SYMPLECTIC HOMOLOGY CAPACITY OF CONVEX BODIES AND LOOP SPACE HOMOLOGY

KEI IRIE

Abstract. Floer-Hofer-Wysocki introduced a capacity invariant for (open) subsets in the symplectic vector space using symplectic homology, which we call symplectic homology capacity. We prove that, for any convex body $K$ in the symplectic vector space, the symplectic homology capacity of $K$ is equal to the Ekeland-Hofer-Zehnder capacity of $K$, which is defined (when $\partial K$ is $C^\infty$) as the minimal action of closed characteristics on $\partial K$. Our proof is based on an isomorphism between the symplectic homology of a convex body in the symplectic vector space and a certain relative homology of loop spaces of the Euclidean space.

1. Introduction

1.1. Symplectic homology capacity. Let $n$ be a positive integer. Let us consider coordinates $q_1, \ldots, q_n, p_1, \ldots, p_n$ on $T^*\mathbb{R}^n$, where $q_1, \ldots, q_n$ are coordinates on $\mathbb{R}^n$ and $p_1, \ldots, p_n$ are coordinates on fibers with respect to the global frame $dq_1, \ldots, dq_n$. We often abbreviate $(q_1, \ldots, q_n)$ by $q$ and $(p_1, \ldots, p_n)$ by $p$. Let $\omega_n := \sum_{1 \leq i \leq n} dp_i dq_i \in \Omega^2(T^*\mathbb{R}^n)$.

For any compact set $K$ in $T^*\mathbb{R}^n$ and real numbers $a < b$, one can assign a $\mathbb{Z}$-graded $\mathbb{Z}/2$-vector space $\text{SH}^{[a,b)}(K)$, which is called symplectic homology. Moreover, for any $a' < b'$ such that $a \leq a'$ and $b \leq b'$, one can assign a linear map $\text{SH}^{[a,b)}(K) \to \text{SH}^{[a',b')} (K)$.

We say that $K$ is of restricted contact type if $K$ is compact, connected, $\text{int} K \neq \emptyset$, $\partial K$ is $C^\infty$, and there exists $X \in \mathcal{X}(T^*\mathbb{R}^n)$ with the following two properties:

- $L_X \omega_n = \omega_n$ at every point in $T^*\mathbb{R}^n$,
- $X$ points strictly outwards at every point on $\partial K$.

The distribution $\ker(\omega_n|_{\partial K})$ on $\partial K$ defines a 1-dimensional foliation on $\partial K$, which is called the characteristic foliation on $\partial K$. The set of closed leaves of the characteristic foliation (which are called closed characteristics) is denoted by $\mathcal{P}(\partial K)$.

The distribution $\ker(\omega_n|_{\partial K})$ is oriented so that $v \in \ker(\omega_n|_{\partial K})$ is positive if and only if $\omega_n(X, v) > 0$ (note that this orientation is independent of the choice of $X$). With this orientation, for each $\gamma \in \mathcal{P}(\partial K)$ we define

$$\mathcal{A}(\gamma) := \int_{\gamma} \left( \sum p_i dq_i \right).$$

2010 Mathematics Subject Classification. 70H12, 53D42.
The next lemma is well-known and easy to prove (see Section 2.3 for the proof):

**Lemma 1.1.** Let $K$ be a set of restricted contact type in $T^*\mathbb{R}^n$. Then every $\gamma \in \mathcal{P}(\partial K)$ satisfies $A(\gamma) > 0$. Moreover, there exists $\gamma_0 \in \mathcal{P}(\partial K)$ such that $A(\gamma_0) = \inf_{\gamma \in \mathcal{P}(\partial K)} A(\gamma)$.

Let $K$ be a set of restricted contact type in $T^*\mathbb{R}^n$. We denote $c_{\text{min}}(K) := \min_{\gamma \in \mathcal{P}(\partial K)} A(\gamma)$. As we see in Section 2, there exists a canonical isomorphism

$$\lim_{\varepsilon \to 0^+} \text{SH}^{[0,\varepsilon]}(K) \cong H_{*-n}(K, \partial K).$$

Hence, for any $a \in \mathbb{R}_{>0}$ one can define a linear map

$$i^a_K : H_*(K, \partial K) \cong \lim_{\varepsilon \to 0^+} \text{SH}^{[0,\varepsilon]}(K) \to \text{SH}^{[0,a]}_{*-n}(K).$$

Then let us define

$$c_{\text{SH}}(K) := \inf \{a \mid i^a_K([K, \partial K]) = 0\},$$

which we call *symplectic homology capacity*. It turns out $c_{\text{SH}}(K)$ is a positive real number for any set $K$ of restricted contact type.

**Remark 1.2.** The capacity $c_{\text{SH}}$ was introduced by Floer-Hofer-Wysocki [8] for arbitrary open subsets in the symplectic vector space. The above definition is different from the original definition in [8]. This definition is due to Hermann [11], which is based on the idea by Viterbo [17] (see Section 5.3 in [17]).

It is easy to see that there exists $\gamma \in \mathcal{P}(\partial K)$ such that $c_{\text{SH}}(K) = A(\gamma)$ (see Section 2.3). In particular $c_{\text{SH}}(K) \geq c_{\text{min}}(K)$. When $n \geq 2$, it is well-known that there exists a set $K$ of restricted contact type such that $c_{\text{SH}}(K) > c_{\text{min}}(K)$.

### 1.2. Main result and background.

In this paper, a *convex body* in a finite-dimensional real vector space means a convex compact set with nonempty interior. Since the invariant $c_{\text{SH}}$ satisfies conformality and monotonicity (see Section 2.3), one can define $c_{\text{SH}}(K)$ for all convex bodies in $T^*\mathbb{R}^n$ in such a way that the invariant $c_{\text{SH}}$ is continuous under $C^0$-perturbations of boundaries of convex bodies. More explicitly, for any convex body $K$ in $T^*\mathbb{R}^n$, we define

$$c_{\text{SH}}(K) := \inf \{c_{\text{SH}}(K') \mid K' \text{ is a convex body with } C^\infty \text{ boundary such that } K \subset K'\}.$$ 

On the other hand, the capacity $c_{\text{min}}$ also extends to all convex bodies (see [4] Section 2.3). This capacity is often called the *Ekeland-Hofer-Zehnder capacity* and denoted by $c_{\text{EHZ}}$. Now let us state the main result of this paper:

**Theorem 1.3.** For any convex body $K$ in $T^*\mathbb{R}^n$, there holds

$$c_{\text{SH}}(K) = c_{\text{EHZ}}(K).$$

**Remark 1.4.** Theorem 1.3 is also proved in a recent preprint [1] by Abbondandolo-Kang. Their proof is based on an isomorphism (which is the main result in [1]) between the filtered Floer complex of a convex quadratic Hamiltonian on $T^*\mathbb{R}^n$ (satisfying some technical conditions) and the filtered Morse complex of its Clarke dual action functional.
Theorem 1.3 is motivated by the following folk conjecture which says that all symplectic capacities coincide for convex bodies (see [14] Section 5 and references therein):

**Conjecture 1.5.** Let $c$ be a symplectic capacity on $T^*\mathbb{R}^n$; namely, $c$ is a map from the set of all subsets of $T^*\mathbb{R}^n$ to $[0,\infty]$ which satisfies the following three properties:

- For any $S \subset T \subset T^*\mathbb{R}^n$, there holds $c(S) \leq c(T)$.
- For any $S \subset T^*\mathbb{R}^n$, $a \in \mathbb{R}_{>0}$ and $\varphi \in \text{Diff} c(T^*\mathbb{R}^n)$ with $\varphi^*\omega_n = a\omega_n$, there holds $c(S) = ac(\varphi(S))$.
- $c\{(q,p) \in T^*\mathbb{R}^n \mid |q|^2 + |p|^2 \leq 1\} = c\{(q,p) \in T^*\mathbb{R}^n \mid q_1^2 + p_1^2 \leq 1\} = \pi$.

Then $c(K) = c_{EHZ}(K)$ for any convex body $K$.

Conjecture 1.5 is very strong and still widely open. As far as the author knows, Conjecture 1.5 was verified only for two invariants: the first Ekeland-Hofer capacity (Viterbo [16]) and the Hofer-Zehnder capacity (Hofer-Zehnder [12]). Our Theorem 1.3 verifies Conjecture 1.5 for the symplectic homology capacity $c_{SH}$.

Following a remark by Felix Schlenk [15], in Section 2.4 we consider the capacities $(c_{SH}^k)_{k \geq 1}$ defined in terms of the $S^1$-equivariant symplectic homology with $\mathbb{Z}/2$-coefficients, and show that Theorem 1.3 implies $c_{SH}^1(K) = c_{SH}(K)$ for any convex body $K$ in $T^*\mathbb{R}^n$.

Here is a very short comment on the proof of Theorem 1.3. Actually, Theorem 1.3 is a consequence of Theorem 3.3 which gives an isomorphism between the symplectic homology of a convex body in $T^*\mathbb{R}^n$ and a certain relative homology of loop spaces in $\mathbb{R}^n$. Theorem 3.3 implies Corollary 3.5 which computes the capacity $c_{SH}$ of a convex body from loop space homology. Finally, Theorem 1.3 follows from Corollary 3.5 and elementary geometric arguments on loop spaces, which will be discussed in Section 3.3.

1.3. Plan of this paper. In Section 2 we review basics of symplectic homology theory. In particular we recall the definition of the capacity $c_{SH}$ and its properties. The content of Section 3 is explained in the last paragraph of the previous subsection. In Section 4 we prove Theorem 1.4 which gives an isomorphism between the filtered Floer homology of a Hamiltonian on $T^*\mathbb{R}^n$ and the filtered Morse homology of its Legendre dual. The proof follows [13], which is based on the method of Abbondandolo-Schwarz [2]. In Section 5 we derive Theorem 1.3 from Theorem 1.4 by a limiting argument.

Acknowledgement. The author thanks Felix Schlenk [15] for pointing out an application discussed in Section 2.4, and his comments on an earlier version of this paper. The author also thanks Alberto Abbondandolo and Jungsoo Kang for sharing their manuscript [11] and having discussions about relations between their approach and the author’s. This research is supported by JSPS KAKENHI Grant No.18K13407.

2. Symplectic homology and capacity

For any $h \in C^\infty(T^*\mathbb{R}^n)$, its Hamiltonian vector field $X_h \in \mathfrak{X}(T^*\mathbb{R}^n)$ is defined by $\omega_n(X_h, \cdot) = -dh(\cdot)$. Let $S^1 := \mathbb{R}/\mathbb{Z}$. For any $H \in C^\infty(S^1 \times T^*\mathbb{R}^n)$ and $t \in S^1$, we define
$H_t \in C^\infty(T^*\mathbb{R}^n)$ by $H_t(q, p) := H(t, q, p)$. Let
\[ \mathcal{P}(H) := \{ \gamma : S^1 \to T^*\mathbb{R}^n \mid \gamma(t) = X_{H_t}(\gamma(t)) \ (\forall t \in S^1) \}. \]

$\gamma \in \mathcal{P}(H)$ is called nondegenerate if 1 is not an eigenvalue of the linearized return map of $\gamma$ which acts on $T_{\gamma(0)}(T^*\mathbb{R}^n)$.

2.1. **Filtered Floer homology.** For any $H \in C^\infty(S^1 \times T^*\mathbb{R}^n)$ we consider the following conditions:

(H0): Every $\gamma \in \mathcal{P}(H)$ is nondegenerate.

(H1): There exist $a \in \mathbb{R}_{>0} \setminus \pi\mathbb{Z}$ and $b \in \mathbb{R}$ such that the function
\[ H(t, q, p) - a(|q|^2 + |p|^2) - b \]
on $S^1 \times T^*\mathbb{R}^n$ is compactly supported.

In the following we assume that $H \in C^\infty(S^1 \times T^*\mathbb{R}^n)$ satisfies (H0) and (H1). Note that (H1) implies that all elements of $\mathcal{P}(H)$ are contained in a compact subset of $T^*\mathbb{R}^n$, and then (H0) implies that $\mathcal{P}(H)$ is a finite set.

