HAMMING POLYNOMIAL OF A DEMIMATROID

JOSÉ MARTÍNEZ-BERNAL, MIGUEL A. VALENCIA-BUCIO AND RAFAEL H. VILLARREAL

Abstract Following Britz, Johnsen, Mayhew and Shiromoto, we consider demimatroids as a(nother) natural generalization of matroids. As they have shown, demimatroids are the appropriate combinatorial objects for studying Wei’s duality. Our results here ap- port further evidence about the trueness of that observation. We define the Hamming polynomial of a demimatroid $M$, denoted by $W(x, y, t)$, as a generalization of the extended Hamming weight enumerator of a matroid. The polynomial $W(x, y, t)$ is a specialization of the Tutte polynomial of $M$, and actually is equivalent to it. Guided by work of Johnsen, Roksvold and Verdure for matroids, we prove that Betti numbers of a demimatroid and its elongations determine the Hamming polynomial. Our results may be applied to simplicial complexes since in a canonical way they can be viewed as demimatroids. Furthermore, following work of Brylawski and Gordon, we show how demimatroids may be generalized one step further, to combina- troids. A combina- troid, or Brylawski structure, is an integer valued function $\rho$, defined over the power set of a finite ground set, satisfying the only condition $\rho(\emptyset) = 0$. Even in this extreme generality, we will show that many concepts and invariants in coding theory can be carried on directly to combina- troids, say, Tutte polynomial, characteristic polynomial, MacWilliams identity, extended Hamming polynomial, and the $r$-th generalized Hamming polynomial; this last one, at least conjecturally, guided by the work of Jurrius and Pellikaan for linear codes. All this largely extends the notions of deletion, contraction, duality and codes to non-matroidal structures.

Key words and phrases. Betti numbers, Combinatroids, Demimatroids, Hamming weight enumerator, Linear codes, Matroids, Rank function, Simplicial complex, Stanley-Reisner, Tutte polynomial, Wei duality.
1. Introduction

Matroids are combinatorial objects introduced by Whitney in 1935 as a generalization of both graphs and matrices. They capture geometric and combinatorial properties of linear independence over finite structures. Demimatroids (Section 3) are a generalization of matroids, and in what follows we will show how demimatroids may be generalized one step further to combinatoroids, via the rank function. We will show that combinatoroids capture many concepts related with duality in coding theory and matroids. For instance, we define invariants as the Tutte polynomial, the generalized Hamming polynomial and the extended Hamming polynomial; or relationships between them, as deletion, contraction and the MacWilliams identity.

Denote by $\mathcal{C}$ the family of combinatoroids defined over the same ground set $E$, and by $\mathcal{D}$ the smaller subfamily of demimatroids. The four operations: identity, dual, nullity and supplement (Section 4), may be seen as duality operators acting on $\mathcal{C}$, actually, these last three operators form a triality, in the sense that the composition of two of them results
in the third one. The restriction to $\mathcal{D}$ of these operators behave even better: $\mathcal{D}$ has a natural structure of a bounded distributive lattice, and each demimatroid determines a weight hierarchy and a Duursma zeta function, which is a largely extension of well-known results for linear codes. All these facts show that $\mathcal{D}$ is a mathematical object that merits a further study.

As a final result, by extending work of Johnsen, Roksvold and Verdure for matroids, we prove that Betti numbers of a demimatroid and its elongations determine the extended Hamming polynomial of a demimatroid. All these results may be applied to simplicial complexes since in a canonical way they can be viewed as demimatroids. For unexplained notions of graph theory, linear codes and matroids we refer to [5], [7] and [12], respectively.

2. Matroids and linear codes

A matroid is a pair $M = (E, \rho)$, where $E$ is a finite set called the ground set of $M$, and $\rho : 2^E \to \mathbb{Z}_+ := \{0, 1, \ldots\}$ is a function satisfying:

$(R_0)$ $\rho(\emptyset) = 0$;
$(R_1)$ If $X \subseteq E$ and $x \in E$, then $\rho(X) \leq \rho(X \cup \{x\}) \leq \rho(X) + 1$;
$(R_2)$ If $X, Y \subseteq E$, then $\rho(X \cup Y) + \rho(X \cap Y) \leq \rho(X) + \rho(Y)$.

The function $\rho$ is called the rank function of the matroid. Condition $(R_2)$ is known as the submodularity condition. An independent set of $M$ is a subset $X \subseteq E$ such that $\rho(X) = |X|$, where $|X|$ denotes the cardinality of $X$; in particular the empty set is always an independent set. A basis is an inclusion maximal independent set; one can verify that bases of a matroid are equicardinal. A subset of the ground set which is not independent is called a dependent set, and a circuit is a minimal dependent set.

Let $X$ be a subset of $E$. From $(R_0)$ and $(R_1)$, and by a direct induction argument, it follows that $0 \leq \rho(X) \leq |X|$ for all $X \subseteq E$. The nullity of $X$, denoted by $\eta(X)$, is defined as $\eta(X) := |X| - \rho(X)$. In particular, the nullity of $M$ is defined as $\eta(M) := \eta(E)$. The $r$-generalized Hamming weight of the matroid $M$ is given by

$$d_r(M) := \min\{|X| : \eta(X) = r\}, \quad 1 \leq r \leq \eta(E),$$

and the sequence $d_1(M), \ldots, d_{\eta(E)}(M)$ is called the weight hierarchy of $M$. 

Let $p$ be a prime, $q$ a positive power of $p$ and $\mathbb{F}_q$ a field with $q$ elements. A linear $[n, k]_q$ code is a $k$-dimensional subspace $C$ of $\mathbb{F}_q^n$. In this context the field $\mathbb{F}_q$ is called the alphabet, the elements of $\mathbb{F}_q^n$ are the words and the elements of $C$ are called codewords of the code. We consider $\mathbb{F}_q^n$ provided with its Hamming distance, which is the number of coordinates in which two words differ. For $c \in C$ its weight, denoted by $w(c)$, is the number of its nonzero coordinates. For a subset $X$ of $\mathbb{F}_q^n$ we define the support of $X$, denoted $\text{supp}(X)$, as the union of all the supports of elements in $X$, i.e.

$$\text{supp}(X) := \{i : \exists (c_1, \ldots, c_n) \in C \text{ such that } c_i \neq 0\}.$$ 

Let $C$ be a linear $[n, k]_q$ code. For $1 \leq r \leq k$, the $r$-th generalized Hamming weight of $C$ is defined as

$$d_r(C) := \min \{|\text{supp}(X)| : X \text{ is a } r\text{-dimensional subspace of } C\}.$$ 

The number $d_1(C)$ is known as the minimum distance of the code and the sequence $d_1(C), \ldots, d_k(C)$ is called the weight hierarchy of $C$.

With each linear code $C$ one associate the vector matroid $M[H]$ on the ground set $E = \{1, \ldots, n\}$, where $H$ is a parity check matrix of $C$. The rank function of $M[H]$ is given by $\rho(X) := \text{rank}(H_X)$ for $X \subseteq E$, where $H_X$ is the submatrix of $H$ obtained by picking the columns indexed by $X$. The matroid $M[H]$ does not depend on the parity check matrix we use. We call $M[H]$ the (parity) matroid of $C$. A basic result in this area, relating codes and matroids, is that the weight hierarchies of both the code $C$ and the matroid $M[H]$ coincide.

3. Demimatroids

A demimatroid is a pair $M = (E, \rho)$, where $E$ is a finite set called the ground set of $M$, and $\rho : 2^E \rightarrow \mathbb{Z}_+$ is a function such that

(R0) $\rho(\emptyset) = 0$;
(R1) If $X \subseteq E$ and $x \in E$, then $\rho(X) \leq \rho(X \cup \{x\}) \leq \rho(X) + 1$;

The function $\rho$ is called the rank function of the demimatroid. Clearly matroids are examples of demimatroids. By abuse of notation we will frequently refer to $\rho$ itself as the demimatroid. The rank of a demimatroid $M$ is defined as $\rho(M) := \rho(E)$. A straightforward verification shows that $0 \leq \rho(X) \leq |X|$ for all $X \subseteq E$. We define the nullity of $X$
as \( \eta(X) := |X| - \rho(X) \). The nullity of a demimatroid \( M \) is defined as \( \eta(M) := \eta(E) \). The dual of a demimatroid \( M = (E, \rho) \) is the pair \( M^* := (E, \rho^*) \), where

\[
\rho^*(X) := |X| + \rho(E \setminus X) - \rho(E).
\]

Clearly \( \rho^*(\emptyset) = 0 \). To simplify notation, from here on we will write \( X \setminus x \) and \( X \cup x \) instead of \( X \setminus \{x\} \) and \( X \cup \{x\} \), respectively. If \( x \in X \), obviously \((R_1)\) is satisfied, and if \( x \notin X \), then \( \rho^*(X) \leq \rho^*(X \cup x) \leq \rho^*(X) + 1 \) if and only if \( \rho(E \setminus X) \leq \rho((E \setminus X) \setminus x) + 1 \leq \rho(E \setminus X) + 1 \). But each of these last two inequalities readily follows from the properties of \( \rho \). So, in fact, \( \rho^* \) is a demimatroid. Moreover, one can verify that \( M^{**} = M \); to see this just note that \( \rho(E) + \rho^*(E) = |E| \), and then

\[
\rho^{**}(X) = |X| + \rho^*(E \setminus X) - \rho^*(E) = |E| + \rho(X) - |E| = \rho(X).
\]

As in the case of matroids, we define independent sets of a demimatroid as those \( X \subseteq E \) such that \( \rho(X) = |X| \); and in a similar fashion, one might define bases, dependent sets and circuits. But in this generality we must remark that bases of a demimatroid are not necessarily equicardinal.

**Example 3.1.** Let \( E \) be a finite set and \( \rho : 2^E \rightarrow \mathbb{Z}_+ \) given by:

(i) \( \rho(X) = 0 \) for all \( X \subseteq E \). Then \( \rho \) is a demimatroid; called the trivial demimatroid.

(ii) \( \rho(X) = |X| \) for all \( X \subseteq E \). Then \( \rho \) is a demimatroid; actually it is a matroid.

(iii) \( \rho(X) = 0 \) if \( X \neq E \) and \( \rho(E) = 1 \). Then \( \rho \) is a demimatroid; if \( E \) has at least two elements, then \( \rho \) is not a matroid.

(iv) \( \rho(\emptyset) = 0 \) and \( \rho(X) = 1 \) for all \( X \neq \emptyset \). Then \( M = (E, \rho) \) is a demimatroid.

**Example 3.2.** Let \( M = (E, \rho) \) be a nontrivial dematroid. For \( X \subseteq E \) define \( \rho^*(X) = \rho(X) \) if \( \rho(X) < \rho(E) \) and \( \rho^*(X) = \rho(X) - 1 \) if \( \rho(X) = \rho(E) \). Then \( (E, \rho^*) \) is a demimatroid.

