(Dated: July 15, 2019)

Experimental investigation of hydrodynamics in electron fluids is a highly topical research area that emerged during the last few years. A recent measurement of the optical conductivity in graphene [P. Gallagher et al., Science 364, 158 (2019)] offers a possibility of experimental determination of microscopic time scales describing scattering processes in the electronic fluid. In this paper, I report a theoretical calculation of the optical conductivity in graphene at arbitrary doping levels, within the whole “hydrodynamic” temperature range, and for arbitrary, non-quantizing magnetic fields.

Recent experiments\textsuperscript{3,9,10} indicate that charge carriers in graphene at nearly room temperatures may exhibit a hydrodynamic flow\textsuperscript{19,20}. Traditional linear-response transport measurements uncovered such remarkable features as the strong violation of the Wiedemann-Franz law\textsuperscript{2} and superballistic transport\textsuperscript{4}. In this type of experiments all information about the flow of electrons is extracted from a small number of measured resistance\textsuperscript{13,14} and Johnson noise power\textsuperscript{2}. Additional information about the flow can be obtained by current density imaging\textsuperscript{3,11,12} or terahertz spectroscopy\textsuperscript{7}. The latter experiment yields the optical conductivity which can be used to extract information about the electron-electron and electron-impurity scattering rates in graphene\textsuperscript{7}.

Hydrodynamic theory of electronic transport\textsuperscript{9,10} can be formulated similarly to the usual hydrodynamics\textsuperscript{13} with the important caveat: the total momentum of the electronic system in a solid is not, strictly speaking, a conserved quantity. In general, this means that one can only hope to observe electronic hydrodynamics in an intermediate temperature window where the electron-electron interaction is the dominant scattering mechanism in the problem\textsuperscript{9}. In the specific case of graphene, there is an additional circumstance due to the linearity of the excitation spectrum: the momentum density is proportional to the energy current\textsuperscript{9,10,14–16} (rather than the “mass” current as in the usual hydrodynamics\textsuperscript{13}). Hence it is the electrical (rather than the thermal) conductivity that appears in the hydrodynamic theory of electronic transport in graphene as a dissipative coefficient\textsuperscript{14,16}.

In traditional hydrodynamics, dissipative processes are described by three coefficients\textsuperscript{13}, the shear and bulk viscosities and the thermal conductivity. In graphene, the bulk viscosity vanishes\textsuperscript{9}, leaving the shear viscosity as the only dissipative coefficient in the generalized Navier-Stokes equation\textsuperscript{14,16}. Under the assumption of approximate conservation of the particle number in each of the two bands in graphene\textsuperscript{12}, electronic hydrodynamics describes two macroscopic quasiparticle currents (the electric and “imbalance” currents\textsuperscript{14,17}). Dissipative corrections to these currents due to electron-electron interaction are described by a $2 \times 2$ matrix of coefficients\textsuperscript{10}.

In addition, disorder scattering not only contributes to these coefficients, but also determines a correction to the energy current\textsuperscript{15} yielding the thermal conductivity\textsuperscript{15}. As a result, the electric and energy currents are relaxed by two different scattering mechanisms leading to the violation of the Wiedemann-Franz law\textsuperscript{2}. The effect is especially pronounced at charge neutrality\textsuperscript{2} where the two currents are completely decoupled.

Assuming the applicability of the kinetic approach, one can derive the dissipative coefficients appearing in hydrodynamics starting with the Boltzmann equation and the local equilibrium distribution function\textsuperscript{2}\textsuperscript{10,11,13}. The resulting viscosities and conductivities are temperature- and material-dependent constants\textsuperscript{15}. In contrast, calculations based on the Kubo formula yield frequency-dependent viscosities\textsuperscript{15,16} and conductivities\textsuperscript{10,22}. The frequency-dependent (optical) conductivity is experimentally measurable\textsuperscript{22} even in the hydrodynamic regime\textsuperscript{2}.

In this paper I extend the kinetic derivation of the dissipative corrections to the hydrodynamic quantities in graphene allowing for the low-frequency optical conductivity (in general, hydrodynamics is valid for frequencies which are much lower than the typical scattering time associated with equilibration processes, $\omega \tau_{ee} \ll 1$). I also use the kinetic theory to extend the hydrodynamic-like macroscopic description\textsuperscript{23} to higher frequencies where the results should be compared to those in the high-frequency collisionless regime\textsuperscript{1,2}.

Previously, optical conductivity in the hydrodynamic regime in graphene was addressed in Refs.\textsuperscript{30–34}. A large part of that research was focused on the two limiting cases, charge neutrality and the degenerate regime. In the absence of the magnetic field, the results for these two limits can be combined in an interpolation formula\textsuperscript{33}

$$
\sigma(\omega; \mathbf{q} = 0) = \frac{A_1}{-i\omega + \tau_{\text{dis}}^{-1}} + \frac{A_2}{-i\omega + \tau_{ee}^{-1} + \tau_{\text{dis}}^{-1}},
$$

where $A_i$ are temperature- and density-dependent constants, $\tau_{\text{dis}}$ is the elastic mean free time, and $\tau_{ee}$ is the typical time scale associated with the electron-electron interaction. Here I report the results of a rigorous calculation of $\sigma(\omega)$ for arbitrary carrier densities, temperatures (within the hydrodynamic range), and classical (non-quantizing) magnetic fields beyond the limiting behavior of Eq.\ (1), as well as of the microscopic times scales determining $\sigma(\omega)$.
I. UNCONVENTIONAL HYDRODYNAMICS IN GRAPHENE

Unconventional hydrodynamics in graphene was derived in Refs.\textsuperscript{14,15} on the basis of the kinetic theory. The need for the derivation was dictated by the lack of symmetry in the problem—the electronic system in graphene is neither Galilean, nor Lorentz invariant. The former follows from the linearity of the excitation spectrum, while the latter is related to the classical, three-dimensional nature of the Coulomb interaction in graphene.

As in any other solid, electrons in graphene may scatter on lattice vibrations (phonons) and imperfections (typically referred to as “disorder”) and hence loose momentum. In this case, one can speak of hydrodynamics only within a limited parameter regime (e.g., at intermediate temperatures) where the electron-electron interaction is the dominant scattering mechanism in the problem. This “hydrodynamic” regime can be defined by the inequality

$$\tau_{ee} \ll \tau_{\text{dis}}, \tau_{e-ph}, \tau_R, \text{ etc,}$$

where $\tau_{e-ph}$ is the typical scale describing the electron-phonon interaction, $\tau_R$ is the quasiparticle “recombination” time and “etc” stands for any other scattering-related time scale in the problem.

Assuming the applicability of the kinetic (Boltzmann) equation at least in some subset of the hydrodynamic region, hydrodynamic equations can be derived from the kinetic equation following the standard procedure.\textsuperscript{18}

Conservation of charge and energy can be expressed in terms of the continuity equations\textsuperscript{14,16}

$$\partial_t n + \nabla \cdot j = 0, \quad (3a)$$

$$\partial_t n + \nabla \cdot j = 0,$$  

$$\partial_t n_E + \nabla \cdot j_E = eE \cdot j.$$  

where $n$ is the carrier density, $j$ is the current (differing from the charge density and electric current by a multiplicative factor of the electric charge, $e$), $n_E$ and $j_E$ are the energy density and current, and $E$ is the electric field ($eE \cdot j$ describing Joule heat). The continuity equation \textsuperscript{(3a)} is valid in any electronic system, while Eq. \textsuperscript{(3b)} neglects possible energy losses due to coupling to collective excitations (e.g., phonons, plasmons, etc.).

The main equations of the hydrodynamic theory, the Euler and Navier-Stokes equations (for ideal and viscous fluids, respectively), are based on the continuity equation for momentum density reflecting momentum conservation. In solids, electronic momentum can be treated as a conserved quantity only approximately, in the sense of Eq. \textsuperscript{(2)}. Hence, the generalized Navier-Stokes equation in graphene\textsuperscript{15} contains a weak disorder scattering term,

$$W(\partial_t + u \cdot \nabla) u + v_g \nabla P + u \partial_t P + e(E \cdot j) u =$$

where $v_g$ is the Fermi velocity in graphene, $u$ is the hydrodynamic velocity, $B$ is the magnetic field, $c$ is the speed of light, and $W$ and $P$ are the enthalpy and pressure, which are related to the energy density in graphene by the “equation of state”\textsuperscript{14,15}

$$W = n_E + P = \frac{3n_E}{2 + u^2/v_g^2}. \quad (3d)$$

The shear, $\eta$, and Hall, $\eta_H$, viscosities in graphene were discussed theoretically in Ref. \textsuperscript{16} and experimentally in Refs. \textsuperscript{14,18}.

Due to kinematic suppression of interband scattering in graphene\textsuperscript{10,12} one may consider conservation of the particle number in each band. This leads to another continuity equation

$$\partial_t n_I + \nabla \cdot j_I = \frac{n_I - n_{I,0}}{\tau_I}, \quad (3e)$$

where the “imbalance” density and current\textsuperscript{12} (together with $n$ and $j$) are related to the densities and currents in each band as

$$n = n_+ - n_- \quad n_I = n_+ + n_-, \quad (3f)$$

$$j = j_+ - j_- \quad j_I = j_+ + j_- \quad (3g)$$

Finally, the quasiparticle currents $j$ and $j_I$ are not related to any conserved quantity and hence acquire dissipative corrections (similarly to the energy current in the traditional hydrodynamics\textsuperscript{13}). The energy current in graphene is proportional to the momentum density and hence cannot be relaxed by electron-electron interaction. However, it can be relaxed by weak disorder (leading to the strong violation of the Wiedemann-Franz law\textsuperscript{2}). Combining the dissipative corrections to the three macroscopic currents in graphene, one defines the second set of dissipative coefficients\textsuperscript{13}

$$j = nu + \delta j, \quad j_I = n_I u + \delta j_I, \quad j_E = Wu + \delta j_E, \quad (3h)$$

where $F_u = eE + \frac{\tau}{\tau_I} u \times B$, while $\mu$ and $\mu_I$ are the chemical potentials conjugate to $n$ and $n_I$, respectively. They are related to the chemical potentials $\mu$ as

$$\mu = (\mu_+ - \mu_-)/2, \quad \mu_I = (\mu_+ + \mu_-)/2. \quad (3i)$$

In this paper I disregard thermoelectric effect\textsuperscript{17} and set $\mu_+ = \mu$ (or $\mu_I = 0$).

In addition to Eqs. \textsuperscript{(3)} the complete hydrodynamic theory includes Maxwell’s equations taking into account electromagnetic fields induced by inhomogeneities of the charge density similarly to the Vlasov self-consistency\textsuperscript{15}. In solids typical velocities are rather small, $v_g \ll c$, and hence the Maxwell’s equations are usually reduced to electrostatics. In gated structures\textsuperscript{14,15} the electrostatics is controlled by the gate voltage further simplifying the relation between the charge density and electric field.
II. DISSIPATIVE COEFFICIENTS

The dissipative coefficients $\Sigma$ and $\Sigma_H$ are related to the electrical conductivity\cite{10} (and are the counterpart of the thermal conductivity in traditional hydrodynamics\cite{13}). In the absence of the magnetic field the Hall term vanishes, $\Sigma_H(B=0) = 0$. The matrix $\Sigma(B=0)$ simplifies at the Dirac point, where it is block diagonal, such that the electric current decouples from the other two. Moreover, at $n = 0$ the “hydrodynamic” contribution to $\dot{j}$ vanishes, see Eq. (3f), leaving the dissipative correction $\delta j$ as the total current. This correction remains finite even in the absence if disorder,

$$\epsilon \delta j(\mu = 0) = \sigma_Q E, \quad \sigma_Q = \mathcal{A} e^2/\alpha_g^2, \quad \mathcal{A} \approx 0.12,$$

where $\sigma_Q$ is known as the “quantum” or “intrinsic” conductivity of graphene\cite{10,11,14,56,66,68}. The quantity $\sigma_Q$ is a constant that depends on temperature only through the logarithmic renormalization of the coupling constant $\alpha_g$\cite{66}. Away from the Dirac point, matrix elements of $\Sigma$ may exhibit more pronounced temperature and density dependence, but within the framework of Ref. 15 they remain independent of frequency.

