SOLUTIONS OF EQUATIONS INVOLVING THE MODULAR $j$ FUNCTION

SEBASTIÁN ETEROVIĆ AND SEBASTIÁN HERRERO

Abstract. Inspired by work done for systems of polynomial exponential equations, we study systems of equations involving the modular $j$ function. We show general cases in which these systems have solutions, and then we look at certain situations in which the modular Schanuel conjecture implies that these systems have generic solutions. An unconditional result in this direction is proven for certain polynomial equations on $j$ with algebraic coefficients.

1. Introduction

A significant body of work has been produced towards studying systems of polynomial exponential equations, and in particular, to determine which algebraic varieties $V \subseteq \mathbb{C}^{2n}$ have generic points of the form $(x_1, \ldots, x_n, \exp(x_1), \ldots, \exp(x_n))$, where exp denotes the usual exponential function $\exp(x) = e^x$ for $x$ in $\mathbb{C}$. Similarly, it is of interest to determine which algebraic varieties $V \subseteq \mathbb{C}^{n+1}$ have generic points of the form $(x, \exp(x), \exp \circ \exp(x), \ldots, \exp \circ \cdots \circ \exp(x))$; see [4], [8], [12], [16], [17] for some important results in this area. These questions are in great part motivated by the work of B. Zilber on pseudo-exponentiation (see [12] and [28]), but due to their geometric nature, they still make sense if we replace exp by another holomorphic function.

In this paper we obtain analogues of some of the main results for exp in [8], [16] and [17] for the modular $j$ function, which is the unique holomorphic function defined on the upper-half plane $\mathbb{H} := \{z \in \mathbb{C} : \text{Im}(z) > 0\}$ that is invariant under the action of the modular group $\text{SL}_2(\mathbb{Z})$ and has a Fourier expansion of the form

\begin{equation}
    j(z) = q^{-1} + \sum_{k=0}^{\infty} a_k q^k \quad \text{with } q := \exp(2\pi i z) \text{ and } a_k \in \mathbb{C}
\end{equation}

(see §2 for details). Specifically, the motivating questions of this paper are the following:

1. Under what conditions on a given irreducible algebraic variety $V \subseteq \mathbb{C}^{2n}$ can we ensure that $V$ contains a point of the form $(z_1, \ldots, z_n, j(z_1), \ldots, j(z_n))$ with $z_1, \ldots, z_n \in \mathbb{H}$, and furthermore, that there is such a point which is generic over a given finitely generated subfield of $\mathbb{C}$?

2. Under what conditions on a given irreducible algebraic variety $V \subseteq \mathbb{C}^{n+1}$ can we ensure that $V$ contains a point of the form $(z, j_1(z), \ldots, j_n(z))$, where $j_n$ denotes the $n$-th fold composition of $j$ with itself and $z$ is in the domain of definition of $j_n$, and when can we assure that generic (over a given finitely generated subfield of $\mathbb{C}$) points exist?

Some versions of the first question have been studied in the setting of differential fields in [2] and [3].
1.1. Main results. The first main theorem of this paper gives a partial answer to the first question. In order to state this result, we introduce the following notation. Given a positive integer \( n \) we define
\[
E_n^n := \left\{ (z_1, \ldots, z_n, j(z_1), \ldots, j(z_n)) : z_1, \ldots, z_n \in \mathbb{H}^n \right\},
\]
which is a subset of \( \mathbb{H}^n \times \mathbb{C}^n \).

**Theorem 1.1.** Let \( V \subseteq \mathbb{C}^{2n} \) be an irreducible algebraic variety and let \( \pi : \mathbb{C}^{2n} \to \mathbb{C}^n \) be the projection onto the first \( n \) coordinates. If \( \pi(V) \) is Zariski dense in \( \mathbb{C}^n \), then \( \pi(E_n^n \cap V) \) is Zariski dense in \( \mathbb{C}^n \). In particular, \( V \) contains infinitely many points of the form \((z_1, \ldots, z_n, j(z_1), \ldots, j(z_n))\).

One of the key ingredients in our proof of Theorem 1.1 is Proposition 4.1 in [1], which is the automorphic analogue of a result due to Masser on the existence of solutions of certain systems of polynomial exponential equations (see [8, Theorem 2.1] and also [7, Proposition 2]). The version of Theorem 1.1 for exp is [8, Lemma 2.10].

The second main theorem of this paper shows that the modular Schanuel conjecture (Conjecture 1 in §2.3) implies the existence of generic points in \( E_n^n \cap V \) when \( V \) is an irreducible plane algebraic curve that is not a horizontal or vertical line. Conjecture 1 is the modular version of Schanuel’s classical conjecture for the exponential function (see [13, pp. 30–31]). We restrict to curves that are not horizontal nor vertical lines since those cases are easy to analyze (see §3).

**Theorem 1.2.** Let \( V \subseteq \mathbb{C}^{n+1} \) be an irreducible algebraic curve that is not a horizontal nor a vertical line, and let \( K \) be a finitely generated subfield of \( \mathbb{C} \) over which \( V \) is defined. Then the modular Schanuel conjecture implies that there exist infinitely many points in \( V \) of the form \((z, j(z))\) with \( z \in \mathbb{H} \) and \( \text{tr.deg.}_K(z, j(z)) = 1 \).

The corresponding result for the exponential function is [16, Theorem 1.2] (which assumes Schanuel’s conjecture). For curves defined over \( \overline{\mathbb{Q}} \) (where \( \overline{\mathbb{Q}} \) denotes the algebraic closure of \( \mathbb{Q} \) in \( \mathbb{C} \)) and \( K \subseteq \overline{\mathbb{Q}} \), we prove an unconditional version of Theorem 1.2 in §7.2 (see Proposition 7.6).

The final two main results of this paper are about solutions of equations involving compositions of \( j \) with itself, and give partial answers to our second question. Even though expressions like \( j_2(z) = j(j(z)) \) are not defined in all of \( \mathbb{H} \), we can still find solutions in some situations. For a positive integer \( n \), we denote by \( \mathbb{H}_n \) the maximum domain of definition of \( j_n \).

**Theorem 1.3.** Let \( V \subseteq \mathbb{C}^{n+1} \) be an algebraic hypersurface defined by an irreducible polynomial \( p(X, Y_1, \ldots, Y_n) \) in \( \mathbb{C}[X, Y_1, \ldots, Y_n] \) with \( \frac{\partial p}{\partial Y_n} \neq 0 \). Then there are infinitely many points \( z \in \mathbb{H}_n \) such that \((z, j(z), \ldots, j_n(z)) \in V \).

Assuming the modular Schanuel conjecture, we prove the existence of generic points in the following setting.

**Theorem 1.4.** Let \( V \subseteq \mathbb{C}^3 \) be an algebraic variety defined by an irreducible polynomial \( p(X, Y_1, Y_2) \) in \( \overline{\mathbb{Q}}[X, Y_1, Y_2] \) with \( \frac{\partial p}{\partial X}, \frac{\partial p}{\partial Y_1}, \frac{\partial p}{\partial Y_2} \neq 0 \). Then, the modular Schanuel conjecture implies that there exist infinitely many points \( z \in \mathbb{H}_2 \) such that \((z, j(z), j_2(z)) \in V \) and \( \text{tr.deg.}_\mathbb{Q}(z, j(z), j_2(z)) = 2 \).

For the corresponding result for the exponential function, see [8, Theorem 4.2].

Although a major part of the background, motivation, and even the guidelines for this work come from model theory, no model theory is employed in the proofs of these results.
Our methods come from algebraic geometry, complex analysis, the theory of automorphic functions, and class field theory.

1.2. Structure of the paper. In §2 we introduce some extra notation and provide some background material that is used in the next sections. The modular Schanuel conjecture can be found in §2.3.

In §3 we give a couple of simple examples of varieties where the problems we are interested in are easy to study.

The purpose of §4 is to prove Proposition 4.1, which shows that certain systems of analytic equations involving meromorphic automorphic functions have solutions. This proposition plays a crucial role in the proofs of all of our main theorems.

In §5 we introduce and study certain family of affine varieties that have a very simple form. These are used in our proofs of Theorems 1.1 and 1.2, and also in the proof of Proposition 7.6 in §7.2.

The proofs of our main theorems are contained in §6, §7, §8 and §9, following the order of their presentation in the introduction.

Finally, in §10 we describe further applications of Proposition 4.1 to other problems that might be of interest.

2. Background material and notation

Following the notation used in the introduction, we denote by $\mathbb{H}$ the complex upper-half plane $\{z \in \mathbb{C} : \text{Im}(z) > 0\}$. The group $\text{GL}_2^+(\mathbb{R})$ of 2 by 2 matrices with coefficients in $\mathbb{R}$ and positive determinant acts on $\mathbb{H}$ via the formula

$$gz := \frac{az + b}{cz + d} \quad \text{for} \quad g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{GL}_2^+(\mathbb{R}).$$

This action can be extended to a continuous action of $\text{GL}_2^+(\mathbb{R})$ on $\mathbb{C} \cup \{\infty\}$. Given a subring $R$ of $\mathbb{R}$ we define $M_2^+(R)$ as the set of 2 by 2 matrices with positive determinant and coefficients in $R$. We put

$$G := \text{GL}_2^+(\mathbb{Q}) = M_2^+(\mathbb{Q}),$$

which is a subgroup of $\text{GL}_2^+(\mathbb{R})$. The modular group is defined as

$$\Gamma := \text{SL}_2(\mathbb{Z}) = \{g \in M_2^+(\mathbb{Z}) : \det(g) = 1\}.$$

The modular $j$ function was defined in the introduction as the unique holomorphic function $j : \mathbb{H} \rightarrow \mathbb{C}$ that satisfies

$$j(gz) = j(z) \quad \text{for every} \quad g \in \Gamma \quad \text{and every} \quad z \in \mathbb{H},$$

and has a Fourier expansion of the form $1.1$. It induces an analytic isomorphism of Riemann surfaces $\Gamma \backslash \mathbb{H} \cong \mathbb{C}$. The quotient space $Y_\Gamma = \Gamma \backslash \mathbb{H}$ is known to be a moduli space for complex tori, or equivalently, elliptic curves over $\mathbb{C}$. If $\Gamma z$ is a point in $Y_\Gamma$ and $E_z$ denotes an elliptic curve in the corresponding isomorphism class, then $j(z)$ is simply the $j$-invariant of the curve $E_z$.

Given a point $\overline{z} = (z_1, \ldots, z_n)$ in $\mathbb{H}^n$, we simply write $j(\overline{z})$ instead of $(j(z_1), \ldots, j(z_n))$. For a positive integer $n$, we define $j_n$ inductively by

$$j_1 = j \quad \text{and} \quad j_{n+1} = j \circ j_n \quad \text{for} \quad n \geq 1.$$

The domain of definition of $j_n$, denoted by $\mathbb{H}_n$, is also defined inductively by

$$\mathbb{H}_1 = \mathbb{H} \quad \text{and} \quad \mathbb{H}_{n+1} = \{z \in \mathbb{H}_n : j(z) \in \mathbb{H}_n\} \quad \text{for} \quad n \geq 1.$$
2.1. Modular polynomials. Let \( \{ \Phi_N(X,Y) \}_{N=1}^{\infty} \subseteq \mathbb{Z}[X,Y] \) denote the family of modular polynomials associated to \( j \) (see [1] Chapter 5, Section 2) for the definition and main properties of this family. We recall that \( \Phi_N(X,Y) \) is irreducible in \( \mathbb{C}[X,Y] \), \( \Phi_1(X,Y) = X - Y \), and for \( N \geq 2 \), \( \Phi_N(X,Y) \) is symmetric of total degree \( \geq 2N \). Also, the action of \( G \) on \( \mathbb{H} \) can be traced by using modular polynomials in the following way: for every \( g \) in \( G \) we define \( \tilde{g} \) as the unique matrix of the form \( rg \) with \( r \in \mathbb{Q}, r > 0 \), so that the entries of \( \tilde{g} \) are all integers and relatively prime. Then, for every \( x, y \) in \( \mathbb{H} \) the following statements are equivalent:

\[
\begin{align*}
\text{(M1)}: \quad & \Phi_N(j(x),j(y)) = 0, \\
\text{(M2)}: \quad & gx = y \text{ for some } g \text{ in } G \text{ with } \det(\tilde{g}) = N.
\end{align*}
\]

2.2. Special and ordinary points. A point \( z \) in \( \mathbb{H} \) is said to be special if there is a matrix \( g \) in \( G \) such that \( z \) is the unique fixed point of \( g \) in \( \mathbb{H} \). This is equivalent to saying that \( z \) satisfies a non trivial quadratic equation with integer coefficients. A theorem of Schneider ([24]), which is an analogue of Lindemann’s theorem\(^1\) for \( \exp \), says that \( \text{tr.deg.}_{\mathbb{Q}}(z,j(z)) = 0 \) if and only if \( z \) is special. The special points of \( \mathbb{H} \) are exactly those points for which the corresponding elliptic curve (more precisely, any representative in the corresponding isomorphism class of elliptic curves) has complex multiplication. For this reason, special points are also known as CM points in the literature.

