^p \left( t - \frac{r}{c} \right), \quad (4) \]

\[ B_{y,z}(-\vec{\kappa}, t) = 12\pi e \sum_{p=0}^{\infty} \frac{(-1)^p k_{y,z} k_x}{k p!} \frac{j_1(ka)}{ka} \int_{0}^{\infty} dr \sin(kr) \dot{w} \left( t - \frac{r}{c} \right) w^p \left( t - \frac{r}{c} \right), \quad (5) \]

where \( \vec{k}_z = k_z \) and \( \vec{k}_y = -k_y \), \( j_1(x) = \sin(x)/x^2 - \cos(x)/x \) is the spherical Bessel function of the first kind, and the Fourier transform of a function \( f(\vec{r}) \) is defined as \( f(\vec{\kappa}) = \int d\vec{r} e^{i\vec{\kappa}\vec{r}} f(\vec{r}) \).

To obtain Eqs. (4), (5), we used

\[ \sum_{k=0}^{\infty} \frac{(-1)^k x^{2k}}{2^k k!(2k + 3)!!} = \frac{j_1(x)}{x}. \]

We calculate the self-force by integrating in the Fourier space

\[ F_x = -\frac{1}{4\pi c} \frac{d}{dt} \int d\vec{r} [E_y(\vec{r}, t)B_z(\vec{r}, t) - E_z(\vec{r}, t)B_y(\vec{r}, t)] \]

\[ = -\frac{1}{32\pi^4 c} \frac{d}{dt} \int d\vec{k} \left[ E_y(\vec{k}, t)B_z(-\vec{k}, t) - E_z(\vec{k}, t)B_y(-\vec{k}, t) \right]. \quad (6) \]
We introduce Eqs. (4), (5) in Eq. (6) and perform the integration over angles using
\[ \int d\Omega_k \ k_y^2 k_x^p = \begin{cases} 4\pi k^{p+2}/(p+1)(p+3), & p \text{ even} \\ 0, & p \text{ odd} \end{cases} \]

One obtains
\[ F_x(t) = -\frac{36e^2}{\pi c^2 a^2} \frac{d}{dt} \sum_{n,p=0}^{\infty} \frac{(-1)^{n+p}}{n!(n+1)(n+p+3)} \int_0^\infty dr \int_0^\infty dr' \int_0^\infty dk \]
\[ \cdot k^{n+p} \left[j_1(ka)\right]^2 \sin(kr) \sin(kr') w^n \left(t - \frac{r}{c}\right) \dot{w} \left(t - \frac{r'}{c}\right) w \left(t - \frac{r'}{c}\right), \]
and, after changing the summation indices \((n,p)\rightarrow(n,\kappa)\), \(n+p=2\kappa\),
\[ F_x(t) = -\frac{36e^2}{\pi c^2 a^2} \frac{d}{dt} \sum_{\kappa=0}^{2\kappa} \sum_{n=0}^{\infty} \frac{(-1)^{n+\kappa}}{n!(2\kappa-n)!(2\kappa+1)(2\kappa+3)} \int_0^\infty dr \int_0^\infty dr' \int_0^\infty dk \]
\[ \cdot k^{2\kappa} \left[j_1(ka)\right]^2 \sin(kr) \sin(kr') w^{2\kappa-n} \left(t - \frac{r}{c}\right) \dot{w} \left(t - \frac{r'}{c}\right) w^n \left(t - \frac{r'}{c}\right). \]

To perform the integral over \(k\), we use the method from [3]. We introduce the auxiliary integral
\[ I(a,b; r, r'; \kappa) \equiv \int_0^\infty dk k^{2\kappa} j_1(ka) j_1(kb) \sin(kr) \sin(kr'), \]
and use
\[ j_1(kx) = \frac{1}{k^2} \frac{\partial}{\partial x} \sin(kx). \]

At the end, we will take \(a = b\). In the following, to shorten the formulas, we will omit \(r, r'\) from the argument of \(I\). We need to consider separately the cases \(\kappa = 0, \kappa = 1\) and \(\kappa \geq 2\).

**Case \(\kappa=0\)**

\[ I(a,b; \kappa = 0) = \frac{\partial}{\partial a} \frac{\partial}{\partial b} \frac{1}{ab} \int_0^\infty dk \frac{\sin(ka) \sin(kb) \sin(kr) \sin(kr')}{k^4} \]

We use Eq. 3.746 (1) from [4], which can be particularized as
\[ \int_0^\infty dk \frac{\sin(ka) \sin(kb) \sin(kr) \sin(kr')}{k^4} = \frac{\pi}{2} \left[ br'\theta(a - b - r - r') + arr'\theta(b - a - r - r') + abr'\theta(r - a - b - r') + abr\theta(r' - a - b - r) \right]. \]
Taking the derivatives in the above equation and using that \( \theta'(x) = \delta(x) \), where the prime denotes the derivative with respect to the argument, we obtain

\[
I(a = b; \kappa = 0) = \frac{\pi}{2} \left[ r' \delta'(r - 2a - r') + r \delta(r' - 2a - r) \right],
\]

where we have written only the terms which will contribute to the integral over \( r' \) in Eq. (12).