A. Kinetic theory approach

Following the standard approach\cite{10} to derivation of the hydrodynamic theory from the kinetic equation, one represents the kinetic equation as an equality between the Liouville operator and the collision integral,

$$\mathcal{L} f = St[f],$$

and looks for an approximate solution in the form

$$f = f^{(0)} + \delta f,$$

where $f^{(0)}$ is the local equilibrium distribution function and $\delta f$ is the nonequilibrium correction. Macroscopic description corresponding to local equilibrium is the ideal (Euler) hydrodynamics, while the nonequilibrium correction is responsible for dissipative terms. Typically\cite{10} one finds $\delta f$ within linear response noticing that the local equilibrium distribution function nullifies the collision integral due to electron-electron interaction: neglecting $\delta f$ in the Liouville’s operator, one writes Eq. (5) in the form

$$\mathcal{L} f^{(0)} = St[f],$$

linearizes the collision integral, and proceeds with the solution of the resulting linear integral equation (which, however nontrivial, is much simpler than the original nonlinear integro-differential equation).

The reason one is justified in neglecting $\mathcal{L} \delta f$ is the long wavelength nature of hydrodynamics – macroscopic quantities are assumed to be varying slowly over long distances such that their gradients are small. In this case, gradients of the correction, $\nabla \delta f$, represent the second-order smallness in the hydrodynamic expansion (formally, the small parameter is the so-called Knudsen number\cite{15,15}). Similar argument can be applied to the electric field. Magnetic field is typically not treated within linear response\cite{15} leading to the field-dependent viscosity and, in particular, to Hall viscosity\cite{16,16,16}. If one treats the time derivative in the Liouville’s operator in the same manner, then the resulting dissipative coefficients will acquire frequency dependence. In other words, instead of Eq. (7) yielding constant, field-independent viscosity and conductivity, I should solve the equation

$$\mathcal{L} \bigg|_{B=0} f^{(0)} + \partial_t \delta f + \frac{e}{c} [\mathbf{v} \times \mathbf{B}] \cdot \nabla \delta f = St_{eq}[\delta f] + St_{dis}[f].$$

In this paper I solve Eq. (8) focusing on the frequency- and field-dependent “effective conductivities” $\Sigma(\omega)$ and $\Sigma_H(\omega)$. A similar analysis of the frequency-dependent viscosity\cite{22} will be reported elsewhere.

B. Dissipative corrections to macroscopic currents in graphene

A comprehensive derivation of the dissipative hydrodynamics in graphene was reported in Ref. 15. In comparison to Eq. (6) that calculation disregarded the time derivative, $\partial_t \delta f$, yielding frequency-independent dissipative coefficients. On the other hand, the other terms in the (linear) equation (8) were evaluated in all the details. In this Section I outline that calculation in order to make the present present paper self-contained focusing on the essential changes that are necessary to evaluate optical conductivity. Technical details can be found in Ref. 15.

The main idea of the calculation is to formulate macroscopic equations for the three currents\cite{15} integrating the kinetic equation and expressing the non-equilibrium correction to the distribution function, $\delta f$, in terms of the dissipative corrections to the three currents\cite{15}

$$\delta f = f - f^{(0)} = f^{(0)} \left( 1 - f^{(0)} \right) h, \quad h = \frac{\mathbf{v}}{v_g} \sum_{i=1}^3 \phi_i \mathbf{h}^{(i)},$$

where the “three modes” (those that do not exhibit the collinear scattering singularity\cite{16,16,16}) are

$$\phi_1 = 1, \quad \phi_2 = \lambda, \quad \phi_3 = \frac{e}{T},$$

and the vectors $\mathbf{h}^{(i)}$ are related to the dissipative corrections to the macroscopic currents\cite{15} as\cite{15}

$$\left( \begin{array}{c} \delta j_l \\ \delta j_f \\ \delta j_{E/T} \end{array} \right) = \frac{v_g T}{2} \hat{M}_h \left( \begin{array}{c} h^{(1)} \\ h^{(2)} \\ h^{(3)} \end{array} \right),$$

where the matrix $\hat{M}_h$ is expressed in terms of equilibrium densities and compressibilities (see Appendix A for their
function (9) one finds

$$\hat{M}_n = \frac{\partial n}{\partial \mu} \hat{m}_n,$$

$$\hat{m}_n = \begin{pmatrix}
1 & \frac{xT}{T} \\
\frac{1}{2\pi^2} & 1 \\
\frac{1}{2\pi^2} \left( x^2 + \frac{x^2}{T^2} \right) & 1 \\
\frac{2\pi^2}{6\pi^2} & 1
\end{pmatrix},$$

(9c)

where \(\hat{n}\) and \(\hat{n}_E\) are the dimensionless carrier and energy densities, respectively, \(x = \mu/T\), and

$$\mathcal{T} = 2\pi v_g^2 \frac{\partial n}{\partial \mu} = 2T \ln \left[ 2 \sinh \frac{\mu}{2T} \right].$$

Multiplying Eq. (8) by velocity, \(\nu_{\lambda k}\), and integrating over all single-particle states (labeled by the momentum \(k\) and the band index \(\lambda = \pm\); \(N = 4\) is the degeneracy factor), one finds the macroscopic equation for the electric current

$$N \sum_k \int \frac{d^2 k}{(2\pi)^2} \nu_{\lambda k} \mathcal{L} f_{\lambda k}^{(0)} = \mathcal{I}_1 [f] - \frac{\partial \mathcal{J}_1}{\partial t} - \omega_B eB \times \mathbf{K}[\mathcal{f}].$$

The generalized cyclotron frequency,

$$\omega_B = \frac{eBv_g^2}{cT},$$

(10b)

and the vector quantity \(\mathbf{K}\)

$$\mathbf{K}[\mathcal{f}] = \mathcal{T} N \sum_k \int \frac{d^2 k}{(2\pi)^2} \frac{k}{k^2} \delta \mathcal{F}_{\lambda k},$$

(10c)

appear after integrating the Lorentz term. Evaluating the integral (10c) with the nonequilibrium distribution function (10) one finds

$$\mathbf{K}[\mathcal{f}] = \frac{eBv_g^2}{cT} \left[ \left( \frac{h^{(1)}{\tanh} \frac{x}{2} + h^{(2)}{\tanh} \frac{x}{2} + h^{(3)}{\tanh} \frac{x}{2} \right) \frac{T}{T} \right].$$

(10d)

The integrated collision integral, \(\mathcal{I}_1[f]\), comprises the electron-electron and disorder scattering terms. I assume the latter to be weak [see Eq. (2)] such that the \(\tau\)-approximation is sufficient (with the disorder scattering time \(\tau\) which in principle is model- and energy-dependent \(\tau\)) assumed to have the appropriate value determined by temperature and chemical potential. In this case,

$$\mathcal{I}_1^{\text{dis}} = -\frac{j^2}{\tau_{\text{dis}}}.$$  

(10e)

Since Eq. (10a) differs from that considered in Ref. [15] by the time derivative term in the right-hand side only, one can anticipate that the frequency-dependent dissipative coefficients can be elucidated from the results of Ref. [15] by adding the frequency to the disorder scattering time,

$$\frac{1}{\tau_{\text{dis}}} \rightarrow \frac{1}{\tau_{\text{dis}}} + \frac{\partial}{\partial t} \rightarrow \frac{1}{\tau_{\text{dis}}} - \text{i}\omega.$$  

The integrated Liouville’s operator, collision integral, and Lorentz term in Eq. (10a) were evaluated in Ref. [15]. To the linear order in \(u\) (representing linear response in \(E\)) one finds

$$N \sum_k \int \frac{d^2 k}{(2\pi)^2} \nu_{\lambda k} \mathcal{L} f_{\lambda k}^{(0)} = n \frac{\partial u}{\partial t} + \frac{v_g^2}{2} \nabla n - \frac{v_g^2}{2} eE \frac{\partial n}{\partial \mu}$$

$$- \frac{1}{\tau_{\text{dis}}} \frac{e}{c} \frac{\partial n}{\partial t} u \times B.$$  

(10f)

Expressing the time derivative in terms of gradients with the help of the Euler equation [i.e., Eq. (4)] without the viscous terms and magnetic field, one may express the integrated Liouville’s operator in terms of the gradient of the electro-chemical potential (in the absence of temperature gradients)

$$N \sum_k \int \frac{d^2 k}{(2\pi)^2} \nu_{\lambda k} \mathcal{L} f_{\lambda k}^{(0)} = v_g^2 \left( \frac{2n^2}{3n_E} - \frac{1}{2} \frac{\partial n}{\partial \mu} \right) \left( F_u - T \nabla \frac{\mu}{T} \right) - \left( \frac{2n_{E}}{3n_E} - \frac{1}{2} \frac{\partial n_{E}}{\partial \mu} \right) T \nabla \frac{\mu}{T}.$$  

Similarly to Eq. (10) one finds the macroscopic equation for the imbalance current. This time the kinetic equation is multiplied by \(\lambda \nu_{\lambda k}\) which upon integration yields

$$N \sum_k \lambda \int \frac{d^2 k}{(2\pi)^2} \nu_{\lambda k} \mathcal{L} f_{\lambda k}^{(0)} = \mathcal{I}_2 [f] - \frac{\partial \mathcal{J}_2}{\partial t} - \omega_B eB \times \mathbf{K}_I [\mathcal{f}].$$

(11a)

In the right-hand side of Eq. (11a), the integrated Lorentz term in Eq. (11a) contains the vector quantity

$$\mathbf{K}_I [\mathcal{f}] = \mathcal{T} N \sum_k \lambda \int \frac{d^2 k}{(2\pi)^2} \frac{k}{k^2} \delta \mathcal{F}_{\lambda k} = \frac{v_g T}{2} \frac{\partial n}{\partial \mu} \left[ h^{(1)}{\tanh} \frac{x}{2} + h^{(2)}{\tanh} \frac{x}{2} + h^{(3)}{\tanh} \frac{x}{2} \right],$$

(11b)

and \(\mathcal{I}_2 [f]\) denotes the integrated collision integral. The left-hand side of Eq. (11a) can be evaluated similarly to that in Eq. (10) such that

$$N \int \frac{d^2 k}{(2\pi)^2} \nu_{\lambda k} \mathcal{L} f_{\lambda k}^{(0)} = v_g^2 \left( \frac{2n_{E}}{3n_E} - \frac{1}{2} \frac{\partial n_{E}}{\partial \mu} \right) \left( F_u - T \nabla \frac{\mu}{T} \right) - \left( \frac{2n_{E}}{3n_E} - \frac{1}{2} \frac{\partial n_{E}}{\partial \mu} \right) T \nabla \frac{\mu}{T}.$$
Finally, the energy current \( j_E \) is proportional to the momentum density and hence the Liouville’s operator acting on the local equilibrium distribution function yields zero. The integrated collision integral in the equation for the energy current vanishes due to momentum conservation. As a result, the macroscopic equation for the energy current contains only the Lorentz and disorder scattering terms

\[
0 = -\frac{\delta j_E}{\tau_{\text{dis}}} - \frac{\partial j_E}{\partial t} - \omega_B \frac{T}{eB} \times \delta j.
\]  

(12)

Combining the three macroscopic currents into a vector, one can write all three macroscopic equations as a single equation in the matrix form

\[
\begin{pmatrix}
\mathbf{m} \\
\end{pmatrix}
\left[
\begin{array}{c}
F_u - T \nabla \left( \frac{\mu}{T} \right) \\
T \nabla \left( \frac{\mu}{T} \right) \\
0
\end{array}
\right] = \left[
\begin{array}{c}
\alpha_g T^2 \frac{\pi}{T} \left( \frac{1}{e} \frac{\tau_{\text{dis}}}{\hbar} \right) \mathbf{m} \\
\frac{\tau_{\text{dis}}}{\hbar} \mathbf{m} \\
\frac{\omega_B}{eB} \mathbf{m} \times \left( \frac{\delta j}{\delta j_E/T} \right)
\end{array}
\right],
\]  