A simplicial complex \( \Delta \) on a finite vertex set \( E \) is an inclusion closed family of subsets of \( E \), i.e. \( \sigma \in \Delta \) and \( \tau \subseteq \sigma \) implies \( \tau \in \Delta \). Elements of \( \Delta \) are called faces and maximal faces are called facets. A face of \( \Delta \) whose cardinality is \( i + 1 \) is said to be of dimension \( i \). The dimension of \( \Delta \) is the maximum dimension of any one of its faces.

5
Example 3.3. Let $\Delta$ be a simplicial complex on the vertex set $E$. We define the demi-matroid $\Delta^\uparrow := (E, \rho)$, where, for all $X \subseteq E$,

$$\rho(X) := \max\{|\sigma| : \sigma \subseteq X, \sigma \in \Delta\}.$$

Example 3.4. A graph may be viewed as a 1-dimensional simplicial complex, and then as a demimatroid. Say the graph has no isolated vertices and let $E$ denote the vertex set. Thus, in this case, the demimatroid in Example 3.3 is given by $\rho(\emptyset) = 0$, $\rho(X) = 1$ if $X$ is an independent vertex set of $G$, and $\rho(X) = 2$ if $X$ is not an independent vertex set of $G$.

Example 3.5. Let $M = (E, \rho)$ be a demimatroid. If $\rho(X) = |X|$ for some $X \subseteq E$, then $\rho(Y) = |Y|$ for all $Y \subseteq X$. Therefore, the set

$$M^\downarrow := \{X \subseteq E : \rho(X) = |X|\}$$

is a simplicial complex.

Example 3.6. Let $\Delta$ be a simplicial complex with vertex set $E$ and $\rho : 2^E \to \mathbb{Z}_+$ given by $\rho(X) = |X|$ if $X \in \Delta$ and $\rho(X) = |X| - 1$ if $X \notin \Delta$. Then $\Delta^\sharp := (E, \rho)$ is a demimatroid.

Example 3.7. Let $M = (E, \rho)$ be a demimatroid. Since $\rho$ is non-decreasing, it follows that, for all nonnegative integers $r$, the set $M_{(r)} := \{X \subseteq E : \rho(X) \leq r\}$ is a simplicial complex.

Let $E$ be a finite set. Denote by $S$ the family of all simplicial complexes with ground set $E$, and make $S$ a poset defining $\Delta \leq \Gamma$ when $\Delta \subseteq \Gamma$. Denote by $D$ the family of all demimatroids with ground set $E$, and make $D$ a poset by defining $(E, \rho) \leq (E, \tau)$ when $\rho(X) \leq \tau(X)$ for all $X \subseteq E$. The next lemma is not hard to prove.

Lemma 3.8. (i) $\Delta \leq \Gamma$ implies $\Delta^\uparrow \leq \Gamma^\uparrow$;
(ii) $(E, \rho) \leq (E, \tau)$ implies $(E, \rho)^\downarrow \leq (E, \tau)^\downarrow$;
(iii) $(\Delta^\uparrow)^\downarrow = \Delta$.
(iv) $M^\downarrow = \Delta$ implies $\Delta^\uparrow \leq M$; in particular, $(M^\downarrow)^\uparrow \leq M$.
(v) $(M^\downarrow)^\uparrow = M$ if and only if $M = \Delta^\uparrow$ for some simplicial complex $\Delta$. 

Proof. (iv): Say \( M = (E, \rho) \) and \( \Delta^\uparrow = (E, \tau) \). Take any \( X \subseteq E \). \( \tau(X) = \max\{|\sigma| : \sigma \subseteq X, \rho(\sigma) = |\sigma|\} \). Choose \( \sigma \subseteq X \) such that \( \tau(X) = |\sigma| \) and \( \rho(\sigma) = |\sigma| \). Then \( \tau(X) = |\sigma| = \rho(\sigma) \leq \rho(X) \). \( \square \)

Example 3.9. Let \( \Delta \) be a simplicial complex and \( M \) a demimatroid. Then \( M^\downarrow = \Delta \) if and only if \( \Delta \leq M \leq \Delta^\sharp \).

A Galois connection between two posets \( P \) and \( Q \) is a pair of functions \( \alpha : P \to Q \) and \( \beta : Q \to P \) with the properties: (1) both \( \alpha \) and \( \beta \) are order-inverting; (2) \( p \leq \beta(\alpha(p)) \) for all \( p \in P \) and \( q \leq \alpha(\beta(q)) \) for all \( q \in Q \).

Proposition 3.10. Let \( D^{\text{op}} \) denote the dual poset of \( D \). The maps \( \uparrow : \mathcal{S} \to D', \Delta \mapsto \Delta^\uparrow \) and \( \downarrow : D^{\text{op}} \to \mathcal{S}, M \mapsto M^\downarrow \) form a Galois connection.

4. Combinatroids

Three important operations on matroids are motivated by graph theory: deletion, contraction and duality. Brylawski realized that it is possible to extend all of these three operations to any finite set \( E \) provided with an arbitrary function \( r : 2^E \to \mathbb{Z} \), see [4]. Thus we define a combinatroid (with values in \( \mathbb{Z} \)) as a pair \( M := (E, \rho) \), where \( E \) is a finite set called the ground set of \( M \), and \( \rho : 2^E \to \mathbb{Z} \) is a function satisfying the only condition \( \rho(\emptyset) = 0 \). The function \( \rho \) is called the rank function of the combinatroid. Clearly demimatroids are examples of combinatroids. Another name for a combinatroid is a (normalized) Brylawski structure, as is done in [4]. One define the dual combinatroid \( M^* = (E, \rho^*) \), where \( \rho^* \), called the dual rank function, is given by

\[
\rho^*(X) = |X| + \rho(E\setminus X) - \rho(E).
\]

Then, the deletion of \( A \subseteq E \), denoted by \( M \setminus A \), is defined as the restriction of the rank function \( \rho \) to \( E \setminus A \), i.e. \( \rho_{M \setminus A}(X) := \rho(X) \) for all \( X \subseteq E \setminus A \). Moreover, contraction, denoted by \( M/A \), is defined using deletion and duality: \( M/A := (M^*/A)^* \). Note that both \( M \setminus A \) and \( M/A \) have the same ground set \( E \setminus A \).

Proposition 4.1. (Brylawski, Gordon; see [4]) Let \( M = (E, \rho) \) be a combinatroid and \( A \subseteq E \).

(i) \( \rho_{M/A}(X) = \rho(X \cup A) - \rho(A) \) for all \( X \subseteq E \setminus A \);
(ii) \((M^*)^* = M\);
(iii) \((M\setminus A)^* = M^*/A\);
(iv) \((M/A)^* = M^\setminus A\).

**Proposition 4.2.** Let \(M = (E, \rho)\) be a demimatroid and \(A \subseteq E\). Then

(i) \(M\setminus A\) is a demimatroid;
(ii) \(M/A\) is a demimatroid.

**Proof.** Let \(X \subset E\setminus A\) and \(x \in (E\setminus A)\setminus X\).

(i): \(\rho_{M\setminus A}(X) \leq \rho_{M\setminus A}(X \cup x) \leq \rho_{M\setminus A}(X) + 1 \Leftrightarrow \rho(X) \leq \rho(X \cup x) \leq \rho(X) + 1\).

(ii): \(\rho_{M/A}(X) \leq \rho_{M/A}(X \cup x) \leq \rho_{M/A}(X) + 1 \Leftrightarrow \rho(X \cup A) - \rho(A) \leq \rho(X \cup x \cup A) - \rho(A) \leq \rho(X \cup A) - \rho(A) + 1 \Leftrightarrow \rho(X \cup A) \leq \rho(X \cup A \cup x) \leq \rho(X \cup A) + 1\).

A minor of a demimatroid \(M\) is any demimatroid obtained from \(M\) by a sequence of deletions and contractions.

One can also define the nullity combinatroid \(M^\circ = (E, \rho^\circ)\), where \(\rho^\circ\), called the nullity function, is given by

\[\rho^\circ(X) = |X| - \rho(X)\].

**Proposition 4.3.** Let \(M = (E, \rho)\) be a combinatroid. Then

(i) \(\rho^{\circ^\circ}(X) = \rho^{\circ^\circ}(X) = \rho(E) - \rho(E\setminus X)\) for all \(X \subseteq E\);
(ii) \((M^\circ)^\circ = M\);
(iii) \((M^\circ)^* = (M^*)^\circ\);
(iv) If \(M\) is a demimatroid, then \(M^\circ\) is a demimatroid.

**Proof.** (iv): Obviously \(\rho^\circ(\emptyset) = 0\). Let \(X \subset E\) and \(x \in E\setminus X\). \(\rho^\circ(X) \leq \rho^\circ(X \cup x) \leq \rho^\circ(X) + 1\) if and only if \(|X| - \rho(X) \leq |X| + 1 - \rho(X \cup x) \leq |X| - \rho(X) + 1\) if and only if \(\rho(X) + 1 \geq \rho(X \cup x) \geq \rho(X)\).

Following [1], we define the supplement combinatroid \(M^\circ := (E, \rho^\circ)\), where \(\rho^\circ\), called the supplement (or supplementary) function, is given by

\[\rho^\circ(X) = \rho(E) - \rho(E\setminus X)\].
Proposition 4.4. Let $M = (E, \rho)$ be a combinatroid. Then

(i) $(M^\circ)^\circ = M$;
(ii) $(M^*)^o = (M^o)^* = M^\circ$;
(iii) $(M^\circ)^* = (M^*)^o = M^*$;
(iv) $(M^*)^\circ = (M^\circ)^* = M^o$;
(v) ([1, Thm. 8]) If $M$ is a demimatroid, then $M^\circ$ is a demimatroid.

Proof. (v): Obviously $\rho^\circ(\emptyset) = 0$. Let $X \subset E$ and $x \in E \setminus X$. $\rho^\circ(X) \leq \rho^\circ(X \cup x) \leq \rho^\circ(X) + 1$ if and only if $\rho(E) - \rho(E \setminus X) \leq \rho(E) - \rho(E \setminus (X \cup x)) \leq \rho(E) - \rho(E \setminus X) + 1$ if and only if $\rho(E \setminus X) \geq \rho((E \setminus X) \setminus x) \geq \rho(E \setminus X) - 1$. But each of these last two inequalities directly follows from the properties of $\rho$. \qed

The identity (denoted by “id”), dual, nullity and supplement operations may be viewed as operators acting on the set of combinatroidal structures defined on the same ground set $E$.

Proposition 4.5. Let $M = (E, \rho)$ be a combinatroid. Then the operators $\{id, *, \circ, \odot\}$ form an abelian group isomorphic to $Z_2 \times Z_2$:

\[
\begin{array}{cccc}
  id & * & \circ & \odot \\
  id & id & * & \circ \\
  * & * & id & \odot \\
  \circ & \circ & \odot & id \\
  \odot & \odot & \circ & * \\
  \odot & \odot & \circ & * \\
\end{array}
\]

Remark 4.6. Note that the operators $\{*, \circ, \odot\}$ form a triality, in the sense that the composition of two of them gives the third one.