Special points are deeply linked to class field theory for imaginary quadratic fields. The following result is a well known application of that relation. We include a proof for completeness.

**Lemma 2.1.** Let \( M \) be a positive integer. Then, the set of \( \Gamma \)-orbits of special points \( z \) in \( \mathbb{H} \) for which the degree \( \left[ \mathbb{Q}(z,j(z)) : \mathbb{Q}(z) \right] \) is bounded above by \( M \) is finite.

**Proof.** If \( z \) is a special point in \( \mathbb{H} \) and \( E_z \) denotes an elliptic curve in the corresponding isomorphism class, then the ring of endomorphisms of \( E_z \) defined over \( \mathbb{C} \) is isomorphic to an imaginary quadratic order \( \mathcal{O}_z \). It is known that the field \( \mathbb{Q}(z,j(z)) \) is the ring class field of \( \mathcal{O}_z \), and the correspondence \( z \mapsto \mathcal{O}_z \) induces a finite to one surjective map between the collection of all \( \Gamma \)-orbits of special points in \( \mathbb{H} \) and the collection of all (isomorphism classes of) imaginary quadratic orders. Under this map, the class number \( h(\mathcal{O}_z) \) of \( \mathcal{O}_z \) equals \( \left[ \mathbb{Q}(z,j(z)) : \mathbb{Q}(z) \right] \). An important result due to Deuring, Hecke and Heilbronn says that given a positive integer \( h \), there are only finitely many imaginary quadratic orders with class number \( h \). Therefore, if \( \left[ \mathbb{Q}(z,j(z)) : \mathbb{Q}(z) \right] \) is bounded above by \( M \), then there is a finite set \( S_M \subseteq \mathbb{H} \) of special points, depending only on \( M \), such that \( z \in \Gamma \cdot S_M = \{ gz_0 : g \in \Gamma, z_0 \in S_M \} \). This proves the lemma. \( \square \)

We extend the definition of special point to higher dimensions as follows. We say that a point \( \mathfrak{T} \) in \( \mathbb{H}^n \) is special if every coordinate of \( \mathfrak{T} \) is special. On the other hand, we say that \( \mathfrak{T} \) is ordinary if no coordinate of \( \mathfrak{T} \) is special.

2.3. The modular Schanuel conjecture. We now state an important conjecture which, just like Schanuel’s conjecture for \( \exp \), is a special case of the generalised period conjecture of Grothendieck–André (see [1 §23.4.4], [6] §1 Conjecture modulaire], and [21] Conjecture 8.3)).

**Conjecture 1** (Modular Schanuel’s Conjecture). If \( z_1, \ldots, z_n \) in \( \mathbb{H} \) are non-special points in distinct \( G \)-orbits, then:

\[
\text{(1.1)} \quad \text{tr.deg.}_{\mathbb{Q}}(z_1, \ldots, z_n, j(z_1), \ldots, j(z_n)) \geq n.
\]

\(^1\)Lindemann’s theorem states that \( \text{tr.deg.}_{\mathbb{Q}}(z, \exp(z)) = 0 \) if and only if \( z = 0 \).
For the rest of the paper we will refer to Conjecture 1 as MSC for short. The merit of this conjecture relies not only on it coming from the generalised period conjecture, but there are also results like the Ax–Schanuel theorem for \(j\) (see [23, Theorem 1.3]) saying that an inequality stronger than MSC holds on differential fields that have a \(j\)-function.

We now give an alternative formulation of MSC that will be used in §5 and §7. Given a subset \(A\) of \(\mathbb{H}\), we define \(\dim^g(A)\) as the number of distinct \(G\)-orbits in

\[
G \cdot A = \{ga : g \in G, a \in A\}
\]

(this number can be infinite). Given another subset \(C \subseteq \mathbb{C}\), we define \(\dim^g(A|C)\) as the number of distinct \(G\)-orbits in \(G \cdot A \setminus G \cdot C\). Let \(\Sigma \subset \mathbb{H}\) be the set of all special points. Note that, by Schneider’s theorem and the equivalence between (M1) and (M2) in §21, MSC is equivalent to the following statement: for any \(z_1, \ldots, z_n\) in \(\mathbb{H}\) we have

\[
\text{tr.deg}_\mathbb{Q}(z_1, \ldots, z_n, j(z_1), \ldots, j(z_n)) \geq \dim^g(z_1, \ldots, z_n|\Sigma).
\]

2.4. Generic points. Given a subfield \(K\) of \(\mathbb{C}\), we denote by \(\overline{K}\) its algebraic closure in \(\mathbb{C}\). Given a collection \(S\) of polynomials in \(n\) variables and complex coefficients, we denote by \(V(S)\) the affine subvariety of \(\mathbb{C}^n\) defined as the zero locus of the polynomials in \(S\). If \(S\) is the finite set \(\{p_1, \ldots, p_m\}\), then we write \(V(S) = V(p_1, \ldots, p_m)\).

Let \(V\) be an algebraic subvariety of \(\mathbb{C}^n\) of dimension \(d\) defined over a subfield \(K\) of \(\mathbb{C}\). A point \(\overline{x}\) in \(V\) is called generic over \(K\) if \(\text{tr.deg}_K(\overline{x}) = d\). For later use, we now recall two well known results from algebraic geometry. We include proofs for the reader’s convenience.

**Lemma 2.2.** Let \(K\) be an algebraically closed field and let \(L \supseteq K\) be a field extension. Assume that \(V\) and \(W\) are algebraic subvarieties of \(\mathbb{L}^n\) defined over \(K\) such that \(V \cap K^n\) is irreducible and of dimension \(d\). Moreover, assume that there exists a point \(\overline{x}\) in \(\mathbb{L}^n\) such that \(\overline{x} \in V \cap W\) and \(\text{tr.deg}_K(\overline{x}) = d\). Then, we have \(V \subseteq W\).

**Proof.** Define \(I\) as the set of polynomials in \(K[X_1, \ldots, X_n]\) vanishing on \(\overline{x}\). Clearly \(I\) is a prime ideal of \(K[X_1, \ldots, X_n]\). Let \(Z\) denote the corresponding irreducible algebraic set in \(K^n\). We have that \(K[X_1, \ldots, X_n]/I\) is isomorphic to \(K[Z]\). Since the field of fractions of \(K[Z]\) has transcendence degree over \(K\) equal to \(d\), we conclude that \(Z\) has dimension \(d\) over \(K\). By hypothesis, \(V\) is defined by certain polynomials \(p_1, \ldots, p_m\) in \(K[X_1, \ldots, X_n]\). Since \(\overline{x} \in V\), we have \(p_1, \ldots, p_m \in I\). This implies that \(Z \subseteq V \cap K^n\). Similarly, \(Z \subseteq W \cap K^n\). Since \(V \cap K^n\) is irreducible over \(K\) and of the same dimension than \(Z\), we must have \(Z = V \cap K^n\) (see, e.g. [23, Theorem 1.19]). We conclude that \(V \cap K^n \subseteq W \cap K^n\). Since \(K\) is algebraically closed, we have that every polynomial in \(K[X_1, \ldots, X_n]\) defining \(W\) is contained in the radical of the ideal generated by \(p_1, \ldots, p_m\). This implies that \(V \subseteq W\) and completes the proof of the lemma. \(\square\)

**Corollary 2.3.** Let \(V\), \(W\) be affine varieties in \(\mathbb{C}^n\) with \(V\) irreducible of dimension \(d\). Let \(\pi : \mathbb{C}^n \to \mathbb{C}^d\) be the projection map over a fixed choice of \(d\) different coordinates, so that \(\pi(x_1, \ldots, x_n) = (x_{i_1}, \ldots, x_{i_d})\) with \(\{i_1, \ldots, i_d\}\) a subset of cardinality \(d\) of \(\{1, \ldots, n\}\). If \(\pi(V \cap W)\) contains a non-empty Euclidean open subset of \(\mathbb{C}^d\), then \(V \subseteq W\).

**Proof.** Let \(K_0\) be a finitely generated subfield of \(\mathbb{C}\) over which \(V\) and \(W\) are defined. Put \(K = \overline{K_0}\) and choose a non-empty Euclidean open subset \(U\) of \(\mathbb{C}^d\) contained in \(\pi(V \cap W)\). Since \(\text{tr.deg}_K \mathbb{C}\) is infinite, we can find \(\overline{y}\) in \(U\) with \(\text{tr.deg}_K(\overline{y}) = d\). Let \(\overline{y}\) be any point in \(V \cap W\) with \(\pi(\overline{y}) = \overline{x}\). We have

\[
d = \text{tr.deg}_K(\overline{x}) \leq \text{tr.deg}_K(\overline{y}) \leq \dim_K(V) = \dim_\mathbb{C}(V) = d,
\]

hence \(\overline{y}\) is generic in \(V\) over \(K\) and by Lemma 2.2 we get \(V \subseteq W\). This proves the result. \(\square\)
3. Some simple examples

As explained in the introduction, the first problem that we are interested in is to find conditions that ensure that if an irreducible algebraic variety $V \subseteq \mathbb{C}^{2n}$ satisfies them, then $E^r_j \cap V$ is non-empty. Here we look at some simple examples of varieties where this problem is easy to analyze.

**Example 3.1.** Let $V \subseteq \mathbb{C}^2$ be the horizontal line defined by the equation $X = r$, for some $r \in \mathbb{C}$. We have $E^r_j \cap V = \emptyset$ if $r \in \mathbb{C} \setminus \mathbb{H}$, while $E^r_j \cap V = \{(r, j(r))\}$ if $r \in \mathbb{H}$. More generally, no variety $V \subseteq \mathbb{C}^{2n}$ contained in a hyperplane defined by an equation of the form $\{X_i = r\}$ with $r \in \mathbb{C} \setminus \mathbb{H}$ can intersect $E^r_j$.

**Example 3.2.** Let $V \subseteq \mathbb{C}^2$ be the vertical line defined by the equation $Y = r$, for some $r \in \mathbb{C}$. Since $j(\mathbb{H}) = \mathbb{C}$, we can choose $z_0 \in \mathbb{H}$ with $j(z_0) = r$. Then, we have $E^r_j \cap V = \{(g z_0, j(z_0)) : g \in \Gamma\}$.

**Example 3.3.** Choose $g = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ in $G$, and put $N = \text{det}(g)$ (see §2.1 for notation). Let $V \subseteq \mathbb{C}^4$ be the affine variety defined as

$$V = \{(x_1, x_2, y_1, y_2) \in \mathbb{C}^4 : x_1 (cx_2 + d) = ax_2 + b, \Phi_N(y_1, y_2) + 1 = 0\}.$$  

By the equivalence between (M1) and (M2) in §2.1, $V$ cannot intersect $E^r_j$.

Observe that the cases of Examples 3.1 and 3.3, which fail to have points in $E^r_j$, are all of algebraic varieties for which the projection map onto the first set of coordinates is not dominant (which is one of the conditions required in Theorem 1.1). However, this is not a necessary condition. As we already saw in Example 3.1, when $r \in \mathbb{H}$ we have $V \cap E^r_j \neq \emptyset$ despite the fact that the projection of $V$ onto the first coordinate is not Zariski dense.

4. On certain systems of equations involving automorphic functions

In this section we prove that certain systems of analytic equations involving meromorphic automorphic functions have infinitely many solutions. This is an automorphic analogue of a result of Masser mentioned in the introduction. By a meromorphic automorphic function we mean a meromorphic function $f(z)$ on $\mathbb{H}$ that satisfies the following conditions:

(A1) There exists a Fuchsian group of the first kind $\Gamma_0 \subset \text{SL}_2(\mathbb{R})$ such that $f(z)$ is automorphic for $\Gamma_0$, namely, $f(\gamma z) = f(z)$ for every $\gamma$ in $\Gamma_0$ and every $z$ in $\mathbb{H}$.

(A2) $f(z)$ is meromorphic at each cusp of $\Gamma_0$.

For a precise definition of (A2), we refer the reader to [19, §2.1].

**Proposition 4.1.** Let $f_1, \ldots, f_n$ be meromorphic automorphic functions, let $U \subseteq \mathbb{C}^n$ be a connected domain such that $U \cap \mathbb{R}^n \neq \emptyset$, and let $p_1, \ldots, p_n : U \to \mathbb{C}$ be holomorphic functions. We assume that the following conditions are satisfied for every $i$ in $\{1, \ldots, n\}$:

(i) If $p_i$ is a constant function, then $f_i$ attains the value of $p_i$ in $\mathbb{H}$.

(ii) If $p_i$ is not constant, then $f_i$ is not constant.

Then, the system of equations

\begin{equation}
\begin{aligned}
f_1(z_1) &= p_1(z_1, \ldots, z_n), \\
\vdots \\
f_n(z_n) &= p_n(z_1, \ldots, z_n),
\end{aligned}
\end{equation}

has infinitely many solutions in $U \cap \mathbb{H}^n$. 