For any real numbers $a < b$ and $k \in \mathbb{Z}$, let $\text{CF}_{k}^{[a, b]}(H)$ denote the $\mathbb{Z}/2$-vector space spanned by
\[ \{ \gamma \in \mathcal{P}(H) \mid \mathcal{A}_H(\gamma) \in [a, b], \text{ind}_{CZ}(\gamma) = k \}. \]

Here, ind\textsubscript{CZ} denotes the Conley-Zehnder index (see Section 1.3 in [6]) and $\mathcal{A}_H$ is defined by
\[ \mathcal{A}_H(\gamma) := \int_{S^1} \gamma^* \left( \sum_i p_i dq_i \right) - H_t(\gamma(t)) \, dt. \]

To define a boundary operator on $\text{CF}_{k}^{[a, b]}(H)$, we take $J = (J_t)_{t \in S^1}$, which is a $C^\infty$-family of almost complex structures on $T^*\mathbb{R}^n$ with the following condition:

(J1): For every $t \in S^1$, $J_t$ is compatible with respect to $\omega_n$. Namely, $g_{J_t}(v, w) := \omega_n(v, J_t w)$ is a Riemannian metric on $T^*\mathbb{R}^n$.

For any $J$ satisfying (J1) and $x_-, x_+ \in \mathcal{P}(H)$, we define
\[ \mathcal{M}_{H,J}(x_-, x_+) := \{ u : \mathbb{R} \times S^1 \to T^*\mathbb{R}^n \mid \partial_s u - J_t(\partial_t u - X_{H_t}(u)) = 0, \lim_{s \to \pm \infty} u_s = x_\pm \}. \]

Here $s$ denotes the coordinate on $\mathbb{R}$ and $t$ denotes the coordinate on $S^1$, and $u_s : S^1 \to T^*\mathbb{R}^n$ is defined by $u_s(t) := u(s, t)$. We set $\mathcal{M}_{H,J}(x_-, x_+) := \mathcal{M}_{H,J}(x_-, x_+) / \mathbb{R}$, where the $\mathbb{R}$ action on $\mathcal{M}_{H,J}(x_-, x_+)$ is defined by
\[ (r \cdot u)(s, t) := u(s - r, t) \quad (u \in \mathcal{M}_{H,J}(x_-, x_+), r \in \mathbb{R}). \]

Let us define the standard complex structure on $T^*\mathbb{R}^n$, which is denoted by $J_{\text{std}}$, by
\[ J_{\text{std}}(\partial_p) = \partial_q, \quad J_{\text{std}}(\partial_q) = -\partial_p \quad (1 \leq i \leq n). \]

Now let us state the relevant $C^0$-estimate.
Lemma 2.1. Suppose $H$ satisfies (H0) and (H1), $J$ satisfies (J1), and \[ \sup_{t \in S^1} \| J_t - J_{\text{std}} \|_{C^0} \] is sufficiently small. Then \[ \sup_{x_-, x_+ \in P(H), \ t \in \mathcal{H}, \ (s,t) \in \mathbb{R} \times S^1} |u(s,t)| < \infty. \]

Proof. This lemma follows from Lemma 2.3 in [13]; note that conditions (H0), (J1) in [13] are the same as (H0), (J1) in this paper, and the condition (H1) in [13] is weaker than (H1) in this paper. \[ \square \]

For a generic (with respect to the $C^\infty$-topology) choice of $J$, the moduli space $\mathcal{M}_{H,J}(x_-, x_+)$ is a finite set for every $(x_-, x_+)$ with $\text{ind}_{\text{CZ}}(x_-) - \text{ind}_{\text{CZ}}(x_+) = 1$, and \[ \partial_{H,J} : \text{CF}^{[a,b]}(H) \to \text{CF}^{[a,b]}_{s-1}(H); \quad x_- \mapsto \sum_{\text{ind}_{\text{CZ}}(x_+) = \text{ind}_{\text{CZ}}(x_-) - 1} \#_{2} \mathcal{M}_{H,J}(x_-, x_+) \cdot x_+ \] satisfies $\partial^2_{H,J} = 0$, where $\#_{2}$ denotes the cardinality modulo 2. The homology of the chain complex $(\text{CF}^{[a,b]}(H), \partial_{H,J})$ does not depend on the choice of $J$. This homology is denoted by $\text{HF}^{[a,b]}(H)$ and called filtered Floer homology of $H$.

Suppose that $H^-, H^+ \in C^\infty(S^1 \times T^*\mathbb{R}^n)$ satisfy (H0), (H1) and \[ (1) \quad H^-(t,q,p) < H^+(t,q,p) \quad (\forall t,q,p \in S^1 \times T^*\mathbb{R}^n). \] Then, for any real numbers $a < b$ one can define a linear map (called monotonicity map) \[ \text{HF}^{[a,b]}(H^-) \to \text{HF}^{[a,b]}(H^+) \] as follows. Firstly, we take $J^- = (J^-_t)_{t \in S^1}$ and $J^+ = (J^+_t)_{t \in S^1}$ such that $J^-$ defines a boundary map on $\text{CF}^s(H^-)$ and $J^+$ defines a boundary map on $\text{CF}^s(H^+)$. Nextly, we take a $C^\infty$-family of Hamiltonians $H = (H_{s,t})_{(s,t) \in \mathbb{R} \times S^1}$ and a $C^\infty$-family of almost complex structures $J = (J_{s,t})_{(s,t) \in \mathbb{R} \times S^1}$ such that the following conditions hold:

(HH1): There exists $s_0 > 0$ such that $H_{s,t} = \begin{cases} H_{s_0,t} & (s \geq s_0) \\ H_{-s_0,t} & (s \leq -s_0). \end{cases}$

(HH2): $\partial_{s,t} H_{s,t}(q,p) \geq 0$ for any $(s,t,q,p) \in \mathbb{R} \times S^1 \times T^*\mathbb{R}^n$.

(HH3): There exist $a(s), b(s) \in C^\infty(\mathbb{R})$ such that the following conditions hold:

- $a'(s) \geq 0$ for any $s$.
- $a(s) \in \pi \mathbb{Z} \implies a'(s) > 0$.
- Setting $\Delta_{s,t}(q,p) := H(s,t,q,p) - a(s)\|q\|^2 + |p|^2 - b(s)$, there holds \[ \sup_{(s,t)} \| \Delta_{s,t} \|_{C^1(T^*\mathbb{R}^n)} < \infty, \quad \sup_{(s,t)} \| \partial_s \Delta_{s,t} \|_{C^0(T^*\mathbb{R}^n)} < \infty. \]

(JJ1): There exists $s_1 > 0$ such that $J_{s,t} = \begin{cases} J_{s_1,t} & (s \geq s_1) \\ J_{-s_1,t} & (s \leq -s_1). \end{cases}$

(JJ2): For every $(s,t) \in \mathbb{R} \times S^1$, $J_{s,t}$ is compatible with $\omega_n$.

Remark 2.2. It is easy to check that, for any $H^-$ and $H^+$ satisfying (H0), (H1) and (H), there exists $H = (H_{s,t})_{(s,t) \in \mathbb{R} \times S^1}$ satisfying (HH1), (HH2) and (HH3); see page 517 in [13]. The existence of $J = (J_{s,t})_{(s,t) \in \mathbb{R} \times S^1}$ satisfying (JJ1) and (JJ2) is straightforward from the fact that the set of almost complex structures compatible with $\omega_n$ is contractible.
For any $x_- \in \mathcal{P}(H^-)$ and $x_+ \in \mathcal{P}(H^+)$, let
$$\mathcal{M}_{H,J}(x_-, x_+) := \{ u : \mathbb{R} \times S^1 \to T^*\mathbb{R}^n \mid \partial_s u - J_{s,t}(\partial_t u - X_{H_{s,t}}(u)) = 0, \lim_{s \to \pm \infty} u_s = x_\pm \}.$$  

The next $C^0$-estimate is a consequence of Lemma 2.4 in [13].

**Lemma 2.3.** Suppose that $H$ satisfies (HH1), (HH2) and (HH3). If $J$ satisfies (JJ1), (JJ2) and $\sup_{(s,t) \in \mathbb{R} \times S^1} \| J_{s,t} - J_{\text{std}} \|_{C^0}$ is sufficiently small, then
$$\sup_{x_- \in \mathcal{P}(H^-), x_+ \in \mathcal{P}(H^+)} \left\{ u \mid \partial_s u - J_{s,t}(\partial_t u - X_{H_{s,t}}(u)) = 0, \lim_{s \to \pm \infty} u_s = x_\pm \right\} < \infty.$$  

For a generic choice of $(H, J)$ which satisfies the assumptions in Lemma 2.3, $\mathcal{M}_{H,J}(x_-, x_+)$ is a finite set for any $x_- \in \mathcal{P}(H_-), x_+ \in \mathcal{P}(H_+)$ satisfying $\text{ind}_{CZ}(x_-) - \text{ind}_{CZ}(x_+) = 0$, and
$$\Phi : \text{CF}_{\ast}^{(a,b)}(H^-) \to \text{CF}_{\ast}^{(a,b)}(H^+); x_- \mapsto \sum_{\text{ind}_{CZ}(x_+) = \text{ind}_{CZ}(x_-)} \sum_{\text{ind}_{CZ}(x_+) = \text{ind}_{CZ}(x_-)} \# 2 \cdot \mathcal{M}_{H,J}(x_-, x_+) \cdot x_+$$
is a chain map, namely $\partial_{H^+,J^+} \circ \Phi = \Phi \circ \partial_{H^-,J^-}$. The induced map on homology
$$H_\ast(\Phi) : \text{HF}_{\ast}^{(a,b)}(H^-) \to \text{HF}_{\ast}^{(a,b)}(H^+)$$
does not depend on the choice of $(H, J)$; this completes the definition of the monotonicity map.

For any $H^0, H^1, H^2 \in C^\infty(S^1 \times T^*\mathbb{R}^n)$ satisfying (H0), (H1) and
$$H^0(t, q, p) < H^1(t, q, p) < H^2(t, q, p) \quad (\forall (t, q, p) \in S^1 \times T^*\mathbb{R}^n),$$
the diagram
$$\begin{array}{ccc}
\text{HF}_{\ast}^{(a,b)}(H^0) & \rightarrow & \text{HF}_{\ast}^{(a,b)}(H^2) \\
\downarrow & & \downarrow \\
\text{HF}_{\ast}^{(a,b)}(H^1) & \rightarrow & \text{HF}_{\ast}^{(a,b)}(H^1)
\end{array}$$
commutes (all three maps are monotonicity maps).

### 2.2. Symplectic homology

For any nonempty compact set $K$ in $T^*\mathbb{R}^n$, let $\mathcal{H}_K$ denote the set of $H \in C^\infty(S^1 \times T^*\mathbb{R}^n)$ which satisfies (H0), (H1) and $H(t, q, p) < 0$ for any $(t, q, p) \in S^1 \times K$. Then $\mathcal{H}_K$ becomes a directed set by setting $H^0 < H^1$ if and only if $H^0(t, q, p) < H^1(t, q, p)$ for any $(t, q, p) \in S^1 \times T^*\mathbb{R}^n$. For any real numbers $a < b$, we set
$$\text{SH}_{\ast}^{(a,b)}(K) := \lim_{H \in \mathcal{H}_K} \text{HF}_{\ast}^{(a,b)}(H),$$
where the limit is taken by monotonicity maps.

There are two natural maps in symplectic homology. Firstly, for any $a, b, a', b' \in \mathbb{R}$ such that $a < b$, $a' < b'$, $a \leq a'$ and $b \leq b'$, one can define $\text{SH}_{\ast}^{(a,b)}(K) \to \text{SH}_{\ast}^{(a',b')} (K)$. Secondly, for any compact sets $K_1 \subset K_2$ one can define
$$\text{SH}_{\ast}^{(a,b)}(K_2) \to \text{SH}_{\ast}^{(a,b)}(K_1),$$
2.3. **Symplectic homology capacity of sets of restricted contact type.** Recall from the introduction that \( K \subset T^*\mathbb{R}^n \) is of restricted contact type if \( K \) is compact, connected, \( \text{int } K \neq \emptyset \), \( \partial K \) is \( C^\infty \) and there exists \( X \in \mathcal{X}(T^*\mathbb{R}^n) \) such that \( L_X \omega_n = \omega_n \) and \( X \) points strictly outwards at every point on \( \partial K \). Let us first prove Lemma 1.1 which is stated in the introduction.

