ANNIHILATORS OF $\mathcal{D}$-MODULES IN MIXED CHARACTERISTIC

RANKEYA DATTA, NICHOLAS SWITALA, AND WENLIANG ZHANG

Abstract. Let $R$ be a polynomial or formal power series ring with coefficients in a DVR $V$ of mixed characteristic with a uniformizer $\pi$. We prove that the $R$-module annihilator of any nonzero $\mathcal{D}(R, V)$-module is either zero or is generated by a power of $\pi$. In contrast to the equicharacteristic case, nonzero annihilators can occur; we give an example of a top local cohomology module of the ring $\mathbb{Z}_2[[x_0, \ldots, x_5]]$ that is annihilated by 2, thereby answering a question of Hochster in the negative.

1. Introduction

In [7], Huneke discussed 4 basic problems concerning local cohomology; these problems have guided the developments in the study of local cohomology modules for over two decades. As mentioned in the introduction of [7], “We will find all of these problems are connected with another question: what annihilates the local cohomology?” More concretely, Hochster’s [6, Question 6] asks the following:

Question 1.1. Is the top local cohomology module of a local Noetherian domain with support in a given ideal faithful? That is, if $R$ is a local Noetherian domain and $I \subseteq R$ is an ideal of cohomological dimension $\delta$, is $H^\delta_I(R)$ a faithful $R$-module?

Here $H^\delta_I(R)$ being faithful amounts to $\text{Ann}_R(H^\delta_I(R)) = (0)$. When $R$ is a regular local ring containing a field, Question 1.1 has a positive answer; this was stated in [9, Theorem 1.1] and was attributed to Hochster and Huneke [8, Lemma 2.2] in characteristic $p > 0$ and to Lyubeznik in characteristic zero. As stated in [9, page 543], when $R$ is a regular local ring of mixed characteristic, Question 1.1 remained open.

Question 1.1 also stems from a conjecture made by Lynch in [9]; Lynch conjectured that Question 1.1 has a positive answer for all Noetherian local rings even without assuming the ring is a domain. In [11, Example 3.2], a counterexample to Lynch’s conjecture was found; note that the local ring in [11, Example 3.2] is not equidimensional.

The main purpose of this paper is to investigate Question 1.1 for regular local rings of mixed characteristic. One of our main results classifies annihilators of $\mathcal{D}$-modules as follows.

Theorem A (Theorem 3.1). Let $R = V[[x_1, \ldots, x_n]]$ or $R = V[x_1, \ldots, x_n]$ where $(V, \pi V)$ is a DVR of mixed characteristic $(0, p)$. Let $M$ be a nonzero $\mathcal{D}(R, V)$-module. Either $\text{Ann}_R(M) = (0)$ or $\text{Ann}_R(M) = (\pi^\ell)$ for some $\ell \geq 1$.

Note that local cohomology modules of $R$ are primary examples of $\mathcal{D}(R, V)$-modules (cf. §2).

Investigating local cohomology from the $\mathcal{D}$-module viewpoint originated in [10]. As shown in [10], in characteristic 0 the fact that local cohomology modules have finite length in the category of $\mathcal{D}$-modules plays a pivotal role. Our next result shows that, for a large class of $\mathcal{D}(R, V)$-modules (including local cohomology modules) in mixed characteristic, having finite $\mathcal{D}(R, V)$-module length is equivalent to having nonzero annihilator in $R$.

Theorem B (Theorem 4.4). Let $M$ be a $\mathcal{D}(R, V)$-module that admits a Lyubeznik filtration. Then $M$ is of finite length in $\text{Mod}_{\mathcal{D}(R, V)}$ if and only if $\text{Ann}_R(M) \neq (0)$.

The notion of a Lyubeznik filtration will be explained in [4] local cohomology modules of $R$ are primary examples of $\mathcal{D}(R, V)$-modules that admit Lyubeznik filtrations.

We also answer Question 1.1 in the negative in the case of regular local rings of mixed characteristic by considering Reisner’s example.

Theorem C (Example 5.2). Let $A = \mathbb{Z}[x_0, \ldots, x_5]$ and $\mathfrak{m} = (2, x_0, \ldots, x_5) \subseteq A$. Let $R$ be the $\mathfrak{m}$-adic completion of $A$, and let $I$ be the ideal of $R$ generated by the 10 monomials

$$\{x_0 x_1 x_2, x_0 x_1 x_3, x_0 x_2 x_4, x_0 x_3 x_5, x_0 x_4 x_5, x_1 x_2 x_5, x_1 x_3 x_4, x_1 x_4 x_5, x_2 x_3 x_4, x_2 x_3 x_5\}.$$  

Then $\text{cd}(R, I) = 4$ and $\text{Ann}_R(H^4_j(R)) = (2) \neq (0)$.

