THE DISTANCE FROM A RANK $n - 1$ PROJECTION TO THE NILPOTENT OPERATORS ON $\mathbb{C}^n$

ZACHARY CRAMER

ABSTRACT. Building on MacDonald’s formula for the distance from a rank-one projection to the set of nilpotents in $M_n(\mathbb{C})$, we prove that the distance from a rank $n - 1$ projection to the set of nilpotents in $M_n(\mathbb{C})$ is $\frac{1}{2} \sec \left( \frac{\pi}{\sqrt{n+1}} \right)$. For each $n \geq 2$, we construct examples of pairs $(Q, T)$ where $Q$ is a projection of rank $n - 1$ and $T \in M_n(\mathbb{C})$ is a nilpotent of minimal distance to $Q$. Moreover, we demonstrate that any two such pairs are unitarily equivalent. We end by discussing possible extensions of these results in the case of projections of intermediate ranks.

§1 Introduction

Let $\mathcal{H}$ be a complex Hilbert space of (possibly infinite) dimension $n$, and let $\mathcal{B}(\mathcal{H})$ denote the algebra of bounded linear operators acting on $\mathcal{H}$. Consider the sets

$$
\mathcal{P}(\mathcal{H}) = \{ P \in \mathcal{B}(\mathcal{H}) : P = P^2 = P^* \} \setminus \{0\}
$$

and

$$
\mathcal{N}(\mathcal{H}) = \{ N \in \mathcal{B}(\mathcal{H}) : N^j = 0 \text{ for some } j \in \mathbb{N} \}
$$

consisting of all non-zero orthogonal projections on $\mathcal{H}$ and all nilpotent operators on $\mathcal{H}$, respectively. We are interested in the problem of understanding the distance between these two sets, measured in the usual operator norm on $\mathcal{B}(\mathcal{H})$. This quantity will be denoted by $\delta_n$:

$$
\delta_n := \text{dist}(\mathcal{P}(\mathcal{H}), \mathcal{N}(\mathcal{H})) = \inf \{ \|P - N\| : P \in \mathcal{P}(\mathcal{H}), N \in \mathcal{N}(\mathcal{H}) \}.
$$

The problem of computing $\delta_n$ is by no means new to the world of operator theory. In 1972, Hedlund [3] proved that $\delta_2 = 1/\sqrt{2}$, and that $1/4 \leq \delta_n \leq 1$ for all $n \geq 3$. This lower bound was increased to $1/2$ by Herrero [4] shortly thereafter. At this time Herrero also showed that $\delta_n = 1/2$ whenever $n$ is infinite, thus reducing the problem to the case in which $\mathcal{H} = \mathbb{C}^n$ for some $n \in \mathbb{N}$, $n \geq 3$.

Various estimates on the values of $\delta_n$ were obtained in the early 1980’s. One such estimate established by Salinas [11] states that

$$
\frac{1}{2} \leq \delta_n \leq \frac{1}{2} + \frac{1 + \sqrt{n - 1}}{2n}
$$

for all $n \in \mathbb{N}$.

One may note that this upper bound approaches $1/2$ as $n$ tends to infinity, and hence Salinas’ inequality leads to an alternative proof that $\delta_{\aleph_0} = 1/2$. Herrero [5] subsequently improved upon this upper bound for large values of $n$ by showing that

$$
\frac{1}{2} \leq \delta_n \leq \frac{1}{2} + \sin \left( \frac{\pi}{\lfloor n+1 \rfloor} \right)
$$

for $n \geq 2$,

where $\lfloor \cdot \rfloor$ denotes the greatest integer function.

For many years the bounds obtained by Salinas and Herrero remained the best known. In 1995, however, MacDonald [8] established a new upper bound that would improve upon these estimates for all values of $n$. In order to describe MacDonald’s approach, we first make the following remarks.

Key words and phrases. Projection, Nilpotent, Matrix, Operator.

Research supported in part by NSERC (Canada).
(i) Any two projections in $M_n(\mathbb{C})$ of equal rank are of equal distance to $\mathcal{N}(\mathbb{C}^n)$. Thus, $\delta_n = \min_{1 \leq r \leq n} \nu_{r,n}$, where

$$\nu_{r,n} := \inf \{ \|P - N\| : P \in \mathcal{P}(\mathbb{C}^n), \text{rank}(P) = r, N \in \mathcal{N}(\mathbb{C}^n) \}.$$ 

(ii) Straightforward estimates show that when computing $\nu_{r,n}$, one need only consider nilpotents of norm at most 2. From here, one may use the compactness of the set of projections in $M_n(\mathbb{C})$ of rank $r$ and the set of nilpotents in $M_n(\mathbb{C})$ of norm at most 2 to show that $\nu_{r,n}$ is achieved by some projection-nilpotent pair, and hence so too is each $\delta_n$.

(iii) If $\{e_i\}_{i=1}^n$ denotes the standard basis for $\mathbb{C}^n$, then

$$\nu_{r,n} = \min \{ \|P - N\| : P \in \mathcal{P}(\mathbb{C}^n), \text{rank}(P) = r, N \in \mathcal{T}_n(\mathbb{C}) \}$$

where $\mathcal{T}_n(\mathbb{C})$ is the algebra of operators that are strictly upper triangular as matrices with respect to $\{e_i\}_{i=1}^n$.

The reduction from $\mathcal{N}(\mathbb{C}^n)$ to $\mathcal{T}_n(\mathbb{C})$ described in (iii) may seem innocuous at first glance. This alternate formulation, however, allows one to make use of a theorem of Arveson [1] that describes the distance from an operator in $\mathcal{B}(\mathcal{H})$ to a nest algebra. The version of this result that we require was established by Power [10], and is presented below for the algebra $\mathcal{T}_n(\mathbb{C})$. Note that for vectors $x, y \in \mathbb{C}^n$, the notation $x \otimes y^*$ is used to denote the rank-one operator $z \mapsto \langle z, y \rangle x$ acting on $\mathbb{C}^n$.

**Theorem 1.1** (Arveson Distance Formula). Let $\{e_i\}_{i=1}^n$ denote the standard basis for $\mathbb{C}^n$. Define $E_0 := 0$ and $E_k := \sum_{i=1}^k e_i \otimes e_i^*$ for each $k \in \{1, 2, \ldots, n\}$. For any $A \in M_n(\mathbb{C})$,

$$\text{dist}(A, \mathcal{T}_n(\mathbb{C})) = \max_{1 \leq i \leq n} \|E_{i-1}^\perp AE_i\|.$$ 

Using Arveson’s formula, MacDonald successfully determined the exact value of $\nu_{1,n}$, the distance from a rank-one projection in $M_n(\mathbb{C})$ to $\mathcal{N}(\mathbb{C}^n)$.

**Theorem 1.2.** [8, Theorem 1] For every positive integer $n$, the distance from the set of rank-one projections in $M_n(\mathbb{C})$ to $\mathcal{N}(\mathbb{C}^n)$ is

$$\nu_{1,n} = \frac{1}{2} \sec \left( \frac{\pi}{n+2} \right).$$

The expression for $\nu_{1,n}$ described above provides an upper bound on $\delta_n$ that is sharper than those previously obtained by Herrero and Salinas for all $n \in \mathbb{N}$. In addition, MacDonald proved that this bound is in fact optimal when $n = 3$ [8, Corollary 4]. These results led to the formulation of the following conjecture.

**Conjecture 1.3** (MacDonald, [8]). The closest non-zero projections to $\mathcal{N}(\mathbb{C}^n)$ are of rank 1. That is,

$$\delta_n = \nu_{1,n} = \frac{1}{2} \sec \left( \frac{\pi}{n+2} \right) \text{ for all } n \in \mathbb{N}.$$ 

Conjecture 1.3 has since been verified for $n = 4$ [9, Theorem 3.4], but remains open for all $n \geq 5$.

MacDonald’s success in computing $\nu_{1,n}$ was largely due to the rigid structure of rank-one projections in $M_n(\mathbb{C})$. Specifically, the decomposition of such a projection as a simple tensor $P = e \otimes e^*$ for some unit vector $e \in \mathbb{C}^n$ made it feasible to obtain a closed-form expression for $\|E_{i-1}^\perp PE_i\|$ in terms of the entries of $P$.

With this in hand, it became possible to show that the rank-one projections of minimal distance to $\mathcal{T}_n(\mathbb{C})$ are such that $\|E_{i-1}^\perp PE_i\| = \nu_{1,n}$ for all $i \in \{1, 2, \ldots, n\}$. An exact expression for $\nu_{1,n}$ was then derived through algebraic and combinatorial arguments.

Extending the above approach to accommodate projections of intermediate ranks appears to be a formidable task; when $P$ is not expressible as a simple tensor $e \otimes e^*$ it becomes significantly more challenging to obtain an explicit formula for $\|E_{i-1}^\perp PE_i\|$. One may note, however, that the rigidity that led to success in the rank-one case can also be observed in projections of rank $n - 1$. It is therefore the goal of this paper to extend MacDonald’s approach to determine the exact value of $\nu_{n-1,n}$.

We accomplish this goal in three stages. Motivated by the analogous result for projections of rank 1, we show in §2 that any projection $Q$ of rank $n - 1$ that is of minimal distance to $\mathcal{T}_n(\mathbb{C})$ must be such that all norms $\|E_{i-1}^\perp QE_i\|$ are equal to $\nu_{n-1,n}$. In §3, we determine a list of possible candidates for $\nu_{n-1,n}$.
by adapting the arguments from [8]. Finally, we prove that exactly one such candidate satisfies a certain necessary norm inequality from [9], and hence this value must be $\nu_{n-1,n}$.

A summary of our findings is presented in §4. There we outline a construction of the closest pairs $(Q,T)$, where $Q \in M_n(\mathbb{C})$ is a projection of rank $n - 1$ and $T$ belongs to $T_n(\mathbb{C})$. We prove that for each $n \in \mathbb{N}$, any two such closest projection-nilpotent pairs are, in fact, unitary equivalent. Lastly, we propose a possible formula for $\nu_{r,n}$ in the case of projections of arbitrary rank, which can be seen to closely resemble numerical estimates for $\nu_{r,n}$ when $n$ is small. We briefly explain how this formula could be used to answer MacDonald’s conjecture in the affirmative.