**Proof of Lemma 1.1.** Since \( K \) is of restricted contact type, there exists \( X \in \mathcal{X}(T^*\mathbb{R}^n) \) which satisfies \( L_X \omega_n = \omega_n \) and points strictly outwards on \( \partial K \). Let us define \( \lambda \in \Omega^1(T^*\mathbb{R}^n) \) by \( \lambda := i_X \omega_n \). Then \( \lambda \) is a contact form on \( \partial K \), and when \( R_\lambda \) denotes its Reeb vector field (i.e. \( i_{R_\lambda}(d\lambda) = 0 \) and \( \lambda(R_\lambda) \equiv 1 \)), \( \mathcal{P}(\partial K) \) is the set of simple closed orbits of \( R_\lambda \). Moreover, for every \( \gamma \in \mathcal{P}(\partial K) \), \( \mathcal{A}(\gamma) \) is equal to the period of \( \gamma \) as an orbit of \( R_\lambda \). Then \( \inf_{\gamma \in \mathcal{P}(\partial K)} \mathcal{A}(\gamma) \) is positive, since \( \partial K \) is compact and \( R_\lambda \) is nonzero at every point on \( \partial K \). To show that there exists a closed orbit which attains the infimum, let \( (\gamma_j)_{j \geq 1} \) be a sequence in \( \mathcal{P}(\partial K) \) such that \( \mathcal{A}(\gamma_j) \) converges to the infimum as \( j \to \infty \). Let us take \( p_j \) on \( \gamma_j \) for each \( j \), and \( p \) be the limit of a certain subsequence of \( (p_j)_j \). Then the orbit \( \gamma_0 \) which passes through \( p \) is closed, and \( \mathcal{A}(\gamma_0) \) is equal to the infimum. 

Recall that \( \min_{\gamma \in \mathcal{P}(\partial K)} \mathcal{A}(\gamma) \) is denoted by \( c_{\text{min}}(K) \).

**Lemma 2.4.** One can assign an isomorphism \( \text{SH}^*_{\{0,\varepsilon\}}(K) \cong H_{*+n}(K, \partial K) \) for every \( \varepsilon \in (0, c_{\text{min}}(K)) \) so that the diagrams

\[
\begin{array}{ccc}
H_{*+n}(K, \partial K) & \cong & \text{SH}^*_{\{0,\varepsilon\}}(K) \\
& \cong & \text{SH}^*_{\{0,\varepsilon'\}}(K)
\end{array}
\begin{array}{ccc}
\text{SH}^*_{\{0,\varepsilon\}}(K') & \longrightarrow & \text{SH}^*_{\{0,\varepsilon\}}(K) \\
& \cong & \text{SH}^*_{\{0,\varepsilon'\}}(K) \\
H_{*+n}(K', \partial K') & \longrightarrow & H_{*+n}(K, \partial K)
\end{array}
\]

are commutative when \( 0 < \varepsilon \leq \varepsilon' < c_{\text{min}}(K) \) (in the left diagram) and \( 0 < \varepsilon < \min\{c_{\text{min}}(K), c_{\text{min}}(K')\} \) (in the right diagram).

**Proof.** The isomorphism \( \text{SH}^*_{\{0,\varepsilon\}}(K) \cong H_{*+n}(K, \partial K) \) follows form the third bullet in Proposition 4.7 of [11]. The commutativity of the diagrams follows from the construction of the isomorphism.

Let us recall the definition of \( c_{\text{SH}} \) from the introduction. Lemma 2.4 implies \( \lim_{\varepsilon \to 0} \text{SH}^*_{\{0,\varepsilon\}}(K) \cong H_{*+n}(K, \partial K) \). For any \( a \in \mathbb{R}_{>0} \) we define

\[
(2) \quad i_K^a : H_{*+n}(K, \partial K) \cong \lim_{\varepsilon \to 0} \text{SH}^*_{\{0,\varepsilon\}}(K) \to \text{SH}^*_{\{0,a\}}(K).
\]

Then we define

\[
c_{\text{SH}}(K) := \inf\{a \mid i_K^a([K, \partial K]) = 0\}.
\]

The next lemma summarizes some properties of the invariant \( c_{\text{SH}} \).

**Lemma 2.5.** Let \( K \) and \( K' \) be sets of restricted contact type in \( T^*\mathbb{R}^n \).
Lemma 2.6. The following lemma for later purposes.

- For any compact star-shaped domain (10) Conjecture 1.9. They conjectured that their capacities are equal to the Ekeland-Hofer capacities and gave combinatorial formulas to compute these capacities of convex and concave toric homology with rational coefficients, established basic properties of these capacities, and finally we need the following lemma for later purposes.

Lemma 2.6. For any convex body $K$ in $T^*\mathbb{R}^n$ and $\epsilon \in (0, c_{EHZ}(K))$, there exists a canonical isomorphism $SH_*^{[0,\epsilon]}(K) \cong H_{s+n}(K, \partial K)$.

Proof. For any neighborhood $N$ of $K$, there exists a convex body $K'$ with $C^\infty$-boundary satisfying $K \subset K' \subset N$. Hence the natural map $\lim_{K \to K'} SH_*^{[0,\epsilon]}(K') \to SH_*^{[0,\epsilon]}(K)$, where $K'$ on the left hand side runs over all convex bodies with $C^\infty$ boundaries containing $K$, is an isomorphism. Then this lemma follows from Lemma 2.4 and the $C^0$-continuity of the Ekeland-Hofer-Zehnder capacity.

2.4. Capacities from equivariant symplectic homology. For any restricted contact type domain $K$ in $T^*\mathbb{R}^n$ (in general, for any Liouville domain) and $a \in \mathbb{R}_{>0}$, one can define the $S^1$-equivariant symplectic homology $SH_*^{[0,a],S^1}(K)$ equipped with a linear map

$$((i^a_K)^{S^1}) : H_{s+n}^{S^1}(K, \partial K) \to SH_*^{[0,a],S^1}(K),$$

where $H_*^{S^1}(K, \partial K)$ is the $S^1$-equivariant homology with the trivial $S^1$-action on $(K, \partial K)$, thus canonically isomorphic to $H_*(K, \partial K) \otimes H_*(\mathbb{C}P^n)$. We assume that all homologies are defined over $\mathbb{Z}/2$-coefficients.

For each positive integer $k$, one can define

$$c_{SH}^{k,S^1}(K) := \inf \{ a \mid (i^a_K)^{S^1}([K, \partial K] \otimes [\mathbb{C}P^{2(k-1)}]) = 0 \}.$$

Let us call the invariants $c_{SH}^{k,S^1}(k \geq 1)$ equivariant symplectic homology capacities.

Remark 2.7. This construction goes back at least to Section 5.3 in Viterbo [17], where the Floer-theoretic analogue of the Ekeland-Hofer capacities was introduced. This construction is revisited in recent papers such as Gutt-Hutchings [10] and Ginzburg-Shon [9]. In particular, [10] introduced a sequence of capacities using positive equivariant symplectic homology with rational coefficients, established basic properties of these capacities, and gave combinatorial formulas to compute these capacities of convex and concave toric domains. They conjectured that their capacities are equal to the Ekeland-Hofer capacities for any compact star-shaped domain (10) Conjecture 1.9.
One has the following inequalities:

\[ c_{\min}(K) \leq c_{\text{SH}s^1}(K) \leq c_{\text{SH}}(K). \]

For the first inequality, see the “contractible Reeb orbits” property in Theorem 1.24 in [10]. For the second inequality, see Lemma 3.2 in [9].

**Remark 2.8.** One has to be careful since [10] and [9] use rational coefficients, while we work over \( \mathbb{Z} \/ 2\)-coefficients. Also, the definitions in these papers use positive (equivariant) symplectic homology, and are superficially different from the definition in this subsection. However, it is straightforward to see that the proofs in these papers also work in our setting.

For each positive integer \( k \), the capacity \( c_{\text{SH}s^1}^k \) satisfies conformality and monotonicity (see [10]), thus extends to all convex bodies. Combined with the above inequalities, Theorem 1.3 implies the following corollary:

**Corollary 2.9.** \( c_{\text{EHZ}}(K) = c_{\text{SH}s^1}(K) = c_{\text{SH}}(K) \) for any convex body \( K \) in \( T^*\mathbb{R}^n \).

### 3. Symplectic homology and loop space homology

Throughout this section, \( K \) denotes a convex body in \( T^*\mathbb{R}^n \) (\( \partial K \) may not be \( C^\infty \)). In Section 3.1, we state a formula (Theorem 3.3) which relates the symplectic homology of \( K \) to a certain relative homology of loop spaces of \( \mathbb{R}^n \). In Section 3.2, we derive a formula which computes \( c_{\text{SH}}(K) \). In Section 3.3, we prove Theorem 1.3.

#### 3.1. Symplectic homology and loop space homology

Let \( \text{pr} : T^*\mathbb{R}^n \rightarrow \mathbb{R}^n \) denote the natural projection map, namely \( \text{pr}(q,p) := q \). For any \( q \in \mathbb{R}^n \), we set \( K_q := K \cap T_q^*\mathbb{R}^n \).

Let \( \Lambda \) denote the space of \( L^{1,2} \)-maps from \( S^1 = \mathbb{R} / \mathbb{Z} \) to \( \mathbb{R}^n \), equipped with the \( L^{1,2} \)-topology. For each \( \gamma \in \Lambda \), we define \( \text{len}_K(\gamma) \) by:

\[
\text{len}_K(\gamma) := \begin{cases} 
\int_{S^1} \left( \max_{p \in K_q^{-1}(t)} p \cdot \dot{\gamma}(t) \right) dt & (\gamma(S^1) \subset \text{pr}(K)) \\
\leq -\infty & (\gamma(S^1) \not\subset \text{pr}(K)).
\end{cases}
\]

**Example 3.1.** If \( K \) is the unit disk cotangent bundle of \( \text{pr}(K) \), namely \( K = \{ (q,p) | q \in \text{pr}(K), |p| \leq 1 \} \), then \( \text{len}_K(\gamma) = \int_{S^1} |\dot{\gamma}(t)| dt \) for any \( \gamma \) satisfying \( \gamma(S^1) \subset \text{pr}(K) \).

Let us summarize elementary properties of \( \text{len}_K \).

**Lemma 3.2.**

(i): \( \text{len}_K \) is well-defined. Namely, for any \( \gamma \in \Lambda \) with \( \gamma(S^1) \subset \text{pr}(K) \), the function \( S^1 \rightarrow \mathbb{R}; t \mapsto \max_{p \in K_q^{-1}(t)} p \cdot \dot{\gamma}(t) \) is measurable.

(ii): Let \( (\gamma_k)_k \) be a sequence in \( \Lambda \) which converges to \( \gamma \in \Lambda \) in the \( L^{1,2} \)-topology, and \( \gamma_k(S^1) \subset \text{pr}(K) \) for every \( k \). Then \( \lim_{k \rightarrow \infty} \text{len}_K(\gamma_k) = \text{len}_K(\gamma) \).

(iii): \( \text{len}_K \) is upper semi-continuous. Namely, for any sequence \( (\gamma_k)_k \) in \( \Lambda \) which has a limit \( \gamma = \lim_{k \rightarrow \infty} \gamma_k \), there holds \( \text{len}_K(\gamma) \geq \limsup_k \text{len}_K(\gamma_k) \).
(iv): Suppose that \( \partial K \) is \( C^\infty \) and strictly convex. Let \( \gamma : S^1 \to \text{int}(\text{pr}(K)) \) be a \( C^\infty \)-map such that \( \dot{\gamma}(t) \neq 0 \) for every \( t \in S^1 \). Then, for each \( t \in S^1 \) there exists a unique point \( p_\gamma(t) \in K_{\gamma(t)} \) such that
\[
p_\gamma(t) \cdot \dot{\gamma}(t) = \max_{p \in K_{\gamma(t)}} p \cdot \dot{\gamma}(t).
\]
Moreover, \( \bar{\gamma} : S^1 \to \partial K \) defined by \( \bar{\gamma}(t) := (\gamma(t), p_\gamma(t)) \) is \( C^\infty \), and there holds
\[
\text{len}_K(\gamma) = \int_{S^1} \bar{\gamma}^*(\sum_{i=1}^n p_i dq_i).
\]

(v): If convex bodies \( K \) and \( K' \) satisfy \( K \subset K' \), then \( \text{len}_K(\gamma) \leq \text{len}_{K'}(\gamma) \) for any \( \gamma \in \Lambda \).