(13a)

where the dimensionless matrix \( \mathbf{m} \) describes the integrated Liouville’s operators in the equations for the quasiparticle currents,

\[
\left[
\begin{array}{ccc}
\frac{2n^2}{\hbar^2} - \frac{1}{e\tau_{\text{dis}}} & 0 & 0 \\
0 & \frac{2n^2}{\hbar^2} & 0 \\
0 & 0 & 0
\end{array}
\right] = \frac{1}{2e\tau_{\text{dis}}} \mathbf{m}, \quad \mathbf{m} = \left[
\begin{array}{ccc}
1 - \frac{2n^2}{\hbar^2} & \frac{\omega_B}{eB} \\
0 & 1 - \frac{2n^2}{\hbar^2} & \frac{\omega_B}{eB} \\
0 & 0 & 1 - \frac{2n^2}{\hbar^2}
\end{array}
\right] \left[
\begin{array}{c}
1 \\
\frac{1}{\hbar^2} \\
0
\end{array}
\right],
\]  

(13b)

the dimensionless matrix \( \mathbf{m}_K \) describes the integrated Lorentz terms,

\[
\mathbf{m}_K = \left[
\begin{array}{ccc}
\tanh \frac{\tau_{\text{dis}}}{2} & 1 & \frac{\tau_{\text{dis}}}{T} \\
1 & \tanh \frac{\tau_{\text{dis}}}{2} & x \\
x & 1 & 2\tau_{\text{dis}}
\end{array}
\right],
\]  

(13c)

the integrated collision integral due to electron-electron interaction is expressed in terms of the “scattering rates” \( \tau_{\text{dis}} \)

\[
\left[
\begin{array}{ccc}
\tau_{\text{dis}}^e & 0 & 0 \\
0 & \tau_{\text{dis}}^e & 0 \\
0 & 0 & 0
\end{array}
\right] = -\frac{v_g T}{2e\tau_{\text{dis}}} \mathbf{m} = \left[
\begin{array}{ccc}
\tau_{\text{dis}}^e & 0 & 0 \\
0 & \tau_{\text{dis}}^e & 0 \\
0 & 0 & 0
\end{array}
\right] \left[
\begin{array}{c}
\hat{h}^{(1)} \\
\hat{h}^{(2)} \\
\hat{h}^{(3)}
\end{array}
\right], \quad \left[
\begin{array}{ccc}
\tau_{\text{dis}}^e & 0 & 0 \\
0 & \tau_{\text{dis}}^e & 0 \\
0 & 0 & 0
\end{array}
\right] = \frac{\alpha_g NT^2}{8\tau_{\text{dis}}} \mathbf{m},
\]  

(13d)

and finally \( \tau_{\text{dis}}^{-1} \) describing disorder scattering enters the equation together with the time derivative (as explained above).

Solving the linear equations \( (13) \) by usual methods\( ^{15} \), one finds for \( \mu_I = 0 \) and neglecting temperature gradients

\[
\left[
\begin{array}{c}
\frac{\delta j}{\delta j_E/T} \\
\end{array}
\right] = \mathbf{m} \left[
\begin{array}{c}
1 + \hat{S}_{xx}^{-1} \hat{S}_{xy}^{-1} \hat{S}_{xx}^{-1} \hat{S}_{xy}^{-1} \mathbf{m} \\
0 \\
0
\end{array}
\right] \left[
\begin{array}{c}
F_u - \nabla \mu \\
0 \\
0
\end{array}
\right],
\]  

(14a)

\[
-\mathbf{m} \left[
\begin{array}{c}
1 + \hat{S}_{xx}^{-1} \hat{S}_{xy}^{-1} \hat{S}_{xx}^{-1} \hat{S}_{xy}^{-1} \\
0 \\
0
\end{array}
\right] \left[
\begin{array}{c}
F_u - \nabla \mu \\
0 \\
0
\end{array}
\right] = \left[
\begin{array}{c}
F_u - \nabla \mu \\
0 \\
0
\end{array}
\right],
\]  

(14b)

where

\[
\hat{S}_{xx} = \frac{\alpha_g T^2}{2e\tau_{\text{dis}}} \mathbf{m} + \frac{\pi}{T} \left( \frac{1}{\hbar} \frac{\tau_{\text{dis}}}{\hbar^2} \right) \mathbf{m}, \quad \hat{S}_{xy} = \frac{\omega_B}{eB} \mathbf{m}_K.
\]  

Eq. \( (14) \) provides a closed expression for the dissipative corrections to the three macroscopic currents in the hydrodynamic picture of electronic transport in graphene. This result generalizes the earlier static solution\(^{15} \) providing the dissipative contribution to optical conductivity. While at charge neutrality the dissipative correction represents the total electric current, see Eq. \( (3) \), away from the Dirac point one has to take into account the time-dependent solution of the hydrodynamic equations, the Navier-Stokes equation\(^{34} \) and continuity equations. Such solution can be obtained in a closed analytic form in the two limiting cases, either close to charge neutrality or in the degenerate regime. These two cases will be considered in detail in the remainder of this paper. In the most general case (e.g., for \( \mu \sim T \)) the hydrodynamic equations have to be solved numerically. Such analysis is beyond the scope of the present paper and will be discussed elsewhere.
III. OPTICAL CONDUCTIVITY IN ZERO MAGNETIC FIELD

Consider first graphene in the absence of magnetic field. Then the dissipative correction to the electric current is given by the first line in Eq. (14), which now simplifies to

\[
\begin{bmatrix}
\delta j \\
\delta j_j \\
\delta j_E/T \\
\end{bmatrix} = \mathbf{m}_h \mathbf{S}_{xx}^{-1} \mathbf{m}_n \begin{bmatrix}
e E - \nabla \mu \\
0 \\
0 \\
\end{bmatrix}.
\]  
(15a)

The corresponding contribution to conductivity can then be formally expressed as

\[
\delta \sigma(\omega) = \begin{bmatrix}
1 \\
0 \\
0 \\
\end{bmatrix} \mathbf{m}_h \mathbf{S}_{xx}^{-1} \mathbf{m}_n \begin{bmatrix}
0 \\
0 \\
1 \\
\end{bmatrix}.
\]  
(15b)

In addition to Eq. (15b), the full electrical conductivity in graphene comprises also the “hydrodynamic” contribution, see the first term in the electric current (3i). In order to distinguish between the two, I will refer to Eq. (15b) as the “kinetic” contribution.

A. Hydrodynamic contribution to optical conductivity

The hydrodynamic contribution to the optical conductivity should be obtained by solving the Navier-Stokes equation (3c). Focusing on the homogeneous (q = 0) solution, I may write Eq. (3c) in the form

\[
W \partial_t u + u \partial_x P = v_g^2 e n E - \frac{W u}{\tau_{\text{dis}}}. 
\]  
(16a)

Looking for homogeneous solutions of the continuity equations (3a) and (3b), I conclude that

\[
\partial_t n = 0, \quad \partial_t n_E = 0, 
\]  
(16b)

hence the time derivative of pressure in the Navier-Stokes equation vanishes as well (P = n_E/2). Then the equation takes the form

\[
W u (\tau_{\text{dis}}^{-1} - i\omega) = v_g^2 e n E, 
\]  
(16c)

with the solution

\[
n u = \frac{v_g^2 n^2}{W} \frac{e E}{\tau_{\text{dis}}^{-1} - i\omega}. 
\]  
(16d)

The resulting hydrodynamic contribution to the optical conductivity is given by

\[
\sigma_h(\omega) = \frac{e^2 v_g^2 n^2}{W} \frac{1}{\tau_{\text{dis}}^{-1} - i\omega}. 
\]  
(17)

1. Hydrodynamic contribution to conductivity in the degenerate regime

In the degenerate regime, x \gg 1, the enthalpy and carrier density can be expressed in terms of the chemical potential,

\[
W = 3P = \frac{3n_E}{2} = \frac{\mu^3}{\pi v_g^2} \left(1 + \frac{\pi^2}{x^2}\right), 
\]  
(18a)

\[
n = \frac{\mu^2}{\pi v_g^2} \left(1 + \frac{\pi^2}{3x^2}\right). 
\]  
(18b)

Substituting these expressions into Eq. (17) and keeping the leading correction only, one finds

\[
\sigma_h(\omega) = \frac{e^2 \mu}{\pi} \frac{1}{\tau_{\text{dis}}^{-1} - i\omega} \left(1 - \frac{\pi^2}{3x^2}\right). 
\]  
(19)

In the limit x \to \infty the result (19) represents the total optical conductivity, since the dissipative correction (15a) vanishes, see below.

2. Hydrodynamic contribution to conductivity near charge neutrality

At charge neutrality, n = 0, the electrical current (3i) is completely determined by the dissipative correction (15a). For nonzero, but small carrier density, x \ll 1, the carrier and energy densities can be expanded as

\[
n = \frac{N T^2}{2\pi v_g^2} 2x \ln 2 + O(x^3), 
\]  
(20a)

\[
n_E = \frac{N T^3}{2\pi v_g^2} \left[3\zeta(3) + 2x^2 \ln 2\right] + O(x^4). 
\]  
(20b)

This yields the following solution (to the leading order in x \ll 1) of the Navier-Stokes equation (16c)

\[
n u = \frac{16 \ln^2 2}{9\pi \zeta(3)} x^2 T e E \frac{\tau_{\text{dis}}^{-1} - i\omega}{\tau_{\text{dis}}^{-1} - i\omega} + O(x^4). 
\]  
(21)

The resulting contribution to the optical conductivity is

\[
\sigma_h(\omega) = \frac{e^2 T 16 \ln^2 2}{\pi 9\zeta(3)} x^2 \frac{\tau_{\text{dis}}^{-1} - i\omega}{\tau_{\text{dis}}^{-1} - i\omega} + O(x^4). 
\]  
(21)

The numerical coefficient in Eq. (21) is of order unity,

\[
\frac{16 \ln^2 2}{9\zeta(3)} \approx 0.71. 
\]

Close to charge neutrality, the result (21) is subleading to the kinetic contribution to conductivity, which I discuss next.
B. Kinetic contribution to optical conductivity

Consider now the second contribution to conductivity, Eq. (15b), which stems from the dissipative correction to the electric current [15a]. Since the general expression is not transparent enough, I now consider the limiting cases.

1. Optical conductivity at charge neutrality

At charge neutrality, $x = 0$, the matrices $\hat{M}_h$ and $\hat{M}_n$ simplify,

$$\hat{M}_n = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & \frac{\pi^2}{6\ln 2} \zeta(3) \\ 0 & \frac{\pi^2}{2\ln 2} & 2\ln 2 \end{pmatrix}, \quad \hat{M}_n = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -\delta & 0 \\ 0 & 0 & \tau \end{pmatrix}, \quad \text{(22a)}$$

where $\zeta(z)$ is the Riemann’s zeta function and $\delta = 1 - \frac{\pi^4}{162\zeta(3)\ln 2} \approx 0.28$.

The matrix of the scattering rates simplifies as well since $\tau_{11}^{-1}(\mu = 0) = [113]$. As a result, the matrix $\hat{S}_{xx}$ has the block-diagonal form

$$\hat{S}_{xx} = \frac{\pi}{2T\ln 2} \begin{pmatrix} \tau_{11}^{-1} & 0 & 0 \\ 0 & \tau_{22}^{-1} & 0 \\ 0 & 0 & \tau \end{pmatrix} + \left(\frac{1}{\tau_{\text{dis}} - i\omega}\right) \hat{M}_h, \quad \text{(22b)}$$

where the electric current decouples from the other two. In the absence of temperature gradients the correction $\delta j_I$ vanishes [also $\delta j_E(B = 0) = 0$]. This can be seen from Eq. (15a) where the source term (i.e., the external electric field) is only present in the electric current sector. The conclusion about the energy current can be reached already from Eq. (12).

At zero frequency, the resulting electrical conductivity is given by Eq. (1):

$$\epsilon \delta j = \frac{2}{\pi} \ln 2 e^2 T \left(\frac{1}{\tau_{11}} + \frac{1}{\tau_{\text{dis}}}\right)^{-1} E \xrightarrow{\tau_{\text{dis}} \to \infty} \alpha \sigma Q E.$$

The coefficient $A$ in Eq. (1) can be found by evaluating the scattering rate numerically [11][14][15]:

$$A = 2(\ln 2)\alpha_g^2 T \tau_{11} \approx 0.12. \quad \text{(23)}$$

The explicit expression for $\tau_{11}$ is given in Appendix [3] Note, that the above value of $A$ was calculated with the unscreened Coulomb potential. At charge neutrality, this is a reasonable approximation for weak coupling (i.e., $\alpha_g \ll 1$). For larger values of $\alpha_g$, which may be more experimentally relevant, screening leads to a quantitatively significant change in $A$.