We remark that in the exponential case, the proof of [8, Theorem 2.1] relies on a theorem of Kantorovich which refines Newton’s approximation method for finding zeros of vector functions. Our proof, instead, goes on a different direction; we use Rouché’s theorem in several variables and standard properties of Fuchsian groups and automorphic functions.

For the convenience of the reader we recall Rouché’s theorem and refer to [25, Theorem 2 in Chapter IV §18.55] for details.

**Theorem 4.2** (Rouché). Let $D \subset \mathbb{C}^n$ be a bounded connected domain with Jordan smooth boundary $\partial D$, and let $f, g : \overline{D} \to \mathbb{C}^n$ be two continuous functions with components $f_i$ and $g_i$, respectively, whose restrictions to $D$ are holomorphic. If at each point $z$ in $\partial D$ for at least one $i$ in $\{1, \ldots, n\}$ we have

$$|f_i(z)| > |g_i(z)|,$$

then the map $f + g$ has as many zeros (counting multiplicities) as $g$ in $D$.

Note that, if we have that $\|f(z)\| > \|g(z)\|$ for some $z$ in $\partial D$, where $\| \cdot \|$ denotes the Euclidean metric on $\mathbb{C}^n$, then condition (4.2) is satisfied for at least one $i$ in $\{1, \ldots, n\}$ automatically.

**Proof of Proposition 4.2.** For simplicity, we fix an integer $m$ in $\{0, \ldots, n\}$ and assume that $p_1, \ldots, p_m$ are non-constant functions and that $p_{m+1}, \ldots, p_n$ are constant, with the obvious conventions if $m = 0$ or $m = n$. For each $i$ in $\{1, \ldots, n\}$ we let $\Gamma_i$ denote the Fuchsian group of the first kind with respect to which $f_i$ is invariant, and let $X_i$ denote the compactification of the Riemann surface $\Gamma_i \setminus \mathbb{H}$. Each $f_i$ induces a meromorphic function $F_i$ on $X_i$. For every $i$ in $\{1, \ldots, m\}$ we have that $F_i : X_i \to \mathbb{C}$ is a non-constant holomorphic map between compact Riemann surfaces, hence $F_i(X_i) = \mathbb{C}$. This implies that there exist finite subsets $A_1, \ldots, A_m$ of $\mathbb{C}$ such that $f_i(\mathbb{H} \setminus F_i^{-1}(\infty)) = \mathbb{C} \setminus A_i$, which gives us the equality of sets

$$(f_1(\mathbb{H} \setminus F_1^{-1}(\infty)) \times \cdots \times f_m(\mathbb{H} \setminus F_m^{-1}(\infty)))^c = \bigcup_{i=1}^m \{(z_k)_{k=1}^n \in \mathbb{C}^n : z_i \in A_i\}.$$ 

Now, if the set

$$\{(p_1(x), \ldots, p_m(x)) : x \in \mathbb{R}^n \}$$

were contained in $f_1(\mathbb{H} \setminus F_1^{-1}(\infty)) \times \cdots \times f_m(\mathbb{H} \setminus F_m^{-1}(\infty))^c$, then the function

$$P : U \to \mathbb{C} \text{ defined as } P(\overline{x}) = \prod_{i=1}^m \prod_{a \in A_i} (p_i(a) - a)$$

would be a holomorphic function on $U$ vanishing over $U \cap \mathbb{R}^n$. This would imply that $P = 0$, see e.g. [25, p. 21], hence at least one $p_i$ among the functions $p_1, \ldots, p_m$ would be constant, which is a contradiction. This proves that there exists a point $\overline{x}_0$ in $U \cap \mathbb{R}^n$ such that for every $i$ in $\{1, \ldots, m\}$, the automorphic function $f_i$ attains the value $p_i(\overline{x}_0)$. By (ii), we conclude that for every $i$ in $\{1, \ldots, n\}$, $f_i$ attains the value $p_i(\overline{x}_0)$.

Put $\overline{\alpha}_i = (p_i(\overline{x}_0))_{k=1}^n$ and choose $\overline{w} = (w_j)_{j=1}^n$ in $\mathbb{H}^n$ such that $f_i(w_j) = \alpha_j$ for every $i$ in $\{1, \ldots, n\}$. Since $\Gamma_i$ is a Fuchsian group of the first kind, we have that $\Gamma_i$ is non-elementary and its limit set $\Lambda(\Gamma_i)$ equals $\mathbb{R} \cup \{\infty\}$ (see [21, §8.1]). By [25, Theorem 5.3.9], for every point $z$ in $\mathbb{H}$ the set of accumulation points of the $\Gamma_i$-orbit of $z$ equals $\Lambda(\Gamma_i)$. In particular, we can find a sequence $(\overline{\gamma_k})_{k=1}^\infty$ of elements in $\Gamma_1 \times \cdots \times \Gamma_n$ such that $|\overline{\gamma_k} \overline{w} - \overline{x}_0|$ tends to zero as $k$ tends to infinity (we recall that $\| \cdot \|$ denotes the standard Euclidean norm on $\mathbb{C}^n$).

Let $g : U \to \mathbb{C}^n$ and $f : \mathbb{H}^n \to \mathbb{C}^n$ be given by $g(\overline{z}) = (p_1(\overline{z}), \ldots, p_n(\overline{z}))$ and $f(\overline{z}) = (f_1(z_1), \ldots, f_n(z_n))$ for $\overline{z} = (z_i)_{i=1}^n$, respectively. If $m = 0$, then for every positive integer $k$ with $\overline{\gamma_k} \overline{w} \in U$ we have $f(\overline{\gamma_k} \overline{w}) = g(\overline{\gamma_k} \overline{w})$ and the desired result holds. In what follows,
we assume $m \geq 1$. Because $f_1$ is not a constant function, the usual identity theorem from complex analysis implies that there exists a small Euclidean closed disk $B_1 \subset \mathbb{H}$ around $w_1$ such that $f_1(z) \neq \alpha_1$ for every $z$ in $B_1 \setminus \{w_1\}$. Choose Euclidean closed disks $B_2, \ldots, B_n \subset \mathbb{H}$ around $w_2, \ldots, w_n$, respectively. Put $B = B_1 \times \cdots \times B_n$, $\delta = \min \{|f(z) - \alpha| : z \in \partial B\}$ and define $d(B)$ as the maximum of the hyperbolic diameters of the closed disks $B_1, \ldots, B_n$. For each $i$ in $\{1, \ldots, n\}$ and each positive integer $k$, let $i_{k}$ and $h_{i,k}$ denote the lowest point and the highest point of $\gamma_k B_i$, respectively. If we denote by $d_{\text{hyp}}(z, w)$ the hyperbolic distance between two points $z, w$ in $\mathbb{H}$, then we have
\[
\log \left( \frac{\text{Im}(h_{i,k})}{\text{Im}(h_{l,k})} \right) = d_{\text{hyp}}(h_{i,k}, l_{i,k}) \leq d(B),
\]
for every $i$ and every $k$. This implies that there exists a positive constant $C$, depending only on $B$, such that $\text{Im}(h_{i,k}) \leq C \cdot \text{Im}(l_{i,k})$ for every $i$ and $k$. Since $\text{Im}(l_{i,k}) \leq \text{Im}(\gamma_k w_i)$ and $\text{Im}(\gamma_k w_i)$ tends to zero as $k$ tends to infinity, we conclude that $\text{Im}(h_{i,k})$ also tends to zero as $k$ tends to infinity. This implies that for every Euclidean neighbourhood $W$ of $\overline{\mathbb{D}_0}$ in $\mathbb{C}^n$ there exists a positive integer $N$ such that $\overline{\gamma_k B} \subset W$ for every $k > N$. By continuity of $g$, we deduce that there exists a positive integer $M$ such that for every $k > M$ we have
\[
\max \{ \|g(\overline{w}) - \alpha\| : \overline{w} \in \overline{\gamma_k B} \} < \delta.
\]
Since $\delta = \min \{|f(\overline{w}) - \overline{\alpha}| : \overline{w} \in \partial(\overline{\gamma_k B})\}$ and $\partial(\overline{\gamma_k B})$ is a Jordan boundary, we can apply Rouché’s theorem to the functions $f - \overline{\alpha}$ and $\overline{\alpha} - g$ on $\overline{\gamma_k B}$ and conclude that these functions have the same number of zeros in $\overline{\gamma_k B}$ for every $k > M$. As $f - \overline{\alpha}$ has a zero there (namely $\overline{\gamma_k w}$), we conclude that $f(\overline{w}) = \overline{\alpha}$ has a solution in $\overline{\gamma_k B}$. Since for every $i$ we know that $h_{i,k}$ tends to zero as $k$ tends to infinity, we can pass to a subsequence, if necessary, and assume that the sets $\overline{\gamma_k B}$ for $k > M$ are all pairwise disjoint. This proves that $f(\overline{w}) = \overline{\alpha}$ has infinitely many solutions and completes the proof of the proposition.

**Remark 4.3.** If we choose each $f_i$ to be the $j$ function in Proposition 4.1, then conditions (i) and (ii) are automatically satisfied since $j(\mathbb{H}) = \mathbb{C}$.

5. **Varieties of Triangular Form**

For the proof of Theorem 4.1, it will be convenient to consider the following type of varieties.

**Definition.** An affine irreducible algebraic variety $V \subseteq \mathbb{C}^n$ of dimension $d \geq n$ will be called of **triangular form** if it can be defined by polynomials $p_1, \ldots, p_{2n-d}$ satisfying the following two conditions:

(i) For every $i \in \{1, \ldots, 2n - d\}$ there exist an integer $d_i \geq 1$, polynomials $q_{i,0}, \ldots, q_{i,d_i-1}$ in $\mathbb{C}[X_1, \ldots, X_n, Y_1, \ldots, Y_{i-1}]$ and $q_{i,d_i}$ in $\mathbb{C}[X_1, \ldots, X_n]$ non-zero such that
\[
(p_i) = q_{i,0}Y_1^{d_i} + \sum_{k=0}^{d_i-1} q_{i,k}Y_i^k.
\]

In particular, each $p_i$ depends only on $Y_1, \ldots, Y_i$ among the variables $Y_1, \ldots, Y_n$.

(ii) If we define $\pi_V : V \to \mathbb{C}^d$ by
\[
\pi_V(x_1, \ldots, x_n, y_1, \ldots, y_n) = (x_1, \ldots, x_n, y_{2n-d+1}, \ldots, y_n),
\]
then $\deg(\pi_V) = d_1 \cdots d_{2n-d}$.

Given an algebraic variety $V \subseteq \mathbb{C}^n$ of triangular form as above, we define $V_0 = \{(x_1, \ldots, x_n, y_1, \ldots, y_n) \in V : q_{i,d_i}(x_1, \ldots, x_n) \neq 0 \text{ for every } i \in \{1, \ldots, 2n - d\}\}$.
Note that $V_0$ is a non-empty Zariski open subset of $V$ and $\pi_V(V_0)$ is a non-empty Zariski open subset of $\mathbb{C}^d$. In particular, $\pi_V$ is dominant and $\deg(\pi_V)$ is well defined.

**Remark 5.1.** For a general irreducible algebraic variety $V \subseteq \mathbb{C}^{2n}$ defined by polynomials $p_1, \ldots, p_{2n-d}$ satisfying (5.1) it might happen that $\deg(\pi_V) < d_1 \cdots d_{2n-d}$. An example is given by the variety

$$V = V(Y_1 - X_1^2, Y_2^2 + 2Y_2X_1 + Y_1) \subset \mathbb{C}^4.$$ 

Note that $V = V(Y_1 - X_1^2, Y_2 + X_1)$ and $\deg(\pi_V) = 1$.

**Lemma 5.2.** Let $V \subseteq \mathbb{C}^2$ be an irreducible algebraic curve that is not a vertical line. Then, $V$ is of triangular form.

**Proof.** Write $V = V(p)$ with $p(X, Y) \in \mathbb{C}[X, Y]$ irreducible. Let us write

$$p(X, Y) = \sum_{i=0}^{d_Y} p_i(X)Y^i,$$

where $p_0(X), \ldots, p_{d_Y}(X) \in \mathbb{C}[X]$ and $p_{d_Y}(X) \neq 0$, so $d_Y$ is the degree of $p$ in the $Y$ variable. Since $V$ is not a vertical line, we have $\partial_Y p \neq 0$, hence $p$ satisfies (5.1) with $d_1 = d_Y$. Put $R := \mathbb{C}[X]$ and define $r$ as the resultant of $p$ and $\partial_Y p$ as polynomials in $R[Y]$, see e.g. [9, Chapter 2, §2]. Since $p$ is irreducible and $\partial_Y p \neq 0$, we have by [9, Theorem 2.2] that $r$ is a non-zero element of $R$. It follows that the set

$$A := \{ z \in \mathbb{C} : p_{d_Y}(z)r(z) \neq 0 \}$$

is a non-empty Zariski open subset of $\mathbb{C}$. Note that $A$ is contained in the image of the map $\pi_V : V \to \mathbb{C}$, $\pi_V(x, y) = x$. By [9, Corollary 2.4] there exist polynomials $f, h$ in $R[Y]$ with $fp + h\partial_Y p = r$. This implies that for every $z$ in $A$ and every $(w_1, w_2)$ in $\pi_V^{-1}(z)$ we have $\partial_Y f(w_1, w_2) \neq 0$, hence $z$ has exactly $d_Y$ preimages under $\pi_V$. This proves that $\deg(\pi_V) = d_Y$ and completes the proof of the lemma. \hfill $\square$

The main properties of algebraic varieties of triangular form that we are going to use are summarized in the following proposition.