**Proof.**

(i): Let us define \( c : \text{pr}(K) \times \mathbb{R}^n \to \mathbb{R} \) by \( c(q,v) := \max_{p \in K_q} p \cdot v \). Using the convexity of \( K \), it is easy to check that \( c \) is continuous. This implies that \( c(\gamma(t), \dot{\gamma}(t)) \) is a measurable function on \( S^1 \). Moreover, there exists a positive constant \( R \) such that \( |c(q,v)| \leq R|v| \). Since \( |\dot{\gamma}(t)| \) is integrable this shows that \( c(\gamma(t), \dot{\gamma}(t)) \) is integrable.

(ii): Suppose that this is not the case. Then there exists a sequence \( (\gamma_k)_k \) which converges to \( \gamma \) in the \( L^{1,2} \)-topology, and inf \( k |\text{len}_K(\gamma_k) - \text{len}_K(\gamma)| > 0 \). By replacing \( (\gamma_k)_k \) with its subsequence if necessary, we may assume \( \lim_{k \to \infty} \gamma_k(t) = \gamma(t) \) for almost every \( t \in S^1 \). On the other hand \( \lim_{k \to \infty} \gamma_k(t) = \gamma(t) \) for every \( t \). Thus \( \lim_{k \to \infty} c(\gamma_k(t), \dot{\gamma_k}(t)) = c(\gamma(t), \dot{\gamma}(t)) \) for almost every \( t \), which implies \( \lim_{k \to \infty} \text{len}_K(\gamma_k) = \text{len}_K(\gamma) \), contradicting our assumption.

(iii): If \( \gamma_k(S^1) \subset \text{pr}(K) \) for infinitely many \( k \), then this is immediate from (ii). If \( \gamma_k(S^1) \subset \text{pr}(K) \) only for finitely many \( k \), then \( \limsup_k \text{len}_K(\gamma_k) = -\infty \), which completes the proof.

(iv): Since \( \partial K \) is \( C^\infty \) and strictly convex, \( \partial K_q \) is \( C^\infty \) and strictly convex for any \( q \in \text{int} \text{pr}(K) \). Then, for any \( t \in S^1 \), there exists unique \( p_\gamma(t) \) which satisfies the required condition, and \( \bar{\gamma} \) is \( C^\infty \) by the inverse function theorem. The last assertion follows from \( \bar{\gamma}^*(\sum_i p_i dq_i) = p_\gamma(t) \cdot \partial_\gamma(t) \ dt \), which is straightforward.

(v): This follows from \( \text{pr}(K) \subset \text{pr}(K') \) and
\[
\max_{p \in K_q} p \cdot v = \max_{p \in K'_q} p \cdot v \quad (q \in \text{pr}(K), v \in \mathbb{R}^n).
\]

For any \( a \in \mathbb{R} \), let \( \Lambda^a_K := \{ \gamma \in \Lambda \mid \text{len}_K(\gamma) < a \} \). By Lemma 3.2 (iii), this is an open set in \( \Lambda \). Moreover, Lemma 3.2 (v) shows that if \( K \subset K' \) then \( \Lambda^a_{K'} \subset \Lambda^a_K \). The next result relates the symplectic homology of a convex body in \( T^*\mathbb{R}^n \) to a certain relative homology of loop spaces of \( \mathbb{R}^n \).

**Theorem 3.3.** For any convex body \( K \) in \( T^*\mathbb{R}^n \) and any real numbers \( a < b \), one can assign an isomorphism
\[
\text{SH}^{[a,b]}_s(K) \cong H_s(\Lambda^b_K, \Lambda^a_K)
\]
so that the following diagrams commute:

\[
\begin{array}{c}
SH_*^{[a,b)}(K) \xrightarrow{\cong} H_\ast(\Lambda_k^b, \Lambda_k^a) \\
\downarrow \\
SH_*^{[a',b')} (K) \xrightarrow{\cong} H_\ast(\Lambda_k^{b'}, \Lambda_k^{a'})
\end{array}
\]

(4)

\[
\begin{array}{c}
SH_*^{[a,b)} (K') \xrightarrow{\cong} H_\ast(\Lambda_{k'}^{b}, \Lambda_{k'}^{a}) \\
\downarrow \\
SH_*^{[a,b)} (K) \xrightarrow{\cong} H_\ast(\Lambda_k^{b}, \Lambda_k^{a})
\end{array}
\]

(5)

Here \(a, b, a', b'\) are real numbers satisfying \(a < b, a' < b', a \leq a', b \leq b'\), and \(K, K'\) are convex bodies satisfying \(K \subset K'\). In both diagrams, right vertical maps are induced by inclusions of loop spaces.

3.2. Symplectic homology capacity and loop space homology. In this subsection, we derive a formula (Corollary 3.5) which computes \(c_{SH}(K)\) by loop space homology. Let us recall that \(c_{SH}(K) := \inf \{a \mid i^a_K([K, \partial K]) = 0\}\), where \(i^a_K\) is defined in (2).

For any \(a \in \mathbb{R}_{>0}\), let us define a map

\[j^a_K : (\mathbb{R}^n, \mathbb{R}^n \setminus \text{pr}(K)) \to (\Lambda_k^a, \Lambda_k^0)\]

which maps each \(q \in \mathbb{R}^n\) to the constant loop at \(q\). Let \(\nu_K\) denote the generator of \(H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \text{pr}(K)) \cong \mathbb{Z}/2\).

**Lemma 3.4.** \(i^a_K([K, \partial K]) \in SH_*^{[0,a)}(K)\) corresponds to \((j^a_K)_\ast(\nu_K) \in H_\ast(\Lambda_k^a, \Lambda_k^0)\) via the isomorphism \(SH_*^{[0,a)}(K) \cong H_\ast(\Lambda_k^a, \Lambda_k^0)\).

**Proof.** For any \(R \in \mathbb{R}_{>0}\) let \(K_R := \{(q, p) \in T^*\mathbb{R}^n \mid |q|, |p| \leq R\}\). First notice that it is sufficient to prove the lemma for \(K = K_R\) for every \(R\). Indeed, for any convex body \(K\) in \(T^*\mathbb{R}^n\) there exists \(R\) such that \(K \subset K_R\), and consider the commutative diagram:

\[
\begin{array}{c}
SH_*^{[0,a)}(K_R) \xrightarrow{\cong} SH_*^{[0,a)}(K) \\
\text{and} \\
H_\ast(\Lambda_k^a, \Lambda_k^0) \xrightarrow{\cong} H_\ast(\Lambda_k^a, \Lambda_k^0).
\end{array}
\]

Then the upper horizontal map sends \(i^a_{K_R}([K_R, \partial K_R])\) to \(i^a_K([K, \partial K])\). Assuming that we have proved the lemma for \(K_R\), the left vertical map sends \(i^a_{K_R}([K_R, \partial K_R])\) to \((j^a_{K_R})_\ast(\nu_K)\), which is sent to \((j^a_K)_\ast(\nu_K)\) by the lower horizontal map. By the commutativity of the diagram, the right vertical map sends \(i^a_{K_R}([K, \partial K])\) to \((j^a_K)_\ast(\nu_K)\), which completes the proof. Thus it is sufficient to consider the case \(K = K_R\). Also, it is sufficient to consider
the case when $a$ is sufficiently small, since for any $a < b$ we have a commutative digram

$$
\begin{align*}
\text{SH}^{[0,a)}(K_R) & \xrightarrow{\cong} \text{SH}^{[0,b)}(K_R) \\
\cong & \quad \cong \\
H_*(\Lambda^a_{K_R}, \Lambda^0_{K_R}) & \rightarrow H_*(\Lambda^b_{K_R}, \Lambda^0_{K_R}).
\end{align*}
$$

Moreover, it is sufficient to prove that $(j^a_K)_*(\nu_K) \neq 0$ when $a$ is sufficiently small. Indeed, when $a$ is sufficiently small Lemma 2.6 implies that $\text{SH}^{[0,a)}_n(K) \cong H_n(\Lambda^a_K, \Lambda^0_K)$ are isomorphic to $\mathbb{Z}/2$, thus $i^*_n([K, \partial K])$ corresponds to a unique nonzero element in $H_n(\Lambda^a_K, \Lambda^0_K)$, that is $(j^a_K)_*(\nu_K)$.

The following argument is essentially the same as the proof of Lemma 6.6 in [13], which we repeat here for the sake of completeness. For any $\gamma \in \Lambda$ let $\text{len}(\gamma) := \int_{S^1} |\dot{\gamma}(t)| \, dt$, and for any $a \in \mathbb{R}_{>0}$ let $U^a := \{ \gamma \in \Lambda \mid \text{len}(\gamma) < a/\mathbb{R} \}$. Also let $B_R := \{ q \in \mathbb{R}^n \mid |q| \leq R \}$ and $V_R := \{ \gamma \in \Lambda \mid \gamma(S^1) \not\subset B_R \}$. Then

$$
\Lambda^a_{K_R} = U^a \cup V_R, \quad \Lambda^0_{K_R} = V_R.
$$

Since both $U^a$ and $V_R$ are open sets in $\Lambda$, the inclusion map

$$
(U^a, U^a \cap V_R) \rightarrow (U^a \cup V_R, V_R) = (\Lambda^a_{K_R}, \Lambda^0_{K_R})
$$

induces an isomorphism on homology. Thus it is sufficient to show that

$$
c^a_R : (\mathbb{R}^n, \mathbb{R}^n \setminus B_R) \rightarrow (U^a, U^a \cap V_R)
$$

which sends each $q$ to the constant loop at $q$, induces an injection on homology if $a$ is sufficiently small.

Let us define $\text{ev} : \Lambda \rightarrow \mathbb{R}^n$ by $\text{ev}(\gamma) := \gamma(0)$. If $a$ is sufficiently small, then $\text{ev}$ maps $U^a \cap V_R$ to $\mathbb{R}^n \setminus \{0\}$, and we obtain a commutative diagram

$$
\begin{align*}
\text{id}_{\mathbb{R}^n} : (\mathbb{R}^n, \mathbb{R}^n \setminus B_R) & \rightarrow (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \\
\text{ev} & \rightarrow (U^a, U^a \cap V_R)
\end{align*}
$$

The diagonal map induces an isomorphism on homology, thus $H_*(c^a_R)$ is injective. This completes the proof.

As an immediate corollary of Lemma 3.4 we obtain the following formula which computes symplectic homology capacity from loop space homology:

**Corollary 3.5.** $c_{\text{SH}}(K) = \inf \{ a \mid (j^a_K)_*(\nu_K) = 0 \}$.

### 3.3. Proof of Theorem 1.3

The goal of this subsection is to prove Theorem 1.3, namely $c_{\text{SH}}(K) = c_{\text{EHZ}}(K)$ for any convex body $K$ in $T^*\mathbb{R}^n$. We may assume $n \geq 2$, since Theorem 1.3 is obvious when $n = 1$. We may assume that $\partial K$ is $C^\infty$ and strictly convex, since this condition can be achieved by a $C^0$-small perturbation of the boundary. We may also assume that there exists a $C^\infty$-map $\Gamma : S^1 \rightarrow \partial K$ satisfying the following conditions:
\begin{itemize}
\item $\hat{\Gamma}(t)$ generates $\ker(\omega|_{T_{\Gamma(t)}\partial K})$ and of positive direction for every $t \in S^1$,
\item $c_{EHZ}(K) = \int_{S^1} \Gamma^* \left( \sum_{i=1}^{n} p_i dq_i \right)$,
\item $\text{pr} \circ \Gamma(S^1) \subset \text{int} (\text{pr}(K))$.
\end{itemize}

This is because, when $n \geq 2$, this condition can be achieved by a $C^0$-small (actually, $C^\infty$-small) perturbation of the boundary.

Let $\gamma := \text{pr} \circ \Gamma : S^1 \to \text{int} (\text{pr}(K))$.

Lemma 3.6. $\dot{\gamma}(t) \neq 0$ for any $t \in S^1$.