\section{Equality in Arveson’s Distance Formula}

Fix an integer $n \geq 3$. Throughout, $Q = (q_{ij})$ will denote a projection in $M_n(\mathbb{C})$ of rank $n - 1$ that is of minimal distance to $T_n(\mathbb{C})$. In addition, $P = (p_{ij})$ will denote the rank-one projection $I - Q$.

Our first task will be to determine a formula for each norm $\|E_{i-1}^\perp QE_i\|$ in terms of the entries of $Q$. To accomplish this goal, it will be helpful to develop an understanding of the algebraic relations that are satisfied by these entries. We will appeal to the following classical result of Cauchy (see [7, Theorem 4.3.17]) to deduce that the entries of $Q$ are, in essence, determined entirely by those on the diagonal.

**Theorem 2.1** (Cauchy’s Interlacing Theorem). Let $B$ be a self-adjoint matrix in $M_n(\mathbb{C})$. Fix an integer $k \in \{1, 2, \ldots, n\}$, and let $\hat{B} \in M_{n-1}(\mathbb{C})$ be the self-adjoint matrix obtained by deleting the $k$th row and $k$th column from $B$. If $\lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_n$ are the eigenvalues of $B$, and $\mu_1 \leq \mu_2 \leq \cdots \leq \mu_{n-1}$ are the eigenvalues of $\hat{B}$, then

$$\lambda_j \leq \mu_j \leq \lambda_{j+1}$$

for all $j \in \{1, 2, \ldots, n-1\}$.

**Corollary 2.2.** Let $B$ be a self-adjoint matrix in $M_n(\mathbb{C})$. Fix an integer $k \in \{1, 2, \ldots, n\}$, and let $\hat{B} \in M_{n-1}(\mathbb{C})$ be the self-adjoint matrix obtained by deleting the $k$th row and $k$th column from $B$.

(i) If $\lambda$ is an eigenvalue of $B$ with multiplicity $m \geq 2$, then $\lambda$ is an eigenvalue of $\hat{B}$ with multiplicity at least $m - 1$.

(ii) If $\lambda$ is an eigenvalue of $\hat{B}$ with multiplicity $m \geq 2$, then $\lambda$ is an eigenvalue of $B$ with multiplicity at least $m - 1$.

The above results have substantial implications for the structure of self-adjoint operators possessing eigenvalues of large multiplicity. Indeed, consider the rank-one projection $P$. By Corollary 2.2(i), any $(n - 1) \times (n - 1)$ principal submatrix of $P$ admits $\lambda = 0$ as an eigenvalue with multiplicity at least $n - 2$. By applying Corollary 2.2 to progressively smaller principal submatrices of $P$, it follows that $\lambda = 0$ is an eigenvalue of

$$\begin{bmatrix} p_{ii} & p_{ij} \\ p_{ji} & p_{jj} \end{bmatrix}$$

for any choice of distinct indices $i$ and $j$. Thus, a determinant calculation shows that for all such $i$ and $j$, there is a complex number $z_{ij}$ of modulus 1 such that

$$p_{ij} = z_{ij} \sqrt{p_{ii}p_{jj}}.$$ 

Consequently, the entries of $Q$ satisfy

$$q_{ij} = -z_{ij} \sqrt{(1-q_{ii})(1-q_{jj})} \quad \text{for all } i \neq j.$$ 

It would be cumbersome to keep track of the complex numbers $z_{ij}$ throughout the coming analysis. Fortunately, however, the following result indicates that one may assume without loss of generality that each $z_{ij}$ is equal to 1.

**Lemma 2.3.** If $R \in M_n(\mathbb{C})$ is a rank-one projection, then there is a diagonal unitary $U \in M_n(\mathbb{C})$ such that the entries of $T := U^*RU$ are non-negative real numbers. Furthermore, $\|E_{i-1}^\perp TE_i\| = \|E_{i-1}^\perp RE_i\|$ for all $i$. 
Proof. Suppose that \( R = (r_{ij}) \) with respect to the standard basis, and choose an index \( k \) so that \( r_{kk} \neq 0 \). Clearly such a \( k \) exists, as \( \text{Tr}(R) > 0 \). Let \( U = \text{diag}(u_1, u_2, \ldots, u_n) \) denote the diagonal unitary in \( M_n(\mathbb{C}) \) obtained by setting \( u_k = 1 \) and
\[
u_j = \begin{cases} \frac{|r_{kj}|}{r_{kj}} & \text{if } r_{kj} \neq 0 \\ 1 & \text{if } r_{kj} = 0 \end{cases}
\]
for all \( j \geq 2 \).

If \( T := U^*RU = (t_{ij}) \), then \( t_{ij} = \overline{u_i} u_j r_{ij} \). In particular, \( t_{jj} = r_{jj} \) and \( t_{kj} = |r_{kj}| \) for all \( j \). Note that since \( T \) has rank 1 and \( t_{kk} = r_{kk} \neq 0 \), every row of \( T \) is a multiple of the \( k^{\text{th}} \) row. But \( T \) has a non-negative diagonal and non-negative \( k^{\text{th}} \) row, so every row of \( T \) must be a non-negative multiple of the \( k^{\text{th}} \) row. Finally, it is evident that \( \|E_{i-1}^TTE_i\| = \|E_{i-1}^TRE_i\| \) for all \( i \), as each projection \( E_i \) commutes with \( U \).

By Lemma 2.3, one may assume that the rank \( n - 1 \) projection \( Q \) of minimal distance to \( T_n(\mathbb{C}) \) is such that every entry of \( P = I - Q \) is a non-negative real number. It then follows that the entries \( p_{ij} \) and \( q_{ij} \) satisfy the relations
\[p_{ij} = \sqrt{p_{ii}p_{jj}} \quad \text{and} \quad q_{ij} = -\sqrt{(1 - q_{ii})(1 - q_{jj})}\]
for all \( i \neq j \). These equations quickly lead to the following useful identities:

\[
p_{ij}p_{ik} = p_{ii}p_{jk} \quad \text{and} \quad q_{ij}q_{ik} = q_{jj}(1 - q_{ii}) \quad \text{for all } i, j, k \text{ distinct.}
\]

In the case of rank-one projections, MacDonald derived the distance formula of Theorem 1.2 by analysing a certain sequence \( \{a_i\}_{i=0}^n \) associated to such a projection. For \( P = (p_{ij}) \), this sequence is defined by setting \( a_0 = 0 \) and
\[
a_k = \sum_{i=1}^k p_{ii} = k - \sum_{i=1}^k q_{ii}, \quad k \in \{1, 2, \ldots, n\}.
\]
When the entries of \( P \) are non-negative, \( P \) and \( Q \) are entirely determined by this sequence. Indeed,
\[P = e \otimes e^* \quad \text{and} \quad Q = I - e \otimes e^*
\]
where \( e = [\sqrt{a_1 - a_0} \quad \sqrt{a_2 - a_1} \quad \cdots \quad \sqrt{a_n - a_{n-1}}]^T \). In particular, the diagonal entries of \( P \) and \( Q \) are given by
\[
p_{kk} = a_k - a_{k-1} \quad \text{and} \quad q_{kk} = 1 - (a_k - a_{k-1}), \quad k \in \{1, 2, \ldots, n\}.
\]

It is easy to see that \( \{a_i\}_{i=0}^n \) increases monotonically from \( a_0 = 0 \) to \( a_n = \text{Tr}(P) = 1 \). As the following result demonstrates, any sequence \( \{a_i\}_{i=0}^n \) that increases monotonically from 0 to 1 can be obtained in this way.

Lemma 2.4. If \( \{a_i\}_{i=0}^n \) is a sequence that increases monotonically from \( a_0 = 0 \) to \( a_n = 1 \), then there is a rank-one projection \( T = (t_{ij}) \) in \( M_n(\mathbb{C}) \) such that \( t_{ij} \geq 0 \) for all \( i \) and \( j \), and \( a_k = \sum_{i=1}^k t_{ii} \) for each \( k \in \{1, 2, \ldots, n\} \).

Proof. The Schur-Horn Theorem \[12, 6\] implies that for any sequence \( \{d_i\}_{i=1}^n \) of non-negative real numbers satisfying \( \sum_{i=1}^n d_i = 1 \), there is a rank-one projection \( T = (t_{ij}) \) in \( M_n(\mathbb{C}) \) such that \( t_{ii} = d_i \) for each \( i \in \{1, 2, \ldots, n\} \). By conjugating \( T \) by a diagonal unitary as in Lemma 2.3 if required, we may always arrange that \( t_{ij} \geq 0 \). The proof is then complete upon setting \( d_i = a_i - a_{i-1} \).

In \[8\], MacDonald computed the values of \( \|E_{i-1}^TPE_i\| \) in terms of the sequence \( \{a_i\}_{i=0}^n \) and subsequently proved that all such norms must be equal when \( P \) is of minimal distance to \( T_n(\mathbb{C}) \). Our goal is to translate MacDonald’s arguments to the case in which \( Q \) is of minimal distance to \( T_n(\mathbb{C}) \). Namely, we wish to obtain a formula for \( \|E_{i-1}^TQE_i\| \) in terms of \( \{a_i\}_{i=0}^n \) and demonstrate that when \( Q \) is of minimal distance to \( T_n(\mathbb{C}) \), these norms share a common value. The following lemma provides the first step in this direction.
Lemma 2.5. Let \( Q = (q_{ij}) \) be a projection in \( \mathbb{M}_n(\mathbb{C}) \) of rank \( n - 1 \), and let \( \{a_i\}_{i=0}^n \) denote the non-decreasing sequence from equation (2). For each \( k \in \{1, 2, \ldots, n\} \), define \( Q_k := E_{k-1}^* Q E_k \), and let \( B_k \) denote the restriction of \( Q_k^* Q_k \) to the range of \( E_k \).