Example 4.7. Let $E$ be a finite set and $\rho : 2^E \to \mathbb{Z}_+, X \mapsto |X|$. Then $\rho^* \equiv \rho^\circ \equiv 0$ and $\rho^\circ \equiv \rho$.

Example 4.8. Let $E$ be a finite set and $\rho : 2^E \to \mathbb{Z}_+, \rho(X) = 0$ if $X \neq E$ and $\rho(E) = 1$. We have that $\rho^*(\emptyset) = 0$ and $\rho^*(X) = |X| - 1$ if $X \neq \emptyset$; $\rho^\circ(X) = |X|$ if $X \neq E$ and $\rho^\circ(E) = |E| - 1$; $\rho^\odot(\emptyset) = 0$ and $\rho^\odot(X) = 1$ if $X \neq \emptyset$. 

Example 4.9. Let \( M = (E = \{1, 2, 3\}, \rho) \) be the matroid whose basis are \( \{1, 2\} \) and \( \{1, 3\} \). We have the following table:

\[
\begin{array}{cccccccc}
X & \emptyset & 1 & 2 & 3 & 12 & 13 & 23 & E \\
\rho & 0 & 1 & 1 & 1 & 2 & 2 & 1 & 2 \\
\rho^* & 0 & 0 & 1 & 1 & 1 & 1 & 1 & . \\
\rho^\circ & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 \\
\rho^\otimes & 0 & 1 & 0 & 0 & 1 & 1 & 1 & 2 \\
\end{array}
\]

Remark 4.10. If \( M \) is a matroid, then \( M^\circ \) and \( M^\otimes \) are demimatroids, but they might not be matroids. For instance, in Example 4.9, \( 1 = \rho^\circ(23) + \rho^\circ(\emptyset) \not\leq \rho^\circ(2) + \rho^\circ(3) = 0 \) and \( 1 = \rho^\otimes(23) + \rho^\otimes(\emptyset) \not\leq \rho^\otimes(2) + \rho^\otimes(3) = 0 \), show that \( \rho^\circ \) and \( \rho^\otimes \) do not satisfy the submodularity condition.

Example 4.11. Let \( G \) be a simple graph with no isolated vertices; we see \( G \) as a 1-dimensional simplicial complex. Let \( E \) denote the vertex set of \( G \) and define \( \rho : 2^E \to \mathbb{Z}_+ \), \( \rho(\emptyset) = 0 \), \( \rho(X) = 1 \) if \( X \) is an independent vertex set of \( G \), and \( \rho(X) = 2 \) if \( X \) is not an independent vertex set of \( G \). Then

\[
\rho^*(X) = \begin{cases} 
|X|, & \text{if } X \text{ is not a covering;} \\
|X| - 1, & \text{if } X \text{ is a covering;}
\end{cases}
\]

\[
\rho^\circ(X) = \begin{cases} 
0, & \text{if } X = \emptyset; \\
|X| - 1, & \text{if } X \text{ is independent;}
\end{cases}
\]

\[
\rho^\otimes(X) = \begin{cases} 
0, & \text{if } X \text{ is not a covering;}
1, & \text{if } X \text{ is a covering.}
\end{cases}
\]

For \( \alpha \) and \( \beta \), combinatroids over \( E \), we define \( (\alpha \lor \beta)(X) = \max\{\alpha(X), \beta(X)\} \) and \( (\alpha \land \beta)(X) = \min\{\alpha(X), \beta(X)\} \) for all \( X \subseteq E \).

Lemma 4.12. If \( \alpha \) and \( \beta \) are demimatroids, then \( \alpha \lor \beta \) and \( \alpha \land \beta \) are demimatroids.

Proof. This follows immediately from the fact that for real numbers \( a_1 \leq a_2 \) and \( b_1 \leq b_2 \) it holds that \( \min\{a_1, b_1\} \leq \min\{a_2, b_2\} \) and \( \max\{a_1, b_1\} \leq \max\{a_2, b_2\} \).

The set of combinatroids on a set \( E \) may be partially ordered by defining \( \alpha \leq \beta \) if \( \alpha(X) \leq \beta(X) \) for all \( X \subseteq E \).
Theorem 4.13. The set of demimatroides on a finite set $E$, with $\lor$ and $\land$ defined as above, form a bounded distributive lattice. The maximum demimatroid is $\cdot : X \mapsto |X|$ and the minimum demimatroid is $0 : X \mapsto 0$.

Example 4.14. This lattice has only one atom, namely, $\rho : 2^E \to \mathbb{Z}_+, \rho(X) = 0$ if $X \neq E$ and $\rho(E) = 1$. And it also has only one coatom, which is the nullity of $\rho$, i.e. $\rho^\circ(X) = |X|$ for all $X \neq E$ and $\rho^\circ(E) = |E| - 1$.

Let $M = (E, \rho)$ be a nontrivial demimatroid, and set $k := \rho(E) \leq |E|$. Define $\sigma_k(M) := \min\{|X| : \rho(X) = k\}$ and choose $X \subseteq E$ such that $\sigma_k(M) = |X|$. For $x \in X$ we know that $\rho(X \setminus x) < \rho(X) \leq \rho(X \setminus x) + 1$. From this it follows that $\rho(X \setminus x) = k - 1$. Define $\sigma_{k-1}(M) := \min\{|Y| : \rho(Y) = k - 1\}$ and choose $Y \subseteq E$ such that $\sigma_{k-1}(M) = |Y|$. For $y \in Y$ we know that $\rho(Y \setminus y) < \rho(Y) \leq \rho(Y \setminus y) + 1$. From this it follows that $\rho(Y \setminus y) = k - 2$. Continuing this process we obtain that $0 = \sigma_0(M) < \sigma_1(M) < \cdots < \sigma_k(M) \leq |E|$. A subset $X$ of $E$ is said to be of level $r$ if $\rho(X) = r$. Thus $\rho$ induce a partition of $2^E$ by level sets. We put this on record as the following lemma, but first a definition. For $1 \leq r \leq \rho(E)$ we define the $r$-th Wei number of the demimatroid as

$$
\sigma_r(M) := \min\{|X| : \rho(X) = r\}.
$$

Lemma 4.15. Let $M = (E, \rho)$ be demimatroid of rank $k := \rho(M)$. Then

(i) The image of $\rho$ is the set $\{0, 1, \ldots, k\}$;

(ii) $0 < \sigma_1(M) < \cdots < \sigma_k(M) \leq |E|$;

(iii) If $\rho(X) \geq r$, then $|X| \geq \sigma_r(M)$;

(iv) $\min\{|X| : \rho(X) = r\} = \min\{|X| : \rho(X) \geq r\}$.

(v) (Generalized Singleton bound) For all $0 \leq r \leq k$ it holds that

$$
k + \sigma_r(M) \leq |E| + r.
$$

Proof. (iii): Say $\rho(X) = r + s$. Then $|X| \geq \sigma_{r+s}(M) \geq \sigma_r(M)$.

(v): $k + \sigma_k(M) \leq |E| + k$ iff $\sigma_k(M) \leq |E|$, which is true. Suppose the result is true for $r, \ldots, k$. Hence $k + \sigma_{r-1}(M) \leq k + \sigma_r(M) - 1 \leq |E| + r - 1$. □
Example 4.16. Let $M = (E = \{1, 2, 3, 4\}, \rho)$ be the matroid whose basis are $\{1, 2\}$, $\{1, 3\}$, $\{1, 4\}$, $\{2, 3\}$, $\{3, 4\}$. We have the following table:

<table>
<thead>

</table>

Since $\rho^\#(E \setminus X) = \rho^\#(E) - \rho(X)$ for all $X \subseteq E$, Eq. (4.1) can be rewritten as

$$\sigma_r(M) = \min\{|X| : \rho^\#(E \setminus X) = \rho^\#(E) - r\}.$$ 

Thus we may interpret the $r$-th Wei number $\sigma_r(M)$ as the minimum number of elements that must be removed from $E$ to decrease the rank of $M^\#$ by $r$. A fundamental result is the following.

Theorem 4.17. (Wei’s duality [1, Thm. 13]) Let $M = (E, \rho)$ be a demimatroid. Then, with $n = |E|$ and $k = \rho(M)$,

$$\{\sigma_1(M), \ldots, \sigma_k(M)\} = \{1, \ldots, n\} \setminus \{n + 1 - \sigma_1(M^*), \ldots, n + 1 - \sigma_{n-k}(M^*)\}.$$ 

Proof. Suppose $\sigma_i(M) = n + 1 - \sigma_j(M^*)$ for some $i, j$. Choose $X \subseteq E$ such that $\rho(X) = i$ and $\sigma_i(M) = |X|$. Hence $|E \setminus X| = n - |X| = \sigma_j(M^*) - 1$. By Lemma 4.15(iii) we have that $\rho^*(E \setminus X) \leq j - 1$. Similarly, choose $Y \subseteq E$ such that $\rho^*(Y) = j$ and $\sigma_j(M^*) = |Y|$. Hence $\rho(E \setminus Y) \leq i - 1$. But this implies that $i + j - 1 = \rho^*(E \setminus X) + \rho(E \setminus Y) \leq i + j - 2$, which is not possible. \hfill $\square$

Remark 4.18. In the literature, $\sigma_r(M^\#)$ is known as the $r$-th generalized Hamming weight of $M$, and since $(M^\#)^\# = M^*$, then $\sigma_r(M^\#)$ is the minimum number of elements that must be removed from $E$ to decrease the rank of $M^*$ by $r$.

Remark 4.19. $\min\{|X| : \eta(X) = r\} + \max\{|Y| : \rho^*(E) - \rho^*(Y) = r\} = |E|$.

Proof of the Remark. Set $a = \min\{|X| : \eta(X) = r\}$ and $b = \max\{|Y| : \rho^*(Y) = \rho^*(E) - r\}$. Choose $X$ such that $a = |X|$. Since $\rho^*(E \setminus X) = \rho(E) - r$, it holds that $|E \setminus X| \leq b$, so $|E| \leq a + b$. To prove the other direction choose $Y$ such that $b = |Y|$. Since $\eta(E \setminus Y) = r$, it holds that $a \leq |E \setminus Y|$, so $a + b \leq |E|$.

\hfill $\square$
Let $M = (E, \rho)$ be a demimatroid. From the Singleton bound we obtain that $\sigma_1(M) \leq |E| - \rho(E) + 1$. When equality is attained, $M$ is called a full demimatroid.

**Corollary 4.20.** Let $M = (E, \rho)$ be a demimatroid, with $n = |E|$ and $k = \rho(E)$.

(i) If $k + \sigma_r(M) = n + r$, then $k + \sigma_s(M) = n + s$ for all $s \geq r$.

(ii) If $M$ is full, then $M^*$ is full.

**Proof.** (i): The result is true for $s = r$. If it is true for $r, \ldots, s$, then $k + \sigma_{s+1}(M) \geq k + \sigma_s(M) + 1 = n + s + 1$.