\textbf{Proof.} Let $\nu$ be a vector which is normal to $T_{\Gamma(t)}(\partial K)$. Since $\hat{\Gamma}(t)$ is parallel to $J_{\text{std}}(\nu)$, it is sufficient to show that the $p$-component of $\nu$ is nonzero. If the $p$-component of $\nu$ is zero, then the convexity of $K$ implies $\gamma(t) \in \partial(\text{pr}(K))$, which contradicts the assumption $\gamma(S^1) \subset \text{int} (\text{pr}(K))$. \hfill \qed

Lemma 3.7. Let $(\gamma_s)_{-1 \leq s \leq 1}$ be a $C^\infty$-family of elements of $C^\infty(S^1, \text{int} (\text{pr}(K)))$ such that $\gamma_0 = \gamma$. Then $\frac{d}{ds} \left( \text{len}_K(\gamma_s) \right)_{s=0} = 0$.

\textbf{Proof.} We may assume that $\dot{\gamma}_s(t) \neq 0$ for every $(s, t) \in [-1, 1] \times S^1$. Let us define $\hat{\gamma}_s : S^1 \to \partial K$ as in Lemma 3.2 (iv). Then $\Gamma = \hat{\gamma}_0$ and $\text{len}_K(\gamma_s) = \int_{S^1} (\hat{\gamma}_s)^* \left( \sum_i p_i dq_i \right)$. Thus
\[
\frac{d}{ds} \left( \text{len}_K(\gamma_s) \right)_{s=0} = \frac{d}{ds} \left( \int_{S^1} (\hat{\gamma}_s)^* \left( \sum_i p_i dq_i \right) \right)_{s=0} = \int_{S^1} \omega_n(\hat{\Gamma}(t), (\partial_s \hat{\gamma}_s)_{s=0}(t)) dt = 0.
\] \hfill \qed

In the course of the proof we have seen that $\text{len}_K(\gamma) = \int_{S^1} \Gamma^* \left( \sum_i p_i dq_i \right) = c_{EHZ}(K)$.

For any $a \in \mathbb{R}_{\geq 0}$ and $x \in \mathbb{R}^n$, let us define $\gamma_{a,x} \in \Lambda$ by $\gamma_{a,x}(t) := a \gamma(t) + x$. Let
\[T := \{(a, x) \in \mathbb{R}_{\geq 0} \times \mathbb{R}^n \mid \gamma_{a,x}(S^1) \subset \text{pr}(K)\}.
\]
It is easy to see that $T$ is a compact convex subset of $\mathbb{R}_{\geq 0} \times \mathbb{R}^n$. Let us define a function $L : T \to \mathbb{R}$ by $L(a, x) := \text{len}_K(\gamma_{a,x})$. Lemma 3.2 (ii) shows that $L$ is continuous. Lemma 3.7 shows that $(1, 0, \ldots, 0)$ is a critical point of $L$.

Lemma 3.8. $L(a, x) \leq L(1, 0, \ldots, 0)$ for any $(a, x) \in T$.

\textbf{Proof.} By the continuity of $L$, it is sufficient to prove the lemma for $(a, x) \in \text{int} T$. For any $s \in [0, 1]$, let
\[\gamma_s := \gamma_{sa+(1-s)x}, \quad L_s := \text{len}_K(\gamma_s) := L(sa + (1-s), sx)\]
Our goal is to prove $L_1 \leq L_0$.

For any $s \in [0, 1]$, we have $(sa + (1-s), sx) \in \text{int} T$. This implies that $\gamma_s(S^1) \subset \text{int} (\text{pr}(K))$ and $sa + (1-s) > 0$, thus $\dot{\gamma}_s(t) = (sa + (1-s)) \dot{\gamma}(t) \neq 0$ for any $t \in S^1$. For
each $t \in S^1$, let us take $p_{\gamma_a}(t) \in \partial K_{\gamma_a(t)}$ as in Lemma 3.2 (iv) and abbreviate it by $p_s(t)$. Then there holds

$$p_s(t) \cdot \dot{\gamma}_s(t) = \max_{p \in K_{\gamma_a(t)}} p \cdot \dot{\gamma}_s(t)$$

and we obtain

$$L_s = \int_{S^1} \dot{\gamma}_s(t) \cdot p_s(t) \, dt.$$ 

By $(\gamma_0(t), p_0(t)), (\gamma_1(t), p_1(t)) \in K$ and the convexity of $K$,

$$(\gamma_s(t), (1 - s)p_0(t) + sp_1(t)) \in K.$$ 

Then (6) implies

$$p_s(t) \cdot \dot{\gamma}_s(t) \geq ((1 - s)p_0(t) + sp_1(t)) \cdot \dot{\gamma}_s(t).$$

On the other hand $\dot{\gamma}_s(t) = (sa + (1 - s))\dot{\gamma}(t)$, thus

$$L_s \geq \int_{S^1} (1 + (a - 1)s)\dot{\gamma}(t) \cdot (p_0(t) + (p_1(t) - p_0(t))s) \, dt$$

and the equality holds for $s = 0$. Hence

$$\partial_s L_s|_{s=0} \geq \int_{S^1} \dot{\gamma}(t) \cdot ((a - 2)p_0(t) + p_1(t)) \, dt.$$ 

On the other hand $\partial_s L_s|_{s=0} = 0$ by Lemma 3.7. Then we obtain

$$\int_{S^1} \dot{\gamma}(t) \cdot p_1(t) \, dt \leq (2 - a) \int_{S^1} \dot{\gamma}(t) \cdot p_0(t) \, dt.$$ 

Now we can finish the proof by

$$L_1 - L_0 = \int_{S^1} a^2 \dot{\gamma}(t) \cdot p_1(t) - \dot{\gamma}(t) \cdot p_0(t) \, dt \leq -(a - 1)^2 L_0 \leq 0.$$ 

The first inequality follows from $a \geq 0$, and the second inequality follows from $L_0 \geq 0$, which is obvious since $L_0 = \text{len}_K(\gamma) = c_{\text{EHZ}}(K)$. \hfill \qed

We have proved

$$\max_{(a, x) \in T} L(a, x) = L(1, 0, \ldots, 0) = \text{len}_K(\gamma) = c_{\text{EHZ}}(K).$$

On the other hand, if $(a, x) \notin T$, then $\text{len}_K(\gamma_{a,x}) = -\infty$. Thus for any $C > c_{\text{EHZ}}(K)$, one can define a map

$$l^C : (\mathbb{R}_{\geq 0} \times \mathbb{R}^n, \mathbb{R}_{\geq 0} \times \mathbb{R}^n \setminus T) \rightarrow (\Lambda^C_K, \Lambda^0_K); \quad (a, x) \mapsto \gamma_{a,x}.$$ 

Now consider the commutative diagram

$$\xymatrix{ H_*(\mathbb{R}^n, \mathbb{R}^n \setminus \text{pr}(K)) \ar[r]^{H_*(j^C_K)} \ar[d]^{H_*(\text{pr})} & H_*(\Lambda^C_K, \Lambda^0_K) \ar[d]^{H_*(l^C)} \ar[l]_{H_*(\text{pr})} \\
H_*(\mathbb{R}_{\geq 0} \times \mathbb{R}^n, \mathbb{R}_{\geq 0} \times \mathbb{R}^n \setminus T) & H_*(\text{pr}) \ar[l]_{H_*(\text{pr})} \ar[r]^{H_*(l^C)} & H_*(\Lambda^C_K, \Lambda^0_K) \ar[l]_{H_*(\text{pr})} \ar[u]^{H_*(\text{pr})} \ar[r]_{H_*(l^C)} & H_*(\Lambda^C_K, \Lambda^0_K) \ar[l]_{H_*(\text{pr})} \ar[u]^{H_*(\text{pr})} \ar[r]_{H_*(l^C)} & H_*(\Lambda^C_K, \Lambda^0_K) \ar[l]_{H_*(\text{pr})} \ar[u]^{H_*(\text{pr})} }$$

where the vertical map is induced by the map $q \mapsto (0, q)$. Since $T$ is bounded and $H_*(\mathbb{R}^n, \mathbb{R}^n \setminus \text{pr}(K))$ is generated by $\nu_K$, the vertical map is 0. Then $H_*(j^C_K) = 0$, which implies $c_{\text{SH}}(K) \leq C$. Since $C$ is any number larger than $c_{\text{EHZ}}(K)$, we obtain $c_{\text{SH}}(K) \leq c_{\text{EHZ}}(K)$. The inverse inequality $c_{\text{SH}}(K) \geq c_{\text{EHZ}}(K)$ follows from Proposition 2.5 (iii), thus this completes the proof of Theorem 1.3.
4. Floer homology and loop space homology

The goal of this section is Theorem 4.4, which relates the filtered Floer homology of a Hamiltonian on $T^*\mathbb{R}^n$ to a certain relative homology of loop spaces of $\mathbb{R}^n$.

4.1. Lagrangian action functional on the loop space. Consider the following conditions (L1), (L2) for $L \in C^\infty(S^1 \times T\mathbb{R}^n)$:

(L1): There exist $a \in \mathbb{R}_{>0}$ and $b \in \mathbb{R}$ such that the function on $S^1 \times T\mathbb{R}^n$

$$L(t, q, v) - \left(\frac{|v|^2}{4a} - a|q|^2 + b\right)$$

is compactly supported.

(L2): There exists $c \in \mathbb{R}_{>0}$ such that $\partial_v^2 L(t, q, v) \geq c$ for any $(t, q, v) \in S^1 \times T\mathbb{R}^n$.

Remark 4.1. $\partial_v^2 L(t, q, v) \geq c$ means that a symmetric matrix $(\partial_v \partial_{v_j} L(t, q, v) - c\delta_{ij})_{1 \leq i, j \leq n}$ is nonnegative, where $\delta_{ij} = \begin{cases} 1 & (i = j) \\ 0 & (i \neq j). \end{cases}$

If $L$ satisfies the condition (L1), then one can define the functional $\mathcal{S}_L : \Lambda \to \mathbb{R}$ by

$$\mathcal{S}_L(\gamma) := \int_{S^1} L(t, \gamma(t), \dot{\gamma}(t)) \, dt.$$ 

Lemma 4.2. If $L \in C^\infty(S^1 \times T\mathbb{R}^n)$ satisfies (L1) and (L2), the functional $\mathcal{S}_L$ satisfies the following properties:

(i): $\mathcal{S}_L$ is a Fréchet $C^1$-function. The differential $d\mathcal{S}_L$ is given by

$$d\mathcal{S}_L(\xi) := \int_{S^1} \partial_q L(t, \gamma(t), \dot{\gamma}(t)) \cdot \xi(t) + \partial_v L(t, \gamma(t), \dot{\gamma}(t)) \cdot \dot{\xi}(t) \, dt.$$ 

Moreover $d\mathcal{S}_L$ is Gâteaux differentiable.

(ii): $\gamma \in \Lambda$ satisfies $d\mathcal{S}_L(\gamma) = 0$ if and only if $\gamma \in C^\infty(S^1, \mathbb{R}^n)$ and satisfies

$$\partial_q L(t, \gamma(t), \dot{\gamma}(t)) - \partial_t (\partial_v L(t, \gamma(t), \dot{\gamma}(t))) = 0.$$ 

(iii): For every $\gamma \in \Lambda$, let us define $D\mathcal{S}_L(\gamma) \in L^{1,2}(S^1, \mathbb{R}^n)$ so that

$$\langle D\mathcal{S}_L(\gamma), \xi \rangle_{L^{1,2}} = d\mathcal{S}_L(\gamma)(\xi) \quad (\forall \xi \in L^{1,2}(S^1, \mathbb{R}^n)).$$ 

Then the pair $(\mathcal{S}_L, D\mathcal{S}_L)$ satisfies the Palais-Smale condition. Namely, if a sequence $(x_k)_k$ on $\Lambda$ satisfies $\sup_k |\mathcal{S}_L(x_k)| < \infty$ and $\lim_{k \to \infty} d\mathcal{S}_L(D\mathcal{S}_L(x_k)) = 0$ then $(x_k)_k$ contains a convergent subsequence.