(i) If \( q_{ij} := 0 \) for all \( i \neq j \), then the entries of \( B_k = (b_{ij}) \) are given by

\[
b_{ij} = \begin{cases} q_{kk} - a_{k-1}(1 - q_{kk}) & \text{if } i = j = k, \\ (1 - a_{k-1})(1 - q_{ii}) & \text{if } i = j \neq k, \\ -(1 - a_{k-1})q_{ij} & \text{if } i, j, k \text{ are distinct}, \\ a_{k-1}q_{ij} & \text{otherwise}. \end{cases}
\]

(ii) If \( \lambda_1 \leq \lambda_2 \leq \ldots \leq \lambda_k \) are the eigenvalues of \( B_k \), then

\[
\lambda_i = \begin{cases} \frac{\text{Tr}(B_k) + \sqrt{2\text{Tr}(B_k^2) - \text{Tr}(B_k)^2}}{2} & \text{if } i = k, \\ \frac{\text{Tr}(B_k) - \sqrt{2\text{Tr}(B_k^2) - \text{Tr}(B_k)^2}}{2} & \text{if } i = k - 1, \\ 0 & \text{otherwise}. \end{cases}
\]

In particular,

\[
\|Q_k\|^2 = \frac{\text{Tr}(B_k) + \sqrt{2\text{Tr}(B_k^2) - \text{Tr}(B_k)^2}}{2}.
\]

Proof. Firstly, suppose that \( q_{ij} := 0 \) for all \( i \neq j \). Since \( Q \) is idempotent, its entries \( q_{ij} \) satisfy the equation

\[
q_{ij} = \sum_{\ell=1}^n q_{i\ell} q_{\ell j}.
\]

This equation, together with the identities from (1), allows one to compute the entries of \( B_k \) directly. Indeed,

\[
b_{kk} = q_{kk}^2 + q_{k+1,k}^2 + \cdots + q_{nk}^2 = q_{kk} - q_{1k}^2 - q_{2k}^2 - \cdots - q_{k-1,k}^2 = q_{kk} - \sum_{\ell=1}^{k-1}(1 - q_{i\ell})(1 - q_{kk}) = q_{kk} - a_{k-1}(1 - q_{kk}),
\]

and if \( i \neq k \), then

\[
b_{ii} = q_{ii}^2 + q_{i+1,i}^2 + \cdots + q_{ni}^2 = q_{ii} - q_{1i}^2 - q_{2i}^2 - \cdots - q_{k-1,i}^2 = q_{ii} - \sum_{\ell=1,\ell\neq i}^{k-1}(1 - q_{i\ell})(1 - q_{ii}) = (1 - q_{ii})(k - 2) - \sum_{\ell=1}^{k-1} q_{i\ell} = (1 - a_{k-1})(1 - q_{ii}).
\]

If \( i, j, k \) are all distinct, then

\[
b_{ij} = q_{ki}q_{kj} + q_{k+1,i}q_{k+1,j} + \cdots + q_{ni}q_{nj} = q_{ij} - q_{i1}q_{1j} - q_{2j}q_{-1,i}q_{k-1,j} = q_{ij} - q_{ii}q_{ij} - q_{jj}q_{ij} + \sum_{\ell=1,\ell\neq i,j}^{k-1} q_{ij}(1 - q_{i\ell}) = q_{ij}(k - 2) - \sum_{\ell=1}^{k-1} q_{i\ell} = -(1 - a_{k-1})q_{ij}.
\]
Lastly, either \( i < j = k \) or \( j < i = k \). Since \( B_k = B_k^* \), it suffices to establish the formula for \( b_{ij} \) in the case that \( i < j = k \). We have

\[
\begin{align*}
\hat{b}_{ik} &= q_{ki}q_{kk} + q_{k+1,k} + \cdots + q_{nk}q_{nk} \\
&= q_{ik} - q_{1i}q_{1k} + \sum_{\ell=1,\ell\neq i}^{k-1} q_{ik}(1 - q_{i\ell}) \\
&= q_{ik} \left( (k-1) - \sum_{\ell=1}^{k-1} q_{i\ell} \right) = a_{k-1}q_{ik}.
\end{align*}
\]

We now turn our attention to the proof of (ii). By Lemma 2.3, one may conjugate \( Q \) by a diagonal unitary if necessary to assume that \( q_{ij} \leq 0 \) for all \( i \neq j \). Since the eigenvalues of \( B_k \) are invariant under such a transformation, this assumption imposes no loss of generality.

From the description of the entries \( b_{ij} \) in (i), it is apparent that if \( B_k \in M_{k-1}(\mathbb{C}) \) denotes the matrix obtained by deleting the final row and column of \( B_k \), then

\[
\hat{B}_k = (1 - a_{k-1})(I - \hat{Q}),
\]

where \( \hat{Q} \in M_{k-1}(\mathbb{C}) \) denotes the \((k-1)^{th}\) leading principal submatrix of \( Q \). Since \( Q \) is a projection of rank \( n - 1 \), Corollary 2.2(ii) ensures that \( \lambda = 1 \) is an eigenvalue of \( \hat{Q} \) of multiplicity at least \( k - 2 \). Thus, \( \lambda = 0 \) is an eigenvalue of \( B_k \) of multiplicity at least \( k - 2 \). It follows that the remaining eigenvalue of \( \hat{B}_k \) is given by

\[
\text{Tr}(\hat{B}_k) = (1 - a_{k-1}) \sum_{i=1}^{k-1} (1 - q_{ii}) = a_{k-1}(1 - a_{k-1}).
\]

This information can now be used to analyse the eigenvalues of \( B_k \). By Corollary 2.2(ii), \( \lambda = 0 \) is an eigenvalue of \( B_k \) with multiplicity no less than \( k - 3 \). Furthermore, Theorem 2.1 indicates that the remaining eigenvalues \( \lambda_1, \lambda_{k-1}, \) and \( \lambda_k \) are such that

\[
\lambda_1 \leq 0 \leq \lambda_{k-1} \leq a_{k-1}(1 - a_{k-1}) \leq \lambda_k.
\]

Since \( B_k \geq 0 \), we have that \( \lambda_1 = 0 \). The final two eigenvalues can be recovered by examining the traces of \( B_k \) and \( B_k^* \). In particular, one may solve the system of equations

\[
\left\{ \begin{array}{c}
\lambda_{k-1} + \lambda_k = \text{Tr}(B_k) \\
\lambda_{k-1}^2 + \lambda_k^2 = \text{Tr}(B_k^*)
\end{array} \right.,
\]

to obtain the values in (ii). This completes the proof.

\[ \blacksquare \]

**Corollary 2.6.** Let \( Q = (q_{ij}) \) be a projection in \( M_n(\mathbb{C}) \) of rank \( n - 1 \), and let \( \{a_i\}_{i=0}^n \) denote the non-decreasing sequence from equation (2). If \( f : [0, 1] \times [0, 1] \to \mathbb{R} \) denotes the function

\[
f(x, y) = \frac{\sqrt{x^2y^2 - 4x^2y + 2xy^2 + 4x^2 - 2xy + y^2 - 2y + 1} - x - y + 2x + 1}{2},
\]

then for each \( k \in \{1, 2, \ldots, n\} \), \( \|E_{k-1}^* Q E_k\| = f(a_{k-1}, a_k) \).

**Proof.** By Lemma 2.3 we may assume without loss of generality that \( q_{ij} \leq 0 \) for all \( i \neq j \). Fix an integer \( k \in \{1, 2, \ldots, n\} \), define \( Q_k := E_{k-1}^* Q E_k \), and let \( B_k \) denote the restriction of \( Q_k^* Q_k \) to the range of \( E_k \). By Lemma 2.5(ii), we have that

\[
\|Q_k\|^2 = \text{Tr}(B_k) + \sqrt{2 \text{Tr}(B_k^*) - \text{Tr}(B_k)^2}/2.
\]
If $\hat{B}_k \in M_{k-1}(\mathbb{C})$ denotes the matrix obtained by deleting the final row and column of $B_k$ as in the proof of Lemma 2.5, then

$$\text{Tr}(B_k) = \text{Tr}(\hat{B}_k) + b_{kk} = a_{k-1}(1 - a_{k-1}) + q_{kk} - a_{k-1}(1 - q_{kk})$$

$$= q_{kk} + a_{k-1}(q_{kk} - a_{k-1}) = q_{kk} + a_{k-1}(1 - a_k).$$

Moreover, if $B_k^2 = (c_{ij})$, then

$$c_{kk} = b_{kk}^2 + \sum_{\ell=1}^{k-1} b_{k\ell}^2$$

$$= (q_{kk} - a_{k-1}(1 - q_{kk})) + \sum_{\ell=1}^{k-1} a_{k-1}^2 q_{k\ell}$$

$$= (q_{kk} - a_{k-1}(1 - q_{kk})) + \sum_{\ell=1}^{k-1} a_{k-1}^2 (1 - q_{kk})(1 - q_{\ell\ell})$$

$$= (q_{kk} - a_{k-1}(1 - q_{kk})) + a_{k-1}^2(1 - q_{kk}).$$

and for $i \leq k - 1$,

$$c_{ii} = b_{ii}^2 + b_{ik}^2 + \sum_{\ell=1, \ell \neq i}^{k-1} b_{i\ell}^2$$

$$= (1 - a_{k-1})^2(1 - q_{ii})^2 + a_{k-1}^2 q_{kk} + \sum_{\ell=1, \ell \neq i}^{k-1} (1 - a_{k-1})^2 q_{k\ell}$$

$$= (1 - a_{k-1})^2(1 - q_{ii})^2 + a_{k-1}^2 (1 - q_{ii})(1 - q_{kk}) + \sum_{\ell=1, \ell \neq i}^{k-1} (1 - a_{k-1})^2(1 - q_{ii})(1 - q_{\ell\ell})$$

$$= a_{k-1}(1 - q_{ii})((1 - a_{k-1})^2 + a_{k-1}(1 - q_{kk})).$$

Thus,

$$\text{Tr}(B_k^2) = c_{kk} + \sum_{\ell=1}^{k-1} a_{k-1}(1 - q_{\ell\ell})((1 - a_{k-1})^2 + a_{k-1}(1 - q_{kk}))$$

$$= (q_{kk} - a_{k-1}(1 - q_{kk})) + a_{k-1}^2 (1 - q_{kk}) + a_{k-1}^2 ((1 - a_{k-1})^2 + a_{k-1}(1 - q_{kk})).$$

These descriptions of $\text{Tr}(B_k)$ and $\text{Tr}(B_k^2)$ allow one to express $\|Q_k\|^2$ as a function of $a_{k-1}, a_k$, and $q_{kk}$. The desired formula for $\|Q_k\|^2$ can then be obtained by writing $q_{kk} = 1 - (a_k - a_{k-1})$ as in equation \[3\].