Keeping the nonzero frequency in Eq. (22b), I find the optical conductivity in graphene at charge neutrality [314]

$$\sigma(\omega; \mu = 0) = \frac{2}{\pi} \ln 2 \frac{e^2 T}{-i\omega + \tau_{\text{dis}} + \tau_{11}}, \quad \text{(24)}$$

FIG. 1: Optical conductivity in graphene at charge neutrality. The real and imaginary parts of Eq. (24) are shown by the solid and dashed curves, respectively. The shown dependence appears to agree with the experimental data of Ref. 7 (see Fig. 3D of that reference). The curves were calculated with $\alpha_g = 0.23$ and $\tau_{\text{dis}} = 0.8$ THz, the values taken from Ref. 7.

where $\tau_{11}$ is the same as in Eq. (23). This result is illustrated in Fig. 1.

2. Optical conductivity in the degenerate regime

Deep in the degenerate (or “Fermi-liquid”) regime, i.e. for $\mu \gg T$, the matrices in Eq. (15b) become degenerate. In particular, the matrix $\hat{M}_h$ determining the relation (9b) between the dissipative corrections to macroscopic currents and the nonequilibrium distribution function takes the form (up to exponentially small corrections)

$$\hat{M}_h = \begin{pmatrix} 1 & 1 & x \left[1 + \frac{x^2}{\pi^2}\right] \\ 1 & 1 & x \left[1 + \frac{x^2}{\pi^2}\right] \\ x \left[1 + \frac{x^2}{3\pi^2}\right] & x \left[1 + \frac{x^2}{\pi^2}\right] & x^2 \left[1 + \frac{x^2}{\pi^2}\right] \end{pmatrix}, \quad \text{(25)}$$

where I have used the asymptotic expressions

$$\tilde{n} \approx \tilde{n}_I = \frac{x^2}{2} + \frac{\pi^2}{6}, \quad \tilde{n}_E \approx \frac{x^3}{6} + \frac{\pi^2 x}{6}, \quad \frac{T}{\tau} \approx x.$$

The first of these equalities follows from the fact that in the degenerate regime only one band of carriers contributes to transport (the contribution of the other is exponentially suppressed; this is the reason why the two first rows in $\hat{M}_h$ are identical). In the limit $x \to \infty$ the factor $\pi^2/x^2 \to 0$ can be neglected. Then the third row of the matrix $\hat{M}_h$ is proportional to the first two, such that all three dissipative corrections in Eq. (6b) are proportional to each other. Now, regardless of the value of $x$, $\delta j_E(B = 0) = 0$, see Eq. (12), and hence we conclude

$$\delta j(x \to \infty) = \delta j_I(x \to \infty) \approx \delta j_E = 0. \quad \text{(26a)}$$

Note, that this result cannot be obtained from Eq. (15b) with the asymptotic form of $\hat{M}_h$ and other matrices since

[Note: The text contains a mix of mathematical and textual content, focusing on the kinetic contribution to optical conductivity in graphene at charge neutrality and the degenerate regime. The equations and results are presented with emphasis on the natural reading, ensuring clarity and coherence in the scientific context.]
in this limit the matrix $S_{xx}$ is degenerate (with or without the power law corrections). To find corrections to Eq. (26b), one has to either to keep track of exponentially small corrections to Eq. (25) or, alternatively, disregard the imbalance mode (since $f_j = \delta f_j$ with exponential accuracy). Inverting the remaining $2 \times 2$ matrix, one finds

$$\delta \sigma(\omega) = \frac{\pi^3 e^2 \mu}{3 x^2 \left[ 3x^2 \tau_{11}^{-1} + \pi^2 (\tau_{1}^{-1} - i \omega) \right]}.$$  \hfill (26b)

The scattering rate $\tau_{11}^{-1}$ in the degenerate regime has the asymptotic form (neglecting screening; see Appendix C)

$$\tau_{11}^{-1}(x \gg 1) \approx \frac{4 \pi}{3} \frac{a_g T^2}{\mu} = \frac{4 \pi}{3} \frac{a_g^2 \mu}{x^2}.$$ \hfill (26c)

Combining both contributions, Eqs. (26b) and (19), I find the optical conductivity in graphene as

$$\sigma(\omega) = \frac{e^2 \mu}{\pi} \left[ 1 - \frac{\tau_{11}^{-1}}{(3x^2/\pi^2) \tau_{11}^{-1} + \tau_{1}^{-1} - i \omega} \right], \hfill (27)$$

where the leading contribution is determined by disorder scattering only. The kinetic contribution to conductivity, $\delta \sigma$, is suppressed as $x^{-2}$. Moreover, the frequency dependence in $\delta \sigma$ becomes important only when it is comparable to $(3x^2/\pi^2) \tau_{11}^{-1} \gg \tau_{11}^{-1}$, see below.

3. Optical conductivity close to the Dirac point

Close to charge neutrality, i.e. for nonzero, but small carrier densities, $x \ll 1$, one finds corrections to Eq. (24). Expanding the matrices $\tilde{m}_{h(n)}$ around the Dirac point, one finds

$$\tilde{m}_{h(n)} = \tilde{m}_{h(n)}(x = 0) + \delta \tilde{m}_{h(n)} + O(x^3),$$

where $\tilde{m}_{h(n)}(x = 0)$ are given in Eq. (22a), while the leading-order corrections are given by

$$\delta \tilde{m}_h = x \begin{pmatrix} 0 & 1/2 \ln 2 & x/2 \ln 2 & 2 \\ 1/2 \ln 2 & 0 & x/2 \ln 2 & 1 - x^2/2 \ln 2 \\ 2 & x/2 \ln 2 & 3x/2 & 1 - 3x^2/16 \ln 2 \\ 2 & x/2 \ln 2 & 3x/2 & 1 - 3x^2/16 \ln 2 \end{pmatrix},$$

and

$$\delta \tilde{m}_n = x \begin{pmatrix} x & -8 \ln 2 & 4\pi^2 \ln 2 & -27 \pi \\ -4\pi^2 \ln 2 & -27 \pi & 2\pi \xi x & 4\pi^2 \ln 2 \\ 2\pi \xi x & -27 \pi & 0 & 2\pi \xi x \\ -2\pi \xi x & 4\pi^2 \ln 2 & -27 \pi & 0 \\ 0 & 2\pi \xi x & 4\pi^2 \ln 2 & 0 \\ 0 & 2\pi \xi x & 4\pi^2 \ln 2 & 0 \\ 0 & 2\pi \xi x & 4\pi^2 \ln 2 & 0 \\ 0 & 2\pi \xi x & 4\pi^2 \ln 2 & 0 \end{pmatrix}. \hfill (28a)$$

The matrix $S_{xx}$ can be expanded in the same way, using the expansion of the scattering rates given in Appendix D. To the leading order, one finds

$$S_{xx} = S_{xx}(x = 0) + \delta S_{xx} + O(x^3),$$

where $S_{xx}(x = 0)$ is given by Eq. (22b) and

$$\delta S_{xx} = \frac{a_g^2}{8 \ln 2} \delta \tilde{T} + \frac{\pi}{2 T \ln 2} (\tau_{1}^{-1} - i \omega) \delta \tilde{m}_h,$$

with

$$\delta \tilde{T} = x \begin{pmatrix} 0 & 1/T_{11} & x/2 \ln 2 & 1/T_{12} \\ 1/T_{11} & 0 & x/2 \ln 2 & 1/T_{12} \\ x/2 \ln 2 & 1/T_{12} & 0 & 0 \\ 0 & 1/T_{12} & 0 & 0 \end{pmatrix},$$

see Eqs. (22) for notations. Substituting the above expansions into Eq. (15b), one finds (see Appendix E for details)

$$\delta \sigma(\omega) = \sigma(\omega; \mu = 0) + x^2 \delta \sigma^{(2)}(\omega) + O(x^3), \hfill (28b)$$

$$\delta \sigma^{(2)} = \frac{\gamma_{11} e^2 T}{-i \omega + \tau_{1}^{-1} + \tau_{11}^{-1}(0)} + \frac{\gamma_{12} e^2 T}{-i \omega + \tau_{1}^{-1} + \tau_{13}^{-1}(0)} + \frac{\gamma_{31} e^2 T}{-i \omega + \tau_{1}^{-1} + \tau_{12}^{-1}(0)} + \frac{\gamma_{32} e^2 T}{-i \omega + \tau_{1}^{-1} + \tau_{13}^{-1}(0)} + \frac{\gamma_{33} e^2 T}{-i \omega + \tau_{1}^{-1} + \tau_{13}^{-1}(0)}, \hfill (28c)$$

where

$$\gamma_{11} \approx 0.075, \quad \gamma_{12} \approx 0.66, \quad \gamma_{13} \approx 3.59, \hfill (28d)$$

$$\gamma_{31} \approx 0.81, \hfill (28e)$$

$$\gamma_{32} = \gamma_{32} + \gamma_{41} \approx 0.91, \quad \gamma_{33} = \gamma_{42} - \gamma_{33} \approx 0.102. \hfill (28f)$$

The total optical conductivity in the vicinity of the Dirac point is given by the sum of the leading term (24), the hydrodynamic contribution (21), and the above correction (28b). The two terms are compared in Fig. 2.
C. Comparison with the existing literature

Optical conductivity in graphene was already studied in several publications, so it is worthwhile to compare the above calculations to the previously known results.

The authors of the pioneering paper, Ref. 30, used general hydrodynamic arguments to find the optical conductivity at a generic charge density in the form

\[ \sigma_{xx} = \sigma_Q + \sigma_h(\omega), \]

where \( \sigma_Q \) is the dissipative constant [1] and the hydrodynamic contribution is given (up to the choice of normalization) by Eq. (17). The specific value of \( \sigma_Q \) for graphene was calculated in Refs. 31, 32, 37, 38.

Conductivity at the Dirac point in the absence of disorder was studied in detail in Ref. 32. The result of this paper is the same as Eq. (24) without the disorder scattering rate. The electron-electron scattering rate estimated in Ref. 32

\[ \tau^{-1}_{11} \rightarrow \kappa \alpha_s^2 T, \quad \kappa = 3.646, \]

perfectly agrees with Eq. (12a), where the numerical prefactor is 3.8. Note that this value was obtained for unscreened Coulomb interaction.

Optical conductivity beyond the charge neutrality was reported in Ref. 31. Here the authors combined the result of Ref. 32 with the hydrodynamic contribution previously reported in Ref. 30. In addition, the effect of disorder scattering was studied not only in the limit of weak disorder, but also for strong disorder, where the hydrodynamic approach is no longer valid. For weak disorder, the authors of Ref. 31 reported an expansion in the disorder strength.

The effect of disorder was also studied in Ref. 33 at charge neutrality. The reported zero-frequency conductivity agrees with Eq. (24) for weak disorder, \( T \tau_{\text{dis}} \gg 1 \). For stronger disorder, the authors of Ref. 33 took into account the effect of disorder scattering on the excitation spectrum in graphene which is beyond the scope of the present paper.

More recently, the interpolation formula [1] was suggested in Ref. 34 with the coefficient \( A_1 \) coinciding with that in Eq. (17) and the coefficient \( A_2 \) given by the difference

\[ A_2 \rightarrow \varepsilon^2 \left[ \frac{T}{\pi} - \frac{v_s^2 \mu^2}{W} \right]. \]

This expression interpolates between the two limiting cases, Eq. (24) at charge neutrality and Eq. (19) in the degenerate regime. In the former case, \( n = 0 \) (such that \( A_1 = 0 \)) and \( T = 2T \ln 2 \), while in the latter case, \( T = \frac{v_s^2 \mu^2}{W} = \mu \), such that \( A_2 = 0 \).