The paper is organized as follows. In §2 we review some basics of the theory of $\mathcal{D}$-modules; in §3 we classify the annihilators of $\mathcal{D}(R, V)$-modules when $R$ is a ring of polynomials or formal power series over a DVR $(V, \pi V)$ of mixed characteristic $(0, p)$; §4 is devoted to investigating the link between the length of $\mathcal{D}(R, V)$-modules and their annihilators; finally, in §5 we answer Question 1.1 in the negative.

Acknowledgments. The second author thanks Tom Marley, who first interested him in these questions. The authors also thank Benjamin Antieau and Kevin Tucker for helpful conversations.

2. Preliminaries on $\mathcal{D}$-modules

We begin by fixing some conventions. All rings are assumed to have a unit element 1. If $R$ is a commutative ring and $r \in R$ is an element, we denote by $(r)$ the principal ideal $rR \subseteq R$. All local commutative rings are assumed to be Noetherian. When we say that $(V, \pi V, k)$ is a DVR of mixed characteristic $(0, p)$, we mean that $V$ is a rank-one discrete valuation ring of characteristic zero whose maximal ideal is the principal ideal $(\pi) = \pi V$ generated by $\pi$, and whose residue field $k = V/\pi V$ has characteristic $p > 0$. If $\omega \in V$, we denote by $\nu_\pi(\omega)$ the $\pi$-adic valuation of $\omega$, that is, $\nu_\pi(\omega)$ is the exponent in the largest power of $\pi$ dividing $\omega$ (so $\nu_\pi(\omega) = 0$ if and only if $\omega$ is a unit in $V$).

We now provide some necessary background material concerning $\mathcal{D}$-modules. If $S$ is any commutative ring and $A \subseteq S$ is a commutative subring, then the ring $\mathcal{D}(S, A)$ of $A$-linear differential operators on $S$, a subring of $\text{End}_A(S)$, is defined recursively as follows [4] §16. A differential operator $S \to S$ of order zero is multiplication by an element of $S$. Supposing that differential operators of order $\leq j - 1$ have been defined, $d \in \text{End}_A(S)$ is said to be a differential operator of order $\leq j$ if, for all $s \in S$, the commutator $[d, s] \in \text{End}_A(S)$ is a differential operator of order $\leq j - 1$. We write $\mathcal{D}^j(S)$ for the set of differential operators on $S$ of order $\leq j$ and set $\mathcal{D}(S, A) = \bigcup_j \mathcal{D}^j(S)$. Every $\mathcal{D}^j(S)$ is naturally a left $S$-module. If $d \in \mathcal{D}^j(S)$ and $d' \in \mathcal{D}^l(S)$, it is easy to prove by induction on $j + l$ that $d' \circ d \in \mathcal{D}^{j+l}(S)$, so $\mathcal{D}(S, A)$ is a ring.

By a $\mathcal{D}(S, A)$-module, we mean a left module over the ring $\mathcal{D}(S, A)$. We denote by $\text{Mod}_{\mathcal{D}(S, A)}$ the Abelian category of (left) $\mathcal{D}(S, A)$-modules. The ring $S$ itself has a $\mathcal{D}(S, A)$-module structure; using the quotient rule, we can give a $\mathcal{D}(S, A)$-module structure to the localization $S_f$ for every $f \in S$ in such a way that the natural localization map $S \to S_f$ is a map of $\mathcal{D}(S, A)$-modules. Using the Čech complex interpretation of local cohomology, it follows [10] Example 2.1] that the local cohomology modules $H^i_f(S)$ have $\mathcal{D}(S, A)$-module structures for all finitely generated ideals $I \subseteq S$ and all $i \geq 0$.

We will be concerned with the special case in which $S = A[[x_1, \ldots, x_n]]$ (resp. $S = A[x_1, \ldots, x_n]$) is a formal power series (resp. polynomial) ring with coefficients in $A$. In this case, we can describe explicitly
the structure of the ring $\mathcal{D}(S, A)$: we have
\[ \mathcal{D}(S, A) = S(\partial_t^{|i|} \mid 1 \leq i \leq t, t \geq 1) \]
by [4, Thm. 16.11.2], where $\partial_t^{|i|}$ denotes the differential operator $\frac{1}{t!} \partial^{|i|}/\partial x_1^{|i|}$ (which is well-defined even if the natural number $t$ is not invertible in $S$). If $a \in A$ is an element, then $a\mathcal{D}(S, A)$ is a two-sided ideal of $\mathcal{D}(S, A)$, and it follows from the displayed equality (with $A$ replaced by the quotient $A/(a)$) that
\[ \mathcal{D}(S, A)/a\mathcal{D}(S, A) \cong \mathcal{D}(S/(a), A/(a)) \]
as rings. In particular, a $\mathcal{D}(S/(a), A/(a))$-module is precisely a $\mathcal{D}(S, A)$-module annihilated by $a$.