Lemma 2.7. If $f : [0, 1] \times [0, 1] \rightarrow \mathbb{R}$ denotes the function

$$f(x, y) = \frac{\sqrt{x^2y^2 - 4x^2y + 2xy^2 + 4x^2 - 2xy + y^2 - 2y + 1} - xy - y + 2x + 1}{2},$$

then $f$ is increasing in $x$ and decreasing in $y$. Moreover, if $0 \leq x \leq y \leq 1$, then $0 \leq f(x, y) \leq 1$.

Proof. Define $g : [0, 1] \times [0, 1] \rightarrow \mathbb{R}$ by

$$g(x, y) = x^2y^2 - 4x^2y + 2xy^2 + 4x^2 - 2xy + y^2 - 2y + 1,$$

so $f(x, y) = \frac{1}{2}((g(x, y) - xy - y + 2x + 1)$. Note that for each fixed $y \in [0, 1]$, the map

$$x \mapsto g(x, y) = (2 - y)^2x^2 - 2y(1 - y)x + (1 - y)^2$$

defines a convex quadratic on $[0, 1]$ with vertex at $x_0 = y(1 - y)/(2 - y)^2$. If $y \in [0, 1)$, then

$$g(x_0, y) = g\left(\frac{y(1 - y)}{(2 - y)^2}, y\right) = \frac{4(1 - y)^3}{(2 - y)^2} > 0.$$
Consequently, \( g(x, y) > 0 \) for all \((x, y) \in [0, 1] \times [0, 1)\). Note as well that at \( y = 1 \) we have \( g(x, 1) = x^2 \).

It follows that \( g(0, 1) = 0 \) and \( g(x, y) > 0 \) for all other values of \((x, y) \in [0, 1] \times [0, 1]\). Thus, \( f(x, y) \) is well-defined, and the partial derivatives

\[
\begin{align*}
  f_x(x, y) &= \frac{g_x(x, y)}{4\sqrt{g(x, y)}} - \frac{y + 2}{2}, \\
  f_{xx}(x, y) &= \frac{2(1-y)^3}{(g(x, y))^{3/2}}, \\
  f_y(x, y) &= \frac{g_y(x, y)}{4\sqrt{g(x, y)}} - \frac{x + 1}{2}, \\
  f_{yy}(x, y) &= \frac{2x^3}{(g(x, y))^{3/2}}
\end{align*}
\]

exist for all \((x, y) \neq (0, 1)\).

Let us begin by showing that \( f(x, y) \) is increasing in \( x \). First observe that \( f(x, 1) = x \) is clearly increasing. Furthermore, for every fixed \( y \in [0, 1) \), \( f_{xx}(x, y) \) is well-defined and strictly positive for all \( x \). Hence,

\[
f_x(x, y) = \frac{xy^2 - 4xy + y^2 + 4x - y}{2\sqrt{g(x, y)}} - \frac{y + 2}{2}
\]

is an increasing function of \( x \). We conclude that for every \( x \in [0, 1] \), \( f_x(x, y) \geq f_x(0, y) = 1 - y > 0 \). Thus, \( f \) is an increasing function of \( x \) on \([0, 1]\).

We now use a similar argument to show that \( f \) is a decreasing function of \( y \). For \( x = 0 \), we have that \( f(0, y) = 1 - y \) is clearly decreasing. Now given a fixed \( x \in (0, 1] \), it is clear from above that \( f_{yy}(x, y) \) is well-defined and strictly positive for all \( y \). It follows that the partial derivative

\[
f_y(x, y) = \frac{x^2y - 2x^2y + 2xy - x + y - 1}{2\sqrt{g(x, y)}} - \frac{x + 1}{2}
\]

is an increasing function of \( y \) on \([0, 1]\). Hence, for every \( y \in [0, 1] \), \( f_y(x, y) \leq f_y(x, 1) = -x < 0 \). This proves that \( f \) is a decreasing function of \( y \) on \([0, 1]\), as desired.

For the final claim suppose that \( 0 < x \leq y \leq 1 \), and consider the sequence \( \{a_k\}_{k=0}^3 \) defined by \( a_0 = 0 \), \( a_1 = x \), \( a_2 = y \), and \( a_3 = 1 \). By Lemma 2.4, there is a rank-two projection \( Q = (q_{ij}) \) in \( M_3(\mathbb{C}) \) that is defined by \( \{a_k\}_{k=0}^3 \) in the sense of equation (2). Turning to Corollary 2.6, we have that

\[
f(x, y) = f(a_1, a_2) = \|E_1^+Q E_2\|^2,
\]

and hence \( 0 \leq f(x, y) \leq 1 \).

\[\blacksquare\]

**Theorem 2.8.** If \( Q \in M_n(\mathbb{C}) \) is a projection of rank \( n - 1 \) that is of minimal distance to \( T_n(\mathbb{C}) \), then \( \|E_{i-1}^+ Q E_i\| = \|E_{j-1}^+ Q E_j\| \) for all \( i \) and \( j \).

**Proof.** By Lemma 2.3, we may assume without loss of generality that \( Q = (q_{ij}) \) is such that \( q_{ij} \leq 0 \) whenever \( i \neq j \). Let \( \{a_i\}_{i=0}^n \) denote the non-decreasing sequence from equation (2), and for each \( i \in \{1, 2, \ldots, n\} \), define \( Q_i := E_{i-1}^+ Q E_i \). Suppose to the contrary that not all values of \( \|Q_i\| \) are equal. Define

\[
\mu := \max_{1 \leq i \leq n} \|Q_i\|,
\]

and let \( j \) denote the largest index in \( \{1, 2, \ldots, n\} \) such that \( \|Q_i\| = \mu \).

First consider the case in which \( j = n \). Let \( k \) denote the largest index in \( \{1, 2, \ldots, n - 1\} \) such that \( \|Q_k\| < \mu \). With \( f \) as in Corollary 2.6, we have that

\[
f(a_{k-1}, a_k) = \|Q_k\|^2 < \|Q_{k+1}\|^2 = f(a_k, a_{k+1}).
\]

Thus, the function \( g : [a_{k-1}, a_k] \to \mathbb{R} \) given by

\[
g(x) = f(a_{k-1}, x) - f(x, a_{k+1})
\]

is such that \( g(a_k) = f(a_{k-1}, a_k) - f(a_{k-1}, a_{k+1}) < 0 \), while \( g(a_{k-1}) = 1 - f(a_{k-1}, a_{k+1}) \geq 0 \) by Lemma 2.7. Since \( g \) is continuous on its domain, the Intermediate Value Theorem gives rise to some \( a'_k \in [a_{k-1}, a_k] \) such that \( g(a'_k) = 0 \). By replacing \( a_k \) with \( a'_k \) in the sequence \( \{a_i\}_{i=0}^n \), one may equate \( \|Q_k\| \) and \( \|Q_{k+1}\| \) while leaving the remaining norms \( \|Q_i\| \) unchanged. Most importantly, since \( a'_k \leq a_k \), Lemma 2.7 implies that the new common value of \( \|Q_k\| \) and \( \|Q_{k+1}\| \) is strictly less than \( \mu \).
This argument may now be repeated to successively reduce the norms \(\|Q_i\|\) for \(i > k\) to values strictly less than \(\mu\). At the end of this process, either the new largest index \(j\) at which the maximum norm occurs is strictly less than \(n\), or the maximum \(\mu\) decreases. Of course, the latter cannot happen as \(Q\) was assumed to be of minimal distance to \(T_n(\mathbb{C})\).

Thus, we may assume that the largest index \(j\) at which \(\mu\) occurs is strictly less than \(n\). In this case we have that
\[
f(a_j, a_{j+1}) = \|Q_{j+1}\|^2 < \|Q_j\|^2 = f(a_{j-1}, a_j).
\]
As above, we may invoke the Intermediate Value Theorem to obtain a root \(a_j\) of the continuous function
\[
h(x) := f(a_{j-1}, x) - f(x, a_{j+1})
\]
on the interval \([a_j, a_{j+1}]\). By replacing \(a_j\) with \(a_j\) in the sequence \(\{a_i\}_{i=0}^n\), one may equate \(\|Q_j\|\) and \(\|Q_{j+1}\|\) while preserving all other norms \(\|Q_i\|\). Since \(a_j' \geq a_j\), Lemma 2.7 demonstrates that the new common value of \(\|Q_j\|\) and \(\|Q_{j+1}\|\) is strictly less than \(\mu\). Thus, this process either decreases the largest index \(j\) at which the maximum norm occurs, or reduces the value of \(\mu\). Since this argument may be repeated for smaller and smaller values of \(j\), eventually \(\mu\) must decrease—a contradiction.

\[\blacksquare\]

§3 Computing the Distance

Here we use the theory developed in §2 to determine the precise value of \(\nu_{n-1,n}\). The first step in this direction is the following proposition, which applies Theorem 2.8 to obtain a recursive description of the sequence \(\{a_i\}_{i=0}^n\).

**Proposition 3.1.** Let \(Q \in M_n(\mathbb{C})\) be a projection of rank \(n - 1\) that is of minimal distance to \(T_n(\mathbb{C})\). If \(\{a_i\}_{i=0}^n\) denotes the non-decreasing sequence from equation (2), then
\[
a_k = \frac{-\nu_{n-1,n}^4 + 2\nu_{n-1,n}^2a_{k-1} + \nu_{n-1,n}^2 - a_{k-1}}{\nu_{n-1,n}^2a_{k-1} + \nu_{n-1,n}^2 - a_{k-1}}
\]
for each \(k \in \{1, 2, \ldots, n\}\).

**Proof.** Since the distance from \(Q\) to \(T_n(\mathbb{C})\) is minimal, Theorems 1.1 and 2.8 imply that \(\|E_{k-1}^\perp QE_k\| = \nu_{n-1,n}\) for all \(k \in \{1, 2, \ldots, n\}\). Thus, with \(f\) as in Corollary 2.6 we have that
\[
f(a_{k-1}, a_k) = \|E_{k-1}^\perp QE_k\|^2 = \nu_{n-1,n}^2.
\]
The desired formula can now be obtained by solving this equation for \(a_k\).

\[\blacksquare\]

The recursive formula for \(a_k\) described in Proposition 3.1 will be the key to computing \(\nu_{n-1,n}\). Our goal will be to use this formula and some basic properties of the sequence \(\{a_i\}_{i=0}^n\) to determine a list of candidates for \(\nu_{n-1,n}^2\). A careful analysis of these terms will reveal that exactly one of them satisfies a certain necessary norm inequality from [3]. This value must therefore be \(\nu_{n-1,n}^2\).