**Proposition 5.3.** Let $V \subseteq \mathbb{C}^{2n}$ be an algebraic variety of dimension $d \geq n$ of triangular form. Then, there exists a non-empty Zariski open subset $B$ of $\mathbb{C}^d$ such that the following properties hold.

1. $B \subseteq \pi_V(V_0)$ and $B \cap \mathbb{R}^d$ contains a non-empty Zariski open subset of $\mathbb{R}^d$.
2. For every point $(z_i)_{i=1}^{2n}$ in $\pi_V^{-1}(B)$, there exist Euclidean neighbourhoods $U_1, U_2$ of $(z_1, \ldots, z_n)$ in $\mathbb{C}^n$ and of $(z_{n+1}, \ldots, z_{3n-d})$ in $\mathbb{C}^{2n-d}$, respectively, and a holomorphic function $H : U_1 \to U_2$ such that

$$V \cap (U_1 \times U_2 \times \mathbb{C}^{d-n}) = \{(\overline{w}_1, H(\overline{w}_1), \overline{w}_2) : \overline{w}_1 \in U_1, \overline{w}_2 \in \mathbb{C}^{d-n}\}.$$

Moreover, if $J$ is a finite subset of $\mathbb{C}^{2n-d}$ such that $V$ is not contained in $\mathbb{C}^n \times J \times \mathbb{C}^{d-n}$, then we have the following properties.

3. For every point $(z_i)_{i=1}^{2n}$ in $\pi_V^{-1}(B \cap \mathbb{R}^d)$ and every triple $U_1, U_2, H$ as in part (2), there exists an Euclidean open subset $U_1' \subseteq U_1$ such that $U_1' \cap \mathbb{R}^d \neq \emptyset$ and $H(U_1') \cap J = \emptyset$.
4. For every point $\overline{w}$ in $B \cap \mathbb{R}^d$ and every Euclidean neighbourhood $U$ of $\overline{w}$ in $\mathbb{C}^d$, the set

$$E^n_3 \cap \pi_V^{-1}(U) \cap (\mathbb{C}^n \times J \times \mathbb{C}^{d-n})^c$$

is infinite.

In particular, there exist infinitely many points in the set $E^n_3 \cap V_0 \cap (\mathbb{C}^n \times J \times \mathbb{C}^{d-n})^c$. 

SOLUTIONS OF EQUATIONS INVOLVING THE MODULAR $j$ FUNCTION 9
Our proof of Proposition \ref{prop:5.3} makes use of the Implicit Function Theorem. Since this result is also used in the proofs of Theorems \ref{thm:1.3} and \ref{thm:1.4}, we recall its formulation for the convenience of the reader (see \cite{25} §4.9, Theorem 3) for details.

**Theorem 5.4 (Implicit Function Theorem).** Let $B$ be a non-empty open subset of $\mathbb{C}^n \times \mathbb{C}^m$, $F = (F_1, \ldots, F_m) : B \to \mathbb{C}^m$ be a holomorphic map on the variables $(z_1, \ldots, z_{n+m})$, and $(\overline{x}_0, \overline{y}_0)$ in $\mathbb{C}^n \times \mathbb{C}^m$ be a point in $B$ satisfying $F(\overline{x}_0, \overline{y}_0) = 0$ and

\begin{equation}
\det \left( \frac{\partial F_i}{\partial \nu}(\overline{x}_0, \overline{y}_0) \right)_{\nu=1, \ldots, n+m} \neq 0.
\end{equation}

Then there is an open neighbourhood $U = U_1 \times U_2$ of $(\overline{x}_0, \overline{y}_0)$ contained in $B$ and a holomorphic map $H : U_1 \to U_2$ such that

\[ \{(\overline{x}, \overline{y}) \in U : F(\overline{x}, \overline{y}) = 0\} = \{(\overline{x}, H(\overline{x})) : \overline{x} \in U_1\}. \]

We now give the proof of Proposition \ref{prop:5.3}.

**Proof of Proposition \ref{prop:5.3}** Let $p_1, \ldots, p_{2n-d}$ be polynomials in $\mathbb{C}[X_1, \ldots, X_n, Y_1, \ldots, Y_{2n-d}]$ defining $V$ satisfying the conditions of triangular form, let $q_i, a_0, \ldots, q_i, d_i$ be the polynomials satisfying \eqref{eq:5.1} and put $D = d_1 \cdot \cdots \cdot d_{2n-d}$. The set

\[ B_0 = \{(x_1, \ldots, x_n, y_{2n-d+1}, \ldots, y_{2n}) \in \mathbb{C}^d : q_i, d_i(x_1, \ldots, x_n) \neq 0 \text{ for every } i \in \{1, \ldots, 2n-d\}\} \]

is a non-empty Zariski open subset of $\mathbb{C}^d$. Since $\mathbb{C}$ is algebraically closed, we have $B_0 \in \pi_V(V)$. By \cite{26} Theorem 2.29 we can find a non-empty Zariski open subset $B \subseteq B_0$ such that for every $\overline{z} \in B$ , $\pi_V$ is unramified over $\overline{z}$, meaning that $\overline{z}$ has exactly $D$ preimages under $\pi_V$. In order to prove (1), we have to check that $B \cap \mathbb{R}^d$ contains a non-empty Zariski open subset of $\mathbb{R}^d$. But this is standard; since the complement of $B$ in $\mathbb{C}^d$ is a proper closed subset, it must be equal to the set of zeros of a finite number of non-zero polynomials $Q_1, \ldots, Q_q$ in $\mathbb{C}[X_1, \ldots, X_n, Y_{2n-d+1}, \ldots, Y_{2n}]$. We have $\mathbb{C}^d \setminus V(Q_1) \subseteq B$. Since $Q_1$ is non-zero and $\mathbb{R}$ is infinite, there must exist $z_0 \in \mathbb{R}^d$ with $Q_1(z_0) \neq 0$, hence $\mathbb{R}^d \setminus V_1(Q)$ is a non-empty Zariski open subset of $\mathbb{R}^d$ contained in $B$. This proves (1).

Let $\overline{w}_0$ be a point in $B$ (hence $\overline{w}_0 \in B_0$) with first $n$ coordinates equal to $x_1, \ldots, x_n$. Note that, starting with the conditions $X_i = x_i$ for $i \in \{1, \ldots, n\}$ we can solve \eqref{eq:5.1} for each $i$ in $\{1, \ldots, 2n-d\}$ as a system of equations on the variables $Y_1, \ldots, Y_{2n-d}$, obtaining at most $D$ different solutions $(y_1, \ldots, y_{2n-d})$ in $\mathbb{C}^{2n-d}$. Moreover, we get exactly $D$ different solutions if and only if each partial derivative $\frac{\partial p_i}{\partial Y_j}$, for $i \in \{1, \ldots, 2n-d\}$, does not vanish at any point of the form $(x_1, \ldots, x_n, y_1, \ldots, y_{2n-d})$ with $(y_1, \ldots, y_{2n-d})$ a solution of the system. Since $\overline{w}_0$ has exactly $D$ preimages under $\pi_V$, we conclude

\[ \det \left( \frac{\partial p_i}{\partial Y_j}(\overline{w}_0) \right)_{i,j=1, \ldots, 2n-d} = \prod_{i=1}^{2n-d} \frac{\partial p_i}{\partial Y_i}(\overline{w}_0) \neq 0, \]

for every $\overline{z}_0$ in $\pi_V^{-1}(\overline{w}_0)$. Hence, for every point $(z_1, \ldots, z_{2n})$ in $\pi_V^{-1}(\overline{w}_0)$ we can apply the Implicit Function Theorem to the map $F = (p_1, \ldots, p_{2n-d}) : \mathbb{C}^{3n-d} \to \mathbb{C}^{2n-d}$ at the point $(z_1, \ldots, z_{3n-d})$. This way, we get the existence of Euclidean neighbourhoods $U_1, U_2$ of $(z_1, \ldots, z_n)$ in $\mathbb{C}^n$ and of $(z_{n+1}, \ldots, z_{3n-d})$ in $\mathbb{C}^{2n-d}$, respectively, and an holomorphic function $H = (H_1, \ldots, H_{2n-d}) : U_1 \to U_2$ such that

\[ V \cap (U_1 \times U_2) = \{ (\overline{w}_1, H(\overline{w}_1), \overline{w}_2) : \overline{w}_1 \in U_1, \overline{w}_2 \in U_2 \}. \]

This proves (2). Now, let $J$ be a finite subset of $\mathbb{C}^{2n-d}$ such that $V$ is not contained in $\mathbb{C}^n \times J \times \mathbb{C}^{d-n}$ and choose a point $\overline{z}_0$ in $\pi_V^{-1}(J)$. Let $U_1, U_2$ and $H = (H_1, \ldots, H_{2n-d})$ be as in part (2) with $U_1 \setminus J = \overline{z}_0$. By shrinking $U_1$ if necessary, we can assume that it is connected. We claim that

\[ \{H(\overline{z}) : \overline{z} \in U_1 \cap \mathbb{R}^n\} \not\subseteq J. \]
Indeed, assume that this is not the case. Since $J$ is finite, $H(z)$ is holomorphic and $U_1$ is connected, we must have $H(U) = \{ \overline{z} \}$ for some $\overline{z}$ in $J$ (see e.g. [25, p. 21]), hence

$$V \cap (U_1 \times U_2 \times \mathbb{C}^{d-n}) = U_1 \times \{ \overline{z} \} \times \mathbb{C}^{d-n} \subseteq V \cap (\mathbb{C}^n \times \{ \overline{z} \} \times \mathbb{C}^{d-n}).$$

This implies, by Corollary 2.3, that $V$ is contained in $(\mathbb{C}^n \times \{ \overline{z} \} \times \mathbb{C}^{d-n})$, which contradicts our hypothesis. This proves our claim. It follows that we can find $w_0$ in $U_1 \cap \mathbb{R}^n$ and $i_0$ in $\{1, \ldots, 2n - d\}$ such that $H_{i_0}(w_0) \notin J$. Take an Euclidean open set $U'_1 \subseteq U_1$ such that $w_0 \in U'_1$ and $H_{i_0}(w) \notin J$ for every $w$ in $U'_1$. It is clear that $U'_1$ satisfies the desired properties. This proves part (3).

In order to prove (4), let $\overline{a}$ be a point in $B \cap \mathbb{R}^d$, let $U$ be an Euclidean neighbourhood of $\overline{a}$ in $\mathbb{C}^d$ and choose a point $z_0$ in $\pi_V^{-1}(\overline{a})$. Let $U_1, U_2$ and $H = (H_1, \ldots, H_{2n-d})$ be given by part (2) with $(z_i)_{i=1}^{2n} = \overline{a}$. By shrinking $U_1$, if necessary, we can assume that there exists an open subset $U_3$ of $\mathbb{C}^{d-n}$ such that

$$V \cap U_1 \times U_2 \times U_3 \subseteq \pi_V^{-1}(U).$$

Let $U'_1$ be the open subset of $U_1$ given by part (3) and fix a point $(\alpha_1, \ldots, \alpha_{d-n})$ in $U_3$. Since $U'_1 \cap \mathbb{R}^n \neq \emptyset$ and $j(\mathbb{H}) = \mathbb{C}$, we can apply Proposition 4.11 to the system of equations

$$\begin{align*}
j(w_1) &= H_1(w_1, \ldots, w_n), \\
j(w_{2n-d}) &= H_{2n-d}(w_1, \ldots, w_n), \\
j(w_{2n-d+1}) &= \alpha_1, \\
j(w_n) &= \alpha_{d-n},
\end{align*}$$

for $(w_1, \ldots, w_n)$ in $U'_1 \cap \mathbb{H}^n$. For each solution $\overline{w} = (w_1, \ldots, w_n)$ of this system of equations we have that

$$(\overline{w}, j(\overline{w})) = (w_1, \ldots, w_n, H_1(\overline{w}), \ldots, H_{2n-d}(\overline{w}), \alpha_1, \ldots, \alpha_{d-n})$$

is in $E^n \cap \pi_V^{-1}(U) \cap (\mathbb{C}^n \times J \times \mathbb{C}^{d-n})^c$. This proves (4) since the system (5.3) has infinitely many solutions in $U'_1 \cap \mathbb{H}^n$.

Finally, taking $U = B$ in part (4), and noting that $\pi_V^{-1}(B) \subseteq \pi_V^{-1}(\pi_V(V_0)) = V_0$, we conclude that $E^n \cap V_0 \cap (\mathbb{C}^n \times J \times \mathbb{C}^{d-n})^c$ is infinite. This completes the proof of the proposition. \qed

**Corollary 5.5.** Let $V \subseteq \mathbb{C}^{2n}$ be an algebraic variety of triangular form of dimension $d \geq n$. Then $\pi_V(E^n \cap V_0)$ is Zariski dense in $\mathbb{C}^d$.