(ii): By (i), $n + 1 - \sigma_r(M) = k - r + 1$. Thus, by Wei’s duality, $\sigma_s(M^*) = k + s$ for $1 \leq s \leq n - k$. In particular, $\sigma_1(M^*) = k + 1 = n - (n - k) + 1 = n - \rho^*(E) + 1$. □

**Example 4.21.** Let $M = (E = \{1, 2, 3\}, \rho)$ be the demimatroid, with $\rho$ given by:

<table>
<thead>
<tr>
<th>$X$</th>
<th>$\emptyset$</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>12</th>
<th>13</th>
<th>23</th>
<th>$E$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\rho$</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>$\rho^*$</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>$\rho^o$</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>$\rho^*$</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>2</td>
<td>2</td>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>$\sigma_1$</th>
<th>$\sigma_2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\rho$</td>
<td>2</td>
</tr>
<tr>
<td>$\rho^*$</td>
<td>3</td>
</tr>
<tr>
<td>$\rho^o$</td>
<td>1</td>
</tr>
<tr>
<td>$\rho^*$</td>
<td>1</td>
</tr>
</tbody>
</table>

We observe that $\rho$ and $\rho^*$ are full, whereas $\rho^o$ and $\rho^*$ are not.

**Lemma 4.22.** Let $M = (E, \rho)$ be a demimatroid, with $n = |E|$ and $k = \rho(E)$. Then $M$ is full if and only if

$$\rho(X) = \begin{cases} 0, & \text{if } |X| \leq n - k; \\ r, & \text{if } |X| = n - k + r \text{ and } r \geq 1. \end{cases}$$

**Proof.** ($\Leftarrow$) Evidently $\sigma_1(M) = \min\{|X| : \rho(X) = 1\} = n - k + 1$.

($\Rightarrow$) By Lemma 4.15(v), $\sigma_s(M) = n - k + s$ for all $1 \leq s \leq k$. In particular, $\sigma_k(M) = n$ implies $\rho(E \setminus x) \leq k - 1$ for $x \in E$. Let $X \subseteq E$ with $|X| = n - 1$. Suppose that $\rho(X) \leq k - 2$. Then $\rho(X) \leq \rho(E) \leq \rho(X) + 1 \leq k - 1$, which is not possible. Thus $\rho(X) = k - 1$. Suppose that if $|X| = n - k + r$, then $\rho(X) = s$. Let $X$ such that $|X| = n - k + r - 1$. If $\rho(X) \leq n - k + r - 2$, then $\rho(X) \leq \rho(X \cup x) \leq \rho(X) + 1$, i.e. $r \leq r - 1$, which is not possible. □

**Lemma 4.23.** Let $M = (E, \rho)$ be a full demimatroid, with $n = |E|$ and $k = \rho(E)$. Then

(i) $\rho^*(X) = \begin{cases} 0, & \text{if } |X| \leq k; \\ r, & \text{if } |X| = k + r \text{ and } r \geq 1. \end{cases}$
there exists \( \rho \) such that \( \{ \rho \} \subset M \).

**Proposition 4.25.** Let \( M = (E, \rho) \) be a nontrivial demimatroid, and set \( k := \rho(E) \leq |E| \). Define \( \sigma^0(M) := \max \{|X| : \rho(X) = 0\} \) and choose \( X \subseteq E \) such that \( \sigma^0(M) = |X| \). For \( x \not\in X \) we know that \( \rho(X) < \rho(X \cup x) \leq \rho(X) + 1 \). From this it follows that \( \rho(X \cup x) = 1 \).

Define \( \sigma^1(M) := \max \{|Y| : \rho(Y) = 1\} \) and choose \( Y \subseteq E \) such that \( \sigma^1(M) = |Y| \). For \( y \not\in Y \) we know that \( \rho(Y) < \rho(Y \cup y) \leq \rho(Y) + 1 \). From this it follows that \( \rho(Y \cup y) = 2 \).

Continuing this process we obtain that \( 0 \leq \sigma^0(M) < \sigma^1(M) < \cdots < \sigma^k(M) = |E| \). We again put this on record as the following lemma, but first a definition. For \( 1 \leq r \leq \rho(E) \) we define the \( r \)-th upper Wei number of the demimatroid as

\[
\sigma^r(M) := \max\{|X| : \rho(X) = r\}.
\]

**Lemma 4.26.** Let \( M = (E, \rho) \) be demimatroid of rank \( k := \rho(M) \). Then

(i) The image of \( \rho \) is the set \( \{0, 1, \ldots, k\} \);

(ii) \( 0 \leq \sigma^0(M) < \cdots < \sigma^k(M) = |E| \);

(iii) If \( \rho(X) \leq r \), then \( |X| \leq \sigma^r(M) \);

(iv) \( \max\{|X| : \rho(X) = r\} = \max\{|X| : \rho(X) \leq r\} \).
(v) (Generalized upper Singleton bound) For all $0 \leq r \leq k$ it holds that

$$k + \sigma^r(M) \leq |E| + r.$$ 

Proof. (iii): Say $\rho(X) = r - s$. Then $|X| \leq \sigma^{r-s}(M) \leq \sigma^r(M)$.

(v) $k + \sigma^k(M) \leq |E| + k$ iff $\sigma^k(M) \leq |E|$, which is true. Suppose the result is true for $r, \ldots, k$. Hence $k + \sigma^{r-1}(M) \leq k + \sigma^r(M) - 1 \leq |E| + r - 1$. \hfill \Box

**Theorem 4.27.** (Upper Wei’s duality [1, Thm. 12]) Let $M = (E, \rho)$ be a demimatroid. Then, with $n = |E|$ and $k = \rho(M)$,

$$\{\sigma^0(M) + 1, \ldots, \sigma^{k-1}(M) + 1\} = \{1, \ldots, n\} \setminus \{n - \sigma^0(M^*), \ldots, n - \sigma^{n-k-1}(M^*)\}.$$ 

Proof. Suppose $\sigma^i(M) + 1 = n - \sigma^j(M^*)$ for some $i, j$. Choose $X \subseteq E$ such that $\rho(X) = i$ and $\sigma^i(M) = |X|$. Hence $|E \setminus X| = n - |X| = \sigma^j(M^*) + 1$. By Lemma 4.26(iii) we have that $\rho^*(E \setminus X) \geq j + 1$. Similarly, choose $Y \subseteq E$ such that $\rho^*(Y) = j$ and $\sigma^j(M^*) = |Y|$. Hence $\rho(E \setminus Y) \geq i + 1$. But this implies that $i + j + 1 = \rho^*(E \setminus X) + \rho(E \setminus Y) \geq i + j + 2$, which is not possible. \hfill \Box

5. **Tutte polynomial**

The Tutte polynomial is an important invariant for graphs and matroids. We define the **Tutte polynomial** of a combinatroid $M = (E, \rho)$ as

$$T_M(x, y) := \sum_{A \subseteq E} (x - 1)^{\rho(E) - \rho(A)}(y - 1)^{|A| - \rho(A)}.$$ 

Using the classical notation $\eta := \rho^*$, this can be rewritten as

$$T_M(x, y) = \sum_{A \subseteq E} (x - 1)^{\eta^*(E \setminus A)}(y - 1)^{\eta(A)}.$$ 

**Remark 5.1.** Since a combinatroid $\rho$ may take negative values, we must remark that $T_M(x, y)$, as defined above, could be a rational function; so, a better name would be the Tutte enumerator or the Tutte rational function. However, since we will not use its properties as a rational function, by abuse of language, we will continuous refering to it as the Tutte polynomial. On the other hand, if $\rho$ is a demimatroid, then $T_M(x, y)$ is in fact a polynomial.
This Tutte polynomial is well-behaved with respect to combinatroidal duality:

**Proposition 5.2.** (Tutte duality) Let $M = (E, \rho)$ be a combinatroid. Then

$$T_{M^*}(x, y) = T_M(y, x).$$

**Proof.** It follows immediately from Eq. (5.2) by noticing that $(\rho^*)^* = (\rho)^* = \eta^*$. □

Let $M = (E, \rho)$ be a combinatroid with Tutte polynomial $T_M(x, y)$. We define its **Hamming polynomial** by:

$$W_M(x, y, t) := (x - y)^{\eta(M)} y^{\rho(M)} T_M\left(\frac{x}{y}, \frac{x + (t - 1)y}{x - y}\right).$$

**Example 5.3.** Let $E$ be a finite set and $\rho : 2^E \to \mathbb{Z}$ given by $\rho(X) = |X|$. Then $\eta(X) = 0$ and $\eta^*(E \setminus X) = |E \setminus X|$ for all $X \subseteq E$. Hence $T(x, y) = W(x, y, t) = x^n$.

**Theorem 5.4.** (MacWilliams identity) Let $M = (E, \rho)$ be a combinatroid. Then

$$W_{M^*}(x, y, t) = t^{-\eta(M)} W_M(x + (t - 1)y, x - y, t).$$

**Proof.**

$$W_M(x + (t - 1)y, x - y, t) = (ty)^{\eta(E)} (x - y)^{\rho(E)} T_M((x + (t - 1)y)/(x - y), x/y)$$

$$= t^{\eta(E)} \left[ (y^{\eta(E)} (x - y)^{\rho(E)} (x - y)^{-\eta^*(E)} y^{\rho^*(E)} \right]$$

$$\times (x - y)^{\eta^*(E)} y^{\rho^*(E)} T_M((x + (t - 1)y)/(x - y), x/y)$$

$$= t^{\eta(E)} (1)(x - y)^{\eta^*(E)} y^{\rho^*(E)} T_M((x + (t - 1)y)/(x - y), x/y)$$

$$= t^{\eta(E)} (x - y)^{\eta^*(E)} y^{\rho^*(E)} T_M(x/y, (x + (t - 1)y)/(x - y))$$

$$= t^{\eta(E)} W_{M^*}(x, y, t).$$ □

We define the **Whitney generating function**

$$f(M; x, y) := \sum_{A \subseteq E} x^{\eta^*(E \setminus A)} y^{\eta(A)}.$$ 

**Theorem 5.5.** (Brylawski, Gordon; see [4]) Let $M = (E, \rho)$ be a combinatroid. Then

(1) **Duality:**

$$f(M^*; x, y) = f(M; y, x).$$

(2) **Deletion-Contraction:** For any $p \in E$,

$$f(M; x, y) = x^{\eta^*(p)} f(M \setminus p; x, y) + y^{1 - \rho(p)} f(M/p; x, y).$$
We now proceed to prove a deletion-contraction formula for the Tutte and Hamming polynomials.