**Definition 2.1.** We denote by $\mathcal{C}(S, A)$ the smallest Serre subcategory of $\text{Mod}_{\mathcal{D}(S, A)}$ containing all $\mathcal{D}(S, A)$-modules of the form $S_f$ for some $f \in S$.

Our interest in the subcategory $\mathcal{C}(S, A)$ is that, if $S$ is Noetherian, this subcategory contains all local cohomology modules of $S$.

**Lemma 2.2.** [11, Lemma 5] Let $S$ be a commutative Noetherian ring and $A \subseteq S$ a commutative subring. For all ideals $I \subseteq S$ and all $i \geq 0$, the local cohomology modules $H^i_I(S)$ are objects of $\mathcal{C}(S, A)$.

We note that Lemma 2.2 is stated in [11] under the assumption that $A$ is a field, but this hypothesis is not used in its proof.

We will need the following two propositions in the sequel.

**Proposition 2.3.** [11, Corollaries 3' and 6] Let $S = k[[x_1, \ldots, x_n]]$ or $k[x_1, \ldots, x_n]$ for some $n \geq 0$, where $k$ is a field. Every object of $\mathcal{C}(S, k)$ is of finite length in $\text{Mod}_{\mathcal{D}(S, k)}$.

**Proposition 2.4.** Let $S = k[[x_1, \ldots, x_n]]$ or $k[x_1, \ldots, x_n]$ for some $n \geq 0$, where $k$ is a field. If $M$ is a nonzero $\mathcal{D}(S, k)$-module, then $\text{Ann}_S(M) = (0)$.

Proposition 2.4 is essentially contained in the proof of [2, Theorem 3.6] which only treats local cohomology modules; it follows from [3, Proposition 3.3] and [2, Theorem 2.4]. Also note that Proposition 2.4 makes no assumption about the characteristic of $k$.

### 3. The Annihilator of a $\mathcal{D}(R, V)$-module

Throughout this section, $(V, \pi V, k)$ denotes a fixed DVR of mixed characteristic $(0, p)$, and $R$ denotes either the ring $V[[x_1, \ldots, x_n]]$ or $V[x_1, \ldots, x_n]$ for some $n \geq 0$. In either case, we denote by $\overline{R}$ the ring $R/(\pi)$, which is either a formal power series or polynomial ring over $k$. Our goal in this section is to classify the possible $R$-module annihilators of $\mathcal{D}(R, V)$-modules, and our main result is the following:

**Theorem 3.1.** Let $M$ be a nonzero $\mathcal{D}(R, V)$-module. Either $\text{Ann}_R(M) = (0)$ or $\text{Ann}_R(M) = \pi^\ell R$ for some $\ell \geq 1$.

In order to prove Theorem 3.1 we begin with a classification of $\mathcal{D}(R, V)$-submodules of $R$.

**Theorem 3.2.** Let $I \subseteq R$ be a nonzero $\mathcal{D}(R, V)$-submodule of $R$. There exists a natural number $\ell \geq 0$ such that $I = \pi^\ell R$.

**Proof.** We write elements $f \in R$ in multi-index notation as follows:
\[ f = \sum_{\beta \in (\mathbb{Z}_{\geq 0})^n} \omega_\beta x^\beta, \]

1The proof of Proposition 3.3 in [3] is incomplete, and was corrected in [3].
where all $\omega_\beta \in V$ and if $\beta = (\beta_1, \ldots, \beta_n) \in (\mathbb{Z}_{\geq 0})^n$, then $x^\beta$ denotes the monomial $x_1^{\beta_1} \cdots x_n^{\beta_n}$. (When $R$ is a polynomial ring over $V$, we of course have $\omega_\beta = 0$ for almost all $\beta \in (\mathbb{Z}_{\geq 0})^n$.)

We prove the formal power series case first. Let $R = V[[x_1, \ldots, x_n]]$, let $I \subseteq R$ be a nonzero $D(R, V)$-submodule, and let $f \in I$ be given. If there exists $\beta \in (\mathbb{Z}_{\geq 0})^n$ such that $\omega_\beta$ is a unit in $V$ (that is, $\nu_\pi(\omega_\beta) = 0$), then $I = R = (\pi^0)$, since

$$\partial_1^{[\beta_1]} \cdots \partial_n^{[\beta_n]}(\omega_\beta x_1^{\beta_1} \cdots x_n^{\beta_n}) = \omega_\beta,$$