**Proof.** Let $A$ be a non-empty Zariski open subset of $\mathbb{R}^d$ contained in $B$, whose existence is given by Proposition 5.3(1). Let $\overline{a}$ be a point in $A$ and let $U$ be a Zariski open subset of $\mathbb{C}^d$ contained in $B$ with $\overline{a} \in U$. Since $U$ is also an open subset of $\mathbb{C}^d$ in the Euclidean topology, we can use Proposition 5.3(4) with $J = \emptyset$ and find a point $\overline{z}$ in $\pi_V^{-1}(U) \cap E^n$. Since $\pi_V(U) \subseteq \pi_V^{-1}(B) \subseteq V_0$, we must have $\overline{z} \in V_0$. This implies that $\pi_V(E^n \cap V_0) \cap U$ is non-empty. Thus, $A$ is contained in the Zariski closure of $\pi_V(E^n \cap V_0)$. Since $A$ is Zariski dense in $\mathbb{R}^d$ and $\mathbb{R}^d$ is Zariski dense in $\mathbb{C}^d$, we have that $A$ is Zariski dense in $\mathbb{C}^d$. This implies that $\pi_V(E^n \cap V_0)$ is Zariski dense in $\mathbb{C}^d$ and completes the proof of the corollary. \qed

6. **Proof of Theorem 1.1**

The proof of Theorem 1.1 is based on Corollary 5.5 and the following result.

**Proposition 6.1.** Let $V \subseteq \mathbb{C}^{2n}$ be an algebraic variety and let $\pi : \mathbb{C}^{2n} \to \mathbb{C}^n$ be the projection onto the first $n$ coordinates. If $\pi(V)$ is Zariski dense in $\mathbb{C}^n$, then there exist an algebraic variety $W \subseteq \mathbb{C}^{2n}$ of dimension $n$ of triangular form with $W \subseteq V$. 
Proof. Let \( p_1, \ldots, p_m \) be polynomials in \( \mathbb{C}[X_1, \ldots, X_n, Y_1, \ldots, Y_n] \) defining \( V \) and let \( F \) be the field generated by the coefficients of \( p_1, \ldots, p_m \). Since the set \( \pi(V) \) is dense in \( \mathbb{C}^n \), it must contain a Zariski open subset of \( \mathbb{C}^n \) (see, e.g. [26 Theorem 1.14]). Since \( \text{tr.deg.}_Q \mathbb{C} \) is infinite, we can find a point \( \overline{x} = (x_1, \ldots, x_n) \) in \( \pi(V) \) such that \( \text{tr.deg.}_F(\overline{x}) = n \). Let \( L \) denote the algebraic closure of \( F(\overline{x}) \) in \( \mathbb{C} \) and consider the polynomials \( g_i(Y_1, \ldots, Y_n) := p_i(\overline{x}, Y_1, \ldots, Y_n) \) in \( L[Y_1, \ldots, Y_n] \) for each \( i \) in \( \{1, \ldots, m\} \). If the set

\[
V_L(q_1, \ldots, q_n) := \{ \overline{y} \in L^n : q_i(\overline{y}) = 0 \text{ for every } i \text{ in } \{1, \ldots, m\} \}
\]

were empty, then the ideal of \( L[Y_1, \ldots, Y_n] \) generated by \( q_1, \ldots, q_m \) would contain 1. But this would imply that the algebraic subset of \( \mathbb{C}^n \) defined by the polynomials \( q_1, \ldots, q_m \) is empty, contradicting the fact that \( \overline{x} \in \pi(V) \). Hence, we can choose a point \( \overline{y} = (y_1, \ldots, y_n) \) in \( V_L(q_1, \ldots, q_n) \), meaning that \( \overline{y} \in \mathbb{C}^n \) and \( (\overline{x}, \overline{y}) \in V \).

Put \( R = F[X_1, \ldots, X_n] \). The minimal polynomial of \( y_1 \) over \( F(\overline{x}) \) is of the form

\[
a_1g_1(\overline{x}, Y_1) \text{ where } g_1(X_1, \ldots, X_n, Y_1) \text{ is a primitive irreducible polynomial in } R[Y_1] \text{ of positive degree and } a_1 \text{ is a non-zero element of } F(\overline{x}).
\]

Similarly, for every \( i \) in \( \{1, \ldots, n\} \) with \( i > 1 \) the minimal polynomial of \( y_i \) over \( F(\overline{x}, y_1, \ldots, y_{i-1}, Y_i) \) is of the form \( a_i, g_i(\overline{x}, Y_1, \ldots, y_{i-1}, Y_i) \) where \( g_i(X_1, \ldots, X_n, Y_1, \ldots, Y_i) \) is a primitive irreducible polynomial in \( R_i[Y_i] \) of positive degree, where \( R_i = F[X_1, \ldots, X_n, Y_1, \ldots, Y_i] \), whose leading coefficient is in \( R \), and \( a_i \) is a non-zero element of \( F(\overline{x}) \).

Let \( W = V(y_1, \ldots, y_n) \). It satisfies condition (i) from the definition of triangular form by construction. Note that \( (\overline{x}, \overline{y}) \in V \cap W \) and \( \text{tr.deg.}_F(\overline{x}, \overline{y}) = n \). We claim that \( W \cap V \). By Lemma 2.2 it is enough to check that \( W \cap \mathbb{C}^{2n} \) is irreducible and of dimension \( n \) as algebraic subvariety of \( \mathbb{C}^{2n} \). First, note that the ring isomorphism \( F[X_1, \ldots, X_n, Y_1, \ldots, Y_n] \to F(\overline{x}, Y_1, \ldots, Y_n) \) given by \( f(X_1, \ldots, X_n, Y_1, \ldots, Y_n) \to f(\overline{x}, Y_1, \ldots, Y_n) \) induces an injective ring morphism

\[
F[X_1, \ldots, X_n, Y_1, \ldots, Y_n] /[g_1, \ldots, g_n] \to F(\overline{x}, Y_1, \ldots, Y_n) /[\alpha_1, \ldots, \alpha_n],
\]

where \( \alpha_i(Y_1, \ldots, Y_n) := g_i(\overline{x}, Y_1, \ldots, Y_n) \). Since replacing \( Y_1 \) by \( y_1 \) gives a ring isomorphism \( F(\overline{x}, Y_1, Y_2, Y_3) \to F(\overline{x}, Y_1, Y_2, Y_3) /[\alpha_1, \ldots, \alpha_n] \), we have

\[
F(\overline{x})[Y_1, \ldots, Y_n] /[\alpha_1, \ldots, \alpha_n] \cong F(\overline{x})[Y_2, \ldots, Y_n] /[\beta_2, \ldots, \beta_n],
\]

where \( \beta_i(Y_2, \ldots, Y_n) := g_i(\overline{x}, y_1, Y_2, \ldots, Y_n) \) for \( i \) in \( \{2, \ldots, n\} \) provided \( n \geq 2 \). Repeating this argument we obtain that

\[
F(\overline{x})[Y_1, \ldots, Y_n] /[\alpha_1, \ldots, \alpha_n] \cong F(\overline{x})[y_1, \ldots, y_n].
\]

By (6.1) we conclude that \( F[X_1, \ldots, X_n, Y_1, \ldots, Y_n] /[g_1, \ldots, g_n] \) is an integral domain. Hence, \( (g_1, \ldots, g_n) \) is a prime ideal of \( F[X_1, \ldots, X_n, Y_1, \ldots, Y_n] \). It also follows from the above arguments that the field of rational functions on \( W \cap \mathbb{C}^{2n} \) is isomorphic to \( F(\overline{x})[\overline{y}] \). Thus, \( W \cap \mathbb{C}^{2n} \) is irreducible in \( \mathbb{C}^{2n} \) and has dimension \( n \).

The above arguments also show that the degree of the morphism \( \pi_W|_{W \cap \mathbb{C}^{2n}} : W \cap \mathbb{C}^{2n} \to \mathbb{F}^l \) equals \( D := \prod_{i=1}^l \deg_Y(g_i) \), where \( \deg_Y(g_i) \) denotes the degree of \( g_i \) in the \( Y_i \) variable. Since \( F \) is algebraically closed, we have that \( V \) is also irreducible over \( \mathbb{C} \) (see, e.g. [11 Exercise II.3.15]) and \( \deg(\pi_V) = D \). This completes the proof of the proposition. \( \square \)

Proof of Theorem 1.1. By Proposition 6.1 there exists an algebraic variety of triangular form \( W \subseteq \mathbb{C}^{2n} \) of dimension \( n \) contained in \( V \). By Corollary 5.5 we have that \( \pi_W(E_0 \cap W_0) \) is Zariski dense in \( \mathbb{C}^n \). This implies the desired result since \( \pi_W(E_0 \cap W_0) \subseteq \pi(E_0 \cap V) \). \( \square \)
7. Proof of Theorem 1.2

The proof of Theorem 1.2 can be found at the end of this section after a few intermediate results.

7.1. Avoiding special points. Here we prove that, in a given algebraic variety $V$ of triangular form, the number of $\Gamma$-orbits of special points lying in $V_0$ is bounded. This is Proposition 7.2 below. First, we need a technical lemma.

Given a finitely generated field extension $L \supseteq K$, we define $[L : K]_{\text{alg}}$ as the smallest positive integer $n$ for which there exists a field $K_0$ satisfying that $L \supseteq K_0 \supseteq K$, $[L : K_0] = n$ and $K_0$ is purely transcendental over $K$.

**Lemma 7.1.** Let $C$ be a finite subset of $\mathbb{C}$, let $x$ be an element of $\mathbb{C}$ and let $M$ be a positive integer. Then, there exists a positive integer $M'$ depending only on $M$ and on $\text{I}_{1}(C, x) : \text{II}_{1}(x)$ such that for every $y$ in $C$ that is algebraic over $\mathbb{Q}(x)$ and satisfies $\text{I}_{1}(C, x, y) : \text{II}_{1}(x) \leq M$ we have $[\mathbb{Q}(x, y) : \mathbb{Q}(x)] \leq M'$.

**Proof.** For any subfield $K$ of $\mathbb{C}$ containing $x$ and any complex number $t$ that is transcendental over $K$, we have $[K(t, y) : K(t)] = [K(y) : K]$ (see, e.g., [15, Chapter VIII, Lemma 4.10]). Now, let $t_1, \ldots, t_m$ in $C$ form a transcendence basis for $\mathbb{Q}(C, x)$ over $\mathbb{Q}(x)$ such that the degree $D = [\mathbb{Q}(C, x) : \mathbb{Q}(t_1, \ldots, t_m, x)]$ equals $[\mathbb{Q}(C, x) : \mathbb{Q}(x)]_{\text{alg}}$. Then, as we have just seen, we have

$$[\mathbb{Q}(t_1, \ldots, t_m, x) : \mathbb{Q}(t_1, \ldots, t_m, x)] = [\mathbb{Q}(x, y) : \mathbb{Q}(x)].$$

Put $M' = MD$ and let $\overline{t} = (t_1, \ldots, t_m)$. By the multiplicative property of the degree of field extensions, we get

$$[\mathbb{Q}(\overline{t}, x, y) : \mathbb{Q}(\overline{t}, x)] \leq [\mathbb{Q}(C, x, y) : \mathbb{Q}(\overline{t}, x)] = [\mathbb{Q}(C, x, y) : \mathbb{Q}(C, x)] \cdot [\mathbb{Q}(C, x) : \mathbb{Q}(\overline{t}, x)] \leq MD = M'.$$

This proves the lemma. \hfill \Box

**Proposition 7.2.** Let $V \subseteq \mathbb{C}^{2n}$ be a variety of triangular form of dimension $n$. Then there is a finite set $S \subset \mathbb{H}$ of special points, such that for every special point $\overline{z}$ in $\mathbb{H}^n$ with $(\overline{z}, j(\overline{z})) \in V_0$, we have that the coordinates of $\overline{z}$ are in $\Gamma \cdot S$.