**Lemma 5.6.** Let $M = (E, \rho)$ be a combinatroid. Then

(a) \[(x - y)^{\eta(E)} y^{\rho(E)} (x/y - 1)^{\rho(E) - \rho(E \setminus p)} = (x - y)^{E \setminus p - \rho(E \setminus p)} y^{\rho(E \setminus p)}.\]

(b) \[(x - y)^{\eta(E)} y^{\rho(E)} (x - y)^{\rho(p) - 1} = y^{\rho(p)} (x - y)^{E \setminus p - \rho(p) + \rho(p)} y^{\rho(E) - \rho(p)}.\]

**Proof.** (a):

\[
(x - y)^{\eta(E)} y^{\rho(E)} (x/y - 1)^{\rho(E) - \rho(E \setminus p)} = (x/y - 1)^{\rho(E) - \rho(E \setminus p)} (x - y)^{\eta(E)} y^{\rho(E)} \\
= (x - y)^{\rho(E) - \rho(E \setminus p)} y^{- \rho(E) + \rho(E \setminus p)} (x - y)^{\eta(E)} y^{\rho(E)} \\
= (x - y)^{\rho(E) - \rho(E \setminus p)} y^{\rho(E \setminus p)} (x - y)^{\eta(E)} \\
= (x - y)^{|E| - \rho(E \setminus p)} y^{\rho(E \setminus p)} \\
= (x - y) (x - y)^{E \setminus p - \rho(E \setminus p)} y^{\rho(E \setminus p)}
\]

(b):

\[
(x - y)^{\eta(E)} y^{\rho(E)} = (x - y)^{1 - \rho(p)} (x - y)^{E \setminus p - \rho(E) + \rho(p)} y^{\rho(E) - \rho(p)} y^{\rho(p)} \\
= (x - y)^{1 - \rho(p)} y^{\rho(p)} (x - y)^{E \setminus p - \rho(E) + \rho(p)} y^{\rho(E) - \rho(p)}.
\]

From the Brylawski recurrence it follows:

**Proposition 5.7.** Let $M = (E, \rho)$ be a combinatroid. Then

\[
T_M(x, y) = (x - 1)^{\eta^*(p)} T_{M \setminus p}(x, y) + (y - 1)^{1 - \rho(p)} T_{M / p}(x, y).
\]

**Example 5.8.** Let $M$ be the demimatroid in Example 4.21, and take $p = 3$.

$T_{M\setminus p}(x, y) = -x - y + 2xy$; \quad $T_{M/p}(x, y) = x^2$.

$$(x - 1)T_{M\setminus p}(x, y) + (y - 1)T_{M/p}(x, y) = T_M(x, y).$$

From this we obtain the following recurrence for the Hamming polynomial.

**Theorem 5.9.**

$$W_M(x, y, t) = (x - y)W_{M\setminus p}(x, y, t) + t^{1 - \rho(p)}yW_{M/p}(x, y, t).$$

**Proof.**

$$W_M(x, y, t) = (x - y)^{\eta(E)}y^{\rho(E)}T_M(x/y, (x + (t - 1)y)/(x - y))$$

$$= (x - y)^{\eta(E)}y^{\rho(E)}[(x/y - 1)^{\rho(E)} - \rho(E)p] T_{M\setminus p}(x/y, (x + (t - 1)y)/(x - y))$$

$$+ (x + (t - 1)y)/(x - y) - 1)^{1 - \rho(p)}T_{M/p}(x/y, (x + (t - 1)y)/(x - y))]$$

$$= (x - y)(x - y)^{|E\setminus p|-\rho(E)p}y^{\rho(E)p} T_{M\setminus p}(x/y, (x + (t - 1)y)/(x - y))$$

$$+ (ty)^{1 - \rho(p)}y^{\rho(p)}$$

$$\times (x - y)^{|E\setminus p|-\rho(E)p + \rho(p)}y^{\rho(E)-\rho(p)} T_{M/p}(x/y, (x + (t - 1)y)/(x - y))$$

(by 5.6) $$= (x - y)W_{M\setminus p}(x, y) + t^{1 - \rho(p)}yW_{M/p}(x, y). \quad \square$$

**Example 5.10.** We continue Example 5.8.

$$W_M(x, y, t) = x^3 + 3(t - 1)x^2y + 3(1 - t)xy^2 + (t - 1)y^3.$$ $\quad$ $W_{M\setminus p}(x, y, t) = x^2 + 2(t - 1)xy + (1 - t)y^2$; $\quad$ $W_{M/p}(x, y, t) = x^2$.

$$(x - y)W_{M\setminus p}(x, y, t) + tyW_{M/p}(x, y, t) = W_M(x, y, t).$$

6. **Extended Hamming polynomials**

For a combinatorial $M = (E, \rho)$ we define its characteristic polynomial as

$$p(M; t) := \sum_{X \subseteq E} (-1)^{|X|}t^{\rho(E) - \rho(X)} = (-1)^{|E|}T_M(1-t, 0) = \sum_{X \subseteq E} (-1)^{|E\setminus X|}t^{\rho*(X)}.$$
Thus the characteristic polynomial of $M^*$ is
\[ p(M^*; t) = \sum_{X \subseteq E} (-1)^{|E \setminus X|} t^{|X|}. \]
We generalize $p(M^*; t)$ for every $\sigma \subseteq E$ as:
\[ p_{M,\sigma}(t) := \sum_{\gamma \subseteq \sigma} (-1)^{|\sigma \setminus \gamma|} t^{|\gamma|}. \]
We define the $j$-th generalized polynomial $P_{M,j}(t)$ as
\[ P_{M,0}(t) := 1 \quad \text{and} \quad P_{M,j}(t) := \sum_{|\sigma| = j} P_{M,\sigma}(t), \quad 1 \leq j \leq n. \]
Identically as for matroids [9], we define the Hamming polynomial of a combinatroid $M$ by
\[ W_M(x, y, t) := \sum_{j=0}^{n} P_{M,j}(t) x^{n-j} y^j. \]
Next, following [9], we will verify that this definition coincides with the one given in Eq. (5.3).

**Lemma 6.1.**
\[ W_M(x, y, t) = \sum_{\sigma \subseteq E} (x - y)^{|E| - |\sigma|} y^{|\sigma|} t^{|\sigma|}. \]

**Proof.** Set $n = |E|$.
\[
\sum_{\sigma} (x - y)^{n - |\sigma|} y^{|\sigma|} t^{|\sigma|} = \sum_{i=0}^{n-|\sigma|} \sum_{\sigma} x^i (-y)^{n-i} y^{|\sigma|} t^{|\sigma|} \\
= \sum_{\gamma \subseteq E \setminus \sigma} x^{|\gamma|} y^{n-|\gamma|} (-1)^{n-|\gamma|} t^{|\sigma|} \\
= \sum_{\gamma} x^{|\gamma|} y^{n-|\gamma|} \sum_{\sigma \subseteq E \setminus \gamma} (-1)^{n-|\gamma| - |\sigma|} t^{|\sigma|} \\
= \sum_{\gamma} x^{|\gamma|} y^{n-|\gamma|} P_{M,E \setminus \gamma}(t) \\
= \sum_{\gamma} x^{n-|\gamma|} y^{|\gamma|} P_{M,\gamma}(t) \\
= W_M(x, y, t). \quad \square
\]

**Theorem 6.2.**
\[ W_M(x, y, t) = (x - y)^{\eta(E)} y^{\rho(E)} T_M \left( \frac{x}{y}, \frac{x + (t - 1)y}{x - y} \right). \]
Proof.

\[ T_M\left(\frac{x}{y}, \frac{x + (t-1)y}{x - y}\right) = \sum_{\sigma} \frac{(x - y)^{\eta(E \setminus \sigma)}}{y^{\eta(E \setminus \sigma)}} \left(\frac{t}{x - y}\right)^{\eta(\sigma)} \]

\[ = \sum_{\sigma} \frac{(x - y)^{\eta(E \setminus \sigma)}}{y^{\eta(E \setminus \sigma)}} (ty)^{\eta(\sigma)} \]

\[ = \sum_{\sigma} \frac{(x - y)^{\eta(E \setminus \sigma) - \eta(\sigma)}}{y^{\rho(E) - \eta(\sigma)}} t^{\eta(\sigma)} \]

\[ = \frac{(x - y)^{\rho(E) - n}}{y^{\rho(E)}} \sum_{\sigma} (x - y)^{n - |\sigma|} |\sigma| t^{\eta(\sigma)} \]

\[ = \frac{(x - y)^{\rho(E) - n}}{y^{\rho(E)}} W_M(x, y, t). \quad \Box \]

**Theorem 6.3.**

\[ T_M(x, y) = (x - 1)^{-\eta(E)} x^{|E|} W_M(1, x^{-1}, (x - 1)(y - 1)). \]

Proof. A straightforward evaluation shows that

\[ W_M(1, x^{-1}, (x - 1)(y - 1)) = (1 - x^{-1})^{n - \rho(E)} x^{-\rho(E)} T_M(x, y) \]

\[ = (x - 1)^{n - \rho(E)} x^{-n} T_M(x, y). \quad \Box \]

**Example 6.4.** Let \( \Delta \) be a simplicial complex of dimension \( d \); so \( d + 1 \) is the largest cardinality of a face. The \( f \)-**polynomial** of \( \Delta \) is defined as

\[ f(\Delta, t) := t^{d+1} + c_1 t^{d-1} + \cdots + c_d, \]

where \( c_i \) is the number of faces of cardinality \( i \), and its \( h \)-**polynomial** is defined as \( h(\Delta, t) := f(\Delta, t - 1) \). It is well known that \( f(\Delta, t) = T(t + 1, 1) \), where \( T(x, y) \) is the Tutte polynomial of \( \Delta \). Thus, by Theorem 6.3,

\[ f(\Delta, t) = (x + 1)^{|E|} x^{-\eta(E)} W(1, (x + 1)^{-1}, 0). \]

For instance, let \( \Delta \) be the simplicial complex with facets \( 12, 234, 345 \), i.e.

\[ \Delta = \{ \emptyset, 1, 2, 3, 4, 5, 12, 23, 24, 34, 35, 45, 234, 345 \}. \]

\[ T_\Delta(x, y) = x - 2x^2 + x^3 + y - 4xy + 4x^2y - y^2 + 2xy^2. \]

\[ W_\Delta(x, y, t) = x^5 + 4(t - 1)x^3y^2 + 4(1 - t)x^2y^3 + (-1 - t + 2t^2)xy^4 + (1 - t)ty^5. \]
Thus, the $f$-polynomial of $\Delta$ is
\[(x + 1)^5x^{-2}W_{\Delta}(1, (x + 1)^{-1}, 0) = x^3 + 5x^2 + 6x + 2.\]

Let $M = (E, \rho)$ be a nontrivial demimatroid, $P_{M,j}(t)$ the polynomial defined in Eq. (6.2), and $\delta$ the minimum $j > 0$ such that $P_{M,j}(t) \neq 0$.

**Proposition 6.5.** $\delta = \sigma_1(M^0)$ and $P_{M,\delta}(t) = c(t - 1)$, where
\[c = |\{X \subseteq E : |X| = \sigma_1(M^0)\}|.\]

**Proof.** Fix $X \subseteq E$ such that $\eta(X) = 1$ and $|X| = \sigma_1(M^0)$. If $\sigma \subseteq E$ and $|\sigma| < |X|$, then by Lemma 4.1(i), applied to the restriction of $\eta$ to $\sigma$, it holds that $\eta(\sigma) = 0$. Thus $0 = P_{M,\sigma}(t) := \sum_{\gamma \subseteq \sigma}(-1)^{|\sigma \setminus \gamma|}t^{\eta(\gamma)}$. The same result holds if $|\sigma| = |X|$ and $\eta(\sigma) = 0$. On the other hand, $P_{M,X}(t) = t - 1$. Therefore, we obtain the desired result. \(\square\)

We call the number $\sigma_1(M^0)$ the **formal minimum distance** of $M$.