To simplify notation, let \(t = \nu_{n-1,n}^2\) and define the function \(h_t : [0, 1] \to \mathbb{R}\) by
\[
h_t(x) := \frac{-t^2 + 2tx + t - x}{tx + t - x}.
\]
Proposition 3.1 states that for each \(k \in \{1, 2, \ldots, n\}\),
\[
a_k = \frac{-t^2 + 2ta_{k-1} + t - a_{k-1}}{ta_{k-1} + t - a_{k-1}} = h_t(a_{k-1}).
\]
Since \(h_t(0) = (t - t^2)/t = 1 - t = a_1\), this formula may be expressed as \(a_k = h_t^{(k)}(0)\) for all \(k \in \{1, 2, \ldots, n\}\). Upon taking into account the condition \(a_n = 1\), we are interested in identifying the values of \(t \in \left[\frac{1}{4}, 1\right]\) that satisfy the equation \(h_t^{(n)}(0) = 1\).
Notice that each expression $h_t^{(k)}(0)$ is a rational function of $t$. For each $k \geq 1$, let $p_{k-1}(t)$ and $q_{k-1}(t)$ denote polynomials in $t$ such that

$$h_t^{(k)}(0) = \frac{p_{k-1}(t)}{q_{k-1}(t)}$$

It then follows that

$$\frac{p_k(t)}{q_k(t)} = h_t\left(h_t^{(k)}(0)\right) = h_t\left(\frac{p_{k-1}(t)}{q_{k-1}(t)}\right) = \frac{-t^2q_{k-1}(t) + 2tp_{k-1}(t) + tq_{k-1}(t) - p_{k-1}(t)}{tp_{k-1}(t) + tq_{k-1}(t) - p_{k-1}(t)},$$

and hence we obtain the relations

$$p_k(t) = t(1-t)q_{k-1}(t) + (2t-1)p_{k-1}(t),$$

$$q_k(t) = tq_{k-1}(t) - (1-t)p_{k-1}(t).$$

The $p_{k-1}(t)$ term in $[5]$ can be replaced using equation $[5]$, thereby leading to a recurrence expressed only in the $q_k(t)$’s. Specifically, we have that

$$q_k(t) = tq_{k-1}(t) - (1-t)p_{k-1}(t)$$

$$= tq_{k-1}(t) - (1-t)[t(1-t)q_{k-2}(t) + (2t-1)p_{k-2}(t)]$$

$$= tq_{k-1}(t) - t(1-t)^2q_{k-2}(t) - (2t-1)[tq_{k-2}(t) - q_{k-1}(t)]$$

$$= (3t - 1)q_{k-1}(t) - t^3q_{k-2}(t)$$

for all $k \geq 2$. We may extend this recurrence relation to include $k = 1$ by choosing a suitable expression for $q_{-1}(t)$. Indeed, note that

$$\frac{p_0(t)}{q_0(t)} = h_t(0) = 1 - t$$

and

$$\frac{p_1(t)}{q_1(t)} = h_t(0) = \frac{-3t^2 + 4t - 1}{-t^2 + 3t - 1},$$

so $q_0(t) = 1$, and $q_1(t) = -t^2 + 3t - 1$. Thus, we may write $q_1(t) = (3t - 1)q_0(t) - t^3q_{-1}(t)$ by defining $q_{-1}(t) := t^{-1}$.

The requirement that $h_t^{(n)}(0) = 1$ is equivalent to asking that $p_{n-1}(t) = q_{n-1}(t)$. Using the relations above, this equation can be restated as $q_{n-2}(t) = p_{n-2}(t)$, or equivalently $q_{n-1}(t) = t^2q_{n-2}(t)$ by $[6]$. Thus, we wish to determine the values of $t \in \left[\frac{1}{4}, 1\right]$ that satisfy

$$q_{n-1}(t) = t^2q_{n-2}(t),$$

where

$$q_{-1}(t) = t^{-1}, \quad q_0(t) = 1, \quad \text{and} \quad q_k(t) = (3t - 1)q_{k-1}(t) - t^3q_{k-1}(t) \quad \forall k \geq 1.$$

A solution to this problem will require closed-form expressions for the polynomials $q_{n-1}(t)$ and $q_{n-2}(t)$. In order to obtain such expressions, we will first rewrite the recurrence relation defining these polynomials in terms of repeated matrix multiplication:

$$\begin{bmatrix} q_k(t) \\ q_{k-1}(t) \end{bmatrix} = \begin{bmatrix} 3t - 1 & -t^3 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} q_{k-1}(t) \\ q_{k-2}(t) \end{bmatrix} = \begin{bmatrix} 3t - 1 & -t^3 \\ 1 & 0 \end{bmatrix}^k \begin{bmatrix} q_0(t) \\ q_{-1}(t) \end{bmatrix}.$$

One may therefore obtain a description of $q_{n-1}(t)$ and $q_{n-2}(t)$ by diagonalizing the matrix

$$A := \begin{bmatrix} 3t - 1 & -t^3 \\ 1 & 0 \end{bmatrix}.$$

Routine computations show that the eigenvalues of $A$ are given by

$$\lambda_1 = \frac{3t - 1 + (1-t)\sqrt{1-4t}}{2} = \frac{3t - 1 + (1-t)i\gamma}{2},$$

and

$$\lambda_2 = \frac{3t - 1 - (1-t)\sqrt{1-4t}}{2} = \frac{3t - 1 - (1-t)i\gamma}{2}.$$
where \( y := \sqrt{4t - 1} \). Furthermore, the columns of the matrix \( P := \begin{bmatrix} \lambda_1 & \lambda_2 \\ 1 & 1 \end{bmatrix} \) form a basis of eigenvectors corresponding to \( \lambda_1 \) and \( \lambda_2 \), respectively. By computing

\[
P^{-1} = \frac{1}{(1-t)iy} \begin{bmatrix} 1 & -\lambda_2 \\ -1 & \lambda_1 \end{bmatrix}
\]

and setting \( D := \text{diag}(\lambda_1, \lambda_2) \), we have that \( A = P^{-1}DP \). Consequently,

\[
\begin{bmatrix} q_{n-1}(t) \\ q_{n-2}(t) \end{bmatrix} = P^{-1}D^n P \begin{bmatrix} q_0(t) \\ q_{-1}(t) \end{bmatrix} = \frac{1}{t(1-t)iy} \begin{bmatrix} \frac{t (\lambda_1^n - \lambda_2^n)}{1 - \lambda_1^n} - \lambda_2 \lambda_1^n + \lambda_1 \lambda_2^n \\ \frac{t (\lambda_1^{n-1} - \lambda_2^{n-1})}{1 - \lambda_1^{n-1}} - \lambda_2 \lambda_1^{n-1} + \lambda_1 \lambda_2^{n-1} \end{bmatrix}.
\]

The expressions for \( q_{n-1}(t) \) and \( q_{n-2}(t) \) derived above can now be used to identify the desired values of \( t \). Indeed, when \( q_{n-1}(t) = t^2 q_{n-2}(t) \), we have that

\[
t (\lambda_1^n - \lambda_2^n) - \lambda_2 \lambda_1^n + \lambda_1 \lambda_2^n = t^2 (t (\lambda_1^{n-1} - \lambda_2^{n-1}) - \lambda_2 \lambda_1^{n-1} + \lambda_1 \lambda_2^{n-1})
\]

\[
\Rightarrow \quad \lambda_1^n (t - \lambda_2) - \lambda_2^n (t - \lambda_1) = t^2 (\lambda_1^{n-1} (t - \lambda_2) - \lambda_2^{n-1} (t - \lambda_1))
\]

\[
\Rightarrow \quad \lambda_1^{n-1} (t^2 - \lambda_1) (t - \lambda_2) = \lambda_2^{n-1} (t^2 - \lambda_2) (t - \lambda_1),
\]

and therefore

\[
(t - \lambda_1) = \left( \frac{\lambda_2}{\lambda_1} \right)^{n-1} \left( \frac{t^2 - \lambda_2}{t^2 - \lambda_1} \right) \frac{t - \lambda_1}{t - \lambda_2}.
\]

This equation may be simplified using the following identities that relate the values of \( t \), \( \lambda_1 \), and \( \lambda_2 \). Verification of these identities is straightforward, and thus their proofs are left to the reader.

**Lemma 3.2.** If \( y = \sqrt{4t - 1}, \lambda_1 = (3t - 1 + (1-t)iy)/2, \) and \( \lambda_2 = (3t - 1 - (1-t)iy)/2, \) then

(i) \( t - \lambda_1 = (1-t) \left( \frac{1 - iy}{2} \right) \) and \( t - \lambda_2 = (1-t) \left( \frac{1 + iy}{2} \right). \)

(ii) \( t^2 - \lambda_1 = (1-t) \left( \frac{1 - 2t + iy}{2} \right) \) and \( t^2 - \lambda_2 = (1-t) \left( \frac{1 - 2t - iy}{2} \right). \)

(iii) \( \frac{1 + iy}{1 - iy} = \frac{1 - 2t + iy}{2t} \) and \( \frac{1 - iy}{1 + iy} = \frac{1 - 2t - iy}{2t}. \)

(iv) \( \frac{\lambda_2}{\lambda_1} = \left( \frac{1 + iy}{1 - iy} \right)^3. \)

One may apply the identities above to simplify equation (7) as follows:

\[
1 = \left( \frac{\lambda_2}{\lambda_1} \right)^{n-1} \left( \frac{t^2 - \lambda_2}{t^2 - \lambda_1} \right) \frac{t - \lambda_1}{t - \lambda_2}
\]

\[
= \left( \frac{1 + iy}{1 - iy} \right)^{3(n-1)} \left( \frac{1 - 2t + iy}{1 - 2t - iy} \right) \left( \frac{1 - iy}{1 + iy} \right)
\]

\[
= \left( \frac{1 + iy}{1 - iy} \right)^{3n-3} \left( \frac{1 + iy}{1 - iy} \right)^2 \left( \frac{1 - iy}{1 + iy} \right)
\]

\[
= \left( \frac{1 + iy}{1 - iy} \right)^{3n-2}.
\]

We therefore conclude that

\[
\frac{1 + iy}{1 - iy} = \rho_m^k,
\]

where \( m := 3n - 2, \rho_m := e^{2\pi i/m}, \) and \( k \) is an integer.
We are now in a position to determine the possible values of $t$. By solving for $y$ in the equation above, we obtain
\[
y = \frac{1}{i} \frac{\rho_m^k - 1}{\rho_m^k + 1} = \frac{1}{i} \frac{\rho_m^{k/2} (\rho_m^{k/2} - \rho_m^{-k/2})}{\rho_m^{k/2} (\rho_m^{k/2} + \rho_m^{-k/2})}
= \frac{\rho_m^{k/2} - \rho_m^{-k/2}}{2i} \frac{2}{\rho_m^{k/2} + \rho_m^{-k/2}}
= \frac{\sin (k\pi/m)}{\cos (k\pi/m)} = \tan \left( \frac{k\pi}{m} \right).
\]
Since $y = \sqrt{4t - 1}$, we have
\[
t = \frac{1}{4} \left( \tan^2 \left( \frac{k\pi}{m} \right) + 1 \right) = \frac{1}{4} \sec^2 \left( \frac{k\pi}{3n - 2} \right)
\]
for some $k \in \mathbb{Z}$. That is, the distance $\nu_{n-1,n}$ from $Q$ to $T_n(\mathbb{C})$ must belong to the set
\[
\left\{ \frac{1}{2} \sec \left( \frac{k\pi}{3n - 2} \right) : k \in \mathbb{Z} \right\}.
\]

It remains to be determined which element of this set represents the value of $\nu_{n-1,n}$. We will accomplish this task by appealing to the following result of MacDonald concerning a lower bound on the distance from a projection to a nilpotent.