The interpolation formula [1] was used to interpret the result of recent measurements of the optical conductivity in graphene reported in Ref. 7. At charge neutrality, the experimental data appears to confirm the result [24] with \( \tau_{\text{dis}} \gg \tau_{11} \) providing a reasonable (in line with previous measurement [31, 39]) estimate for the value of \( \alpha_s \) in real graphene. Data away from charge neutrality were measured at rather low charge densities, where the scattering rates [15] exhibit only small deviations from the Dirac point values (this conclusion agrees with the results of Ref. 7). In addition, the kinetic contribution to optical conductivity [15b] has a Lorentzian shape as a function of frequency. Hence, Eq. (15b) can be represented in the form of the second term in Eq. (1) by choosing the appropriate values for \( \tau_{\alpha} \) and \( \tau_{\text{dis}} \) (as was done in Ref. 7) where the data was fitted by Eq. (1) with the electronic temperature and \( \tau_{\text{dis}} \) used as fitting parameters. Note, that this procedure neglects renormalization of \( v_g \) due to electron-electron interaction [10, 12, 19].
IV. MAGNETOCONDUCTIVITY IN GRAPHENE

Consider now the effect of classical magnetic fields on the optical conductivity in graphene. The classical approach is justified at high enough temperatures where quantized transport is smeared out.

The general expression for the dissipative corrections to macroscopic currents is given by Eqs. (14). In the presence of the magnetic field, these corrections become "entangled" with the hydrodynamic velocity due to the Lorentz contribution to \( F_u \).

A. Magnetoconductivity at charge neutrality

The dissipative correction to the energy current was defined through Eq. (12). Substituting this relation into the Navier-Stokes equation (3c) at charge neutrality, one finds a stationary and uniform solution, \( u = 0 \). Evaluating all matrices in Eqs. (14), one has to consider not only Eqs. (22), but also the matrix (13c). At \( x = 0 \) I find

\[
\begin{pmatrix}
0 & 1 & 2\ln 2 \\
1 & 0 & 0 \\
2\ln 2 & 0 & 0
\end{pmatrix}
\]

(29)

Instead of multiplying the matrices in the general solution (14a), it appears to be more instructive to write Eq. (13a) explicitly at \( x = 0 \) and proceed with solving the resulting equations.

Using Eq. (22a), the left-hand side of Eq. (13a) takes the form

\[
\begin{pmatrix}
\hat{\mathbf{M}}_n \\
\hat{\mathbf{M}}_n^{-1}
\end{pmatrix}
\begin{pmatrix}
e^E \\
0 \\
0
\end{pmatrix}
= \begin{pmatrix}
e^E \\
0 \\
0
\end{pmatrix}.
\]

The longitudinal part of the right-hand side of Eq. (13a) is given by multiplying Eq. (22b) by \( \hat{\mathbf{M}}_n^{-1} \), see Eq. (22a),

\[
\frac{\pi}{2T \ln 2} \begin{pmatrix}
\frac{\tau_{11}^{-1}}{1 - \frac{i\omega}{\tau_{11}^{-1}} - \frac{\delta_1^{-2}}{2\zeta(3)\delta}} \\
0 \\
0
\end{pmatrix} = \frac{1}{\tau_{\text{dis}} - i\omega} + \frac{\tau_{11}^{-1}}{1 - \frac{i\omega}{\tau_{11}^{-1}} - \frac{\delta_1^{-2}}{2\zeta(3)\delta}}.
\]

while the Hall part is given by

\[
\frac{\pi \omega B}{2T \ln 2} \begin{pmatrix}
0 & \delta_1 - \delta_2 \\
1 & 0 \\
2\ln 2 & 0
\end{pmatrix} e_B \times \begin{pmatrix}
\delta j \\
\delta j_{E/T}
\end{pmatrix},
\]

where

\[
\delta_1 = \frac{1}{\delta} - \frac{2\pi^2 \ln 2}{27\zeta(3)\delta} \approx 2.08, \quad \delta_2 = \frac{\pi^2 - 12 \ln^2 2}{27\zeta(3)\delta} \approx 0.45.
\]

As a result, the three equations for macroscopic currents simplify admitting a simple analytical solution. This solution is analogous to the solution of the stationary equations leading to the zero-frequency conductivity, see Refs. [15][23].

The third such equation stems from Eq. (12) and allows one to express the correction to the energy current, \( \delta j_E \), in terms of the correction to the electric current, \( \delta j \),

\[
\delta j_E = -2(\ln 2) \frac{\omega B T}{\tau_{\text{dis}} - i\omega} e_B \times \delta j. \quad (30a)
\]

The second equation determines the correction to the imbalance current

\[
\delta j_1 = -\frac{\omega B}{\tau_{\text{dis}} - i\omega} \left[ \frac{1}{1 - \frac{\delta_1^{-2}}{\tau_{22}^{-1} - \tau_{11}^{-1} - i\omega}} - \frac{\delta_1^{-2}}{\tau_{22}^{-1} - \tau_{11}^{-1} - i\omega} \right] e_B \times \delta j. \quad (30b)
\]

The first equation determines the electrical current

\[
e^E = \frac{\pi}{2T \ln 2} \left( \tau_{11}^{-1} + \tau_{\text{dis}}^{-1} - i\omega \right) \delta j + \frac{\pi \omega B}{2T \ln 2} \left( \delta_1 e_B \times \delta j_1 - \delta_2 e_B \times \delta j_{E/T} \right). \quad (30c)
\]

Both of the corrections (30a) and (30b) are orthogonal to the electric current, hence \( \delta j || E \). This means that no orthogonal component of the current is generated, in other words, there is no classical Hall effect in graphene at charge neutrality, as expected. Substituting the relations (30a) and (30b) into Eq. (30c), I find

\[
\sigma_{xx}(\omega) = \frac{2}{\pi} \frac{\pi \ln 2}{\tau_{\text{dis}}^{-1} - i\omega} e^2 T \left( \tau_{\text{dis}}^{-1} - i\omega \right) \frac{\delta_2 e_1 \times \delta j_{E/T}}{\tau_{11}^{-1} + \tau_{\text{dis}}^{-1} - i\omega}
\]

(31)

magnetoresistance previously found in Refs. [15][23][31].

Let me now estimate the relative value of various parameters in Eq. (31) using the data of Ref. [7]. Measurements at charge neutrality yield the following value of the coupling constant, \( \alpha_g = 0.23 \). Using Eqs. (12), this lead to the following estimates of the scattering rates at
The disorder scattering rate at 267 K was estimated as
\[ \tau_{\text{dis}}^{-1} \approx 0.8 \text{THz}. \]

Finally, evaluating Eq. (10b) at a reference magnetic field, \( B = 1 \text{T} \), the frequency \( \omega_B \) can be estimated as
\[ \omega_B = \frac{|e|v_f^2B}{2eT\ln 2} \approx 27.9 \text{THz} \frac{B}{1 \text{T}} \frac{300 \text{K}}{T}, \]
such that at 267 K and 0.1 T one finds \( \omega_B \approx 3.13 \text{THz} \).

For comparison, 267 K \( \rightarrow 34.96 \text{THz} \), so the hydrodynamic picture is fully justified.

At higher frequencies and magnetic fields the hydrodynamic picture breaks down\([31]\) in the sense that the local equilibrium (underlying the traditional derivation of the hydrodynamic equations\([10,11,14,15]\)) cannot be formed. At the same time, the kinetic (Boltzmann) equation has a much wider range of applicability. Within linear response, the kinetic equation can be integrated to obtain the macroscopic equations for quasiparticle current\([23,24–29]\) without referring to local equilibrium. Remarkably, these linear response equations coincide with the macroscopic current equations\([10,11,14,15]\) and\([12]\), see Ref. 15 for more details. On one hand, this means that the results for linear response quantities, e.g. the electrical conductivity, obtained within the hydrodynamic theory coincide with the results of the linear response theory. On the other hand, the result\([31]\), which has not been worked out within the linear response theory, has a wider regime of applicability than the concept of local equilibrium.

Extending the range of frequencies and magnetic fields in Eq. (33) one arrives at the resonance-like picture illustrated in Fig. 4. Note that at these frequencies one typically assumes the system to be in the collisionless regime,\([21,22]\) where the optical conductivity is given by the universal value (up to weak interaction corrections)
\[ \sigma_U(\omega) = \frac{\pi e^2}{2h} \left[ 1 + C_\sigma \alpha_g(\omega) \right], \]  
(32a)  
where the renormalized coupling constant \( \alpha_g(\omega) \) and the numerical coefficient are given by
\[ \alpha_g(\omega) = \frac{\alpha_g}{1 + \frac{\alpha_g}{4} \ln \frac{\omega}{\omega_0}}, \quad C_\sigma \approx 0.01. \]  
(32b)

Physically, the universal value (32) is due to interband transitions and is hence beyond the semiclassical Boltzmann equation discussed in this paper. One typically assumes that the solutions to the Boltzmann equation yield the conductivity decaying with frequency, such that in the high-frequency regime Eq. (32) dominates. In the hydrodynamic regime this is illustrated in Fig. 3, where the universal value (32) is shown by the horizontal red line. Extending the kinetic theory beyond the hydrodynamic regime leads to the cyclotron resonance at high frequencies where the solution to the Boltzmann equation dominates over Eq. (32), see Fig. 4.

**B. Magnetoconductivity in the degenerate regime**

In the degenerate or Fermi-liquid regime only one band contributes to electronic transport and hence \( j = j_j \) with exponential accuracy (see above). At the same time, away from charge neutrality the dissipative corrections depend on the hydrodynamic velocity \( u \) and hence the “hydrodynamic” and “kinetic” contributions to conductivity become entangled. In this case, it seems more transparent to consider the macroscopic equations for the electrical and energy currents explicitly. As shown in Ref. 15, these equations are exactly the same as the macroscopic linear response equations considered in Ref. 23. Similar equations have been derived in Ref. 40.

The equation for the energy current is just the Navier-Stokes equation\([9c]\). For a homogeneous flow the gradient terms and the time derivative of pressure vanish, see the above derivation of Eq. (10c), such that the equation takes the form
\[ j_E (\tau_{\text{dis}}^{-1} - i\omega) = v_g^2 n E + v_g^2 \frac{e}{c} j \times B. \]
(33a)

The equation for the electric current is given by Eq. (10).

For a homogeneous flow this equation takes the form
\[ j (\tau_{\text{dis}}^{-1} - i\omega) = \frac{1}{2} v_g^2 \frac{\partial n}{\partial \mu} e E + \omega_B K \times e B + \mathcal{I}_\text{ee}. \]
(33b)

To the leading order\([23]\) \( j_E \approx \mu j, K \approx j, \) and \( \mathcal{I}_\text{ee} \rightarrow 0. \)

In this case, the two equations (33) are identical yielding the standard Drude-like result\([15]\)
\[ \sigma_{xx} = \frac{e^2 \mu \tau_{\text{dis}}}{\pi} \frac{1 - i\omega \tau_{\text{dis}}}{(1 - i\omega \tau_{\text{dis}})^2 + \omega_B^2 \tau_{\text{dis}}^2}, \]  
(34a)
\[ \sigma_{xy} = -\frac{e^2 \mu \tau_{\text{dis}}}{\pi} \frac{\omega_B \tau_{\text{dis}}}{(1 - i\omega \tau_{\text{dis}})^2 + \omega_B^2 \tau_{\text{dis}}^2}. \]  
(34b)

Here the electric field is taken to be directed along the \( x \)-axis, the magnetic field – along the \( z \)-axis. Note that the electric field is assumed to be oscillating, \( E \sim \exp(-i\omega t) \), and the magnetic field is assumed to be static. For \( \omega = 0, \) I recover the standard magnetoconductivity\([23,19]\).

At \( B = 0 \) the results\([31]\) yield the Drude conductivity given by Eq. (19) where one has to set \( x \rightarrow \infty \). The leading correction to the Drude result is given by Eq. (27) where both the correction in Eq. (19) and the kinetic contribution\([26b]\) are taken into account.