**Proof.** Let $p_1, \ldots, p_n$ be polynomials defining $V$ satisfying the conditions of triangular form and let $C_0$ be the set of coefficients of the $p_i$’s. Suppose that $\overline{z}$ in $\mathbb{H}^n$ is special and satisfies $(\overline{z}, j(\overline{z})) \in V_0$. Put $C = C_0 \cup \{z_1, \ldots, z_n\}$ and $D = d_1 \cdots d_n$. Since $[\mathbb{Q}(\overline{z}) : \mathbb{Q}] \leq 2^n$, we have $[\mathbb{Q}(C) : \mathbb{Q}(z_i)]_{\text{alg}} \leq 2^n[\mathbb{Q}(C_0) : \mathbb{Q}]_{\text{alg}}$ and $[\mathbb{Q}(C, j(z_i)) : \mathbb{Q}(C)] \leq D$ for every $i$ in $\{1, \ldots, n\}$. As both $z_i$ and $j(z_i)$ are algebraic over $\mathbb{Q}$ we can apply Lemma 7.1 and conclude that $[\mathbb{Q}(z_i, j(z_i)) : \mathbb{Q}(z_i)]$ is bounded above by a number $M$ depending only on $p_1, \ldots, p_n$. By Lemma 2.1 there is a finite subset $S_M$ of $\mathbb{H}$ of special points, depending only on $M$, such that $z_i \in \Gamma \cdot S_M$ for every $i$ in $\{1, \ldots, n\}$. \hfill \Box

**Corollary 7.3.** Let $V \subseteq \mathbb{C}^{2n}$ be an algebraic variety of dimension $n$ of triangular form. Assume that $V$ is not contained in any subvariety of the form $\mathbb{C}^n \times \{j(\overline{z})\}$ with $\overline{z}$ in $\mathbb{H}^n$ special. Then, $V_0$ contains infinitely many points of the form $(\overline{z}_0, j(\overline{z}_0))$ with $\overline{z}_0$ in $\mathbb{H}^n$ not special.

**Proof.** By Proposition 7.2, the set of special points $\overline{z}$ in $\mathbb{H}^n$ with $(\overline{z}, j(\overline{z})) \in V_0$ is contained in $(\Gamma \cdot S)^n$ for some finite set $S \subset \mathbb{H}$ of special points. Put $J = j(S)^n$. By the last statement
in Proposition 5.3 the set \( E^n_0 \cap V_0 \cap (\mathbb{C}^n \times J)^c \) is infinite. This proves the desired result since every point in this set has at least one non-special coordinate. \( \square \)

When working with varieties of triangular form defined over \( \bar{\mathbb{Q}} \) and assuming MSC, we can prove stronger versions of Proposition 7.2 and Corollary 7.3.

**Proposition 7.4.** Let \( V \subseteq \mathbb{C}^{2n} \) be a variety of triangular form of dimension \( n \) defined over \( \bar{\mathbb{Q}} \). Then MSC implies that there is a finite set \( S \subset \mathbb{H}^n \) of special points, such that for every \( \mathfrak{z} \) in \( \mathbb{H}^n \) with \( (\mathfrak{z}, j(\mathfrak{z})) \in V_0 \), we have that the special coordinates of \( \mathfrak{z} \) are in \( \Gamma \cdot S \).

**Proof.** Let \( p_1, \ldots, p_n \) be polynomials defining \( V \) satisfying the conditions of triangular form and let \( C_0 \) be the set of coefficients of the \( p_i \)'s. Suppose that \( \mathfrak{z} \) in \( \mathbb{H}^n \) has at least one special coordinate and satisfies \( (\mathfrak{z}, j(\mathfrak{z})) \in V_0 \). By Proposition 7.2 we can assume that \( \mathfrak{z} \) is not special. Observe that by definition of \( V_0 \) we have

\[
\text{tr.deg}_{\mathbb{Q}}(\mathfrak{z}, j(\mathfrak{z})) = \text{tr.deg}_{\mathbb{Q}}(\mathfrak{z}).
\]

As we are assuming MSC, we have

\[
\text{tr.deg}_{\mathbb{Q}}(\mathfrak{z}, j(\mathfrak{z})) \geq \dim^g(\mathfrak{z}|\Sigma)
\]

(see 8.3). Points in \( \mathbb{H} \) that are algebraically independent must be in different \( G \)-orbits and cannot be in the \( G \)-orbit of special points, as special points are algebraic. This implies that \( \text{tr.deg}_{\mathbb{Q}}(\mathfrak{z}) \leq \dim^g(\mathfrak{z}|\Sigma) \). We conclude

\[
(7.1) \quad \text{tr.deg}_{\mathbb{Q}}(\mathfrak{z}) = \dim^g(\mathfrak{z}|\Sigma).
\]

Put \( A = \{i \in \{1, \ldots, n\} : z_i \text{ is special}\} \), and \( B = \{1, \ldots, n\} \setminus A \). Note that \( B \neq \emptyset \). Choose \( T \subseteq B \) so that \( \mathfrak{z}_T := (z_i)_{i \in T} \) satisfies

\[
\text{tr.deg}_{\mathbb{Q}}(\mathfrak{z}_T) = \text{tr.deg}_{\mathbb{Q}}(\mathfrak{z}) = \dim^g(\mathfrak{z}|\Sigma).
\]

In particular, the set \( \{z_i : i \in T\} \) is algebraically independent over \( \mathbb{Q} \). By (7.1) for every \( k \) in \( B \), \( z_k \) is in the \( G \)-orbit of a point \( \{z_i : i \in T\} \). This implies that

\[
(7.2) \quad z_k \in \mathbb{Q}(\{z_i : i \in T\}) \quad \text{for every } k \text{ in } B.
\]

Let \( \ell \) denote the number of elements of \( A \). Put \( C = C_0 \cup \{z_i : i \in A \cup T\} \) and \( D = d_1 \cdots d_n \) where \( d_i = \deg_{\mathbb{Q}}(p_i) \). For every \( i \) in \( A \) we have

\[
[Q(C) : Q(z_i)]_{\text{alg}} \leq [Q(C_0 \cup \{z_k : k \in A\}) : Q] \leq 2^\ell [Q(C_0) : Q].
\]

By (7.2) and the fact that \( (\mathfrak{z}, j(\mathfrak{z})) \in V_0 \) we also have \([Q(C, j(z_i)) : Q(C)] \leq D \) for every \( i \) in \( \{1, \ldots, n\} \). As both \( z_i \) and \( j(z_i) \) are algebraic over \( \mathbb{Q} \) when \( i \in A \), we can apply Lemma 7.1 and conclude that for every \( i \) in \( A \), \([Q(z_i, j(z_i)) : Q(z_i)] \) is bounded above by a number \( M \) depending only on \( p_1, \ldots, p_n \). By Lemma 2.1 there is a finite subset \( S_M \) of \( \mathbb{H} \) of special points, depending only on \( M \), such that \( z_i \in \Gamma \cdot S_M \) for every \( i \) in \( \{1, \ldots, n\} \). This completes the proof. \( \square \)

Using essentially the same proof as in Corollary 7.3 we conclude the following.

**Corollary 7.5.** Let \( V \subseteq \mathbb{C}^{2n} \) be an algebraic variety of dimension \( n \) of triangular form defined over \( \bar{\mathbb{Q}} \). Assume that \( V \) is not contained in any subvariety of the form \( \mathbb{C}^n \times \{j(\mathfrak{z})\} \) with \( \mathfrak{z} \) in \( \mathbb{H}^n \) non-ordinary. Then MSC implies that \( V_0 \) contains infinitely many points of the form \((\mathfrak{z}_0, j(\mathfrak{z}_0))\) with \( \mathfrak{z}_0 \) in \( \mathbb{H}^n \) ordinary.
7.2. An unconditional case of Theorem 1.2. With the results we have so far, we can already prove a weaker but unconditional version of Theorem 1.2.

**Proposition 7.6.** Let \( V \subset \mathbb{C}^2 \) be an irreducible curve defined over \( \overline{\mathbb{Q}} \). Assume that \( V \) is not a vertical line nor a horizontal line. Then \( V \) has infinitely many points of the form \((z, j(z))\) that are generic over \( \overline{\mathbb{Q}} \).

**Proof.** By Schneider’s theorem, it is enough to prove that \( V \) has infinitely many points of the form \((z, j(z))\) with \( z \) not special. By Lemma 5.2, \( V \) is of triangular form. Moreover, since \( V \) is not a horizontal line, it satisfies the hypothesis of Corollary 7.3, thus there are infinitely many points in \( V_0 \) of the form \((z, j(z))\) with \( z \) not special. \( \square \)

**Remark 7.7.** Here is the analogous result for the exponential function. By [17, Corollary 2.4] we know that an irreducible plane curve \( V \subset \mathbb{C}^2 \) that is not a vertical nor a horizontal line has infinitely many points of the form \((z, \exp(z))\). So by Lindemann’s theorem, we know that if \( V \) is defined over \( \overline{\mathbb{Q}} \), then for any non-zero \( z \in \mathbb{C} \) with \((z, \exp(z)) \in V \) we must have \( \text{tr.deg}_{\overline{\mathbb{Q}}}(z, \exp(z)) = 1 \).

7.3. Points in the same \( G \)-orbit. Here we prove that points in the same \( G \)-orbit and lying in \( V_0 \), where \( V \) is a given algebraic variety of triangular form, are somehow bounded in their orbit. This is the content of Proposition 7.8 below, but first we need to introduce some notation. Recall from §2.1 that for a matrix \( g \in G \), \( \tilde{g} \) represents a matrix obtained by re-scaling \( g \) so that all the entries of \( \tilde{g} \) are integers and relatively prime. Let \( x, y \in \mathbb{H} \) and \( g \) be such that \( gx = y \). In this case, we denote by \( g_{x,y} \) any element in \( G \) satisfying that

\[
\det(\tilde{g}_{x,y}) = \min \{ \det(\tilde{g}) : g \in G, gx = y \}.
\]

Note that, if \( x \) is not special, then any other \( h \) in \( G \) satisfying \( hx = y \) is of the form \( rg \) for some non-zero rational number \( r \). Hence, we have \( \det(\tilde{g}_{x,y}) = \det(\tilde{g}) \) if \( x \) is not special.

**Proposition 7.8.** Let \( V \subset \mathbb{C}^{2n} \) be a variety of triangular form of dimension \( n \). Then for every \( \bar{z} \in \mathbb{H}^n \) there is a positive integer \( M_0 \) such that for every \( g_1, \ldots, g_n \) in \( G \) satisfying

\[
(g_1z_1, \ldots, g_nz_n, j(g_1z_1), \ldots, j(g_nz_n)) \in V_0,
\]

we have \( \det(\tilde{g}_{z_i, g_i z_i}) < M_0 \) for every \( i \) in \( \{1, \ldots, n\} \).

**Proof.** Let \( p_1, \ldots, p_n \) be polynomials defining \( V \) and satisfying the conditions of triangular form. For \( i \) in \( \{1, \ldots, n\} \) let \( d_i \) and \( g_{i,k} \), for \( k \) in \( \{1, \ldots, d_i\} \), be given by [5.1]. Let \( C_0 \) be the set of coefficients of the \( p_i \)'s. Fix \( \bar{z} = (z_i)_{i=1}^n \) in \( \mathbb{H}^n \) such that \((\bar{z}, j(\bar{z})) \in V_0\), put \( C = C_0 \cup \{z_1, \ldots, z_n\} \) and define \( D = d_1 \cdots d_n \). Let \( g_1, \ldots, g_n \) be elements of \( G \). For every \( i \) in \( \{1, \ldots, n\} \) we have that \( g_i z_i \in \mathbb{Q}(z_i) \). If \( g_1, \ldots, g_n \) are such that \((g_1 z_1, \ldots, g_n z_n, j(g_1 z_1), \ldots, j(g_n z_n)) \in V_0 \), then \( j(g_1 z_1) \) is algebraic over \( \mathbb{Q}(C) \) and it generates a field extension whose degree is bounded above by \( d_1 \). Similarly, for \( i \) in \( \{2, \ldots, n\} \), \( j(g_i z_i) \) is algebraic over \( \mathbb{Q}(C, j(g_1 z_1), \ldots, j(g_{i-1} z_{i-1})) \) and it generates a field extension whose degree is bounded above by \( d_i \). This implies that for each \( i \) in \( \{1, \ldots, 2n-d\} \) we have \( [\mathbb{Q}(C, j(g_i z_i)), \mathbb{Q}(C)] \leq D \). By the equivalence between (M1) and (M2) in §2.1 and Lemma 7.1 the degree \([\mathbb{Q}(j(z_i), j(g_i z_i)) : \mathbb{Q}(j(z_i))] \) is bounded above by a constant depending only on \( p_1, \ldots, p_n \) and \( \bar{z} \).