Proof. For (i) and (ii), see [3] Proposition 3.1 (i), (ii). (iii) is proved in [13] Corollary 3.4, which is based on [3] Proposition 3.3. □

Suppose that $L \in C^\infty(S^1 \times T\mathbb{R}^n)$ satisfies (L1) and (L2). Let $\mathcal{P}(L)$ denote the set of critical points of $\mathcal{S}_L$, namely

$$\mathcal{P}(L) := \{ \gamma \in \Lambda \mid d\mathcal{S}_L(\gamma) = 0 \}.$$
For any $\gamma \in \mathcal{P}(L)$, the second Gâteaux differential $d^2J_L(\gamma)$ is Fredholm and has finite Morse index (see Proposition 3.1 (iii) of [3]). The Morse index is denoted by $\text{ind}_{\text{Morse}}(\gamma)$. We say that $\gamma$ is nondegenerate if $0$ is not an eigenvalue of $d^2J_L(\gamma)$. Let us introduce the following condition for $L \in C^\infty(S^1 \times T\mathbb{R}^n)$:

(L0): Every $\gamma \in \mathcal{P}(L)$ is nondegenerate.

4.2. Statement of the isomorphism. Let us consider the following condition for $H \in C^\infty(S^1 \times T^*\mathbb{R}^n)$:

(H2): There exists $c \in \mathbb{R}_{>0}$ such that $\partial^2_pH(t, q, p) \geq c$ for any $(t, q, p) \in S^1 \times T^*\mathbb{R}^n$.

For any $H \in C^\infty(S^1 \times T^*\mathbb{R}^n)$ which satisfies (H1) and (H2), its Legendre dual $L_H \in C^\infty(S^1 \times T\mathbb{R}^n)$ is defined by

$$L_H(t, q, v) := \max_{p \in L_q^\mathbb{R}^n} (p \cdot v - H(t, q, p)) \quad (t \in S^1, q \in \mathbb{R}^n, v \in T_q\mathbb{R}^n).$$

Lemma 4.3. (i): If $H$ satisfies (H1) and (H2), then $L_H$ satisfies (L1) and (L2). There exists a bijection from $\mathcal{P}(H)$ to $\mathcal{P}(L_H)$ which sends $x \in \mathcal{P}(H)$ to $\gamma_x := \text{pr} \circ x \in \mathcal{P}(L_H)$. $\gamma_x$ is nondegenerate if and only if $x$ is nondegenerate, and there holds $\text{ind}_{\text{Morse}}(\gamma_x) = \text{ind}_{\text{Morse}}(x)$.

(ii): If $H$ and $H'$ satisfy (H1), (H2) and $H(t, q, p) < H'(t, q, p)$ for any $(t, q, p) \in S^1 \times T^*\mathbb{R}^n$, then $L_H(t, q, v) > L_{H'}(t, q, v)$ for any $(t, q, v) \in S^1 \times T\mathbb{R}^n$.

Proof. (i): The first and second sentences are checked by direct computations. For the last sentence, see Weber [18] Theorem 1.2. (ii): Let us take $p_0$ so that $L_{H'}(t, q, v) = p_0 \cdot v - H'(t, q, p_0)$. Then

$L_H(t, q, v) = \max_p (p \cdot v - H(t, q, p)) \geq p_0 \cdot v - H(t, q, p_0) > p_0 \cdot v - H'(t, q, p_0) = L_{H'}(t, q, v).$

Now we can state the main result of this section.

Theorem 4.4. For any $H \in C^\infty(S^1 \times T^*\mathbb{R}^n)$ which satisfies (H0), (H1), (H2), and any real numbers $a < b$, one can define an isomorphism

$$HF^{|a,b]}_s(H) \cong H_*(\mathcal{I}_{L_H}^{-1}(\mathbb{R}_{<b}), \mathcal{I}_{L_H}^{-1}(\mathbb{R}_{<a}))$$

such that the following diagrams commute:

(7) $\begin{array}{ccc}
HF^{|a,b]}_s(H) & \cong & HF^{|a',b'}_s(H) \\
\downarrow & & \downarrow \\
H_*(\mathcal{I}_{L_H}^{-1}(\mathbb{R}_{<b}), \mathcal{I}_{L_H}^{-1}(\mathbb{R}_{<a})) & & H_*(\mathcal{I}_{L_H}^{-1}(\mathbb{R}_{<b}), \mathcal{I}_{L_H}^{-1}(\mathbb{R}_{<a'}))
\end{array}$

(8) $\begin{array}{ccc}
HF^{|a,b]}_s(H) & \cong & HF^{|a,b]}_s(H') \\
\downarrow & & \downarrow \\
H_*(\mathcal{I}_{L_H}^{-1}(\mathbb{R}_{<b}), \mathcal{I}_{L_H}^{-1}(\mathbb{R}_{<a})) & & H_*(\mathcal{I}_{L_H'}^{-1}(\mathbb{R}_{<b}), \mathcal{I}_{L_H'}^{-1}(\mathbb{R}_{<a}))
\end{array}$
where $H, H' \in C^\infty(S^1 \times T^*\mathbb{R}^n)$ satisfy (H0), (H1), (H2) and $H(t, q, p) < H'(t, q, p)$ for any $(t, q, p) \in S^1 \times T^*\mathbb{R}^n$, and $a, b, a', b' \in \mathbb{R}$ satisfy $a < b$, $a' < b'$, $a \leq a'$, $b \leq b'$.

4.3. Morse theory on the loop space. Suppose that $L \in C^\infty(S^1 \times T\mathbb{R}^n)$ satisfies (L0), (L1) and (L2). The goal of this subsection is to recall the construction of the Morse complex of $\mathcal{L}_L$.

For each $k \in \mathbb{Z}_{\geq 0}$, let $CM_k(L)$ denote the free $\mathbb{Z}/2$-module generated over
\[
\{\gamma \in \mathcal{P}(L) \mid \text{ind}_{\text{Morse}}(\gamma) = k \}.
\]
To define the boundary operator we need the following lemma. For definitions of "Lyapunov function", "Morse vector field", "Morse-Smale condition", see Section 2 of [3].

**Lemma 4.5.** If $L \in C^\infty(S^1 \times T\mathbb{R}^n)$ satisfies (L0), (L1), (L2), there exists a smooth vector field $X$ on $\Lambda$ which satisfies the following conditions:

(i): $X$ is complete.

(ii): $\mathcal{L}_L$ is a Lyapunov function for $X$.

(iii): $X$ is a Morse vector field. $X(\gamma) = 0$ if and only if $\gamma \in \mathcal{P}(L)$, and the Morse index of $X$ at $\gamma$ is equal to the Morse index of $\gamma$ as a critical point of $\mathcal{L}_L$.

(iv): The pair $(\mathcal{L}_L, X)$ satisfies the Palais-Smale condition.

(v): $X$ satisfies the Morse-Smale condition up to every order.

**Proof.** This lemma follows from Lemma 3.5 in [13] (which is essentially same as Theorem 4.1 in [3]), since the condition (L2) in [13] is weaker than the condition (L2) in this paper. □

Let us take a vector field $X$ on $\Lambda$ which satisfies the conditions in Lemma 4.5. Let $(\varphi^t_X)_{t \in \mathbb{R}}$ denote the flow on $\Lambda$ generated by $X$. For any $\gamma \in \mathcal{P}(L)$ let us set
\[
W^u(\gamma : X) := \{x \in \Lambda \mid \lim_{t \to -\infty} \varphi^t_X(x) = 0 \}
\]
\[
W^s(\gamma : X) := \{x \in \Lambda \mid \lim_{t \to +\infty} \varphi^t_X(x) = 0 \}.
\]

For any real numbers $a < b$, let $CM^a_{\text{M}}(L)$ denote the free $\mathbb{Z}/2$-module generated over
\[
\{\gamma \in \mathcal{P}(L) \mid a \leq \mathcal{L}_L(\gamma) < b \}.
\]
For any two generators $\gamma$ and $\gamma'$, let
\[
\mathcal{M}_X(\gamma, \gamma') := W^u(\gamma : X) \cap W^s(\gamma' : X).
\]
When $\gamma \neq \gamma'$, let $\mathcal{M}_X(\gamma, \gamma')$ denote the quotient of $\mathcal{M}_X(\gamma, \gamma')$ by the natural $\mathbb{R}$-action. Since $X$ satisfies the Morse-Smale condition, the boundary operator $\partial_{L,X}$ on $CM^a_{\text{M}}(L)$ defined by
\[
\partial_{L,X}(\gamma) := \sum_{\text{ind}_{\text{Morse}}(\gamma') = \text{ind}_{\text{Morse}}(\gamma) - 1} \#_2 \mathcal{M}_X(\gamma, \gamma') \cdot \gamma'
\]
is well-defined and satisfies $\partial^2_{L,X} = 0$. Homology of the chain complex $(CM^a_{\text{M}}(L), \partial_{L,X})$ does not depend on the choice of $X$, and denoted by $HM^a_{\text{M}}(L)$. There exists a natural isomorphism $HM^a_{\text{M}}(L) \cong H_*(\mathcal{L}_L^{-1}(\mathbb{R}_{<a}), \mathcal{L}_L^{-1}(\mathbb{R}_{<a}))$.

Consider $L^0, L^1 \in C^\infty(S^1 \times T\mathbb{R}^n)$ which satisfy (L0), (L1), (L2) and $L^0(t, q, v) > L^1(t, q, v)$ for any $(t, q, v) \in S^1 \times T\mathbb{R}^n$. We also assume that $\mathcal{P}(L^0) \cap \mathcal{P}(L^1) = \emptyset$. 17
Take vector fields $X^0, X^1$ on $\Lambda(\mathbb{R}^n)$ such that $(L^0, X^0)$ and $(L^1, X^1)$ satisfy the conditions in Lemma 4.3. By taking small perturbations of $X^0$ and $X^1$ (note that these perturbations do not change Morse complexes for $L^0$ and $L^1$), we can achieve the following condition:

For any $\gamma^0 \in \mathcal{P}(L^0)$ and $\gamma^1 \in \mathcal{P}(L^1)$, $W^u(\gamma^0 : X^0)$ is transverse to $W^s(\gamma^1 : X^1)$.

If this assumption is satisfied, $\mathcal{M}_{X^0, X^1}(\gamma^0, \gamma^1) := W^u(\gamma^0 : X^0) \cap W^s(\gamma^1 : X^1)$ is a smooth manifold of dimension $\text{ind}_{\text{Morse}}(\gamma^0) - \text{ind}_{\text{Morse}}(\gamma^1)$. Then we define a chain map

$$\varphi : \text{CM}^{[a, b]}(L^0, X^0) \to \text{CM}^{[a, b]}(L^1, X^1); \quad \gamma \mapsto \sum_{\text{ind}_{\text{Morse}}(\gamma') = \text{ind}_{\text{Morse}}(\gamma)} \mathcal{M}_{X^0, X^1}(\gamma, \gamma') \cdot \gamma'.$$

$\varphi$ induces a linear map on homology $\text{HM}^{[a, b]}(L^0) \to \text{HM}^{[a, b]}(L^1)$, which does not depend on the choices of $X^0$, $X^1$. Via isomorphisms between the Morse homology and the loop space homology, this map corresponds to the map

$$H_* (\mathcal{J}_L^{-1}(\mathbb{R}_{<b}), \mathcal{J}_L^{-1}(\mathbb{R}_{<a})) \to H_* (\mathcal{J}_L^{-1}(\mathbb{R}_{<b}), \mathcal{J}_L^{-1}(\mathbb{R}_{<a}))$$

which is induced by the inclusion map.

### 4.4. Isomorphism at chain level.

Let us take $H \in C^\infty(S^1 \times T^*\mathbb{R}^n)$ satisfying (H0), (H1), (H2). Its Legendre dual $L_H$ satisfies (L0), (L1), (L2) by Lemma 4.3 (i). Let us also take real numbers $a < b$. The goal of this subsection is to define a chain map $\text{CM}^{[a, b]}(L_H) \to \text{CF}^{[a, b]}(H)$ which induces an isomorphism $\text{HM}^{[a, b]}(L_H) \cong \text{HF}^{[a, b]}(H)$.

The definition of the chain map involves “hybrid moduli spaces” introduced by Abbondandolo-Schwarz [2]. Let us take $X$ and $J$ as follows:

- $X$ is a vector field on $\Lambda$ such that $\text{CM}^{[a, b]}(L_H, X)$ is well-defined.
- $J = (J_t)_{t \in S^1}$ is a family of almost complex structures on $T^*\mathbb{R}^n$ such that $\text{CF}^{[a, b]}(H, J)$ is well-defined.