and so, $\partial_1^{[\beta_1]} \cdots \partial_n^{[\beta_n]}(f)$ (which belongs to $I$ by hypothesis) has a unit constant term, it is itself a unit in $R$. On the other hand, assume that for every $f = \sum_{\beta \in (\mathbb{Z}_{\geq 0})^n} \omega_\beta x^\beta \in I$, we have $\nu_\pi(\omega_\beta) > 0$ for all $\beta \in (\mathbb{Z}_{\geq 0})^n$. Under this assumption, let $\ell$ be the minimal value of $\nu_\pi(\omega_\beta)$ among all $\omega_\beta$ occurring as coefficients in any $f \in I$. This $\ell$ is a well-defined, nonzero natural number; we claim that $I \subseteq (\pi^\ell)$. It is clear that $I \subseteq (\pi^\ell)$. For the converse inclusion, choose $f = \sum_{\beta \in (\mathbb{Z}_{\geq 0})^n} \omega_\beta x^\beta \in I$ such that for some $\beta \in (\mathbb{Z}_{\geq 0})^n$ we have $\nu_\pi(\omega_\beta) = \ell$. Applying the differential operator $\partial_1^{[\beta_1]} \cdots \partial_n^{[\beta_n]}$, we obtain an element $g \in I$ whose constant term is of the form $\pi^\ell$ times a unit in $V$. But by the minimality $\ell$, every other coefficient in $g$ is divisible by $\pi^\ell$; factoring out $\pi^\ell$, we can write $g$ as $\pi^\ell$ times a unit $h$ in $R$, from which it follows that $(\pi^\ell h) h^{-1} = \pi^\ell \in I$. Thus, $I = (\pi^\ell)$ as claimed.

On the other hand, suppose that $R = V[x_1, \ldots, x_n]$. Again let $I \subseteq R$ be a nonzero $D(R, V)$-submodule, and let $f \in I$ be given. Let $\gamma = (\gamma_1, \ldots, \gamma_n) \in (\mathbb{Z}_{\geq 0})^n$ be such that $\omega_\gamma x^\gamma$ is the leading term of $f$ with respect to the grlex term order. Then $\partial_1^{[\gamma_1]} \cdots \partial_n^{[\gamma_n]}(f) = \omega_\gamma \in I$. Scaling by a unit if needed, we conclude that $\pi^{\nu_\pi(\omega_\gamma)} \in I$. Now let $\ell$ be the minimal $\pi$-adic valuation of any of the (grlex) leading coefficients of elements of $I$. Since $I \neq (0)$, $\ell$ is a natural number. By the preceding argument, $\pi^\ell \in I$. We claim that, conversely, $I \subseteq (\pi^\ell)$ and so the two are equal. Indeed, if $f \in I$ is not divisible by $\pi^\ell$, then some nonzero term $\omega_\beta x^\beta$ has $\nu_\pi(\omega_\beta) < \ell$. Multiplying by enough powers of the $x_i$, we obtain an element of $I$ whose leading coefficient is not divisible by $\pi^\ell$, violating the minimality of $\ell$. This completes the proof.

Before we proceed to a proof of Theorem 3.1, we need the following lemma. In this lemma, and the rest of the results in this section, the proofs for the formal power series and polynomial cases are identical.

**Lemma 3.3.** Let $M$ be a $D(R, V)$-module. Set $I = \Ann_R(M)$ and

$$J = (I : \pi^\infty) := \{a \in R \mid a \pi^m \in I \text{ for some integer } m \geq 0\}.$$

Then $J$ is a $D(R, V)$-submodule of $R$.

**Proof.** Let $p = \pi^l u$, for some $u \in V^\times$. Then it is easy to see that

$$J = (I : \pi^\infty) = (I : (\pi^l)^\infty) = (I : p^\infty),$$

and so, it suffices for us to show that $J = (I : p^\infty) = \{a \in R \mid ap^m \in I \text{ for some integer } m \geq 0\}$ is a $D(R, V)$-submodule of $R$. It further suffices to show that $\partial_i^{[l]}(r)$ remains in $J$ for every $1 \leq i \leq n$, $t \geq 1$, and $r \in J$.

Since $r \in J$, there is an integer $\ell$ such that $(p^r)M = 0$. First we consider the case when $t = 1$. For each $m \in M$, we have

$$0 = \partial_i(p^r m) = p^r \partial_i(m) = p^r(\partial_i(r)m + r\partial_i(m)) = p^r \partial_i(r)m,$$

which shows that $\partial_i(r) \in J$. Now an easy induction on $t$ shows that $\partial_i^{[t]}(r) \in J$ for all $t \geq 1$. Since $\partial_i^{[t]} = t! \partial_i^{[t]}$, it follows that $t! \partial_i^{[t]}(r) \in J$ for all $t \geq 1$. Since every integer coprime to $p$ is a unit in $R$, we have $p^{t^2+\nu_\pi(t)} \partial_i^{[t]}(r) \in J$. By definition of $J = (I : p^\infty)$, there exists $m \geq 0$ such that $p^m(p^{t^2+\nu_\pi(t)} \partial_i^{[t]}(r)) = p^{m+\nu_\pi(t)} \partial_i^{[t]}(r) \in I$; again by definition of $J$, this means $\partial_i^{[t]}(r) \in J$.}

We will also need the following consequence of Proposition 2.4.
Lemma 3.4. Let $M$ be a nonzero $\mathcal{D}(R, V)$-module such that $\pi M = (0)$. Then $\text{Ann}_R(M) = \pi R$.