The origin of these corrections is in the differences between the two equations (33). Indeed, setting \( B = 0 \) and subtracting Eq. (33a) from Eq. (33b), one finds
\[ \left( j - j_E \right) (\tau_{\text{dis}}^{-1} - i\omega) = v_g^2 \left( \frac{1}{2} \frac{\partial n}{\partial \mu} - \epsilon \right) e E + \mathcal{I}_1^{\text{ee}} = -\frac{\pi e^2}{3x^2} \frac{\mu}{\pi} \epsilon E + \mathcal{I}_1^{\text{ee}}, \]
where I used the equilibrium carrier density and compressibility in the limit \( x \rightarrow \infty \), see Appendix A keeping only the leading power law term.
In the same limit, the collision integral $I_{1}^{ee}$ can be expressed in terms of the two currents as

$$I_{1}^{ee} = \frac{1}{2} v_{g} T \frac{\partial n}{\partial \mu} \tau_{11}^{-1} h^{(1)} = \frac{3 x^{2}}{\pi^{2}} \left( 1 + \frac{\pi^{2} \gamma}{3 x^{2}} \right) \left( 1 + \frac{\pi^{2}}{3 x^{2}} \right) \frac{j_{\mu}}{\mu}.$$  

Note that although Eq. (9b) relates the function $h^{(1)}$ to the dissipative corrections $\delta j_{\alpha}$ and $\delta j_{E}$, the hydrodynamic part of the macroscopic currents does not contribute to the collision integral as can be seen from the above expression by direct substitution.

Finally, the difference in the Lorentz terms in Eqs. (33) can be found by evaluating the quantity $K$ to the sub-leading order

$$K = \frac{1}{1 - \frac{\pi^{2}}{3 x^{2}}} \left( 2 j - \frac{j_{\mu}}{\mu} \right).$$

Using the above expressions, solving Eqs. (33) is a straightforward although tedious task. The result can be expressed as

$$\sigma_{xx} = \frac{e^{2} \mu T_{\text{dis}}}{\pi} \left( 1 + i \omega T_{\text{dis}} \right) \left[ S_{0} + \frac{\omega_{B}^{2} T_{\text{dis}} S_{1} S_{2}}{1 - i \omega T_{\text{dis}}} \right], \tag{35a}$$

$$\sigma_{xy} = -\frac{e^{2} \mu T_{\text{dis}}}{\pi} \frac{\omega_{B} T_{\text{dis}} (S_{0} S_{1} - S_{2})}{1 - i \omega T_{\text{dis}}} + \frac{S_{2}}{1 - i \omega T_{\text{dis}}^{2}}, \tag{35b}$$

where

$$S_{0} = 1 - \frac{\tau_{11}^{-1} \left( (3 x^{2} / \pi)^{2} \tau_{11}^{-1} - \tau_{\text{dis}}^{-1} - i \omega \right)}{\left( (3 x^{2} / \pi)^{2} \tau_{11}^{-1} + \tau_{\text{dis}}^{-1} - i \omega \right)^{2} + \omega_{B}^{2}},$$

$$S_{1} = 1 - \frac{3 \tau_{11}^{-1} \left( (3 x^{2} / \pi)^{2} \tau_{11}^{-1} + \tau_{\text{dis}}^{-1} - i \omega \right)}{\left( (3 x^{2} / \pi)^{2} \tau_{11}^{-1} + \tau_{\text{dis}}^{-1} - i \omega \right)^{2} + \omega_{B}^{2}},$$

$$S_{2} = \frac{(\tau_{\text{dis}}^{-1} - i \omega)^{2}}{3 x^{2} \left[ (3 x^{2} / \pi)^{2} \tau_{11}^{-1} + \tau_{\text{dis}}^{-1} - i \omega \right]^{2} + \omega_{B}^{2}}.$$  

In the limit $x \to \infty$, one finds $S_{0} = S_{1} = 1, S_{2} = 0$ and one recovers Eqs. (33). For $B = 0$, the result (35a) coincides with Eq. (27).

**V. DISCUSSION**

In this paper I have considered optical conductivity in graphene in the hydrodynamic regime. Within the hydrodynamic approach, the electric current is split into the hydrodynamic and kinetic contributions, see Eq. (31), with the latter representing the dissipative correction. Unlike the traditional hydrodynamics in systems with exact momentum conservation, the hydrodynamic equations in graphene include weak impurity scattering. As a result, both contributions to the electric current decay yielding Eqs. (17) and (15b).

Exactly at the neutrality point, the hydrodynamic contribution to electric current [and hence the conductivity (17)] vanishes. In this case, the optical conductivity in graphene is given by Eq. (21) illustrated in Fig. 1. Assuming the disorder scattering time in Eq. (21) to be negligibly small, one recovers the result of Ref. [32]. This result was recently used in Ref. [7] to establish the experimental value of the electron-electron scattering time and ultimately the coupling constant, $\alpha_{g}$. In the experiment, one treats $\alpha_{g}$ as a fitting parameter using the expression $\tau_{11}^{-1} = C \alpha_{g}^{2} T$, with the numerical coefficient $C$ calculated in Refs. [14, 32, 38, 39] assuming the unscreened Coulomb interaction. Such approach can be justified by 1/N expansion suggesting that all interaction effects including screening and renormalization are confined to establishing the value of the effective coupling constant but do not significantly alter the momentum dependence of the matrix elements of the Coulomb interaction [39] (in the typical momentum range contributing to the collision integral).

At high enough doping levels, the electronic system in graphene is degenerate and most results resemble their counterparts in the usual Fermi liquid. In particular, the optical conductivity is given by Eq. (19). This expression is independent of the electron-electron scattering rate, which could be interpreted as “restoration” of Galilean invariance in the Fermi liquid regime. This result is fully “hydrodynamic” whereas the kinetic contribution to conductivity vanishes in this limit.

At intermediate carrier densities, the electrical conductivity is determined by the interplay of the above two mechanisms. While the hydrodynamic contribution keeps the simple form (17), the general expression for the kinetic contribution, Eq. (14), is extremely cumbersome. It is therefore tempting to use the interpolation formula, Eq. (1), instead. As evidenced by the leading corrections in both limits, Eqs. (27) and (28), the “exact” result (15b) differs from Eq. (1). However, the resulting optical conductivity is still roughly Lorentzian and hence could be fit by Eq. (1) using the two scattering rates as fitting parameters. Such approach was adopted in Ref. [7] (even the electronic temperature was obtained from the fit).

External magnetic field further complicates the theory by entangling the two contributions to the electric current. While not affecting the leading-order behavior in the degenerate regime, Eq. (34), the leading correction to the Drude behavior, Eq. (35), is dominated by the coupling between the two modes. At charge neutrality, the homogeneous electric current is still unaffected by the coupling to the hydrodynamic modes, but this is expected to change in finite size samples where the flow becomes inhomogeneous. Previously, this physics was used to explain giant magnetoresistance in graphene [40] and to predict linear magnetoresistance in classically strong magnetic fields [23, 24, 25, 26].
Finally, linear response transport in electronic systems can be described within the kinetic theory in wider parameter range as compared to the applicability region of hydrodynamics. The latter assumes that strong electron-electron interaction establishes local equilibrium [11,15] describing the ideal hydrodynamic flow. In contrast, the linear response theory [23] assumes that in the absence of external fields the system is in the global equilibrium state described by the Fermi-Dirac distribution function and characterized by vanishing currents. Here the currents appear only as a response to the external electric field. Remarkably, linearizing the hydrodynamic equations in graphene (in order to find the linear response coefficients, such as electrical conductivity) yields exactly the same macroscopic equations [e.g., Eqs. (33)] as in the linear response theory rendering these equations more general than the concept of local equilibrium. Consequently, the results for optical conductivity obtained in this paper are valid in a wider frequency range than expected from the purely hydrodynamic perspective. This conclusion is most pronounced for the cyclotron response in moderately strong magnetic fields, see Fig. 4, where the kinetic contribution to the magnetoconductance is beyond the scope of this paper and will be reported elsewhere.

Appendix A: Local equilibrium quantities

Under the assumption of local equilibrium, the macroscopic quantities appearing in the hydrodynamic theory can be computed explicitly [12]. The quasiparticle densities and the energy density have the following form

\[ n = n_+ - n_- = \frac{T^2}{v_g^2} \frac{g_2 (\mu_+/T) - g_2 (-\mu_-/T)}{(1-u^2/v_g^2)^{3/2}}, \]  
\[ n_I = n_{+,0} + n_- = \frac{T^2}{v_g^2} \frac{g_2 (\mu_+/T) + g_2 (-\mu_-/T)}{(1-u^2/v_g^2)^{3/2}}, \]

where

\[ g_2 \left( \frac{\mu}{T} \right) = -\frac{N}{2\pi} \text{Li}_2 \left( -e^{\mu/T} \right), \]  
\[ g_3 \left( \frac{\mu}{T} \right) = -\frac{N}{2\pi} \text{Li}_3 \left( -e^{\mu/T} \right), \]

with \( \text{Li}_n \) being the polylogarithm. It is convenient to express the densities \( [A1] \) in the dimensionless form

\[ n = \frac{NT^2}{2\pi v_g^2} \tilde{n}, \quad n_I = \frac{NT^2}{2\pi v_g^2} \tilde{n}_I, \quad n_E = \frac{NT^3}{\pi v_g^2} \tilde{n}_E. \]

In the simplest case considered in this paper, \( \mu_{\pm} = \mu \), the dimensionless imbalance density simplifies to

\[ \tilde{n}_I = x^2 - \pi^2/6, \quad x = \frac{\mu}{T}. \]

Similarly, the compressibilities (for \( \mu_{\pm} = \mu \)) are given by

\[ \frac{\partial n}{\partial \mu} = \frac{NT}{2\pi v_g^2}, \quad \frac{\partial n_I}{\partial \mu} = \frac{N\mu}{2\pi v_g^2}, \quad T = 2T \ln \left[ 2 \cosh \frac{x}{2} \right]. \]

The two thermodynamic quantities in the hydrodynamic theory, the pressure and enthalpy are given by

\[ P = n_E \frac{1 - u^2/v_g^2}{2 + u^2/v_g^2}, \]  
\[ W = n_E + P = \frac{3n_E}{2 + u^2/v_g^2}. \]

They can be used to determine the stress-energy tensor

\[ \Pi_{\alpha\beta}^{E,g} = P \delta_{\alpha\beta} + v_g^{-2} W u_\alpha u_\beta, \]

and the energy current (proportional to the momentum density \( n_k \))

\[ j_E = v_g^2 n_k = W u. \]

This relation is the key feature of the hydrodynamic description of the electronic system in graphene showing that it is the energy and not electric current that is described by the hydrodynamic flow. The quasiparticle currents are determined by the corresponding densities

\[ j = nu, \quad j_I = n_I u. \]

Unlike the energy current, the quasiparticle currents are not conserved in electron-electron collisions and hence acquire the dissipative corrections \( [33] \). Furthermore, the energy current can be relaxed by disorder scattering and hence acquires a dissipative correction of its own.