**Case \( \kappa = 1 \)**

\[
I(a, b; \kappa = 1) = \frac{\partial}{\partial a} \frac{\partial}{\partial b} \frac{1}{ab} \int_0^\infty dk \frac{\sin(ka) \sin(kb) \sin(kr) \sin(kr')}{k^2}. \tag{13}
\]

We transform the products of trigonometric functions into sums, and use Eq. 3.828 (2) from [4]

\[
\int_0^\infty dx \frac{\sin(px) \sin(qx)}{x^2} = \frac{\pi}{2} \left[ p \theta(q - p) + q \theta(p - q) \right]. \tag{14}
\]

After taking the derivatives, we will use the identities \( \theta(x) - \theta(-x) = \text{sign}(x) \), where \( \text{sign} \) is the signum function, and \( x \cdot \text{sign}(x) = |x| \). After a little algebra, one obtains

\[
I(a = b; \kappa = 1) = \frac{\pi}{8} \left[ -\left\lfloor \frac{|r - r'|}{a^4} \right\rfloor + \frac{r + r'}{a^4} + \frac{4}{a^2} \delta(r - r') + 2 \frac{r - r'}{a^2} \delta'(r - r') \right], \tag{15}
\]

where, again, we have written only the terms which will contribute to the integral over \( r' \).

**Case \( \kappa \geq 2 \)**

\[
I(a, b; \kappa \geq 2) = \frac{\partial}{\partial a} \frac{\partial}{\partial b} \frac{1}{ab} \int_0^\infty dk \ k^{2\kappa - 4} \ \sin(ka) \sin(kb) \sin(kr) \sin(kr'). \tag{16}
\]

We transform the products of trigonometric functions into sums, and use \( \int_0^\infty dx \ x^m \cos(kx) = \pi^{\frac{m}{2}} \delta^{(m)}(k) \), where the upper index between parenthesis is the order of the derivative with respect to the argument. Keeping only the terms which will give contribution to the integral over \( r' \), one obtains:

\[
I(a = b; \kappa \geq 2) = \frac{\pi}{8} (-1)^\kappa \left[ \frac{2}{a^4} \delta(2\kappa - 4)(r - r') - \frac{2}{a^2} \delta(2\kappa - 2)(r - r') - \frac{1}{a^4} \delta(2\kappa - 4)(2a + r - r') - \frac{1}{a^2} \delta(2\kappa - 2)(2a - r + r') \right]. \tag{17}
\]

We can see from Eq. (17) that \( \int_0^\infty dr' I(a = b; r; r'; \kappa) \cdot f(r') \) is a discontinuous function of variable \( r \), because \( \delta(2a - r + r') \) will give contribution only for \( r > a \). So, if we try to
evaluate the integral by expanding the spherical Bessel functions in Taylor series and integrating term by term, the result will not be accurate in the whole domain $r \in (0, \infty)$, because a discontinuous function cannot be well approximated by a single power series.

With the results \([12], [15], [17]\), we can return to Eq. (18) and perform the integral over $r'$ and $r$, as explained in \([1]\). We denote the results obtained for $\kappa = 0$, $\kappa = 1$, $\kappa \geq 2$ by $F_0^1(t)$, $F_1^1(t)$, respectively. So, we have $F_x(t) = F_0^1(t) + F_1^1(t) + F_2(t)$. Compared to the calculations from \([1]\), a supplementary difficulty appears in the evaluation of $F_1^1(t)$, because the first two terms from Eq. (15) are not Dirac delta functions. So, in the following, we present the detailed calculations only for $F_1^1(t)$.