**Proposition 3.3.** [9 Lemma 3.3] If $P$ is a projection of rank $r$ in $M_n(\mathbb{C})$, and $N$ is a nilpotent in $M_n(\mathbb{C})$, then
\[
\|P - N\| \geq \sqrt{\frac{r}{2n} \left( 1 + \frac{r}{n} \right)}.
\]

In the analysis that follows, we will demonstrate that the only value in $\left\{ \frac{1}{2} \sec \left( \frac{k\pi}{3n - 2} \right) : k \in \mathbb{Z} \right\}$ that respects the lower bound of Proposition 3.3 for projections of rank $r = n - 1$ occurs when $k = n - 1$. We begin with the following lemma, which proves that MacDonald’s lower bound is indeed satisfied for this choice of $k$.

**Lemma 3.4.** For every integer $n \geq 3$,
\[
\frac{n - 1}{2n} \left( 1 + \frac{n - 1}{n} \right) \leq \frac{1}{4} \sec^2 \left( \frac{(n-1)\pi}{3n - 2} \right) \leq 1
\]

**Proof.** Define $\alpha_n := (3n - 2)/(n - 1)$. By considering reciprocals, this problem is equivalent to that of establishing the inequalities
\[
\frac{1}{4} \leq \cos^2 \left( \frac{\pi}{\alpha_n} \right) \leq \frac{n^2}{2(n - 1)(2n - 1)}
\]
for all $n \geq 3$. In the computations that follow, it will be helpful to view $n$ as a continuous variable on $[3, \infty)$.

To establish the inequality
\[
\frac{1}{4} \leq \cos^2 \left( \frac{\pi}{\alpha_n} \right),
\]
simply note that $\pi/\alpha_n$ is an increasing function of $n$ tending to $\pi/3$, $\cos(x)$ is decreasing on $[0, \pi/3]$, and $\cos(\pi/3) = 1/2$. The second inequality will require a bit more work. Since $(2n - \frac{3}{2})^2 \geq 2(n - 1)(2n - 1)$ for all $n \geq 3$, it suffices to prove that
\[
\cos^2 \left( \frac{\pi}{\alpha_n} \right) \leq \frac{n^2}{(2n - \frac{3}{2})^2}.
\]
This inequality can be reduced further by taking square roots. Indeed, the above inequality holds if and only if
\[
f(n) := \frac{2n}{4n - 3} - \cos \left( \frac{\pi}{\alpha_n} \right) \geq 0 \quad \text{for } n \in [3, \infty).
\]
We will prove that \( f'(n) < 0 \) for all \( n \in [3, \infty) \), so that \( f \) is monotonically decreasing on this interval. Since
\[
\lim_{n \to \infty} f(n) = 0 \quad \text{and} \quad f(3) = \frac{2}{3} - \cos \left( \frac{2\pi}{3} \right) \approx 0.043 > 0,
\]
this will demonstrate that \( f(n) \geq 0 \) for all \( n \geq 3 \). To this end, we compute
\[
f'(n) = \frac{16\pi \sin \left( \frac{\pi}{\alpha_n} \right) n^2 - 24\pi \sin \left( \frac{\pi}{\alpha_n} \right) n + 9\pi \sin \left( \frac{\pi}{\alpha_n} \right) - 54n^2 + 72n - 24}{(4n - 3)^2(3n - 2)^2}.
\]
Of course \((4n - 3)^2(3n - 2)^2 \geq 0\), so the sign of \( f'(n) \) depends only on the sign of
\[
g(n) := 16\pi \sin \left( \frac{\pi}{\alpha_n} \right) n^2 - 24\pi \sin \left( \frac{\pi}{\alpha_n} \right) n + 9\pi \sin \left( \frac{\pi}{\alpha_n} \right) - 54n^2 + 72n - 24.
\]
But since \( \pi/\alpha_n \in [\pi/4, \pi/3] \) for \( n \geq 3 \), we have that \( \sin \left( \frac{\pi}{\alpha_n} \right) \in [\sqrt{3}/2, \sqrt{3}/2] \) for all such \( n \), and hence
\[
g(n) \leq 16\pi \left( \frac{\sqrt{3}}{2} \right) n^2 - 24\pi \left( \frac{\sqrt{3}}{2} \right) n + 9\pi \left( \frac{\sqrt{3}}{2} \right) - 54n^2 + 72n - 24
\]
\[
= \left( 8\sqrt{3}\pi - 54 \right) n^2 - \left( 12\sqrt{2} - 72 \right) n + \left( \frac{9\sqrt{3}}{2} - 24 \right).
\]
This upper bound for \( g \) is a concave quadratic whose largest root occurs at \( n \approx 1.8105 \). It follows that \( g \) is negative on \([3, \infty)\), and therefore so too is \( f'\).

\[\Box\]

**Lemma 3.5.** For any integer \( n \geq 3 \), the set
\[
\left\{ \frac{1}{4} \sec^2 \left( \frac{k\pi}{3n-2} \right) : k \in \mathbb{Z} \right\}
\]
contains exactly one value in \( \left[ \frac{n-1}{2n} \left( 1 + \frac{n-1}{n} \right), 1 \right] \), and it occurs when \( k = n - 1 \).

**Proof.** Fix an integer \( n \geq 3 \), and define
\[\mathcal{A} := \left\{ \cos^2 \left( \frac{k\pi}{3n-2} \right) : k \in \mathbb{Z} \right\} \quad \text{and} \quad \mathcal{I} := \left[ \frac{1}{4}, \frac{n^2}{4n^2 - 6n + 2} \right].\]

We wish to show that \( \mathcal{A} \) contains exactly one value in \( \mathcal{I} \). Since Lemma 3.4 demonstrates that this is the case when \( k = n - 1 \), it suffices to show that no other values in \( \mathcal{A} \) are within distance
\[
\beta(n) := \frac{n^2}{4n^2 - 6n + 2} - \frac{1}{4}
\]
of \( \cos^2((n-1)\pi/(3n-2)) \).

Note, however, that not all values of \( k \in \mathbb{Z} \) need to be considered. In particular, one may exploit the periodicity of the function \( k \mapsto \cos^2(k\pi/(3n-2)) \) to deduce that only integers \( k \) between 0 and \( 3n - 2 \) must be checked. Additionally, since
\[
\cos^2 \left( \frac{(3n - 2) - k\pi}{3n - 2} \right) = \cos^2 \left( \frac{k\pi}{3n - 2} \right)
\]
for all \( k \), we may restrict our attention to those \( k \) in \( \{0, 1, 2, \ldots, (3n-2)/2\} \).

Although we are solely concerned with the integer values of \( k \) described above, it will be useful to view \( k \) as a continuous real variable. With this in mind, define the function \( f_n : [0, (3n-2)/2] \to \mathbb{R} \) by
\[f_n(k) := \sin \left( \frac{(n-k-1)\pi}{3n-2} \right) \sin \left( \frac{(n+k-1)\pi}{3n-2} \right).
\]
It follows from the identity \( \cos^2(x) - \cos^2(y) = -\sin(x - y)\sin(x + y) \) that
\[
\left| \cos^2 \left( \frac{k\pi}{3n-2} \right) - \cos^2 \left( \frac{(n-1)\pi}{3n-2} \right) \right| < \beta(n) \iff |f_n(k)| < \beta(n).
\]
Notice, however, that
\[ f_n'(k) = \left(-\frac{\pi}{3n-2}\right) \sin \left(\frac{2k\pi}{3n-2}\right), \]
so \( f_n'(k) < 0 \) on \([0,(3n-2)/2]\), and hence \( f_n \) is decreasing on its domain. Since \( f_n(n-1) = 0 \), it therefore suffices to prove that
\[ f_n(n-2) > \beta(n) \quad \text{and} \quad -f_n(n) > \beta(n). \]

We will demonstrate that these inequalities hold for all \( n \geq 3 \) via application of Taylor’s Theorem.

Consider the approximation of \( \sin(x) \) by its third degree MacLauren polynomial \( x - x^3/6 \). On \([0,\pi/6]\), the error in this approximation is at most
\[ E(x) = \frac{\sin(\pi/6)}{4!} |x|^4 = \frac{x^4}{48}. \]

Thus, since \( 1/n \leq \pi/(3n-2) \leq \pi/6 \) for all \( n \geq 3 \), we have
\[ \sin \left(\frac{\pi}{3n-2}\right) \geq \sin \left(\frac{1}{n}\right) \geq \left(\frac{1}{n} - \frac{1}{6n} - E \left(\frac{1}{n}\right)\right) \geq \left(\frac{1}{n} - \frac{1}{6n} - \frac{1}{48n}\right) = \frac{13}{16n}. \]

It is routine to verify that \( \sin \left((2n-1)\pi/(3n-2)\right) \) is an increasing function of \( n \) on \([3,\infty)\). Consequently, this function is bounded below by \( \sin \left(5\pi/6\right) \), its value at \( n = 3 \). We conclude that
\[ -f_n(n) = \sin \left(\frac{\pi}{3n-2}\right) \sin \left(\frac{2n-1}{3n-2}\right) \geq \frac{13}{16n} \sin \left(\frac{5\pi}{7}\right) \geq \frac{13}{16n} \cdot \frac{3}{4} = \frac{39}{64n}. \]

Lastly, one may show directly that
\[ \frac{39}{64n} > \beta(n) \quad \text{for all} \quad n > \frac{101 + \sqrt{5521}}{60} \approx 2.9217, \]
and hence \( -f_n(n) > \beta(n) \) for all \( n \geq 3 \).