Acknowledgments

I thank A.D. Mirlin, J. Schmalian, M. Schütt, and especially I.V. Gornyi for numerous fruitful discussions. Appendix B: Collision integral

The integrated collision integrals \[ B2d \] are expressed in terms of the following scattering rates\[ B2f \]

\[
\frac{1}{\tau_{11}} = \pi^2 \alpha_s^2 NT \int \frac{d^2Q \ dW}{(2\pi)^2 2\pi} \frac{|\tilde{U}|^2}{\sinh^2 W} (Y_{00}Y_{11} - Y_{01}^2),
\]

(B1a)

\[
\frac{1}{\tau_{12}} = \pi^2 \alpha_s^2 NT \int \frac{d^2Q \ dW}{(2\pi)^2 2\pi} \frac{|\tilde{U}|^2}{\sinh^2 W} (Y_{00}Y_{12} - Y_{02}Y_{01}),
\]

(B1b)

\[
\frac{1}{\tau_{22}} = \pi^2 \alpha_s^2 NT \int \frac{d^2Q \ dW}{(2\pi)^2 2\pi} |\tilde{U}|^2 \sinh^2 W (Y_{00}Y_{22} - Y_{02}^2),
\]

(B1c)

with

\[
Y_{00}(\omega, q) = \frac{1}{4\pi} \left[ \frac{\theta(|\Omega| \leq 1)}{\sqrt{1 - \Omega^2}} Z_0^\omega[I_1] + \frac{\theta(|\Omega| \geq 1)}{\sqrt{\Omega^2 - 1}} Z_0^\omega[I_1] \right],
\]

(B2a)

\[
Y_{01}(\omega, q) = -\frac{1}{2\pi} \left[ \theta(|\Omega| \leq 1)\sqrt{1 - \Omega^2} Z_1^\omega[I] + \theta(|\Omega| \geq 1)\sqrt{\Omega^2 - 1} Z_1^\omega[I] \right],
\]

(B2b)

\[
Y_{02}(\omega, q) = \frac{1}{2\pi} \left[ \theta(|\Omega| \leq 1)\sqrt{1 - \Omega^2} Z_2^\omega[I_1] + \theta(|\Omega| \geq 1)\frac{|\Omega|}{\sqrt{\Omega^2 - 1}} Z_2^\omega[I_1] \right],
\]

(B2c)

\[
Y_{11}(\omega, q) = \frac{1}{\pi} \left[ \theta(|\Omega| \leq 1)\sqrt{1 - \Omega^2} Z_1^\omega[I_1] + \theta(|\Omega| \geq 1)\sqrt{\Omega^2 - 1} Z_1^\omega[I_1] \right],
\]

(B2d)

\[
Y_{12}(\omega, q) = -\frac{1}{\pi} \theta(|\Omega| \leq 1)\sqrt{1 - \Omega^2} Z_1^\omega[I],
\]

(B2e)

\[
Y_{22}(\omega, q) = \frac{1}{\pi} \left[ \theta(|\Omega| \leq 1)\sqrt{1 - \Omega^2} Z_2^\omega[I_1] + \theta(|\Omega| \geq 1)\frac{|\Omega|}{\sqrt{\Omega^2 - 1}} Z_2^\omega[I_1] \right],
\]

(B2f)

where

\[
Z_0^\omega[I] = \int_1^\infty dz \frac{1}{\sqrt{z^2 - 1}} I(z), \quad Z_0^\omega[I] = \int_0^1 dz \frac{1}{\sqrt{1 - z^2}} I(z),
\]

(B3a)

\[
Z_1^\omega[I] = \int_1^\infty dz \frac{1}{\sqrt{z^2 - 1}} I(z), \quad Z_1^\omega[I] = \int_0^1 dz \frac{1}{\sqrt{1 - z^2}} I(z),
\]

(B3b)

\[
Z_2^\omega[I] = \int_1^\infty dz \frac{z}{\sqrt{z^2 - \Omega^2}} I(z), \quad Z_2^\omega[I] = \int_0^1 dz \frac{z}{\Omega^2 - z^2} I(z),
\]

(B3c)

\[
Z_3^\omega[I] = \int_1^\infty dz \frac{z^2 - 1}{z^2 - \Omega^2} I(z), \quad Z_3^\omega[I] = \int_0^1 dz \frac{z^2 - 1}{(\Omega^2 - z^2)^{3/2}} I(z),
\]

(B3d)

The functions \( I \) and \( I_1 \) are given by

\[
I_1(z) = \tanh \frac{zQ + W + x}{2} + \tanh \frac{zQ + W - x}{2} - \tanh \frac{zQ - W + x}{2} - \tanh \frac{zQ - W - x}{2},
\]

(B4a)

\[
I(z) = \tanh \frac{zQ + W + x}{2} - \tanh \frac{zQ + W - x}{2} - \tanh \frac{zQ - W + x}{2} + \tanh \frac{zQ - W - x}{2}.
\]

(B4b)
The scattering rates [B1] can be expressed in terms of dimensionless integrals as
\[
\tau_{ij}^{-1} = \alpha_g^2 NT \int \frac{d\eta}{v_g^2 \partial n_{ij}} \int f_i f_j^{-1},
\]
which form the elements of the matrix \( \mathbf{T} \), see Eqs. (13).

In the above integrals the frequency and momentum are expressed in terms of the dimensionless variables
\[
Q = \frac{v_g \eta}{2T}, \quad W = \frac{\omega}{2T}.
\]

Finally, the Coulomb interaction has the form
\[
U(\omega, \eta) = \frac{2\pi \epsilon^2}{q} \tilde{U} = \frac{2\pi \alpha_g v_g}{q} \tilde{U}, \quad \alpha_g = \frac{\epsilon^2}{v_g \epsilon},
\]
where \( \epsilon \) is the dielectric constant of the environment and the dimensionless factor \( \tilde{U} \) accounts for screening.

Appendix C: Collision integral in the degenerate regime

Here I evaluate the electron-electron scattering rates [B1] in the degenerate (or Fermi-liquid) regime. Consider first the functions [B4]. In the degenerate regime, \( \mu \gg T \), but the frequency \( \omega \) is of order \( T \), i.e., \( W \sim 1 \). As a result, \( W \ll x \), and one can expand the functions [B4] in \( W \). The expansion is simplified by the following observation. For \( x \gg 1 \), the difference between two hyperbolic tangents is sharply peaked at \( zQ \sim x \). For positive \( z \) one finds
\[
I_1(z; x \gg 1) \approx -I(z; x \gg 1) \approx I_p(z; x \gg 1), \quad (C1a)
\]
\[
I_p(z) = \frac{\tanh \frac{zQ + W - x}{2} - \tanh \frac{zQ - W - x}{2}}{2}. \quad (C1b)
\]

The relaxation rates [B1] comprise two integrals each, one over large and another over small values of the integral variable \( z, z \gg 1 \) and \( 0 \gg z \gg 1 \), respectively. For small \( z \), the peak at \( zQ \sim x \) translates into very large values of the momentum, \( Q > x \). At the same time, typical values of the frequency are of order temperature, \( W \sim 1 \), meaning \( W \ll x \) and hence \( \Omega = |W|/Q \ll 1 \). This conclusion has the following two consequences.

First, only the region \( \Omega \ll 1 \) contributes to the scattering rates (up to exponentially small corrections, see below), hence one only needs to evaluate the integrals [B9] over \( z > 1 \). Taking into account Eq. (C1), I find that all three relaxation rates [B1] coincide,
\[
\tau_{11} = \tau_{12} = \tau_{22}, \quad (C2)
\]
such that the matrix of the relaxation rates is degenerate even in the \( 2 \times 2 \) sector. This degeneracy is due to the fact that in this regime only one band contributes to any physical quantity.

Second, the calculation of the single remaining rate, \( \tau_{11}^{-1} \), can be simplified by expanding the function \( I_p \) in powers of \( W \),
\[
I_p(z) \approx \frac{2W}{1 + \cosh(zQ - x)} + \frac{W^3}{3} \frac{\cosh(zQ - x) - 2}{[1 + \cosh(zQ - x)]^2}. \quad (C3)
\]

Noticing that the integrand in Eq. (B1a) is an even function of \( W \) and at the same time is independent of the direction of \( Q \), the integral can be simplified as
\[
\tau_{11}^{-1} = \alpha_g^2 \frac{N T^2}{4\pi \mu} \int_0^\infty \frac{dW}{\sinh^2 W} \int \frac{QdQ}{W} \int \frac{QdQ}{W} [Z_0^2[I_p]Z_1^2[I_p] - (1 - \Omega^2) (Z_2^2[I_p])^2]. \quad (C4)
\]

The function (C1) depends only on the combination of variables, \( y = zQ - x \). Changing the integration variable to \( y \), I find for the three functions \( Z_i^2 \) appearing in Eq. (C4)
\[
Z_0^2[I_p] = \frac{1}{Q^2} \int \frac{dy I_p(y, W)}{Q - x} \sqrt{(x+y)^2 - Q^2} \approx \frac{1}{Q^2} \left[ x J_1 \sqrt{1 - \frac{Q^2}{x^2}} + \frac{J_1}{\sqrt{1 - \frac{Q^2}{x^2}}} - \frac{J_2 Q^2}{2x^3 (1 - \frac{Q^2}{x^2})^{3/2}} \right], \quad (C5a)
\]
\[
Z_1^2[I_p] = \int \frac{dy I_p(y, W)}{Q - x} \sqrt{(x+y)^2 - Q^2} \approx \frac{J_0}{x} \sqrt{1 - \frac{Q^2}{x^2}} - J_1 \frac{1 + \frac{W^2}{x^2} - 2Q^2}{\sqrt{1 - \frac{Q^2}{x^2} (1 - \frac{W^2}{x^2})}} \cdot \frac{J_2}{x^3} \frac{1 + \frac{W^2}{x^2} - 2Q^2}{\sqrt{1 - \frac{Q^2}{x^2} (1 - \frac{W^2}{x^2})}} \cdot \frac{3}{\sqrt{3} - \frac{Q^2}{x^2}} + \frac{3}{\sqrt{3} - \frac{Q^2}{x^2}}, \quad (C5b)
\]
\[Z_2^\ast [I_P] = \frac{1}{Q} \int_{Q^{-x}} dy I_P(y, W) \frac{(x+y)\sqrt{(x+y)^2 - Q^2}}{(x+y)^2 - W^2} \approx J_0 \frac{1}{x} \frac{Q^2}{x^2} \left( 1 + \frac{W^2}{x^2} \right) - 2 \frac{W^2}{x^2} \left( 1 - \frac{Q^2}{x^2} \right)^2 \]

\[J_n = \int_{Q^{-x}} dy I_P(y, W)y^n, \quad (C6)\]

and the expansion of the algebraic functions in Eqs. (C5) is justified by the fact that the function \(I_P(y)\) has a form of a sharp peak centered at \(y = 0\) [and in fact exponentially decaying beyond \(y \sim 1\) as can be seen from the expansion (C3)], while \(x \gg 1\).

Assuming \(W \ll x\) in the degenerate limit, I now disregard the factors \(W^2/x^2\) in the algebraic functions in Eqs. (C5) and form the integrand in Eq. (C4) as (alternatively one can integrate the algebraic functions over momentum while keeping the frequency finite and then compute the limit \(x \to \infty\); the results for both the leading and subleading terms are the same)

\[Z_0^\ast [I_P]Z_0^\ast [I_P] - (1-\Omega^2) \left( Z_0^\ast [I_P] \right)^2 \approx \frac{1}{Q^2} \left( 1 - \frac{Q^2}{x^2} \right) \left[ J_0 \frac{W^2}{Q^2} + \frac{J_0 J_2 - J_1^2}{x^2} - \frac{J_0 J_2 Q^2}{x^2} \left( \frac{17}{2} - 4 \frac{Q^2}{x^2} \right)^2 + \ldots \right], \quad (C7)\]

where the frequency in the first term comes from the factor \(1-\Omega^2\) in Eq. (C4), which cannot be neglected before one determines the order of magnitude of the typical values of \(Q\) in the integral in Eq. (C4).

Consider now the functions \(J_n\). The integral for \(n = 0\) yields [the exact result is followed by an approximation obtained by integrating Eq. (C3); the same approximation can be obtained by series expansion]

\[J_0 = 2 \left[ W - \ln \left( e^{Q+W} + e^x \right) + \ln \left( e^Q + e^{x+W} \right) \right] \approx 2W \left( 1 + \tanh \frac{x-Q}{2} \right) - \frac{4W^3}{3} \frac{\sinh^3 \frac{x-Q}{2}}{\sinh (x-Q)} \approx 4W \theta(Q < x), \quad (C8a)\]

where the second equality can be directly obtained by using the first term in the expansion (C3).