For any $\gamma \in \mathcal{P}(L_H)$ with $\mathcal{J}_{L_H}(\gamma) \in [a, b]$ and $x \in \mathcal{P}(H)$ with $\mathcal{A}_H(x) \in [a, b]$, let $\mathcal{M}^{[a, b]}_{X, H, J}(\gamma, x)$ denote the set of $u \in L^{1,3}(\mathbb{R}_{\geq 0} \times S^1, T^*\mathbb{R}^n)$ such that

$$\partial_s u - J_t(\partial_t u - X_{H_t}(u)) = 0, \quad \text{pr} \circ u_0 \in W^u(\gamma : X), \quad \lim_{s \to \infty} u_s = x.$$ 

Here $u_s : S^1 \to T^*\mathbb{R}^n$ is defined by $u_s(t) := u(s, t)$.

**Remark 4.6.** The above Sobolev space $L^{1,3}$ can be replaced with $L^{1,r}$ for any $2 < r \leq 4$; see pp.299 of [2].

**Lemma 4.7.** Let $\gamma$ and $x$ be as above.

(i): For any $u \in \mathcal{M}^{[a, b]}_{X, H, J}(\gamma, x)$, there holds

$$\mathcal{J}_{L_H}(\gamma) \geq \mathcal{J}_{L_H}(\text{pr} \circ u_0) \geq \mathcal{A}_H(u_0) \geq \mathcal{A}_H(x).$$

In particular, if $\mathcal{M}^{[a, b]}_{X, H, J}(\gamma, x) \neq \emptyset$ then $\mathcal{J}_{L_H}(\gamma) \geq \mathcal{A}_H(x)$. 

(ii): If $\mathcal{J}_{L_H}(\gamma) = \mathcal{A}_H(x)$, then $\mathcal{M}_{X,H,J}(\gamma, x) \neq \emptyset$ if and only if $x = \text{pr} \circ \gamma$. Moreover, the moduli space $\mathcal{M}_{X,H,J}(\gamma, \text{pr} \circ \gamma)$ consists of a point which is cut out transversally.

**Proof.** See pp.299 in [2] for (i) and the first sentence in (ii). For the second sentence in (ii), see Proposition 3.7 in [2]. □

**Lemma 4.8.** For generic $J$, $\mathcal{M}_{X,H,J}(\gamma, x)$ has a structure of a $C^\infty$-manifold of dimension $\text{ind}_{\text{Morse}}(\gamma) - \text{ind}_{\text{CZ}}(x)$ for any $\gamma$ and $x$ as above.

**Proof.** The case $x = \text{pr} \circ \gamma$ is discussed in Lemma 4.7 (ii). The other cases follow from the standard argument using [7]. See pp.313 of [2]. □

Finally we state the relevant $C^0$-estimate. For comments on the proof see Section 4.6.

**Lemma 4.9.** If $\sup_{t \in S^1} \| J_t - J_{\text{std}} \|_{C^0}$ is sufficiently small, then for any $\gamma$ and $x$ as above

$$\sup_{u \in \mathcal{M}_{X,H,J}(\gamma, x)} \left| u(s, t) \right| < \infty.$$  

By these results and the standard compactness and glueing arguments (see Sections 3.3 and 3.4 in [2]), generic $J$ which is sufficiently close to $J_{\text{std}}$ satisfies the following properties:

- For any $\gamma$ and $x$ as above satisfying $\text{ind}_{\text{Morse}}(\gamma) - \text{ind}_{\text{CZ}}(x) = 0$, the moduli space $\mathcal{M}_{X,H,J}(\gamma, x)$ is a finite set.
- A linear map

$$\Psi : \text{CM}^{(a,b)}([a,b); H, J) \to \text{CF}^{[a,b)}([a,b); H, J) ; \gamma \mapsto \sum_{\text{ind}_{\text{CZ}}(x) = \text{ind}_{\text{Morse}}(\gamma)} \#_2 \mathcal{M}_{X,H,J}(\gamma, x) \cdot x$$

is a chain map with respect to boundary operators $\partial_X$ and $\partial_{H,J}$.

Finally, Lemma 4.4 implies that $\Psi$ is an isomorphism (see Section 3.5 in [2]). In particular, $H_*\Psi : \text{HM}^{(a,b)}([a,b); H) \to \text{HF}^{(a,b)}([a,b); H)$ is also an isomorphism.

For any $a, b, a', b' \in \mathbb{R}$ satisfying $a < b$, $a' < b'$, $a \leq a'$ and $b \leq b'$, the commutativity of the following diagram is straightforward from the definition of $\Psi$:

$$\begin{array}{ccc}
\text{CM}^{(a,b)}([a,b); H) & \longrightarrow & \text{CM}^{(a',b')}([a,b); H) \\
\downarrow & & \downarrow \\
\text{CF}^{(a,b)}([a,b); H) & \longrightarrow & \text{CF}^{(a',b')}([a,b); H).
\end{array}$$

This implies the commutativity of (7).

4.5. **Commutativity of monotonicity maps.** The goal of this subsection is to prove the commutativity of (8). Let us take the following data:

- $H, H' \in C^\infty(S^1 \times T^*\mathbb{R}^n)$ satisfying (H0), (H1), (H2) and $H(t, q, p) < H'(t, q, p)$ for any $(t, q, p) \in S^1 \times T^*\mathbb{R}^n$. Moreover, we assume that $\mathcal{P}(L_H) \cap \mathcal{P}(L_{H'}) = \emptyset$.
- Real numbers $a < b$.  

• Almost complex structures $J$, $J'$ and vector fields $X$, $X'$ such that chain complexes $\text{CF}_{\ast}^{[a,b]}(H, J)$, $\text{CF}_{\ast}^{[a,b]}(H', J')$, $\text{CM}_{\ast}^{[a,b]}(L_H, X)$, $\text{CM}_{\ast}^{[a,b]}(L_{H'}, X')$ are defined.

In the previous subsection we defined chain maps $\Psi : \text{CM}_{\ast}^{[a,b]}(L_H, X) \to \text{CF}_{\ast}^{[a,b]}(H, J)$ and $\Psi' : \text{CM}_{\ast}^{[a,b]}(L_{H'}, X') \to \text{CF}_{\ast}^{[a,b]}(H', J')$. We also defined chain maps $\Phi^L : \text{CM}_{\ast}^{[a,b]}(L_H, X) \to \text{CM}_{\ast}^{[a,b]}(L_{H'}, X')$ and $\Phi^H : \text{CF}_{\ast}^{[a,b]}(H, J) \to \text{CF}_{\ast}^{[a,b]}(H', J')$. The goal of this subsection is to show that the following diagram commutes up to homotopy:

$$
\begin{array}{ccc}
\text{CM}_{\ast}^{[a,b]}(L_H, X) & \overset{\Psi}{\longrightarrow} & \text{CF}_{\ast}^{[a,b]}(H, J) \\
\downarrow{\Phi^L} & & \downarrow{\Phi^H} \\
\text{CM}_{\ast}^{[a,b]}(L_{H'}, X') & \overset{\Psi'}{\longrightarrow} & \text{CF}_{\ast}^{[a,b]}(H', J')
\end{array}
$$

This immediately implies the commutativity of the diagram (8). Since vector spaces in the diagram (10) are generated by finitely many critical points, boundary operators and chain maps in this diagram do not change under $C^\infty$-small perturbations of $X$, $X'$, $J$, $J'$. Hence we may assume that these data are taken so that all moduli spaces which appear in the following arguments of this subsection are cut out transversally.

To prove that (10) commutes up to homotopy, we first define a linear map

$$
\Theta : \text{CM}_{\ast}^{[a,b]}(L_H, X) \to \text{CF}_{\ast}^{[a,b]}(H', J'); \quad \gamma \mapsto \sum_{\text{ind}_{\text{Morse}}(\gamma) = \text{ind}_{\text{CZ}}(x)} \#_2 \mathcal{M}_{X,H',J'}(\gamma, x) \cdot x.
$$

$\Theta$ is a chain map (namely $\partial_{H', J'} \circ \Theta = \Theta \circ \partial_{L,H}$) by the same reason that $\Psi$ in the previous subsection is a chain map. We are going to prove $\Phi^H \circ \Psi \sim \Theta \sim \Psi' \circ \Phi^L$.

First we prove $\Psi' \circ \Phi^L \sim \Theta$. For any $\gamma \in \mathcal{P}(L_H)$ and $x \in \mathcal{P}(H')$, let $\mathcal{M}_0^0(\gamma, x)$ denote the set of $(\alpha, u, v)$ where

$$
\alpha \in \mathbb{R}_{\geq 0}, \quad u : [0, \alpha] \to \Lambda, \quad v \in L^{1,2}(\mathbb{R}_{\geq 0} \times S^1, T^* \mathbb{R}^n)
$$

such that

$$
\begin{align*}
&u(0) \in W^u(\gamma : X), \quad u(s) = \varphi_{X'}^s(u(0)) \ (\forall s \in [0, \alpha]), \\
&\partial_s v - J'_0(\partial_t v - X_{H'}(v)) = 0, \\
&\lim_{s \to \infty} v_s = x.
\end{align*}
$$

Let us state the relevant $C^0$-estimate:

**Lemma 4.10.** If $\sup_{t \in S^1} \|J_t - J_{\text{std}}\|_{C^0}$ is sufficiently small, then for any $\gamma$ and $x$ as above

$$
\sup_{(\alpha, u, v) \in \mathcal{M}_0^0(\gamma, x), (s, t) \in \mathbb{R}_{\geq 0} \times S^1} |v(s, t)| < \infty.
$$

For generic $J'$ which is sufficiently close to $J_{\text{std}}$, $\mathcal{M}_0^0(\gamma, x)$ is a finite set for any $\gamma$ and $x$ satisfying $\text{ind}_{\text{CZ}}(x) = \text{ind}_{\text{Morse}}(\gamma) + 1$, and the linear map

$$
K^0 : \text{CM}_{\ast}^{[a,b]}(L) \to \text{CF}_{\ast+1}^{[a,b]}(H'); \quad \gamma \mapsto \sum_{\text{ind}_{\text{CZ}}(x) = \text{ind}_{\text{Morse}}(\gamma) + 1} \#_2 \mathcal{M}_0^0(\gamma, x) \cdot x
$$

satisfies $\partial_{H', J'} \circ K^0 + K^0 \circ \partial_{L,H} = \Theta - \Psi' \circ \Phi^L$. For details see Section 4.3 in [13].
Secondly we prove $\Phi^H \circ \Psi \sim \Theta$. Let us take $(H^s_{s,t})_{s,t} \in \mathbb{R} \times S^1$ and $(J^s_{s,t})_{s,t} \in \mathbb{R} \times S^1$ which satisfy (HH1), (HH2), (HH3) and (JJ1), (JJ2). In particular there exists $s_2 > 0$ such that

$$(H^s_t, J^s_t) = \begin{cases} (H^t_s, J^t_s) & (s \leq -s_2) \\ (H^t_s, J^t_s) & (s \geq s_2) \end{cases}.$$

For any $\gamma \in \mathcal{P}(L)$ and $x \in \mathcal{P}(H')$, let $N^1(\gamma, x)$ denote the set of $(\beta, w)$ where

$$\beta \in \mathbb{R}_{\leq s_2}, \quad w \in L^{1,3}(\mathbb{R} \times S^1, T^*\mathbb{R}^n)$$

such that

$$\text{pr} \circ w_\beta \in W^u(\gamma : X), \quad \partial_s w - J^t_s(\partial_t w - X_{H^s_{s,t}}(w)) = 0$$

$$\lim_{s \to \infty} w^t_s = x.$$

Let us state the relevant $C^0$-estimate:

**Lemma 4.11.** If $\sup_{t \in S^1} \|J^t_t - J^t_{std}\|_{C^0}$ is sufficiently small, then for any $\gamma$ and $x$ as above

$$\sup_{(\beta, w) \in \mathcal{N}^1(\gamma, x)} \sup_{(s,t) \in \mathbb{R}_{\leq s_2} \times S^1} \|w(s,t)\| < \infty.$$

For generic $J$ which is sufficiently close to $J_{std}$, $N^1(\gamma, x)$ is a finite set for any $\gamma \in \mathcal{P}(L_H)$ and $x \in \mathcal{P}(H')$ satisfying $\text{ind}_{cz}(x) = \text{ind}_{\text{Morse}}(\gamma) + 1$, and the linear map

$$K^1 : \text{CM}^{[a,b)}(L) \to \text{CF}^{[a,b)}(H') ; \quad \gamma \mapsto \sum_{\text{ind}_{cz}(x) = \text{ind}_{\text{Morse}}(\gamma) + 1} \#_2 N^1(\gamma, x) \cdot x$$

satisfies $\partial L, X \circ K^1 + K^1 \circ \partial L, X = \Theta - \Phi^H \circ \Psi$. For details see Section 4.3 in [13].