A similar analysis may now be used to prove that \( f_n(n-2) > \beta(n) \). Indeed, it is straightforward to verify that \( \sin \left((2n-3)\pi/(3n-2)\right) \) is bounded below by \( \sin \left(2\pi/3\right) \), and therefore
\[ f_n(n-2) = \sin \left(\frac{\pi}{3n-2}\right) \sin \left(\frac{2n-3}{3n-2}\right) \geq \frac{13}{16n} \sin \left(\frac{2\pi}{3}\right) = \frac{13}{16n} \cdot \frac{\sqrt{3}}{2} \geq \frac{13}{16n} \cdot \frac{3}{4} = \frac{39}{64n}. \]

It now follows from the arguments of the previous case that \( f_n(n-2) > \beta(n) \) for all \( n \geq 3 \).

\[ \Box \]

§4 CONCLUSION

The analysis of §3 demonstrates that the distance from a projection in \( M_n(\mathbb{C}) \) of rank \( n-1 \) to the set \( \mathcal{N}(\mathbb{C}^n) \) is \( \frac{1}{2} \sec \left((n-1)\pi/(3n-2)\right) \). Interestingly, this expression can be rewritten to bear an even stronger resemblance to MacDonald’s formula in the rank-one case.

**Theorem 4.1.** For every integer \( n \geq 2 \), the distance from the set of projections in \( M_n(\mathbb{C}) \) of rank \( n-1 \) to \( \mathcal{N}(\mathbb{C}^n) \) is
\[ \nu_{n-1,n} = \frac{1}{2} \sec \left(\frac{\pi}{n-1} + 2\right). \]

Given a projection \( Q = (q_{ij}) \) in \( M_n(\mathbb{C}) \) of rank \( n-1 \) that is of minimal distance to \( \mathcal{T}_n(\mathbb{C}) \), the following theorem provides a means for determining an element \( T \in \mathcal{T}_n(\mathbb{C}) \) that is closest to \( Q \). As we will see in Theorem 4.3, this element of \( \mathcal{T}_n(\mathbb{C}) \) is unique to \( Q \).

**Theorem 4.2.** \([2][9]\) Fix \( \gamma \in [0, \infty) \). For \( A \in M_n(\mathbb{C}) \), \( \|E_{i-1}^T AE_i\| = \gamma \) for all \( i \in \{1,2,\ldots,n\} \) if and only if \( A - T = \gamma U \) for some \( T \in \mathcal{T}_n(\mathbb{C}) \) and unitary \( U \in M_n(\mathbb{C}) \). Moreover, if \( \|E_{i-1}^T AE_i\| = \gamma \) and \( \|E_i^T AE_i\| < \gamma \) for all \( i \in \{1,2,\ldots,n\} \), then the operators \( T \) and \( U \) are unique.
Theorem 4.3. Fix a positive integer \( n \geq 2 \), and let \( \{a_i\}_{i=0}^n \) be the sequence given by \( a_0 = 0 \) and

\[
a_k = \frac{-v_{n-1,n}^2 + 2v_{n-1,n}a_{k-1} + \nu_{n-1,n}^2 - a_{k-1}}{v_{n-1,n}^2} \quad \text{for} \quad k \geq 1.
\]

Let \( \{z_i\}_{i=1}^n \) be a sequence of complex numbers of modulus 1, define

\[
e := \begin{bmatrix} z_1 \sqrt{a_1 - a_0} & z_2 \sqrt{a_2 - a_1} & \cdots & z_n \sqrt{a_n - a_{n-1}} \end{bmatrix}^T,
\]

and let \( Q = I - e \otimes e^* \).

(i) \( Q \) is a projection of rank \( n - 1 \), and \( \text{dist}(Q, T_n(\mathbb{C})) = \nu_{n-1,n} \). Moreover, every projection of rank \( n - 1 \) that is of minimal distance to \( T_n(\mathbb{C}) \) is of this form.

(ii) There is a unique \( T \in T_n(\mathbb{C}) \) of minimal distance to \( Q \), and this \( T \) is such that \( Q - T = \nu_{n-1,n} U \) for some unitary \( U \in M_n(\mathbb{C}) \). Thus, if \( q_k := Qe_k \) and \( t_k := Te_k \) denote the columns of \( Q \) and \( T \), respectively, then one can iteratively determine columns \( t_k \) by solving the system of linear equations

\[
\begin{cases}
\langle q_1 - t_1, q_k - t_k \rangle &= 0 \\
\langle q_2 - t_2, q_k - t_k \rangle &= 0 \\
& \vdots \\
\langle q_{k-1} - t_{k-1}, q_k - t_k \rangle &= 0
\end{cases}
\]

for \( k = 2, 3, \ldots, n \).

Proof. Statement (i) follows immediately from the results of §2 and §3. For statement (ii), the existence of \( T \) and \( U \) is guaranteed by Theorems 2.8 and 4.2. All that remains to show is the uniqueness of these operators.

To accomplish this task, first note that it suffices to prove uniqueness in the case that \( z_i = 1 \) for all \( i \) (i.e., when \( q_{ij} \leq 0 \) for all \( i \neq j \)). For each \( k \in \{1, 2, \ldots, n\} \), let \( Q_k \) denote the restriction of \( E_{k-1}Q E_k \) to the range of \( E_k \), and define \( B_k := Q_k^* Q_k \). Let \( Q'_k = E_k^* Q_k \), so that

\[
Q_k = \begin{bmatrix} v_k^* \\
Q'_k
\end{bmatrix},
\]

where \( v_k := [q_{k1} \ q_{k2} \ \cdots \ q_{kk}]^T \).

We will demonstrate that \( \|Q'_k\| < \|Q_k\| \) for all \( k \in \{1, 2, \ldots, n\} \), and therefore obtain the uniqueness of \( T \) and \( U \) via Theorem 4.2. Observe that this inequality holds when \( k = 1 \), as

\[
\|Q_1\|^2 - \|Q'_1\|^2 = q_{11}^2 > 0.
\]

Suppose now that \( k \in \{2, 3, \ldots, n\} \) is fixed, and define \( B'_k := Q_k^* Q'_k = B_k - v_k v_k^* \). One may determine the entries of \( B'_k = (b'_{ij}) \) using the formulas for the entries of \( B_k = (b_{ij}) \) from Lemma 2.5(i). Indeed,

\[
b'_{kk} &= b_{kk} - q_{kk}^2 \\
&= q_{kk} - a_{k-1}(1 - q_{kk}) - q_{kk}^2 \\
&= (q_{kk} - a_{k-1})(1 - q_{kk}) = (1 - a_k)(1 - q_{kk}),
\]

and for if \( i < k \),

\[
b'_{ii} &= b_{ii} - q_{ii}^2 \\
&= (1 - a_{k-1})(1 - q_{ii}) - (1 - q_{kk})(1 - q_{ii}) \\
&= (q_{kk} - a_{k-1})(1 - q_{ii}) = (1 - a_k)(1 - q_{ii}).
\]

If \( i, j, \) and \( k \) are all distinct, then

\[
b'_{ij} &= b_{ij} - q_{ki} q_{kj} \\
&= -(1 - a_{k-1})q_{ij} + q_{ij}(1 - q_{kk}) \\
&= -(q_{kk} - a_{k-1})q_{ij} = -(1 - a_k)q_{ij}.
\]
Finally, either \( i < j = k \) or \( j < i = k \). In the case that the former holds, we have

\[
\begin{align*}
b'_{ik} &= b_{ik} - q_{ki}q_{kk} \\
&= a_{k-1}q_{ki} - q_{ki}q_{kk} \\
&= -(q_{kk} - a_{k-1})q_{ik} = -(1 - a_k)q_{ik}.
\end{align*}
\]

The fact that \( B'_k \) is self-adjoint implies that \( b'_{kj} = -(1 - a_k)q_{kj} \) for all \( j < k \) as well.

The above expressions for the entries \( b'_{ij} \) reveal that

\[
B'_k = (1 - a_k)(I - \hat{Q}),
\]

where \( \hat{Q} \in \mathbb{M}_k(\mathbb{C}) \) denotes the \( k^{th} \) leading principal submatrix of \( Q \). Since \( Q \) has rank \( n - 1 \), Corollary 2.2 implies that \( \lambda = 1 \) occurs as an eigenvalue of \( \hat{Q} \) with multiplicity at least \( k - 1 \), and hence \( 0 \) occurs as an eigenvalue of \( B'_k \) with multiplicity at least \( k - 1 \). It follows that

\[
\|B'_k\| = \text{Tr}(B'_k) = \sum_{\ell=1}^{k}(1 - a_{k-1})(1 - q_{k\ell}) = a_k(1 - a_k).
\]

Now let \( f : [0, 1] \times [0, 1] \to \mathbb{R} \) denote the function from Corollary 2.6 so \( \|Q_k\|^2 = f(a_{k-1}, a_k) \). Suppose, for sake of contradiction, that \( \|B_k\| = \|B'_k\| \) and hence \( f(a_{k-1}, a_k) = a_k(1 - a_k) \). One may verify that for this equation to hold, we necessarily have

\[
a^3_{k-1}(a_k - a_{k-1}) = 0,
\]

and thus either \( a_{k-1} = 0 \) or \( a_k = a_{k-1} \). If the former is true, then \( a_j = 0 \) for all \( j \in \{1, 2, \ldots, k - 1\} \). In particular,

\[
\text{dist}(Q, T_n(\mathbb{C})) = \|Q_1\| = \sqrt{1 - a_1} = 1.
\]

If instead \( a_k = a_{k-1} \), then from equation (3) we have \( q_{kk} = 1 - (a_k - a_{k-1}) = 1 \). This then implies that \( \text{dist}(Q, T_n(\mathbb{C})) = \|Q_k\| \geq 1 \). Since either possibility contradicts the minimality of \( \text{dist}(Q, T_n(\mathbb{C})) \), we conclude that \( \|B'_k\| < \|B_k\| \), and thus \( \|Q'_k\| < \|Q_k\| \).