**Proposition 6.6.** Let $M = (E, \rho)$ be a uniform matroid, with $n = |E|$ and $k = \rho(E)$. Then
\[T_M(x, y) = \sum_{i=0}^{k-1} \binom{n}{i}(x - 1)^{k-i} + \binom{n}{k}(y - 1)^{i-k}.\]

**Proof.** $\rho(X) = |X|$ if $|X| \leq k$ and $\rho(X) = k$ if $|X| > k$. Hence, $\eta(X) = 0$ if $|X| \leq k$ and $\eta(X) = r$ if $|X| = k + r$ with $r > 0$. Moreover, $\eta^*(X) = 0$ if $|E \setminus X| \geq k$, i.e. $|X| \leq n - k$, and $\eta^*(X) = r$ if $|E \setminus X| = k - r$ with $r > 0$, i.e. $|X| = n - k + r$. \(\square\)

Let $M = (E, \rho)$ be a demimatroid. Set $n = |E|$ and write
\[W_M(x, y, t) = x^n + \sum_{j=\delta}^{n} A_j(t)x^{n-j}y^j,\]
where $\delta$ is the formal minimum distance of $M$.

**Proposition 6.7.** Let $M = (E, \rho)$ be a uniform matroid, with $n = |E|$, $k = \rho(E)$ and $\delta = \sigma_1(M^0)$. Then, for $\delta \leq i \leq n$,
\[A_i(t) = (t - 1)\binom{n}{i} \sum_{j=0}^{i-\delta} (-1)^j \binom{i - 1}{j} t^{i-\delta-j}.\]

**Proof.** The proof readily follows from Proposition 6.6. \(\square\)
Example 6.8. Let \( M^o = (E, \rho^o) \) be as in Example 4.21. \( M^o \) is a uniform matroid of rank 1. \( T_{M^o}(x, y) = x + y + y^2, M^o(x, y, t) = x^3 + 3(t-1)xy^2 + (2-3t+t^2)y^3, \) \( \delta = 2, A_1(t) = 0, A_2(t) = 3(t-1), A_3(t) = 2 - 3t + t^2. \)

Example 6.9. Let \( M^o = (E = \{1, 2, 3, 4\}, \rho^o) \) be the uniform matroid given by:

| \( X \) | \( \emptyset \) | 1 | 2 | 3 | 4 | 12 | 13 | 14 | 23 | 24 | 34 | 123 | 124 | 134 | 234 | \( E \) |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| \( \rho \) | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 2 |
| \( \rho^x \) | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 2 |
| \( \rho^y \) | 0 | 1 | 1 | 1 | 2 | 2 | 2 | 2 | 2 | 2 | 2 | 2 | 2 | 2 |
| \( \rho^z \) | 0 | 1 | 1 | 1 | 2 | 2 | 2 | 2 | 2 | 2 | 2 | 2 | 2 | 2 |

\( M^o \) is a uniform matroid of rank 2. \( T_{M^o}(x, y) = 2x + x^2 + 2y + y^2, W_{M^o}(x, y) = x^4 + 4(t-1)xy^3 + (3-4t+t^2)y^4, \) \( \delta = 3, A_1(t) = 0, A_2 = 0, A_3(t) = 4(t-1), A_4(t) = 3 - 4t + t^2. \)

7. Elongations

Let \( M = (E, \rho) \) be a demimatroid with nullity function \( \eta. \) For \( 0 \leq i \leq \eta(M) \) we define the \( i \)-th elongation of \( M \) as the demimatroid \( M[i] := (E, \rho[i]), \) where

\[
\rho[i](\sigma) := \min\{ |\sigma|, \rho(\sigma) + i \},
\]
or equivalently,

\[
\rho[i](\sigma) = \begin{cases} 
|\sigma|, & \eta(\sigma) \leq i \\
\rho(\sigma) + i, & \eta(\sigma) > i.
\end{cases}
\]

Note that \( \rho[0] \equiv \rho, \rho[i] \equiv (\rho[1])^{i-1} \) and \( \rho^o[M](\sigma) = |\sigma| \) for all \( \sigma \subseteq E. \) When there is no confusion, we will write \( M[i] \) instead of \( M[i]. \)

Proposition 7.1. Let \( M = (E, \rho) \) be a demimatroid. Then \( M[i], \) as defined above, is a demimatroid.

**Proof.** Obviously \( \rho[i](\emptyset) = 0. \) Let \( X \subseteq E \) and \( x \in E. \)

If \( x \in X, \) obviously \( \rho[i](X) \leq \rho[i](X \cup x) \leq \rho[i](X) + 1, \) so we may assume \( x \not\in X. \)

If \( \rho[i](X \cup x) = |X| + 1, \) thus \( \rho[i](X) = |X| \) and \( \rho[i](X) \leq \rho[i](X \cup x) \leq \rho[i](X) + 1. \)

If \( \rho[i](X \cup x) = \rho(X) + i, \) thus \( \rho[i](X) = \rho(X) + i \) and \( \rho[i](X) \leq \rho[i](X \cup x) \leq \rho[i](X) + 1. \)

Since \( 1 \leq i \leq \eta(M) = |E| - \rho(E), \) it holds that \( \rho(E) + i \leq |E|, \) so \( \rho[i](M[i]) = \rho(M) + i. \)

If \( X \subseteq E, \) then the rank function of \( M[X] \) is the restriction of \( \rho \) to \( X. \) We point out that from this it follows that \( (M[i])[X] = (M[X])[i]. \)
The nullity function of $M[i]$ is given by
\[ \eta^*[i](\sigma) = \max\{0, \eta(\sigma) - i\}, \]
or equivalently,
\[ \eta^*[i](\sigma) = \begin{cases} 0, & \eta(\sigma) \leq i \\ \eta(\sigma) - i, & \eta(\sigma) > i. \end{cases} \]
An easy verification shows that
\[ \eta^*[i](\sigma) = 0 \text{ if and only if } \eta(\sigma) \leq i. \]

**Proposition 7.2.** Let $M = (E, \rho)$ be a demimatroid. Then $\sigma_{r+1}(M^\circ) = \sigma_1(M[r]^\circ)$.

**Proof.** Choose $X \subseteq E$ such that $\eta(X) = r + 1$ and $|X| = \sigma_{r+1}(M^\circ)$. Hence $\eta^*[r](X) = \max\{0, \eta(X) - r\} = 1$, and so $\sigma_1(M[r]^\circ) \leq |X| = \sigma_{r+1}(M^\circ)$. Similarly, choose $Y \subseteq E$ such that $\eta^*[r](Y) = 1$ and $|Y| = \sigma_1(M[r]^\circ)$. Hence $\eta(Y) = r + 1$, and so $\sigma_{r+1}(M^\circ) \leq |Y| = \sigma_1(M[r]^\circ)$. \(\square\)

**8. Betti numbers**

Let $R = K[x_1, \ldots, x_n]$ be a polynomial ring over the field $K$. We consider $R$ provided with its canonical $\mathbb{Z}$-grading. Associated with each homogeneous ideal $I$ of $R$ there is a minimal graded free resolution
\[ 0 \rightarrow \bigoplus_j R(-j)^{\beta_{pj}} \rightarrow \cdots \rightarrow \bigoplus_j R(-j)^{\beta_{1j}} \rightarrow R \rightarrow R/I \rightarrow 0, \]
where $R(-j)$ denotes the $R$-module obtained by shifting the degrees of $R$ by $j$, i.e $R(-j)_a = R_{a-j}$. The number $\beta_{ij}$ in the resolution may be interpreted as the minimum number of generators of degree $j$ in the $i$-th syzygy of $R/I$; or equivalently
\[ \beta_{ij}(R/I) := \beta_{ij} = \dim \text{Tor}_i(R/I, K)_j. \]
These $\beta_{ij}$'s are called the graded Betti numbers of $R/I$. We collect all they together by defining the graded Betti polynomial of $R/I$ as
\[ B(R/I; x, y) := \sum_{i=0}^p \sum_j \beta_{ij} x^i y^j. \]

**Example 8.1.** Let $I \subset R = K[x_1, \ldots, x_5]$ be the monomial ideal
\[ I = \langle x_1 x_2, x_2 x_3, x_3 x_4, x_4 x_5 \rangle. \]
We have the resolution

\[ 0 \rightarrow R(-5) \rightarrow R^3(-3) \oplus R(-4) \rightarrow R^4(-2) \rightarrow R \rightarrow R/I \rightarrow 0, \]

so that

\[ B(R/I; x, y) = 1 + 4xy^2 + 3x^2y^3 + x^2y^4 + x^3y^5. \]

Let \( \Delta \) be a simplicial complex; we assume that all the vertices belong to \( \Delta \). It is convenient, abusing notation, to identify \( \sigma \subseteq \left[ n \right] \) with the characteristic vector \( \sigma = (\sigma_i) \in \{0, 1\}^n \) such that \( \sigma_i = 1 \) if \( i \in \sigma \); and write \( |\sigma| := \sigma_1 + \cdots + \sigma_n \). For \( \sigma \subseteq \left[ n \right] \) we denote by \( \Delta_\sigma \) the simplicial complex that results from the restriction of \( \Delta \) to the vertex set \( \sigma \).

Given a simplicial complex \( \Delta \), let \( I_\Delta \) denote its Stanley-Reisner ideal and \( K[\Delta] \) its Stanley-Reisner ring, i.e. \( I_\Delta = \langle x_{i_1} \cdots x_{i_r} : \{i_1, \ldots, i_r\} \notin \Delta \rangle \subset R \) and \( K[\Delta] = R/I_\Delta \). Let’s also denote by \( \tilde{H}_i(\Delta; K) \) the \( i \)-th reduced homology group of \( \Delta \) with coefficients in the field \( K \). We have the fundamental result:

**Theorem 8.2.** (Hochster’s Formula [6]) Let \( \Delta \) be a simplicial complex with vertex set \( \left[ n \right] \). Then

\[ \beta_{i\sigma}(R/I_\Delta) = \sum_{\sigma \subseteq \left[ n \right] ; |\sigma| = j} \dim \tilde{H}_{j-i-1}(\Delta_\sigma). \]

If, instead of the \( \mathbb{Z} \)-grading, we consider \( R \) provided with its \( \mathbb{Z}^n \)-grading, and for any \( \sigma \subseteq \left[ n \right] \) we define \( \beta_{i\sigma}(R/I) := \dim \text{Tor}_i(R/I, K)_\sigma \), then we have

**Theorem 8.3.** (Multigraded Hochster’s Formula) Let \( \Delta \) be a simplicial complex with vertex set \( \left[ n \right] \). For any \( \sigma \subseteq \left[ n \right] \) we have that

\[ \beta_{i\sigma}(R/I_\Delta) = \dim \tilde{H}_{|\sigma|-i-1}(\Delta_\sigma). \]

**9. Hamming polynomial vs Betti numbers**

Let \( \Delta \) be a simplicial complex of dimension \( d \) and denote by \( f_i \) the number of \( i \)-dimensional faces of \( \Delta \). The reduced Euler characteristic of \( \Delta \) is defined as

\[ \tilde{\chi}(\Delta) := \sum_{i=-1}^{d} (-1)^i \dim \tilde{H}_i(\Delta; K). \]

24
Lemma 9.1. (Euler-Poincaré formula) The reduced Euler characteristic of a simplicial complex does not depend of the field and
\[ \widetilde{\chi}(\Delta) = -1 + f_0 - \cdots + (-1)^d f_d. \]

Let \( M = (E, \rho) \) be a demimatroid with nullity function \( \eta \), and let \( M[i] \) be its \( i \)-th elongation. Set \( n = |E| \) and denote by \( I_{M[i]} \) the Stanley-Reisner ideal of \( M[i] \), viewed as a simplicial complex.