Proof. By hypothesis, $(\pi) \subseteq \text{Ann}_R(M)$. For the converse inclusion, observe that since $M$ is annihilated by $\pi$, it has a natural structure of $\mathcal{D}(R, V)/\pi \mathcal{D}(R, V) = \mathcal{D}(R/\pi, V/\pi) = \mathcal{D}(R, k)$-module. Since $M \neq (0)$ and $k$ is a field, we have $\text{Ann}_R(M) = (0)$ by Proposition 2.4, so that $\text{Ann}_R(M) \subseteq (\pi)$. □

We are now ready to prove Theorem 3.1.

Proof of Theorem 3.1. Let $L = \text{Ann}_R(M)$ and assume that $L \neq (0)$. By Lemma 3.3, $L = (I : \pi^\infty)$ is a nonzero $\mathcal{D}(R, V)$-submodule of $R$, so by Theorem 3.2, we have $J = (\pi^n)$ for some natural number $n \geq 1$. In particular, $\pi^n \in J$, so for some $\ell \geq e$, $\pi^\ell \in I$ by definition of $J$. Assume that $\ell$ is the minimal integer such that $\pi^\ell \in I$. Since $M \neq (0)$, we must have $\ell \geq 1$.

We will use induction on $\ell$ to show that $L = (\pi^n)$. The base case, $\ell = 1$, is precisely Lemma 3.4. If $\ell \geq 2$, we consider $\pi M$. The definition of $\ell$ implies that $\pi M \neq (0)$. Since $\pi \in V$, the module $\pi M$ is naturally a $\mathcal{D}(R, V)$-submodule of $M$. Applying the induction hypotheses to $\pi M$ (which is annihilated by $\pi^{\ell-1}$), by minimality of $\ell$ we have $\text{Ann}_R(\pi M) = (\pi^{\ell-1})$. It follows immediately that $\text{Ann}_R(M) = (\pi^\ell)$. □

Theorem 3.1 in conjunction with Theorem 3.2 has the following interpretation: the $R$-module annihilators of $\mathcal{D}(R, V)$-modules are precisely the $\mathcal{D}(R, V)$-submodules of $R$.

4. Lyubeznik filtrations and $\mathcal{D}$-module length

In this section, our notation is the same as in Section 3. $(V, \pi V, k)$ denotes a fixed DVR of mixed characteristic $(0, p)$, and $R$ denotes either the ring $V[[x_1, \ldots, x_n]]$ or $V[x_1, \ldots, x_n]$ for some $n \geq 0$. In either case, we denote by $\bar{R}$ the ring $R/\pi$, which is either a formal power series or polynomial ring over $k$.

Objects of the category $\mathcal{C}(\bar{R}, k)$ are of finite length in $\text{Mod}_{\mathcal{D}(\bar{R}, k)}$, by Proposition 2.3. When we replace the coefficient field $k$ with the coefficient ring $V$, however, the situation changes entirely. For example, the ring $\bar{R}$ itself clearly belongs to $\mathcal{C}(\bar{R}, V)$, but since $\pi^\ell R$ is a $\mathcal{D}(R, V)$-submodule of $R$ for all $\ell \geq 0$ (as $\pi \in V$) and $\pi^\ell R \neq \pi^{\ell+1} R$ for all $\ell \geq 0$, we see that $R$ is not of finite length in $\text{Mod}_{\mathcal{D}(R, V)}$. In this section, we study the relationship between the $\mathcal{D}(R, V)$-module length of objects of $\mathcal{C}(R, V)$ and their annihilators when viewed as $R$-modules.

The following class of two-tiered filtrations on $\mathcal{D}(R, V)$-modules was introduced by Lyubeznik in [12].

Definition 4.1. Let $M$ be a $\mathcal{D}(R, V)$-module. We say that $M$ admits a Lyubeznik filtration if there exists a finite filtration

$$(0) = M_0 \subseteq M_1 \subseteq \cdots \subseteq M_{t-1} \subseteq M_t = M$$

and, for $i = 1, \ldots, t$, there exist filtrations

$$\cdots \subseteq N_{j-1}^i \subseteq N_j^i \subseteq N_{j+1}^i \subseteq \cdots$$

of $M_i = M_i/M_{i-1}$ (indexed by $j \in \mathbb{Z}$) such that

(1) all $M_i$ are $\mathcal{D}(R, V)$-submodules of $M$, and all $N_j^i$ are $\mathcal{D}(R, V)$-submodules of $M_i$;
(2) for all $i$, $\cap_{j \in \mathbb{Z}} N_j^i = (0)$ and $\cup_{j \in \mathbb{Z}} N_j^i = M_i$;
(3) for all $i$ and $j$, $\pi N_j^i \subseteq N_j^i$;
(4) for all $i$ and $j$, the quotient $N_j^i/N_{j-1}^i$, which is a $\mathcal{D}(\bar{R}, k)$-module by property (3), belongs to $\mathcal{C}(\bar{R}, k)$;
(5) for all $i$, the $\mathcal{D}(R, V)$-module homomorphism

$$N_j^i/N_{j-1}^i \xrightarrow{\pi} N_{j-1}^i/N_{j-2}^i$$

is an isomorphism for almost all (that is, all but finitely many) $j \in \mathbb{Z}$. 
In such a case we say that \( \{ M_i, \{ N^i_j \} \} \) is a Lyubeznik filtration of \( M \).