To save the reader from lengthy computations, we have included a few examples of pairs \( (Q, T) \) where \( Q \in \mathbb{M}_n(\mathbb{C}) \) is a projection of rank \( n - 1 \), \( T \) belongs to \( T_n(\mathbb{C}) \), and \( \|Q - T\| = \nu_{n-1,n} \). Theorem 4.3 implies that if \( (Q', T') \) is any other projection-nilpotent pair such that \( \text{rank}(Q') = n - 1 \) and \( \|Q' - T'\| = \nu_{n-1,n} \), then there is a unitary \( V \in \mathbb{M}_n(\mathbb{C}) \) such that \( Q' = V^*QV \) and \( T' = V^*TV \).

**Example 1 (n=3)**

\[
Q = \begin{bmatrix}
0.64310 & -0.31960 & -0.35689 \\
-0.31960 & 0.71379 & -0.31960 \\
-0.35689 & -0.31960 & 0.64310
\end{bmatrix}, \quad T = \begin{bmatrix}
0 & 0 & -0.49697 \\
0 & 0 & -0.49697 \\
0 & 0 & 0
\end{bmatrix};
\]

**Example 2 (n=4)**

\[
Q = \begin{bmatrix}
0.72361 & -0.24860 & -0.24860 & -0.27639 \\
-0.24860 & 0.77639 & -0.22361 & -0.24860 \\
-0.24860 & -0.22361 & 0.77639 & -0.24860 \\
-0.27639 & -0.24860 & -0.24860 & 0.72361
\end{bmatrix}, \quad T = \begin{bmatrix}
0 & 0 & -0.34356 & -0.46094 & -0.65836 \\
0 & 0 & -0.34164 & -0.46094 & 0 \\
0 & 0 & 0 & -0.34356 & 0 \\
0 & 0 & 0 & 0 & 0
\end{bmatrix};
\]

**Example 3 (n=5)**

\[
Q = \begin{bmatrix}
0.77471 & -0.20512 & -0.19907 & -0.20512 & -0.22528 \\
-0.20512 & 0.81324 & -0.18126 & -0.18676 & -0.20512 \\
-0.19907 & -0.18126 & 0.82409 & -0.18126 & -0.19907 \\
-0.20512 & -0.18676 & -0.18126 & 0.81324 & -0.20512 \\
-0.22528 & -0.20512 & -0.19907 & -0.20512 & 0.77472
\end{bmatrix}, \quad T = \begin{bmatrix}
0 & 0 & -0.26477 & -0.32678 & -0.41846 & -0.55566 \\
0 & 0 & -0.26373 & -0.32453 & -0.41846 & 0 \\
0 & 0 & 0 & -0.26373 & -0.32678 & 0 \\
0 & 0 & 0 & 0 & -0.26477 & 0 \\
0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}.
\]
Remark 4.4. It is interesting to note that each projection above is symmetric about its anti-diagonal, the diagonal from the \((n,1)\)-entry to the \((1,n)\)-entry. This symmetry is, in fact, always present in the optimal projection \(Q = (q_{ij})\) from Theorem 4.3 obtained by taking \(z_i = 1\) for all \(i\). To see this, first observe that the function \(h_t\) from equation (4) satisfies the identity
\[
h_t(x) + h_t^{-1}(1-x) = 1, \quad x \in [0,1].
\]
From here we have that \(a_1 + a_{n-1} = h_t(0) + h_t^{-1}(1) = 1\), and by induction,
\[
a_k + a_{n-k} = h_t(a_{k-1}) + h_t^{-1}(a_{n-k+1}) = h_t(a_{k-1}) + h_t^{-1}(1-a_{k-1}) = 1
\]
for all \(k \in \{1, 2, \ldots, n\}\). Consequently,
\[
q_{kk} = 1 - (a_k - a_{k-1}) = a_{n-k} + a_{k-1} = a_{n-k} + (1 - a_{n-k} + 1) = 1 - (a_{n-k+1} - a_n) = q_{n-k+1, n-k+1}
\]
for all \(k\). We now turn to the identity \(q_{ij} = -\sqrt{(1-q_{ii})(1-q_{jj})}\) to conclude that that \(q_{ij} = q_{n-j+1, n-i+1}\) for all \(i\) and \(j\), which is exactly the statement that \(Q\) is symmetric about its anti-diagonal. An analogous argument using the formulas from [8] demonstrates a similar phenomenon for optimal projections of rank 1.

Of course, it is natural to wonder about the value of \(\nu_{r,n}\) when \(r\) is neither 1 nor \(n-1\). The difficulty in extending the above arguments to intermediate-rank projections \(P \in M_n(\mathbb{C})\) is in deriving formulas for \(\|E_{i-1}^r PE_i\|\). Indeed, computing these norms for projections of rank \(r = 1\) or \(r = n-1\) was made possible by the rigid structure afforded by such projections. Perhaps the best testament to this fact is Corollary 2.2 and its subsequent remarks, which demonstrate that a projection matrix of rank 1 or \(n-1\) is determined by its diagonal up to conjugation by a diagonal unitary.

For small values of \(r\) and \(n\), the mathematical programming software Maple was used to construct examples of rank \(r\) projections \(P_{r,n}\) in \(M_n(\mathbb{C})\) which we believe are of minimal distance to \(T_n(\mathbb{C})\). To ease the computations, the program was tasked with minimizing the maximum norm \(\|E_{i-1}^r PE_i\|\) over all projections \(P\) of rank \(r\) with real entries and symmetry about the anti-diagonal. While it may not always be possible for such conditions to be met by an optimal projection of rank \(r\), the computations that follow may still shed light on a potential formula for \(\nu_{r,n}\).

The smallest value of \(n\) for which \(\mathcal{P}(\mathbb{C}^n)\) contains projections of intermediate ranks is \(n = 4\). In this case, the intermediate-rank projections are those of rank 2. We found that
\[
P_{2,4} = \begin{bmatrix}
1/2 & 1/2 & 0 & 0 \\
1/2 & 1/2 & 0 & 0 \\
0 & 0 & 1/2 & 1/2 \\
0 & 0 & 1/2 & 1/2
\end{bmatrix}
\]
is an optimal projection of rank 2 satisfying the conditions above. It is easy to see that
\[
\|E_{i-1}^r P_{2,4} E_i\| = \|1/\sqrt{2}\| = \nu_{1,2}
\]
and hence \(P_{2,4}\) is a direct sum of optimal rank-one projections in \(M_2(\mathbb{C})\).

In \(M_5(\mathbb{C})\), the intermediate-rank projections are those of rank \(r = 2\) or \(r = 3\). For such \(r\), we obtained
\[
P_{2,5} = \begin{bmatrix}
0.42602 & -0.07632 & 0.22568 & 0.42334 & -0.09248 \\
-0.07632 & 0.42127 & 0.23481 & -0.06022 & 0.42334 \\
0.22568 & 0.23481 & 0.30541 & 0.23481 & 0.22568 \\
0.42334 & -0.06022 & 0.23481 & 0.42127 & -0.07632 \\
-0.09248 & 0.42334 & 0.22568 & -0.07632 & 0.42602
\end{bmatrix}
\]
and
\[
P_{3,5} = \begin{bmatrix}
0.58296 & -0.29271 & -0.10684 & 0.12213 & 0.36209 \\
-0.29271 & 0.62479 & -0.33169 & -0.15433 & 0.12213 \\
-0.10684 & -0.33169 & 0.58448 & -0.33169 & -0.10684 \\
0.12213 & -0.15433 & -0.33169 & 0.62479 & -0.29271 \\
0.36209 & 0.12213 & -0.10684 & -0.29271 & 0.58296
\end{bmatrix}
\]
Again, the norms \( \| E_i^{-1} P_{r,n} E_i \| \) share a common value, with
\[
\| E_i^{-1} P_{2,5} E_i \| = 0.65270 \approx \frac{1}{2} \sec \left( \frac{\pi}{2} + 2 \right) \quad \text{for all } i,
\]
and
\[
\| E_i^{-1} P_{3,5} E_i \| = 0.76352 \approx \frac{1}{2} \sec \left( \frac{\pi}{3} + 2 \right) \quad \text{for all } i.
\]

In light of these findings, as well as the distance formulas that exist for projections of rank 1 or \( n-1 \), we propose the following generalized distance formula for projections of arbitrary rank.

**Conjecture 4.5.** For every \( n \in \mathbb{N} \) and each \( r \in \{1, 2, \ldots, n\} \), the distance from the set of projections in \( M_n(\mathbb{C}) \) of rank \( r \) to \( N(\mathbb{C}^n) \) is
\[
\nu_{r,n} = \frac{1}{2} \sec \left( \frac{\pi}{n} + 2 \right).
\]

Using a random walk process implemented by the computer algebra system \( PARI/GP \), we estimated the values of \( \nu_{r,n} \) for all \( r \leq n \leq 10 \) without the additional assumptions stated above. We observed only minute differences between these estimates and the expression from Conjecture 4.5. In many cases, these quantities differed by no more than \( 1 \times 10^{-3} \).

We end by noting that the proposed formula from Conjecture 4.5 merits several interesting consequences. Firstly, this formula suggests that \( \nu_{r,n} = \nu_{kr,kn} \) for every positive integer \( k \), meaning that an optimal projection of rank \( kr \) in \( M_{kn}(\mathbb{C}) \) could be obtained as a direct sum of \( k \) optimal projections of rank \( r \) from \( M_n(\mathbb{C}) \). Notice as well that if the equation \( \nu_{r,n} = \nu_{kr,kn} \) were true, it would follow that
\[
\nu_{1,n} = \nu_{r,rn} \leq \nu_{r,n}
\]
for each \( n \) and \( r \). Thus, a proof of Conjecture 4.5—or of the formula \( \nu_{r,n} = \nu_{kr,kn} \)—would validate Conjecture 1.3.

**Acknowledgements**

The author would like to thank Paul Skoufranis for many stimulating conversations, as well as Boyu Li for providing the \( PARI/GP \) script used to estimate \( \nu_{r,n} \).