Lemma 9.2. For \( \sigma \subseteq E \) the coefficient of \( t^r \) in \( P_{M, \sigma}(t) \) is equal to
\[ \sum_{i=0}^{n} (-1)^i \left( \beta_i(\rho/I_{M[i]}) - \beta_i(\rho/I_{M[i-1]}) \right). \]

Proof. According to Eq. (6.1), the coefficient of \( t^r \) is
\[ s_{r, \sigma} = (-1)^{|\sigma|} \sum_{\gamma \subseteq \sigma; \eta(\gamma) = r} (-1)^{|\gamma|}. \]
From Eq. (7.1) we have
\[ s_{r, \sigma} = (-1)^{|\sigma|} \left( \sum_{\gamma \subseteq \sigma; \eta^{(i)}(\gamma) = 0} (-1)^{|\gamma|} - \sum_{\gamma \subseteq \sigma; \eta^{(r-1)}(\gamma) = 0} (-1)^{|\gamma|} \right). \]
By Eq. 7.1 and Lemma 9.1,
\[ (-1)^{|\sigma|} \sum_{\gamma \subseteq \sigma; \eta^{(i)}(\gamma) = 0} (-1)^{|\gamma|} = (-1)^{|\sigma|+1} \left( \sum_{\rho^{(i)}(\sigma)} (-1)^{|\gamma|} \dim \widetilde{H}_i(M[r]; K) \right) \]
\[ = (-1)^{|\sigma|+1} \left( \sum_{i=1}^{\rho^{(r)}(\sigma)} (-1)^{i} \dim \widetilde{H}_i(M[r]; \rho^{(r)}(\sigma)) \right) \]
\[ = (-1)^{|\sigma|+1} \left( \sum_{j=\eta^{(r)}(\sigma)-1}^{\rho^{(r)}(\sigma)} (-1)^{|\gamma|-j-1} \dim \widetilde{H}_{|\gamma|-j-1}(M[r]; \rho^{(r)}(\sigma)) \right) \]
\[ = \sum_{j=\eta^{(r)}(\sigma)-1}^{\rho^{(r)}(\sigma)} (-1)^j \dim \widetilde{H}_{|\gamma|-j-1}(M[r]; \rho^{(r)}(\sigma)) \]
(by 8.3) \[ = \sum_{j=0}^{|\sigma|} (-1)^j \beta_{j, \sigma}(R/I_{M[r]}). \]
Similarly,

\[ (-1)^{|\gamma|} \sum_{\gamma \subseteq \sigma; \eta^{r-1}(\gamma) = 0} (-1)^{|\gamma|} = \sum_{j=0}^{n} (-1)^{j} \beta_{j\sigma}(R/I_{M|r-1}). \]  

\[ \square \]

**Corollary 9.3.** For each \(1 \leq j \leq n\) the coefficient of \(t^r\) in \(P_{M,j}(t)\) is equal to

\[ \sum_{i=0}^{n} (-1)^{i} \left( \beta_{ij}(R/I_{M|r}) - \beta_{ij}(R/I_{M|r-1}) \right). \]

**Proof.** Recall that \(P_{M,j}(t) = \sum_{|\sigma| = j} P_{M,\sigma}(t)\) and \(\beta_{ij}(R/I_{M|r}) = \sum_{|\sigma| = j} \beta_{i\sigma}(R/I_{M|r})\). Hence the coefficient of \(t^r\) in \(P_{M,j}\) is

\[ \sum_{i=0}^{n} (-1)^{i} \left( \beta_{ij}(R/I_{M|r}) - \beta_{ij}(R/I_{M|r-1}) \right). \]  

\[ \square \]

**Theorem 9.4.**

\[ W(x, y, t) = x^n \sum_{r=0}^{\eta} (B_{M[r]}(-1, y/x) - B_{M[r-1]}(-1, y/x)) t^r. \]

**Proof.** By definition \(W(x, y, t) = \sum_{j=0}^{n} P_{M,j}(t)x^{n-j}y^j\). By Corollary 9.3,

\[
W(x, y, t) = \sum_{r=0}^{\eta} \left( \sum_{j=0}^{n} \left( \sum_{i=0}^{n} (-1)^{i} \left( \beta_{ij}(R/I_{M|r}) - \beta_{ij}(R/I_{M|r-1}) \right) \right) t^r \right) x^{n-j}y^j \\
= \sum_{r=0}^{\eta} \left( \sum_{j=0}^{n} \left( \sum_{i=0}^{n} (-1)^{i} \left( \beta_{ij}(R/I_{M|r}) - \beta_{ij}(R/I_{M|r-1}) \right) \right) x^{n-j}y^j \right) t^r \\
= \sum_{r=0}^{\eta} \left( \sum_{i=0}^{n} (-1)^{i} \left( \sum_{j=0}^{n} \left( \beta_{ij}(R/I_{M|r}) - \beta_{ij}(R/I_{M|r-1}) \right) x^{n-j}y^j \right) \right) t^r \\
= x^n \sum_{r=0}^{\eta} \left( \sum_{i=0}^{n} \left( \beta_{ij}(R/I_{M|r}) - \beta_{ij}(R/I_{M|r-1}) \right) (-1)^{i}(y/x)^j \right) t^r \\
= x^n \sum_{r=0}^{\eta(E)} \left( B_{M[r]}(-1, y/x) - B_{M[r-1]}(-1, y/x) \right) t^r. \]  

\[ \square \]

**Remark 9.5.**

(i) \(B_{M[-1]}(x, y) = 0\) and \(B_{M[y(E)]}(x, y) = 1\).

(ii) \(W(x, y, 0) = x^n B_M(-1, y/x)\).
Example 10.1. Let $G$ be the graph

and let $\Delta$ be the simplicial complex whose facets are the nine edges of this graph. Let us consider $\Delta$ provided with its natural structure of demimatroid, i.e. $\rho(\sigma) = \max\{|X| : X \subseteq \sigma \text{ and } X \in \Delta\}$. The circuits of $\Delta$ are $\{24, 25, 26, 35, 36, 46, 123, 134, 145, 156\}$; here we have written 24 instead of $\{2, 4\}$, and so on. We have

$$T(x, y) = -x + x^2 - y + 4xy + 2y^2 + xy^2 + 2y^3 + y^4$$

and

$$W(x, y, t) = (x - y)^4 y^2 T\left(\frac{x}{y}, \frac{x + (t - 1)y}{x - y}\right)$$

$$= x^6 + 6(-1 + t)x^4y^2 + (4 - 5t + t^2)x^3y^3$$
$$+ 3(3 - 7t + 4t^2)x^2y^4 + 3(-4 + 11t - 9t^2 + 2t^3)xy^5$$
$$+ (4 - 13t + 14t^2 - 6t^3 + t^4)y^6.$$ 

The Betti polynomial of the elongations of $\Delta$, over $\mathbb{Q}$, are

$$B_0(x, y) = 1 + 6xy^2 + 4xy^3 + 8x^2y^3 + 12x^2y^4 + 3x^3y^4 + 12x^3y^5 + 4x^4y^6;$$
$$B_1(x, y) = 1 + xy^3 + 12xy^4 + 21x^2y^5 + 9x^3y^6;$$
$$B_2(x, y) = 1 + 6xy^5 + 5x^2y^6;$$
$$B_3(x, y) = 1 + xy^6;$$
$$B_4(x, y) = 1.$$
From this we obtain

\[ x^6 \sum_{r=0}^{4} \left( B_{M[r]}(-1, y/x) - B_{M[r-1]}(-1, y/x) \right) t^r = x^6 + 6(-1 + t)x^4y^2 + \]
\[ + (4 - 5t + t^2)x^3y^3 + 3(3 - 7t + 4t^2)x^2y^4 + \]
\[ + 3(-4 + 11t - 9t^2 + 2t^3)xy^5 + \]
\[ + (4 - 13t + 14t^2 - 6t^3 + t^4)y^6. \]

**Example 10.2.** Let \( \Delta \) be the simplicial complex whose faces are the independent vertex sets of the graph \( G \) in Example 10.1, i.e. the facets of \( \Delta \) are \{1, 25, 35, 36, 246\}. The circuits of \( \Delta \) are all the edges of \( G \). We have

\[ T(x, y) = x - 2x^2 + x^3 + y - 2xy + x^2y + y^2 - 5xy^2 + 4x^2y^2 - 2y^3 + 3xy^3 \]

and

\[ W(x, y, t) = (x - y)^3y^3 T\left( \frac{x}{y}, \frac{x + (t - 1)y}{x - y} \right) = x^6 + 9(-1 + t)x^4y^2 + (17 - 21t + 4t^2)x^3y^3 + \]
\[ + 12(-1 + t)x^2y^4 + 3(1 + t - 3t^2 + t^3)xy^5 + t(-3 + 5t - 2t^2)y^6. \]

The Betti polynomial of the elongations of \( \Delta \) are

\[ B_0(x, y) = 1 + 9xy^2 + 17x^2y^3 + x^2y^4 + 13xy^3 + 2x^3y^4 + 5x^4y^5 + x^4y^6 + x^5y^6; \]

\[ B_1(x, y) = 1 + 4xy^3 + 3xy^4 + 3x^2y^4 + 6x^2y^5 + 3xy^6; \]

\[ B_2(x, y) = 1 + 3xy^5 + 2x^2y^6; \]

\[ B_3(x, y) = 1. \]

From this we obtain

\[ x^6 \sum_{r=0}^{3} \left( B_{M[r]}(-1, y/x) - B_{M[r-1]}(-1, y/x) \right) t^r = x^6 + 9(-1 + t)x^4y^2 + \]
\[ + (17 - 21t + 4t^2)x^3y^3 + 12(-1 + t)x^2y^4 + \]
\[ + 3(1 + t - 3t^2 + t^3)xy^5 + t(-3 + 5t - 2t^2)y^6. \]

**Example 10.3.** Let \( C \) be the Hamming linear \([8, 4, 4]_2\) code, with parity check matrix

\[
H = \begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 1 & 1 & 1 \\
0 & 1 & 0 & 0 & 1 & 0 & 1 & 1 \\
0 & 0 & 1 & 0 & 1 & 0 & 1 & 1 \\
0 & 0 & 0 & 1 & 1 & 1 & 0 & 1
\end{pmatrix}.
\]

28
We have
\[ T(x, y) = 6x + 10x^2 + 4x^3 + x^4 + 6y + 14xy + 10y^2 + 4y^3 + y^4 \]
and
\[
W(x, y, t) = x^8 + 14(-1 + t)x^4y^4 + 28(2 - 3t + t^2)x^2y^6
+ 8(-8 + 14t - 7t^2 + t^3)xy^7 + (21 - 42t + 28t^2 - 8t^3 + t^4)y^8.
\]
The Betti polynomial of the elongations of \( M[H] \) are
\[
B_0(x, y) = 1 + 14xy^4 + 56x^2y^6 + 64x^3y^7 + 21x^4y^8;
B_1(x, y) = 1 + 28xy^6 + 48x^2y^7 + 21x^3y^8;
B_2(x, y) = 1 + 8xy^7 + 7x^2y^8;
B_3(x, y) = 1 + xy^8;
B_4(x, y) = 1.
\]
From this we obtain
\[
x^8 \sum_{r=0}^{4} (B_{M[r]}(-1, y/x) - B_{M[r-1]}(-1, y/x)) t^r = W(x, y, t).
\]

**Example 10.4.** Let \( \Delta \) be the simplicial complex whose facets are the 2-dimensional faces determined by the triangulation of the projective plane

![Diagram of the projective plane triangulation](image)

i.e., the facets of \( \Delta \) are \{124, 234, 345, 135, 125, 256, 236, 136, 146, 456\}.  