We say that a Lyubeznik filtration \( \{ M_i, \{ N^i_j \} \} \) of \( M \) is of finite type if, for all \( i \) such that \( 1 \leq i \leq t \), there exist integers \( a_i < b_i \) such that \( N^i_{a_i} = (0) \) and \( N^i_{b_i} = M_i \).

The following result, obtained in [12], is crucial to the study of finiteness properties of local cohomology modules in the unramified case.

**Proposition 4.2.** [12] Lemma 1] Every object \( M \) of \( \mathcal{C}(R, V) \) (in particular, every local cohomology module \( H^i_1(R) \)) admits a Lyubeznik filtration.

Proposition 4.2 is stated in [12] only in the formal power series case, but the same proof works in the polynomial case, since \( V[x_1, \ldots, x_n] \) is also a UFD.

**Example 4.3.** Let \( f \in R \) be given. Since \( R \) is a UFD, we can write \( f = \pi^e g \) for some \( e \geq 0 \) where \( g \in R \) is not divisible by \( \pi \). We can construct a Lyubeznik filtration on \( M = R_f \) as follows: we take \( t = 1 \) (so \( (0) = M_0 \subseteq M_1 = M \)) and the filtration \( \{ N^1_j \} = \{ N_j \} \) of the sole quotient \( M_1 = M \) is given by \( N_j = \pi^{-j} R_g \) for all \( j \) (if \( e > 0 \)) and \( N_j = \pi^{-j} R_f \) for \( j < 0 \), \( N_j = R_f \) for \( j \geq 0 \) (if \( e = 0 \)).

The proof of Proposition 4.2 proceeds from Example 4.3 by patching together and modifying the “base case” filtrations of the example for \( \mathcal{D}(R, V) \)-module subquotients and extensions.

The following is the main result of this section. Combined with Theorem 3.1, it says in particular that if \( M \) is a local cohomology module of \( R \), then \( M \) is of finite (resp. infinite) length in \( \text{Mod}_{\mathcal{D}(R, V)} \) if and only if its \( R \)-module annihilator is generated by a power of \( \pi \) (resp. is zero).

**Theorem 4.4.** Let \( M \) be a \( \mathcal{D}(R, V) \)-module that admits a Lyubeznik filtration. Then \( M \) is of finite length in \( \text{Mod}_{\mathcal{D}(R, V)} \) if and only if \( \text{Ann}_R(M) \neq (0) \). In this case \( \text{Ann}_R(M) \) is generated by a non-zero power of \( \pi \).

**Proof.** Fix a Lyubeznik filtration \( \{ M_i, \{ N^i_j \} \}_{i=0}^t \) on \( M \). By discarding redundant terms, we may assume that \( M_i \neq M_{i-1} \) for \( i = 1, \ldots, t \). We will prove our theorem by proving the following statements:

(i) if the given filtration is of finite type, then \( M \) is of finite length in \( \text{Mod}_{\mathcal{D}(R, V)} \);

(ii) if the given filtration is of finite type, then \( \pi^\ell M = (0) \) for some \( \ell \geq 0 \);

(iii) if the given filtration is not of finite type, then \( M \) is not of finite length in \( \text{Mod}_{\mathcal{D}(R, V)} \);

(iv) if the given filtration is not of finite type, then \( \text{Ann}_R(M) = (0) \).

Suppose first that the given filtration is of finite type, and fix \( i \) such that \( 1 \leq i \leq t \). By condition (4) of Definition 4.1 the quotients

\[
N^i_{b_i}/N^i_{b_i-1}, N^i_{b_i-1}/N^i_{b_i-2}, \ldots, N^i_{a_i+2}/N^i_{a_i+1}, N^i_{a_i+1}/N^i_{a_i},
\]