Given \( \bar{z} \in \mathbb{H} \) and \( g \) in \( G \), let \( N \) be the smallest positive integer such that \( \Phi_N(j(z), j(gz)) = 0 \). We have \( N = \det(\tilde{g}_{z_i, gz}) \). We will now show that the degree \([\mathbb{Q}(j(z), j(gz)) : \mathbb{Q}(j(z))] \) is bounded below by a number depending on \( N \) and \( z \). This will be achieved by recollecting known results about gonality of modular curves and isogeny estimates. Observe first that \( j(z) \in \overline{\mathbb{Q}} \) if and only if \( j(gz) \in \overline{\mathbb{Q}} \).
We first consider the case \( j(z) \notin \mathbb{Q} \). Using [22, Lemma 7.3] we get that there are two positive constants \( c \) and \( \delta \) depending only on the field \( \mathbb{Q}(j(z)) \) such that
\[
[\mathbb{Q}(j(z), j(g(z)) : \mathbb{Q}(j(z))] \geq cN^{\delta}.
\]
We now consider the case \( j(z) \in \mathbb{Q} \). We have \( j(g(z)) \in \mathbb{Q} \). Let \( E_1 \) and \( E_2 \) be two elliptic curves defined over the number field \( K = \mathbb{Q}(j(z), j(g(z))) \) such that \( j(E_1) = j(z) \) and \( j(E_2) = j(g(z)) \) (see, e.g. [27, Chapter III, Proposition 1.4(c)]). By [14, Chapter 5, §3, Theorem 5] we know that there is an isogeny \( \lambda : E_1 \to E_2 \) with cyclic kernel of degree \( N \). Define \( N' \) as the smallest positive integer such that there exists an isogeny \( \psi : E_1 \to E_2 \) of degree \( N' \). By [20, Theorem 1] there is a positive constant \( c \) depending only on \( E_1 \) such that
\[
N' \leq c[K : \mathbb{Q}]^6.
\]
On the other hand, by [13, Lemmas 6.1 and 6.2] we have that \( \psi \) is cyclic. This implies that \( N = N' \) and \( c_0N^{\frac{1}{6}} \leq [\mathbb{Q}(j(z), j(g(z)) : \mathbb{Q}(j(z))] \) where \( c_0 = (c^{1/6}[\mathbb{Q}(j(z)) : \mathbb{Q}])^{-1} \). This proves the desired lower bound for \( [\mathbb{Q}(j(z), j(g(z)) : \mathbb{Q}(j(z))] \).
Since \( [\mathbb{Q}(j(z), j(g,z)) : \mathbb{Q}(j(z))] \) is bounded above by a constant depending only on \( p_1, \ldots, p_n \) and \( \tau \) we conclude the same for \( \det(\mathcal{g}_{z,g,z}) \). This proves the proposition.

Remark 7.9. Obtaining results like Proposition 7.8 for the exponential function has proven to be a rather difficult problem, which has only been fully solved for the case of plane irreducible curves (see [10, Theorem 1.1] and [16, §2]).

7.4. Finishing the proof. We will complete the proof of Theorem 1.2 after one last technical lemma, which is the only conditional result used in our proof.

Lemma 7.10. Let \( V \subseteq \mathbb{C}^{2m} \) be a variety of triangular form of dimension \( n \), let \( K \) be a finitely generated subfield of \( \mathbb{C} \) and let \( B \) be the set of non-special coordinates of points \( \tau \) in \( (\mathbb{H} \cap K)^n \) such that \( (\tau, j(\tau)) \in V_0 \). Then MSC implies that \( \dim^g(B) \) is finite.

Proof. Let \( b_1, \ldots, b_m \) be elements of \( B \). For every \( i \in \{1, \ldots, m\} \), choose a point \( \tau_i \) in \( (\mathbb{H} \cap K)^n \) such that \( (\tau_i, j(\tau_i)) \in V_0 \) and at least one of the coordinates of \( \tau_i \) equals \( b_i \). Let \( F \) be a finitely generated field over which \( V \) is defined. By hypothesis and the definition of \( V_0 \) we have
\[
\text{tr.deg.}(\tau_1, \ldots, \tau_m, j(\tau_1), \ldots, j(\tau_m)) \leq \text{tr.deg.}(\tau_1, \ldots, \tau_m, j(\tau_1), \ldots, j(\tau_m), F) = \text{tr.deg.}(\tau_1, \ldots, \tau_m, F) \leq \text{tr.deg.}(\tau_1, \ldots, \tau_m) + \text{tr.deg.} F.
\]
Now, \( \text{tr.deg.}(\tau_1, \ldots, \tau_m) \leq \text{tr.deg.} \mathbb{Q}(K) \), which is finite. On the other hand, under MSC,
\[
\text{tr.deg.}(\tau_1, \ldots, \tau_m, j(\tau_1), \ldots, j(\tau_m)) \geq \dim^g(\tau_1, \ldots, \tau_m|\Sigma) \geq \dim^g(b_1, \ldots, b_m),
\]
hence \( \dim^g(B) \leq \text{tr.deg.} F + \text{tr.deg.} \mathbb{Q}(K) \). This completes the proof.

Remark 7.11. Lemma 7.10 can be seen as an analogue of [16, Proposition 2.2].

We can now give the proof of Theorem 1.2.

Proof of Theorem 1.2. By Lemma 5.2, \( V \) is of triangular form. By Lemma 7.10 we know that there is a finite subset \( R \) of \( \mathbb{H} \cap K \) such that, if \( z \in \mathbb{H} \cap K \) is not special and satisfies \( (z, j(z)) \in V_0 \), then \( z \in G \cdot R \). By Proposition 7.8 there is a positive integer \( M \) such that for every \( z \in R \) and every \( g \in G \) we have
\[
(gz, j(gz)) \in V_0 \Rightarrow \det(\mathcal{g}) \leq M.
\]
The group $\Gamma$ acts by left multiplication on the set $A = \{ g \in M_2^+(\mathbb{Z}) : \det(g) \leq M \}$ decomposing $A$ into finitely many $\Gamma$-orbits. This implies that the set

$$J_1 = \{ j(g(z)) : z \in R, g \in G, (gz, j(gz)) \in V_0 \}$$

is finite. On the other hand, by Proposition 7.2, the set

$$J_2 = \{ j(z) : z \in \mathbb{H} \text{ special}, (z, j(z)) \in V_0 \}$$

is also finite. Put $J = J_1 \cup J_2$. Since $V$ is not contained in $\mathbb{C} \times J$, we can apply Proposition 5.3. We obtain that the set

$$E_n^c \cap V_0 \cap (\mathbb{C} \times J)^c$$

is infinite. Every point in this set is of the form $(z, j(z))$ with $z$ in $\mathbb{H}$ not special and not in $\mathbb{R}$, hence satisfying tr.deg.$_{\mathbb{R}}(z, j(z)) = 1$. This completes our proof. \qed

8. Proof of Theorem 1.3

In this section we present the proof of Theorem 1.3. The main ingredient is our Proposition 4.1.

Proof of Theorem 1.3. We can write

$$p(X, Y_1, \ldots, Y_n) = \sum_{i=0}^{d} p_i(X, Y_1, \ldots, Y_{n-1})Y_n^i$$

where $d$ is a positive integer and $p_0, \ldots, p_d$ are polynomials in $\mathbb{C}[X, Y_1, \ldots, Y_{n-1}]$ with $p_d \neq 0$. Let $R$ denote the ring $\mathbb{C}[X, Y_1, \ldots, Y_{n-1}]$ and let $r$ in $R$ be the resultant of $p$ and $\frac{\partial p}{\partial Y_n}$ as polynomials in $R[Y_n]$ (\cite{9} Chapter 2, \S 2). Since $p$ is irreducible, we have $r \neq 0$. There exist polynomials $F, G$ in $R[Y_n]$ such that $Fp + G \frac{\partial p}{\partial Y_n} = r$. Since the product $rp_d$ is a non-zero polynomial in $R$, we can find a point $\overline{v} = (x, y_1, \ldots, y_{n-1})$ in $\mathbb{R}^n$ with $r(\overline{v})p_d(\overline{v}) \neq 0$. Since $p_d(\overline{v}) \neq 0$ and $\mathbb{C}$ is algebraically closed, we can find $y_n$ in $\mathbb{C}$ such that $p(\overline{v}, y_n) = 0$. Since $r(\overline{v}) \neq 0$, we must have $\frac{\partial p}{\partial Y_n}(\overline{v}, y_n) \neq 0$. By the Implicit Function Theorem, there exists neighbourhoods $U_1, U_2$ of $\overline{v}$ in $\mathbb{C}^n$ and of $y_n$ in $\mathbb{C}$, respectively, and a holomorphic function $H : U_1 \to U_2$ such that

$$\{ \overline{v} \in U_1 \times U_2 : p(\overline{v}) = 0 \} = \{ (\overline{w}, H(\overline{w})) : \overline{w} \in U_1 \}.$$ 

Since $U_1 \cap \mathbb{R}^n \neq \emptyset$, we can apply Proposition 4.1 to the system of equations

$$j(z) = z_1,$$
$$j(z_1) = z_2,$$
$$\vdots$$
$$j(z_{n-1}) = H(z_1, \ldots, z_{n-1}),$$

for $(z, z_1, \ldots, z_{n-1})$ in $U_1 \cap \mathbb{H}^n$. Hence, this system has infinitely many solutions. Different solutions of this system give different complex numbers $z$ in $\mathbb{H}^n$ with $(z, j(z), \ldots, j_n(z)) \in V$. This completes the proof of the theorem. \qed

9. Proof of Theorem 1.4

The proof of Theorem 1.4 is given at the end of this section after a couple of lemmas.

Lemma 9.1. Let $p(X, Y)$ be a non-zero polynomial in $\mathbb{C}[X, Y]$ and let $m$ denote the degree of $p(X, Y)$ with respect to the $X$ variable. Define

$$D(p, G) = \left\{ g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in M_2^+(\mathbb{Z}) : \gcd(a, b, c, d) = 1, (cX + d)^m p(gX, X) = 0 \right\}.$$
Then, \( D(p; G) \) is finite.

**Proof.** Let \( g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \) be a matrix in \( M_2^+(\mathbb{Z}) \). We have \((cX + d)^mp(gX, X) = 0\) if and only if \( p \) vanishes on \( V(L_g) \), where \( L_g(X, Y) := aY + bX(cY + d) \). Since \( L_g \) is irreducible, this means that \( L_g \) divides \( p \). For \( g, g' \) in \( D(p; G) \) with \( g \neq \pm g' \) we have that the irreducible polynomials \( L_g \) and \( L_g' \) are not associated. Since \( p \) is divisible by only finitely many non-associated irreducible polynomials, we conclude that \( D(p; G) \) is finite. This proves the lemma. \( \square \)

**Lemma 9.2.** Let \( p(X, Y_1, Y_2) \) be a non-zero polynomial in \( \overline{\mathbb{Q}}[X, Y_1, Y_2] \) with \( \frac{\partial p}{\partial Y_2} \neq 0 \). Write

\[
p(X, Y_1, Y_2) = \sum_{i=0}^{d} p_i(X, Y_1) Y_2^i,
\]

where \( p_i(X, Y_1) \in \overline{\mathbb{Q}}[X, Y_1] \) and \( p_d \neq 0 \), and let

\[
W = \{(x, y_1, y_2) \in V(p) : p_d(x, y_1) \neq 0\}.
\]

Then there exist finite sets \( J_1, J_2 \subset \mathbb{C} \) such that

\[
\{z \in \mathbb{H}_2 : z \text{ is special and } (z, j(z), j_2(z)) \in W\} \subseteq J_1
\]

and

\[
\{z \in \mathbb{H}_2 : z \text{ is not special, } j(z) \text{ is special and } (z, j(z), j_2(z)) \in W\} \subseteq J_2.
\]

**Proof.** We claim that there exist only finitely many \( \Gamma \)-orbits of special points \( z \) in \( \mathbb{H}_2 \) with \((z, j(z), j_2(z)) \in W\). Indeed, choose \( C_0 \) as the set of coefficients of \( p \). If \( z \) is special and \((z, j(z), j_2(z)) \in W\), then \( j_2(z) \) is algebraic over \( \mathbb{Q}(C_0, z, j(z)) \). Since \( \mathbb{Q}(C_0, z, j(z)) \subset \overline{\mathbb{Q}} \), \( j_2(z) \) must be algebraic over \( \mathbb{Q} \). This implies that \( j(z) \) is a special point in \( \mathbb{H} \), hence \([\mathbb{Q}(z) : \mathbb{Q}(z, j(z))] \leq 4\). By Lemma 2.1 we have that \( z \) must belong to a finite list of \( \Gamma \)-orbits that is independent of \( z \), as claimed. We conclude that there exists a finite set \( J_1 \subset \mathbb{C} \) independent of \( z \) such that \( j(z) \in J_1 \).