The other functions \(J_n\) cannot be integrated in a closed form. One can either evaluate them approximately using the leading order expansion (C3) or compute them numerically. The approximate calculation yields

\[J_0^2 \approx 16W^2 \theta(Q < x), \quad J_0 J_2 - J_1^2 \approx J_0 J_2 \approx \frac{16(\pi^2+1)}{3} W^2 \theta(Q+2 < x), \quad (C8b)\]

Substituting the first term in Eq. (C7) into Eq. (C4) I find

\[t_1 = \alpha_s^2 N \frac{T^2}{4\pi} \mu \int_0^\infty \frac{dW}{\sinh^2 W} \int_0^\infty QdQ |\bar{U}|^2 W^2 Q^4 \left( 1 - \frac{Q^2}{x^2} \right) J_0^2 \approx \alpha_s^2 \frac{4N T^2}{\pi} \mu \int_0^\infty dW W^4 \int_0^\infty \frac{dQ}{Q^3} \left( 1 - \frac{Q^2}{x^2} \right) |\bar{U}|^2. \]

For bare Coulomb interaction, \(|\bar{U}|^2 = 1\), I evaluate the integrals as

\[\int_0^\infty \frac{dW W^4}{\sinh^2 W} \int_0^\infty \frac{dQ}{Q^3} \left( 1 - \frac{Q^2}{x^2} \right) = \frac{1}{2} \int_0^\infty \frac{dW W^4}{\sinh^2 W} \left( \frac{1}{W^2} - 1 - \frac{2}{x^2} \ln \frac{x}{W} \right) = \frac{\pi^2}{12} - \frac{\pi^4}{60x^2} \left( 1 + 2 \ln \frac{\gamma}{T} \right), \quad \gamma = 0.474. \]

For statically screened Coulomb, \(|\bar{U}|^2 = Q^2/(Q + x)^2\), where the Thomas-Fermi screening yields \(x = N\alpha_s x\), I find

\[\int_0^\infty \frac{dQ}{Q} \frac{1 - Q^2}{x^2} = \left[ 1 + \frac{x^2}{x^2} \right] \left[ \frac{W}{W + x} - \ln \frac{x}{W + x} \right] + \left[ 1 + \frac{x^2}{x^2} \right] \left[ \ln \frac{x}{x + x} - \ln \frac{W}{W + x} \right] + \frac{1}{x^2} \ln W, \]

\[= \frac{1}{x^2} - \frac{x}{x^2} \left[ \frac{W}{W + x} - \ln \frac{x}{W + x} \right] + \frac{1}{x^2} \left[ \ln \frac{x}{x + x} - \ln \frac{W}{W + x} \right] + \frac{1}{x^2} \ln W, \]

\[= \frac{1}{x^2} - \frac{x}{x^2} \left[ \frac{W}{W + x} - \ln \frac{x}{W + x} \right] + \frac{1}{x^2} \left[ \ln \frac{x}{x + x} - \ln \frac{W}{W + x} \right] + \frac{1}{x^2} \ln W, \]
which recovers the above result in the limit $\kappa \to 0$. The limit $x \to \infty$ here is non-trivial since $x \propto x$ and one can discern three regimes: $\kappa \ll 1$, $1 \ll \kappa \ll x$, and $\kappa \gg x$. In the first regime, the integral differs from the above result for $\kappa = 0$ by small corrections. The last regime has only a formal interest, since in order to achieve this one has to consider large $\alpha_g$ contradicting the assumptions of the present approach. In the second regime, the above expression can be represented as a series expansion in $x^{-1}$. For not too small $\alpha_g \gtrsim 0.1$

\[
\int_x^\infty \frac{dQ}{Q (Q + \kappa)^2} = \frac{1}{N^2 \alpha_g^2 x^2} \left[ \ln \frac{N\alpha_g}{W} - g(\alpha_g) \right] + \frac{W}{2N^2 \alpha_g^3 x^3} + O(x^{-4}),
\]

where

\[g(\alpha_g) = 1 - N\alpha_g + \ln(1 + N\alpha_g) + N^2 \alpha_g^2 \ln \frac{1 + N\alpha_g}{N\alpha_g}, \quad g(\alpha_g \gtrsim 0.25) \approx \ln(1 + N\alpha_g) + \frac{1}{2}.
\]

Note that the subleading term in this expansion is essential since the leading term changes sign at not too large $W$, while the integral is explicitly positive. Integrating over the frequencies, I find

\[
\int_0^\infty \frac{dW W^4}{\sinh^2 W} \int_x^\infty \frac{dQ}{Q (Q + \kappa)^2} = \frac{\pi^4}{30 N^2 \alpha_g^2 x^2} \left[ \ln(\gamma N\alpha_g) - g(\alpha_g) \right] + \frac{15\zeta(5)}{4N^2 \alpha_g^3 x^3}.
\]

Again, while formally subleading in the limit $x \to \infty$, the second term is important since for small $\alpha_g$ the first term is negative.

Consider now the contribution of the second term in Eq. (C7). Similarly to the above, I find

\[t_2 = \alpha_g^2 \frac{N T^2}{4\pi \mu} \int_0^\infty \frac{dW}{\sinh^2 W} \int_x^\infty Q dQ \frac{1-\frac{Q^2}{x^2}}{Q^2} \left( \frac{J_0 J_2 - J_2^2}{x^2} \approx \alpha_g^2 \frac{4N}{3\pi} (\pi^2 + 1) \frac{T^2}{\mu x^2} \right) \int_0^\infty \frac{dW W^4}{\sinh^2 W} \int_x^\infty \frac{dQ}{Q (1-\frac{Q^2}{x^2})},\]

which in the limit $x \to \infty$ is clearly subleading to $t_1$.

### Appendix D: Collision integral close to charge neutrality

At charge neutrality $I(x=0) = 0$ and hence $\tau_{12}^{-1} = 0$.

In vicinity of charge neutrality the dependence on the chemical potential (or on the dimensionless variable $x = \mu/T$) comes from the compressibility in the dimensionfull prefactor in Eq. (B5) and the functions $I$ and $I_1$ determining the dimensionless scattering rates $t_{ij}^{-1}$.

The prefactor in Eq. (B5) can be expressed as follows

\[
\alpha_g^2 \frac{N T}{16\pi^2} \left[ \frac{N T}{\alpha_g^2} \frac{\partial n}{\partial \mu} \right] \approx \frac{\alpha_g^2 T}{4\pi \ln 2} \left( 1 - \frac{x^2}{8 \ln 2} \right).
\]

Expanding both functions (B4) for $x \ll 1$, one finds

\[
I_1 = I_1^{(0)} + x^2 I_1^{(2)} + O(x^3), \quad (D1a)
\]

\[
I_1^{(0)} = \frac{4 \sinh W}{\cosh W + \cosh z Q}, \quad I_1^{(2)} = \frac{2 \sinh W (\cosh 2z Q - 2 \cosh W \cosh z Q - 3)}{(\cosh W + \cosh z Q)^3}.
\]
\[ I = -x I^{(1)} + \mathcal{O}(x^3), \quad I^{(1)} = 4 \frac{\sinh zQ \sinh W}{(\cosh W + \cosh zQ)^2}. \]  

(D1b)

Substituting these expansions into Eqs. (D1), one can establish the leading terms in the expansion of the scattering rates

\[ \frac{1}{\tau_{11}} = \frac{\alpha_g^2 T}{4 \pi \ln 2} \left[ \frac{1}{t_{11}^{(0)}} + x^2 \left( \frac{1}{t_{11}^{(2)}} - \frac{1}{8 \ln 2} t_{11}^{(0)} \right) + \mathcal{O}(x^3) \right], \]

(D2a)

\[ \frac{1}{\tau_{12}} = \frac{\alpha_g^2 T}{4 \pi \ln 2} \frac{x}{t_{12}^{(1)}} + \mathcal{O}(x^3), \]

(D2b)

\[ \frac{1}{\tau_{22}} = \frac{\alpha_g^2 T}{4 \pi \ln 2} \left[ \frac{1}{t_{22}^{(0)}} + x^2 \left( \frac{1}{t_{22}^{(2)}} - \frac{1}{8 \ln 2} t_{22}^{(0)} \right) + \mathcal{O}(x^3) \right]. \]

(D2c)

The quantities \( t_{1j}^{(0,1,2)} \) in Eqs. (D2) are the expansion coefficients of the dimensionless integral in Eq. (D5) close to the Dirac point in the self-evident notation similar to that in Eqs. (D1). For unscreened Coulomb interaction these quantities are just numbers without any dependence on any physical parameter. If screening is taken into account, then these numbers depend on the screening length, i.e., on a fixed combination of the coupling constant and temperature.

For unscreened Coulomb interaction, one finds the following numerical values (neglecting the small exchange contribution):

\[ (t_{11}^{(0)})^{-1} \approx 33.13, \quad (t_{11}^{(2)})^{-1} \approx 3.38, \]

\[ (t_{12}^{(1)})^{-1} \approx 5.45, \quad (t_{22}^{(0)})^{-1} \approx 18.02, \quad (t_{22}^{(2)})^{-1} \approx 4.73. \]

Appendix E: Optical conductivity close to charge neutrality

Inverting the matrix \( \mathbf{S}_{xx} \) using the identity

\[ [\mathbf{S}_{xx}(0) + \delta \mathbf{S}_{xx}]^{-1} \approx \mathbf{S}_{xx}^{-1}(0) - \mathbf{S}_{xx}^{-1}(0) \delta \mathbf{S}_{xx} \mathbf{S}_{xx}^{-1}(0), \]

and substituting the result into the general expression (15b) together with the expansions of the matrices \( \mathbf{M}_{h(n)} \), one finds the leading contribution to Eq. (24) as

\[ \delta \sigma_1 = \frac{\gamma_{11} e^2 T x^2}{-i \omega + \tau_{\text{dis}}^{-1} + \tau_{11}^{-1}(0)} + \frac{\gamma_{12} e^2 T x^2}{-i \omega + \tau_{\text{dis}}^{-1} + \gamma_{13} \tau_{22}^{-1}(0)}, \]

where the scattering rates are evaluated at the Dirac point, \( x = 0 \), and the numerical coefficients are

\[ \gamma_{11} = \frac{2 \ln 2 \times 8 \ln 2}{27 \zeta(3)} \approx 0.17 \times \frac{2 \ln 2}{\pi} \approx 0.075, \]

\[ \gamma_{12} = \frac{3 [4 \pi^2 \ln 2 - 2 \zeta(3)]^2}{16 \pi^2 \zeta(3) \ln 2 - \pi^5} \approx 0.66, \]

\[ \gamma_{13} = \frac{16 \pi^2 \zeta(3) \ln 2}{16 \pi^2 \zeta(3) \ln 2 - \frac{\pi^5}{2}} \approx 3.59. \]

The second line yields

\[ \delta \sigma_2 = \frac{e^2 T x^2}{2 \pi^2} \left[ \frac{1}{\tau_{11}^{(0)}} - \frac{1}{8 \ln 2} \tau_{11}^{(0)} \right]^2, \]

where the numerator represents the leading correction to the scattering rate \( \tau_{11}^{-1} \), see Eq. (D2a). Finally, the last two lines give rise to two similar contributions

\[ \delta \sigma_3 = \frac{e^2 T x^2}{-i \omega + \tau_{\text{dis}}^{-1} + \tau_{11}^{-1}(0)} - \frac{1}{-i \omega + \tau_{\text{dis}}^{-1} + \gamma_{13} \tau_{22}^{-1}(0)} \times \left[ \gamma_{31} \tau_{22}^{-1}(0) + \gamma_{32} (-i \omega + \tau_{\text{dis}}^{-1}) - \gamma_{33} / \tau_{12}^{(1)} \right], \]

\[ \delta \sigma_4 = \frac{e^2 T x^2}{-i \omega + \tau_{\text{dis}}^{-1} + \tau_{11}^{-1}(0)} - \frac{1}{-i \omega + \tau_{\text{dis}}^{-1} + \gamma_{13} \tau_{22}^{-1}(0)} \times \left[ \gamma_{41} (-i \omega + \tau_{\text{dis}}^{-1}) + \gamma_{42} / \tau_{12}^{(1)} \right], \]

where

\[ \gamma_{31} = \frac{288 \ln^3 2}{16 \pi^2 \zeta(3) \ln 2 - \frac{\pi^5}{2}} \approx 0.81, \]

\[ \gamma_{32} = \frac{3 (96 \ln^3 2 + 2 \zeta(3) - 8 \pi^2 \ln 2)}{16 \pi^2 \zeta(3) \ln 2 - \frac{\pi^5}{2}} \approx 0.246, \]

\[ \gamma_{33} = \frac{3 [8 \pi^2 \ln 2 - 2 \zeta(3)]}{16 \pi^2 \zeta(3) \ln 2 - \frac{\pi^5}{2}} \approx 0.57, \]

\[ \gamma_{41} = \frac{3 [4 \pi^2 \ln 2 - 2 \zeta(3)] [8 \pi^2 \ln 2 - 54 \zeta(3)]}{2 (16 \pi^2 \zeta(3) \ln 2 - \frac{\pi^5}{2})} \approx 0.66, \]

\[ \gamma_{42} = \frac{81 \zeta(3) [4 \pi^2 \ln 2 - 2 \zeta(3)]}{2 (16 \pi^2 \zeta(3) \ln 2 - \frac{\pi^5}{2})} \approx 0.67. \]