all of which are \( \mathcal{D}(R, V) \)-modules annihilated by \( \pi \), are in fact objects of \( \mathcal{C}(R, k) \). By Proposition 2.3 these quotients are all of finite length in \( \text{Mod}_{\mathcal{D}(R, k)} \). Every \( \mathcal{D}(R, V) \)-submodule of such a quotient is also a \( \mathcal{D}(R, k) \)-submodule, so the displayed quotients are all of finite length in \( \text{Mod}_{\mathcal{D}(R, V)} \). The \( \mathcal{D}(R, V) \)-modules of finite length form a Serre subcategory of \( \text{Mod}_{\mathcal{D}(R, V)} \), so since the displayed list of quotients is finite, we conclude (by repeatedly considering extensions) that \( N^i_{b_i}/N^i_{a_i} = M_i/(0) = M_i \) is of finite length in \( \text{Mod}_{\mathcal{D}(R, V)} \). Since this is true for \( i = 1, \ldots, t \), the same extension argument shows that \( M_t/M_0 = M/(0) = M \) is of finite length in \( \text{Mod}_{\mathcal{D}(R, V)} \), proving (i). Since each of the displayed quotients is annihilated by \( \pi \), we see immediately that \( M_i = N^i_{b_i}/N^i_{a_i} \) is annihilated by \( \pi^{b_i-a_i} \), and therefore that \( M = M_t/M_0 \) is annihilated by \( \pi^\ell \) where \( \ell = \sum_{i=1}^t (b_i - a_i) \), proving (ii).

Now suppose that the given filtration is not of finite type. This means that there exists some \( i \) with \( 1 \leq i \leq t \) such that either \( N^i_j \neq (0) \) for all \( j \in \mathbb{Z} \) or \( N^i_j \neq M_i \) for all \( j \in \mathbb{Z} \). By condition (2) of Definition
if the filtration \( \{ N_j \} \) stabilizes downward, its stable value must be \((0)\), and if it stabilizes upward, its stable value must be \( \overline{M}_j \). This means that since the filtration is not of finite type, it either fails to stabilize downward or fails to stabilize upward: there exist infinitely many \( j \in \mathbb{Z} \) such that \( N_j \neq N_{j+1} \). It follows that \( \overline{M}_j \), and a fortiori \( M \), cannot be of finite length in \( \Mod_{D(R,V)} \), proving (iii).

To prove statement (iv), since \( \Ann_R(M) \subseteq \Ann_R(M_i) \subseteq \Ann_R(\overline{M}_i) \), it suffices to show that \( \Ann_R(\overline{M}_j) \) is \((0)\). Replacing \( M \) by \( \overline{M}_j \), we simplify notation by writing \( \{ N_j \} \) for the filtration of \( M \).

Suppose first that the filtration \( \{ N_j \} \) of \( M \) does not stabilize downward, so \( N_j \neq (0) \) for all \( j \in \mathbb{Z} \). By condition (5) of Definition 4.1, there exists an integer \( a \) such that for all \( j \leq a \), we have \( N_j/N_{j-1} \cong \mathcal{D}(R,V) \)-modules. If \( N_j = N_{j-1} \) for some \( j \leq a \), then \( N_{j-1} = N_{j-2} \) (since the quotient must also be zero) and, by induction, \( N_{j-s} = N_{j-s-1} \) for all \( s \geq 0 \); but then the filtration stabilizes downward after all. We conclude that the quotients \( N_j/N_{j-1} \) for \( j \leq a \) are all isomorphic and are nonzero. By condition (3) of Definition 4.1, each \( N_j/N_{j-1} \) is a nonzero \( \mathcal{D}(\overline{R},k) \)-module. Since \( \pi(N_j/N_{j-1}) = (0) \), we have \( \Ann_R(N_j/N_{j-1}) = \pi R \) for \( j \leq a \) by Lemma 4.4.

We claim that \( \Ann_R(N_a/N_{a-s}) \subseteq \pi^s R \) for all \( s \geq 1 \). We will prove this claim by induction on \( s \), the case \( s = 1 \) having been established above. Let \( s \geq 1 \) be given, suppose that \( \Ann_R(N_a/N_{a-s}) \subseteq \pi^s R \), and let \( f \in R \) be an element of \( \Ann_R(N_a/N_{a-s-1}) \). Then \( fN_a \subseteq N_{a-s-1} \subseteq N_{a-s} \), so \( f \in \Ann_R(N_a/N_{a-s}) \) and by the inductive hypothesis we can write \( f = \pi^s g \) for some \( g \in R \). Now let \( z \in N_{a-s} \) be given. Since \( N_a/N_{a-1} \rightarrow N_{a-s}/N_{a-s-1} \) is a composite of \( s \) isomorphisms and therefore an isomorphism, there exist \( x \in N_a \) and \( y \in N_{a-s-1} \) such that \( z = y + \pi^s x \). But then \( gz = g(y + \pi^s x) = gy + f x \), which belongs to \( N_{a-s-1} \) since \( y \in N_{a-s-1} \) and \( fN_a \subseteq N_{a-s-1} \). As \( z \) was arbitrary, we conclude that \( gN_{a-s} \subseteq N_{a-s-1} \), so by the previous paragraph, \( g \in \pi R \) and hence \( f = \pi^s g \in (\pi^{s+1}) \). That is, we have proved that \( \Ann_R(N_a/N_{a-s}) \subseteq \pi^{s+1} R \), completing the induction. We can now prove that \( \Ann_R(M) = (0) \). Let \( f \in \Ann_R(M) \) be given. Then in particular, \( f \in \Ann_R(N_a) \), and for every \( s \geq 1 \), \( f \in \Ann_R(N_{a-s}) \). By the statement just proved, \( f \in \pi^s R \) for all \( s \geq 1 \). But \( \cap_{s \geq 1} \pi^s R = (0) \) by Krull’s intersection theorem, so \( f = 0 \) as desired.