Now, assume that \( z \) is not special, \( j(z) \) is special and \((z, j(z), j_2(z)) \in W\). Since \( j(z) \) is algebraic and \( z \) is not special, we must have that \( z \) is transcendental. Choose \( C = C_0 \cup \{z\} \). We have that \( j_2(z) \) is algebraic over \( \mathbb{Q}(j(z)) \),

\[
[\mathbb{Q}(C, j(z), j_2(z)) : \mathbb{Q}(C, j(z))] = [\mathbb{Q}(C_0, z, j(z), j_2(z)) : \mathbb{Q}(C_0, z, j(z))] \leq d
\]

and

\[
[\mathbb{Q}(C, j(z)) : \mathbb{Q}(j(z))]_{\text{alg}} = [\mathbb{Q}(C_0, z, j(z)) : \mathbb{Q}(j(z))]_{\text{alg}} \\
\leq [\mathbb{Q}(C_0, z, j(z)) : \mathbb{Q}(j(z), z)] \\
\leq [\mathbb{Q}(C_0) : \mathbb{Q}].
\]

By Lemma 7.4 we conclude that \([\mathbb{Q}(j_2(z), j(z)) : \mathbb{Q}(j(z))] \) is bounded above by a constant depending only on \( p \). Then, by Lemma 7.1 we have that \( j(z) \) must belong to a finite list of \( \Gamma \)-orbits that depends only on \( p \). This implies that there exists a finite set \( J_2 \subset \mathbb{C} \) depending only on \( p \) such that \( j_2(z) \in J_2 \). This proves the lemma. \( \square \)

**Proof of Theorem 1.4.** There exists an integer \( d \geq 1 \) and polynomials \( p_0, \ldots, p_d \in \overline{\mathbb{Q}}[X, Y_1] \) with \( p_d \neq 0 \) such that

\[
p(X, Y_1, Y_2) = \sum_{i=0}^{d} p_i(X, Y_1) Y_2^i.
\]
Put $W = \{(x, y_1, y_2) \in V : p_d(x, y_1) \neq 0\}$ and let $J_1, J_2$ be the finite subsets of $\mathbb{C}$ given by Lemma [9]. Define $r$ in $\mathbb{C}[X, Y]$ as the resultant of the polynomials $p$ and $\frac{\partial p}{\partial Y^2}$ ([9] Chapter 2, §2). The set
\[
A = \{(x, y_1) \in \mathbb{C}^2 : r(x, y_1) \neq 0, y_1 \notin J_1\}
\]
is Zariski open in $\mathbb{C}^2$ and non-empty. Thus, we can find a point $(x_0, y_0)$ in $A \cap \mathbb{R}^2$. We choose a point $y_1$ in $\mathbb{C}$ with $p(x_0, y_0, y_1) = 0$ and use the Implicit Function Theorem in order to find open neighbourhoods $U_1$ of $(x_0, y_0)$ in $\mathbb{C}$ and $U_2$ of $y_1$ in $\mathbb{C}$ such that
\[
V \cap (U_1 \times U_2) = \{(z, z_1, H(z, z_1)) : (z, z_1) \in U_1\}
\]
for some holomorphic function $H : U_1 \rightarrow U_2$. By shrinking $U_1$, if necessary, we can assume that $U_1$ is connected and $U_1 \subseteq A$. For a positive integer $N$ (to be chosen conveniently later) we define $F_N$ in $\mathbb{C}[Y_1, Y_2]$ as
\[
F_N(Y_1, Y_2) = \prod_{i=1}^{N} \Phi_i(Y_1, Y_2) \cdot \prod_{t \in J_2} (Y_2 - t),
\]
where $\Phi_1, \ldots, \Phi_N$ are the first $N$ modular polynomials. We claim that
\[
(9.1) \quad \{(z, z_1) \in U_1 \cap \mathbb{R}^2 : F_N(z_1, H(z, z_1)) \neq 0\} \neq \emptyset.
\]
Indeed, if this set were empty, then we would have $F_N(z_1, H(z, z_1)) = 0$ for every $(z, z_1)$ in $U_1$ and then
\[
V \cap (U_1 \times U_2) \subseteq V(p, F_N).
\]
By Corollary [2.3] we get that $V$ is contained in $V(p, F_N)$ thus $p$ must divide $F_N$, which is impossible since $F_N$ depends only on $Y_1$ and $Y_2$ while $p$ depends also on $X$. This proves (9.1).

Consider the system of equations
\[
\begin{align*}
    j(z) &= z_1, \\
    j(z_1) &= H(z, z_1), \\
    \frac{1}{j(w)} &= F_N(z_1, H(z, z_1)),
\end{align*}
\]
for $(z, z_1, w)$ in $\mathbb{H}^3 \cap (U_1 \times \mathbb{C})$. Since $\frac{1}{j}$ attains all values in $\mathbb{C} \setminus \{0\}$ and $F_N(z_1, H(z, z_1))$ is non identically zero (by (9.1)) we can apply Proposition [4.1]. This way we obtain infinitely many solutions of this system. Clearly, for each solution $(z, z_1, w)$ we have $z \in \mathbb{H}_2$ and
\[
(z, j(z), j_2(z)) = (z, z_1, H(z, z_1)) \in W \subseteq V.
\]
Since $U_1 \subseteq A$ we have $j(z) \notin J_1$ thus $z$ is not special. Moreover, since $F(z_1, H(z, z_1)) = \frac{1}{j(w)} \neq 0$, we have $H(z, z_1) \notin J_2$ and $j(z)$ is also not special. Now, assuming MSC we get the inequality
\[
\text{tr.deg}_Q(z, j(z), j_2(z)) \geq \dim_Q(z, j(z)).
\]
In order to complete our proof, we will show that $z$ and $j(z)$ cannot be in the same $G$-orbit if $N$ is big enough. Indeed, let $m$ be the degree of $p(X, Y_1, Y_2)$ in the $X$ variable, let $D(p_d; G)$ be the set defined in Lemma [9] and put $N_1 = \max\{\text{det}(g) : g \in D(p_d; G)\}$ (choose $N_1 = 1$ if $D(p_d; G)$ is empty). Define $N_2$ as the total degree of $p$. We choose $N$ to be the maximum between $N_1$ and $N_2$ (or any integer greater than both $N_1$ and $N_2$). Now, assume that $z$ and $j(z)$ are in the same $G$-orbit. Let $g$ be an element of $G$ such that $z = gj(z)$. Using the notation of §2.4 let $a, b, c, d$ be the entries (in the usual way) of $g$. Put $M = \det(g)$. Then $\Phi_M(j(z), j_2(z)) = 0$. Define the polynomial
\[
q(X, Y) := (cX + d)^m p(\tilde{g}X, X, Y) \in \mathbb{Q}[X, Y],
\]
and set \( V_1 = \{ q(X, Y) = 0 \} \) and \( V_2 = \{ \Phi_M(X, Y) = 0 \} \) as affine subvarieties of \( \mathbb{C}^2 \). Observe that \((j(z), j_2(z)) \in V_1 \cap V_2 \). As \( j(z) \) is not special, it cannot happen that both \( j(z) \) and \( j_2(z) \) are algebraic. Since \( V_2 \) is irreducible and defined over \( \mathbb{Q} \) (hence over \( \mathbb{Q} \)), and \( \text{tr.deg}_\mathbb{Q}(j(z), j_2(z)) = 1 \), we get \( V_2 \subseteq V_1 \) by Lemma 2.2. This means that either \( V_1 = \mathbb{C}^2 \) or \( \Phi_M(X, Y) \) divides \( q(X, Y) \). In the first case we have \( q(X, Y) = 0 \), thus \( (cX + d)^m p_d(\tilde{g}X, X) = 0 \) and \( \tilde{g} \in D(p_d; G) \). This implies that \( M \leq N \) hence \( F_N(j(z), j_2(z)) = 0 \), which is a contradiction since \( F_N(j(z), j_2(z)) = \frac{1}{\gamma_j(w)} \neq 0 \). In the second case \( \Phi_M(X, Y) \) divides \( q(X, Y) \), thus
\[
M \leq \deg(\Phi_M) \leq \deg q \leq N_2 \leq N,
\]
and \( F_N(j(z), j_2(z)) = 0 \), which gives the same contradiction as in the first case. This proves that \( z \) and \( j(z) \) cannot be in the same \( G \)-orbit and, by MSC, we conclude that \( \text{tr.deg}_\mathbb{Q}(z, j(z), j_2(z)) = 2 \). By choosing different points \((x_0, y_0)\) in \( A \cap \mathbb{R}^2 \) one can show that there are actually infinitely many \( z \) in \( \mathbb{H}_2 \) satisfying the desired conditions. This completes the proof of the theorem.  

\[\square\]

### 10. Further directions

In this final section, we want to show how the same ideas used in our proof of Proposition 10.1 can be applied in other contexts. Specifically, we present two examples: the existence of solutions of certain analytic equations involving \( j' \) (the usual derivative of the \( j \) function, which is a weakly holomorphic modular form of weight 2), and of equations involving the function \( \exp(1/z) \).

**Proposition 10.1.** Let \( U \) be an open subset of \( \mathbb{C} \) with \( U \cap \mathbb{R} \neq \emptyset \) and let \( H : U \to \mathbb{C} \) be a holomorphic function. Then there are infinitely many \( z \) in \( \mathbb{H} \cap U \) such that
\[
j'(z) = H(z).
\]

**Proof.** Let \( \rho \) denote the complex number \( \frac{1}{2} + i \frac{\sqrt{3}}{2} \). It is known that \( j(\rho) = j'(\rho) = 0 \). Since \( j \) is \( \Gamma \)-invariant and \( j' \) satisfies the transformation property
\[
j'(\gamma z) = (cz + d)^2 j'(z) \quad \text{for every } \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma,
\]
we have \( j(\gamma \rho) = j'(\gamma \rho) = 0 \) for every \( \gamma \) in \( \Gamma \). Choose a small closed disk \( B \subset \mathbb{H} \) around \( \rho \) such that \( j \) does not vanish on the boundary of \( B \) and put \( \delta = \min \{|j(z)| : z \in \partial B| \}. \) Let \( x \) be a point in \( U \cap \mathbb{R} \) and let \( (\gamma_n)_{n=1}^\infty \) be a sequence of elements in \( \Gamma \) such that \( |\gamma_n \rho - x| \to 0 \) as \( n \) goes to infinity. Then, we have \(|\gamma_n z - x| \to 0 \) as \( n \) goes to infinity, uniformly for \( z \) in \( B \) (see the proof of Proposition 10.1 in Section 8). This implies that there exists a positive integer \( N \) such that for every integer \( n > N \) we have \( \gamma_n B \subset U \) and
\[
\max \{|z - x| : z \in \partial(\gamma_n B)| < \delta.
\]

Since \( \delta = \min \{|j(z)| : z \in \partial(\gamma_n B)| \}, \) we can apply Rouche’s theorem to the functions \( f(z_1, z_2) = (j(z_1), j'(z_2)) \) and \( g(z_1, z_1) = (z_1 - x, -H(z_2)) \) on \( (\gamma_n B) \times (\gamma_n B) \). Since \( f \) has a zero in the interior of \( (\gamma_n B) \times (\gamma_n B) \) (namely \( (\gamma_n \rho, \gamma_n \rho) \)), we get that \((f + g)(z_1, z_2) = (j(z_1) + z_1 - x, j'(z_2) - H(z_2)) \) also has a zero there. In particular, the equation \( j'(z) = H(z) \) has a solution in \( \gamma_n B \). This implies the desired result.  

\[\square\]

**Remark 10.2.** We point out that the proof of Proposition 10.1 can be easily adapted to show that the equation \( j''(z) = H(z) \) has infinitely many solutions. This is because the second derivative of \( j \) also satisfies \( j''(\gamma \rho) = 0 \) for every \( \gamma \in \Gamma \).
Proposition 10.3. Let $U$ be an open subset of $\mathbb{C}$ containing 0, and let $f$ be a holomorphic function defined on $U$ such that $f(0) \neq 0$. Then there are infinitely many $z$ in $U$ such that 
\[ \exp(1/z) = f(z). \]

Proof. Let $\Lambda$ denote the group of matrices
\[ \Lambda = \left\{ \gamma_n := \begin{pmatrix} 1 & 0 \\ 2\pi i n & 1 \end{pmatrix} : n \in \mathbb{Z} \right\}. \]
Then $\Lambda$ acts on $\mathbb{C}^\times \cup \{\infty\}$ through Möbius transformations and $\exp(1/z)$ is invariant under this action. Put $\alpha = f(0)$. Let $x$ in $\mathbb{C}^\times$ be such that $\exp(1/x) = \alpha$. Let $B$ be a small closed disk around $x$ contained in $\mathbb{C}^\times$ so that $\exp(1/z) \neq \alpha$ for all $z$ in $\partial B$. Set $g(z) := \exp(1/z) - \alpha$ and $h(z) := \alpha - f(z)$. As $g(z)$ does not vanish on $\partial B$, the real number $\delta := \min \{|g(z)| : z \in \partial B\}$ is positive. Furthermore, as $g$ is invariant under the action of $\Lambda$, we have $\delta = \min \{|g(z)| : z \in \partial(\gamma_n B)\}$ for every integer $n$.

Observe that for every $z \in \mathbb{C}^\times$, $\gamma_n z \to 0$ as $n$ goes to infinity. Moreover, the convergence is uniform for $z$ in a compact subset of $\mathbb{C}^\times$. As $f$ is continuous at 0 we have that $f(\gamma_n z) \to \alpha$ as $n$ goes to infinity, uniformly for $z$ in $B$. This implies that there exists a positive integer $N$ such that for every integer $n > N$, we have $|h(z)| < \delta$ for every $z$ in $\partial(\gamma_n B)$. Hence, if $n > N$ we have $|g(z)| \geq \delta > |h(z)|$ for every $z$ in $\partial(\gamma_n B)$. By Rouché’s theorem, we get that $g(z)$ and $g(z) + h(z)$ have the same number of zeros in $\gamma_n B$, for all $n > N$. Now, $g(\gamma_n x) = g(x) = 0$ so $g(z) + h(z) = \exp(1/z) - f(z)$ has at least one zero in $\gamma_n B$. This implies the desired result and completes the proof of the proposition. \hfill \Box