### 4.6. Proofs of $C^0$-estimates

$C^0$-estimates in this section, namely Lemmas 4.9, 4.10, 4.11 are slight generalizations of Lemmas 4.8, 4.9, 4.10 in [13]. These results in [13] are stated for Hamiltonians of special type (i.e. elements of the sequence $(H^m)_m$ defined in Section 4.1 in [13]), however their proofs in [13] use only assumptions (JJ1), (JJ2), (HH1), (HH2), (HH3). Hence the proofs in [13] work without modification for Lemmas 4.9, 4.10, 4.11.

**Remark 4.12.** Strictly speaking, the condition (HH3) in [13] requires $b(s) \equiv 0$ in the condition (HH3) in this paper. Namely, if $H \in C^\infty(\mathbb{R} \times S^1 \times T^*\mathbb{R}^n)$ satisfies (HH3) in this paper, then there exists $b \in C^\infty(\mathbb{R})$ such that

$$(11) \quad H^0(s, t, q, p) := H(s, t, q, p) - b(s)$$

satisfies the condition (HH3) in [13]. However, this difference does not affect Floer equations, since $(11)$ obviously implies $X_{H^0_{s,t}}(q, p) = X_{H^s_{s,t}}(q, p)$.

### 5. Proof of Theorem 3.3

The goal of this section is to prove Theorem 3.3 from Theorem 4.4.
5.1. Preliminary results on convex functions. In this subsection we prove some preliminary results on convex functions. Let $m$ be any positive integer. Recall that $h \in C^\infty(\mathbb{R}^m)$ is called strictly convex if $(\partial x, \partial y_j h(x))_{1 \leq i, j \leq m}$ is positive definite for every $x \in \mathbb{R}^m$.

Lemma 5.1. For any convex body $K$ in $\mathbb{R}^m$, there exists a sequence $(h_j)_j$ which satisfies the following conditions:

(i): $(h_j)_j$ is a strictly increasing sequence of strictly convex $C^\infty$ functions on $\mathbb{R}^m$.

(ii): There exist sequences $(a_j)_j$ and $(b_j)_j$ which satisfy the following conditions:

- $(a_j)_j$ is a strictly increasing sequence in $\mathbb{R}_{>0} \setminus \pi \mathbb{Z}$, and $(b_j)_j$ is a sequence in $\mathbb{R}$.
- For each $j$, the function $h_j(x) - a_j|x|^2 - b_j$ is compactly supported.

(iii): $\lim_{j \to \infty} h_j(x) = \begin{cases} 0 & (x \in K) \\ \infty & (x \notin K). \end{cases}$

Proof. We explain the construction of $(h_j)_j$ in three steps.

Step 1: We construct a sequence $(f_j)_j$ of convex (thus continuous) functions on $\mathbb{R}^m$. For any $a, b, c \in \mathbb{R}_{>0}$, let $\mathcal{F}_{a,b,c}$ denote the set of convex functions $f$ such that

- $f(x) \leq a|x|^2 + b$ for any $x \in \mathbb{R}^n$,
- $f(x) \leq -c$ for any $x \in K$.

Let us define a function $f_{a,b,c}$ so that

$$f_{a,b,c}(x) := \sup\{f(x) \mid f \in \mathcal{F}_{a,b,c}\}.$$ 

Then $f_{a,b,c}$ is convex, in particular continuous. Moreover $f_{a,b,c}(x) = -c$ for any $x \in K$, and the function $f_{a,b,c}(x) - a|x|^2 - b$ is compactly supported.

Let us take a strictly increasing sequence $(a_j)_j$ in $\mathbb{R}_{>0} \setminus \pi \mathbb{Z}$ which goes to $\infty$, a strictly decreasing sequence $(c_j)_j$ in $\mathbb{R}_{>0}$ which converges to 0, and a sequence $(b_j)_j$ in $\mathbb{R}_{>0}$ which increases sufficiently fast. Then, setting $f_j := f_{a_j,b_j,c_j}$, the sequence $(f_j)_j$ is strictly increasing and satisfies $\lim_{j \to \infty} f_j(x) = \begin{cases} 0 & (x \in K) \\ \infty & (x \notin K). \end{cases}$

Step 2: We construct a sequence $(g_j)_j$ of $C^\infty$ convex functions. Let us take $\rho \in C_c^\infty(\mathbb{R}^m, \mathbb{R}_{\geq 0})$ which satisfies

$$\rho(x) = \rho(-x), \quad \int_{\mathbb{R}^m} \rho(x) \, dx_1 \cdots dx_m = 1.$$ 

For any $\varepsilon \in \mathbb{R}_{>0}$, let $\rho_\varepsilon(x) := \varepsilon^{-m} \rho(x/\varepsilon)$. For each $j$, let us take $\varepsilon_j \in \mathbb{R}_{>0}$ so that

$$g_j(x) := (f_j * \rho_{\varepsilon_j})(x) = \int_{\mathbb{R}^m} f_j(x - y) \rho_{\varepsilon_j}(y) \, dy_1 \cdots dy_m$$

satisfies $f_j(x) \leq g_j(x) < f_{j+1}(x)$ for every $x \in \mathbb{R}^m$. Then, the sequence $(g_j)_j$ is strictly increasing and satisfies $\lim_{j \to \infty} g_j(x) = \begin{cases} 0 & (x \in K) \\ \infty & (x \notin K). \end{cases}$
Step 3: Finally we construct a sequence \((h_j)_j\) of \(C^\infty\) strictly convex functions. For each \(j\), let us choose \(a_j > a_j'\) such that \(a_j \notin \pi \mathbb{Z}\) and \((a_j - a_j')|x|^2 < g_{j+1}(x) - g_j(x)\) for every \(x \in \mathbb{R}^m\). Then, setting \(h_j(x) := g_j(x) + (a_j - a_j')|x|^2\), the sequence \((h_j)_j\) satisfies the required conditions in the lemma.

\[\text{Lemma 5.2. Suppose that a sequence } (h_j)_j \text{ satisfies the conditions in Lemma 5.1. Then, for any } v \in \mathbb{R}^m, \text{ there holds}\]
\[
\lim_{j \to \infty} \left( \max_{p \in \mathbb{R}^m} (p \cdot v - h_j(p)) \right) = \max_{p \in K} p \cdot v.
\]

\[\text{Proof. Let } \mathcal{H} \text{ denote the set of functions } h : \mathbb{R}^m \to \mathbb{R} \text{ such that}\]

- \(h\) is a convex \(C^\infty\) function.
- There exists a quadratic function \(Q(x)\) of the form

\[
Q(x_1, \ldots, x_m) = \sum_{1 \leq i,j \leq m} a_{ij}x_i x_j + \sum_{1 \leq i \leq m} b_i x_i + c
\]

where \((a_{ij})_{1 \leq i,j \leq m}\) is a non-negative symmetric matrix, such that \(h(x) - Q(x)\) is compactly supported.
- \(h(x) < 0\) for any \(x \in K\).

Then \(\lim_{j \to \infty} \left( \max_{p \in \mathbb{R}^m} (p \cdot v - h_j(p)) \right) = \inf_{h \in \mathcal{H}} \left( \max_{p \in \mathbb{R}^m} (p \cdot v - h(p)) \right)\).

For any \(h \in \mathcal{H}\), there holds

\[
\max_{p \in \mathbb{R}^m} (p \cdot v - h(p)) \geq \max_{p \in K} (p \cdot v - h(p)) \geq \max_{p \in K} p \cdot v.
\]

Thus \(\inf_{h \in \mathcal{H}} \left( \max_{p \in \mathbb{R}^m} (p \cdot v - h(p)) \right) \geq \max_{p \in K} p \cdot v\). To complete the proof, it is sufficient to prove the opposite inequality \(\inf_{h \in \mathcal{H}} \left( \max_{p \in \mathbb{R}^m} (p \cdot v - h(p)) \right) \leq \max_{p \in K} p \cdot v\). To prove this, it is sufficient to show that for any \(\delta > 0\) there exists \(h \in \mathcal{H}\) such that

\[
\max_{p \in \mathbb{R}^m} (p \cdot v - h(p)) \leq \delta + \max_{p \in K} p \cdot v.
\]

When \(v = 0\) it is easy to see. When \(v \neq 0\), one can find such \(h\) of the form \(h(p) = \varphi(p \cdot v)\) where \(\varphi \in C^\infty(\mathbb{R})\) is convex and a compact perturbation of a certain quadratic function on \(\mathbb{R}\).

\[\text{5.2. Proof of Theorem 3.3.} \text{ Now we can complete the proof of Theorem 3.3.} \text{ By applying Lemma 5.1 for } m = 2n \text{ and identifying } \mathbb{R}^{2n} \text{ with } T^* \mathbb{R}^n, \text{ there exists a sequence } (H^j)_j \text{ on } C^\infty(S^1 \times T^* \mathbb{R}^n) \text{ which satisfies the following conditions:}\]

- \(H^j\) satisfies (H0), (H1), (H2) for every \(j \geq 1\).
- \(H^j(t,q,p) < H^{j+1}(t,q,p)\) for every \(j \geq 1\) and \((t,q,p) \in S^1 \times T^* \mathbb{R}^n\).
- For any \((t,q,p) \in S^1 \times T^* \mathbb{R}^n\), there holds \(\lim_{j \to \infty} H^j(t,q,p) = \begin{cases} 0 & ((q,p) \in K) \\ \infty & ((q,p) \notin K). \end{cases}\)

For each \(j\), let \(L_j := L_{H^j} \in C^\infty(S^1 \times T^* \mathbb{R}^n)\) denote the Legendre dual of \(H^j\). Then the sequence \((L_j)_j\) is strictly decreasing by Lemma 4.3(ii).
Lemma 5.3. For any $\gamma \in \Lambda$, there holds $\lim_{j \to \infty} S_{L_j}^\gamma = \text{len}_K(\gamma)$.

**Proof.** If $\gamma(S^1) \not\subset \text{pr}(K)$, then $\text{len}_K(\gamma) = -\infty$ by the definition of $\text{len}_K$, and it is easy to see that $\lim_{j \to \infty} S_{L_j}^\gamma = -\infty$. Thus we may assume that $\gamma(S^1) \subset \text{pr}(K)$; in this case we have to prove

$$\lim_{j \to \infty} \int_{S^1} L_j(t, \gamma(t), \dot{\gamma}(t)) \, dt = \int_{S^1} \left( \max_{p \in K_\gamma(t)} p \cdot \dot{\gamma}(t) \right) \, dt.$$  \tag{12}

For each $t \in S^1$ where $\dot{\gamma}(t)$ is defined, Lemma 5.2 shows that $\lim_{j \to \infty} L_j(t, \gamma(t), \dot{\gamma}(t)) = \max_{p \in K_\gamma(t)} p \cdot \dot{\gamma}(t)$. Then (12) holds since $(L_j)_{j}$ is decreasing and $L_1(t, \gamma(t), \dot{\gamma}(t))$ is integrable (since $\dot{\gamma}(t)$ is square-integrable). \hfill \Box

Lemma 5.3 implies $\bigcup_{j \geq 1} S_{L_j}^{-1}(R < c) = \Lambda^c_K$ for any $c \in \mathbb{R}$. Finally, we obtain

$$\text{SH}^*_{[a,b)}(K) = \lim_{j \to \infty} \text{HF}^*_{[a,b)}(H_j)$$

$$\cong \lim_{j \to \infty} H_*(S_{L_j}^{-1}(R < b), S_{L_j}^{-1}(R < a))$$

$$\cong H_* \left( \bigcup_{j \geq 1} S_{L_j}^{-1}(R < b), \bigcup_{j \geq 1} S_{L_j}^{-1}(R < a) \right)$$

$$= H_*(\Lambda^b_K, \Lambda^a_K).$$

The commutativity of (4) (resp. (5)) follows from the commutativity of (7) (resp. (8)). This completes the proof of Theorem 3.3. \hfill \Box