From Eqs. (8), (15), we obtain

$$F_1^1(t) = 3 \frac{e^2}{10 \kappa c^2 a^2} \sum_{n=0}^{2} \frac{(-1)^n}{n!(2-n)!} \left[ -\frac{1}{a^4} f^1 + \frac{1}{a^4} f^2 + \frac{2}{a^2} f^3 \right],$$  \hspace{1cm} (18)

where

$$f^1 = \frac{d}{dt} \int_0^\infty dr \int_0^\infty dr' |r - r'| w^{2-n} \left( t - \frac{r}{c} \right) \dot{w} \left( t - \frac{r}{c} \right) w^n \left( t - \frac{r}{c} \right),$$  \hspace{1cm} (19)

$$f^2 = \frac{d}{dt} \int_0^\infty dr \int_0^\infty dr' (r + r') w^{2-n} \left( t - \frac{r}{c} \right) \dot{w} \left( t - \frac{r}{c} \right) w^n \left( t - \frac{r}{c} \right),$$  \hspace{1cm} (20)

$$f^3 = \frac{d}{dt} \int_0^\infty w^2 \left( t - \frac{r}{c} \right) \dot{w} \left( t - \frac{r}{c} \right).$$  \hspace{1cm} (21)

In Eqs. (19), (20), we change the variables of integration $(r, r') \to (y, x)$, $t - r'/c = x$, $t - r/c = y$, and then we use the formula

$$\frac{d}{dx} \int_0^x dy \int_0^x dz f(y, z) = \int_0^x dz f(x, z) + \int_0^x dy f(y, x),$$

which can be easily inferred from the Leibniz integral rule. One obtains

$$f^1 = f^2 = c^3 \left[ \int_{-\infty}^{t} dy(t - y) w^{2-n}(t)\dot{w}(y)w^n(y) + \int_{-\infty}^{t} dy(t - y) w^{2-n}(y)\dot{w}(t)w^n(t) \right],$$  \hspace{1cm} (22)

so, the contributions from $f^1$ and $f^2$ cancel each other in Eq. (18). In Eq. (21), we change the variable of integration $r \to x$, $t - r/c = x$ and we obtain

$$f^3 = cw^2(t)\dot{w}(t).$$  \hspace{1cm} (23)
From Eqs. (18), (22), (23), one obtains \( F^1_x(t) = 0 \). Analogously, we calculate \( F^0_x(t) \) and \( F^2_x(t) \), and we obtain the final result

\[
F_x(t) = -\frac{6e^2}{ca^2} \dot{w}(t) + \frac{9e^2}{2a^2} \sum_{\kappa=2}^{\infty} \sum_{p=0}^{\infty} \frac{a^{2p} 2^{2p+2} (2p^2 + 7p + 8)}{(2\kappa + 1)(2\kappa + 3)(2\kappa + 1)!(2p + 3)!(p + 2)}
\]

\[
\cdot \frac{d^{2\kappa+2p+1}}{dr^{2\kappa+2p+1}} \left[ w(t) - \frac{1}{r} \right]_{r=0}^{2\kappa+1},
\]  

(24)

The first terms of the above equation are

\[
F_x(t) = -\frac{6e^2}{ca^2} \dot{w}(t) + \frac{12e^2}{a^2} 15(\beta^2 - 1) \tanh^{-1} \beta - 2\beta^5 - 10\beta^3 + 15\beta
\]

\[
+ \frac{34\gamma^2}{5c^2} \left[ \frac{\gamma^2 + 2}{3} \dot{w}(t)(\ddot{w}(t))^4 + (\gamma^4 + \gamma^2 + 1) (\ddot{w}(t))^2(\dot{w}(t))^3 \right] + O(a^2),
\]  

(25)

where \( \beta = \dot{w}(t)/c, \gamma = 1/(1 - \beta^2) \), where the summation over \( \kappa \) has been performed as in [1], Eq. (28). Using \( \tanh^{-1} \beta \approx \beta + \frac{\beta^3}{3} + \frac{\beta^5}{5} + \frac{\beta^7}{7} + \ldots \), we obtain

\[
F_x(t) \approx -\frac{6e^2}{ca^2} \dot{w}(t) + \frac{144e^2}{a^2} \beta^7
\]

\[
+ \frac{34\gamma^2}{5c^2} \left[ \frac{\gamma^2 + 2}{3} \dot{w}(t)(\ddot{w}(t))^4 + (\gamma^4 + \gamma^2 + 1) (\ddot{w}(t))^2(\dot{w}(t))^3 \right] + O(a^2).
\]  

(26)

3. Conclusions

We have calculated in this paper the electromagnetic self-force of a uniformly charged ball moving on a rectilinear trajectory, neglecting the Lorentz contraction. Our result (26) contains a dominant term \(-\frac{6e^2}{ca^2} \dot{w}(t)\), which is directly proportional to the velocity and inversely proportional to the square of the radius. It is different from the dominant term of the Sommerfeld-Page equation \(-\frac{2e^2}{3ca^2} \dot{w}(t)\), which is directly proportional to the acceleration and inversely proportional to the radius, and which is usually dropped because it is indistinguishable from the term \( m\ddot{w}(t) \) in the equation of motion. This result supports the idea that, even for small dimensions, the self-force is strongly dependent on the charge density.