29
In characteristic 2 the Betti polynomials are

\[ B_0(x, y) = 1 + 10xy^3 + 15x^2y^4 + 6x^3y^5 + x^3y^6 + x^4y^6; \]
\[ B_1(x, y) = 1 + 6xy^5 + 5x^2y^6; \]
\[ B_2(x, y) = 1 + xy^6; \]
\[ B_3(x, y) = 1. \]

In characteristic 3 the Betti polynomials are

\[ B_0(x, y) = 1 + 10xy^3 + 15x^2y^4 + 6x^3y^5; \]
\[ B_1(x, y) = 1 + 6xy^5 + 5x^2y^6; \]
\[ B_2(x, y) = 1 + xy^6; \]
\[ B_3(x, y) = 1. \]

Even though these polynomials do depend of the characteristic of the field, in both cases it results that

\[ T(x, y) = -4x + 3x^2 + x^3 - 4y + 10xy + 3y^2 + y^3 \]

and

\[ W(x, y, t) = x^6 + 10(-1 + t)x^3y^3 - 15(-1 + t)x^2y^4 + 6(-1 + t^2)xy^5 + t(5 - 6t + t^2)y^6. \]

Note that the coefficient of \( x^2y^4 \), i.e. \(-15(t - 1)\), is negative for any \( t > 1 \), so \( W(x, y, t) \) cannot be the weight enumerator of any code over a finite field.

The Duursma zeta polynomial corresponding to \( W(x, y, t) \) is

\[ P_q(t) = (1/2)(1 + (1 - q)t + qt^2). \]

This polynomial has negative discriminant for \( q \in (3 - 2\sqrt{2}, 3 - 2\sqrt{2}) \approx (0.17, 5.82) \).

For \( q \) in this interval, the roots of \( P_q(t) \) lie in the circle \((x + 1)^2 + y^2 = 2\), moreover all roots have module \( 1/\sqrt{q} \), so that \( P_q(t) \) satisfies the Riemann hypothesis. See [3].

**Example 10.5.** Let \( M \) be the Vamos matroid, i.e. the ground set is \( E = \{1, \ldots, 8\} \) and the bases are all the subsets of \( E \) of size 4, except \( \{1234, 2356, 1456, 2378, 1478\} \). We have

\[ T(x, y) = x^4 + 4x^3 + 10x^2 + 15x + 5xy + 15y + 10y^2 + 4y^3 + y^4 \]
and
\[
W(x, y, t) = x^8 + 5(-1 + t)x^4y^4 + 36(-1 + t)x^3y^5 + 2(55 - 69t + 14t^2)x^2y^6 \\
+ 4(-25 + 37t - 14t^2 + 2t^3)xy^7 + (30 - 51t + 28t^2 - 8t^3 + t^4)y^8.
\]

11. GENERALIZED HAMMING POLYNOMIAL

For positive integers \( j \leq m \) and \( q \) an indeterminate, let us define
\[
\begin{align*}
[m]_q & := 1 + q + \cdots + q^{m-1} \\
[m]_q! & := [1]_q [2]_q \cdots [m]_q \\
[m \choose j]_q & := \frac{[m]_q!}{[j]_q! [m-j]_q!} \\
\langle m \rangle_q & := (q^m - 1)(q^m - q) \cdots (q^m - q^{m-1}).
\end{align*}
\]
Since
\[
\begin{align*}
[m \choose j]_q & = \left[ m - 1 \right]_q - q^{m-j} - m - 1 \right]_q,
\end{align*}
\]
it follows that all these are polynomials in \( q \) with integer coefficients.

Let \( M = (E, \rho) \) be a combinatroid. Set \( n = |E| \) and \( k = \rho(E) \). Following [10], for \( 1 \leq r \leq n \), we define the \( r \)-generalized Hamming weight enumerator
\[
W(r)(x, y, q) := \frac{1}{(r)_q} \sum_{j=0}^{r} \left( \begin{array}{c} r \\ j \end{array} \right)_q (-1)^{r-j} q^{(r-j)/2} (x-y)^{n-k} y^k T_M(\frac{x}{y}, \frac{x+(q^j-1)y}{x-y}).
\]

Conjecture 11.1. Let \( M = (E, \rho) \) be a combinatroid. Set \( n = |E| \) and \( k = \rho(E) \). Then
\[
T_M(x, y) = x^n(x-1)^{k-n} \sum_{r=0}^{n-k} \left( \prod_{j=0}^{r-1} ((x-1)(y-1) - q^j) \right) W(r)(1, 1/x, q). \tag{11.1}
\]

Remark 11.2. When \( M \) is the associated matroid to a linear code, via its parity check matrix, this conjecture has been proved by Jurrius [11, Thm. 3.3.5].

Example 11.3. Let \( C \) be the binary linear \([6, 3]\) code with parity check matrix
\[
H = \begin{bmatrix}
1 & 1 & 1 & 1 & 0 & 0 \\
1 & 1 & 1 & 0 & 1 & 0 \\
1 & 1 & 1 & 0 & 0 & 1
\end{bmatrix}.
\]
(See Example C_1 of Section 5.2 in [11]) The bases of the matroid \( M[H] \) are
\[
\{145, 146, 156, 245, 246, 256, 345, 346, 356, 456\},
\]
and its Tutte polynomial is

\[ T(x, y) = x + x^2 + x^3 + y + xy + x^2y + y^2 + xy^2 + x^2y^2 + y^3. \]

\[ W^{(0)}(x, y, t) = x^6; \]
\[ W^{(1)}(x, y, t) = 3x^4y^2 + (-2 + t)x^3y^3 + 3x^2y^4 + 3(-2 + t)xy^5 + (3 - 3t + t^2)y^6; \]
\[ W^{(2)}(x, y, t) = x^3y^3 + 3xy^5 + (-3 + t + t^2)y^6; \]
\[ W^{(3)}(x, y, t) = y^6. \]

Substituting these \( W^{(r)} \)'s in Eq. (11.1) we recover \( T(x, y) \).

**Example 11.4.** Let \( C \) be the binary linear \([6, 3]\) code with parity check matrix

\[
H = \begin{bmatrix}
1 & 0 & 0 & 1 & 0 & 0 \\
0 & 1 & 0 & 0 & 1 & 0 \\
0 & 0 & 1 & 0 & 0 & 1
\end{bmatrix}.
\]

(See Example \( C_1 \) of Section 5.2 in [11]) The bases of the matroid \( M[H] \) are

\{123, 126, 135, 156, 234, 246, 345, 456\},

and its Tutte polynomial is

\[ T(x, y) = x^3 + 3x^2y + 3xy^2 + y^3. \]

\[ W^{(0)}(x, y, t) = x^6; \]
\[ W^{(1)}(x, y, t) = 3x^4y^2 + 3(-1 + t)x^3y^3 + 3(-1 + t)xy^4 + (-1 + t)^2y^6; \]
\[ W^{(2)}(x, y, t) = 3x^2y^4 + (-2 + t + t^2)y^6; \]
\[ W^{(3)}(x, y, t) = y^6. \]

Substituting these \( W^{(r)} \)'s in Eq. (11.1) we recover \( T(x, y) \).

**Example 11.5.** Let \( C \) be the binary Hamming linear \([7, 4]\) code with parity check matrix

\[
H = \begin{bmatrix}
0 & 1 & 1 & 1 & 1 & 0 & 0 \\
1 & 0 & 1 & 1 & 1 & 0 & 1 \\
1 & 1 & 0 & 1 & 1 & 0 & 0
\end{bmatrix}.
\]

The Tutte polynomial of \( M[H] \) is

\[ T(x, y) = 3x + 4x^2 + x^3 + 3y + 7xy + 6y^2 + 3y^3 + y^4. \]
\( W^{(0)}(x, y, t) = x^7; \)
\( W^{(1)}(x, y, t) = 7x^4y^3 + 7x^3y^4 + 21(-2 + t)x^2y^5 + 7(6 - 5t + t^2)xyy^6 \)
\( + (-13 + 15t - 6t^2 + t^3)y^7; \)
\( W^{(2)}(x, y, t) = 21x^2y^5 + 7(-5 + t + t^2)xyy^6 + (15 - 6t^2 + t^3 + t^4)y^7; \)
\( W^{(3)}(x, y, t) = 7xy^6 + (-6 + t + t^2 + t^3)y^7; \)
\( W^{(4)}(x, y, t) = y^7. \)

Substituting these \( W^{(r)} \)'s in Eq. (11.1) we recover \( T(x, y) \).

**Example 11.6.** Let \( M \) be the demimatroid in Example 4.21.

\[
\begin{array}{cccccccc}
X & \emptyset & 1 & 2 & 3 & 12 & 13 & 23 & E \\
\hline
\rho & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 2 \\
\rho^* & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
\rho^+ & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
\rho^+ & 0 & 1 & 1 & 2 & 2 & 2 & 2 & 2 \\
\end{array}
\]

\( T_M(x, y) = x - 2x^2 + y - 3xy + 3x^2 y. \)

\( W_M(x, y, t) = x^3 + 3(t - 1)x^2y + 3(1 - t)xyy^2 + (t - 1)y^3. \)

\[
\begin{align*}
W^{(0)}(x, y, t) &= (x - y)^3x^3; \\
W^{(1)}(x, y, t) &= (x - y)^3y(3x^2 - 3xy + y^2); \\
W^{(2)}(x, y, t) &= 0. \\
\end{align*}
\]

\( x^6(x - y)^{-4}[W^{(0)}(1, 1/x, t) + ((x - 1)(y - 1) - 1)W^{(1)}(1, 1/x, t)] = T_M(x, y). \)