On the other hand, suppose that the filtration \( \{ N_j \} \) of \( M \) does not stabilize upward, so \( N_j \neq M \) for all \( j \in \mathbb{Z} \). The argument in this case is in some sense dual to the one just given. By condition (5) of Definition 4.1, there exists an integer \( b \) such that for all \( j \geq b \), we have \( N_{j+1}/N_j \cong \mathcal{D}(R,V) \)-modules. The quotients \( N_{j+1}/N_j \) for \( j \geq b \) are all nonzero, for otherwise the filtration would stabilize upward. Moreover, we know that \( \Ann_R(N_{j+1}/N_j) = \pi R \) for all \( j \geq b \), and therefore, by repeating the inductive argument in the previous paragraph we conclude that \( \Ann_R(N_{b+s}/N_b) \subseteq \pi^s R \) for all \( s \geq 1 \). For each such \( s \), we have \( \Ann_R(M) \subseteq \Ann_R(N_{b+s}) \subseteq \Ann_R(N_{b+s}/N_b) \subseteq \pi^s R \); again by Krull’s intersection theorem, it follows that \( \Ann_R(M) = (0) \). This proves (iv) and hence the theorem.

Remark 4.5. The hypothesis in Theorem 4.4 that \( M \) admits a Lyubeznik filtration is necessary: there exist \( \mathcal{D}(R,V) \)-modules that are of infinite length in \( \Mod_{D(R,V)} \) but have nonzero \( R \)-module annihilators. To see this, simply take any \( \mathcal{D}(\overline{R},k) \)-module that is of infinite length in \( \Mod_{D(\overline{R},k)} \), and therefore does not belong to \( C(\overline{R},k) \) (for example, a direct sum of infinitely many copies of \( \overline{R} \)) and view it as a \( \mathcal{D}(R,V) \)-module by restricting scalars. Then this module also is of infinite length in \( \Mod_{D(R,V)} \), but is annihilated by \( \pi \).

5. Reisner’s Example

The main purpose of this section is to produce an example of a top local cohomology module of a regular local ring of mixed characteristic that has nonzero annihilator. Such an example provides a negative answer to Question 1.1 even in the special case of regular rings. We will begin with the following observation.

Proposition 5.1. Let \( A = \mathbb{Z}[x_1, \ldots, x_n] \) for some \( n \geq 0 \) and let \( I \subseteq A \) be a monomial ideal.
(a) For all \( \ell \geq 1 \), let \( I_\ell \) be the ideal generated by the \( \ell \)-th powers of a given set of monomial generators for \( I \). Suppose that \( 0 \neq \alpha \in \mathbb{Z} \) is such that \( \alpha \) annihilates \( \text{Ext}^j_A(A/I, A) \) for some \( j \geq 0 \). Then \( \alpha \) annihilates \( \text{Ext}^j_A(A/I_\ell, A) \) for all \( \ell \geq 1 \).

(b) If \( \alpha \) is as in part (a), then \( \alpha \) annihilates \( H^j_I(A) \); therefore, if \( H^j_I(A) \neq (0) \) and such a nonzero \( \alpha \) exists, then \( \text{Ann}_A(H^j_I(A)) \) is a nonzero proper ideal of \( A \).

**Proof.** Part (b) follows immediately from part (a) since \( H^j_I(A) \cong \varprojlim_{\ell} \text{Ext}^j_A(A/I_\ell, A) \). To prove part (a), let \( \ell \geq 1 \) be given and consider the ring \( A_\ell = \mathbb{Z}[x_1^\ell, \ldots, x_n^\ell] \). Since \( \alpha \) is an integer, \( I \) (and therefore \( I_\ell \)) is generated by monomials, and \( \alpha \text{Ext}^j_A(A/I, A) = (0) \), it follows that \( \alpha \text{Ext}^j_A(I_\ell/A_\ell, A_\ell) = (0) \). It is clear that \( A \) is a free \( A_\ell \)-module, and hence

\[
\text{Ext}^j_A(A/I_\ell, A) \cong \text{Ext}^j_{A_\ell}(A_\ell/I_\ell, A_\ell) \otimes_{A_\ell} A
\]

as \( A \)-modules. It follows immediately that \( \alpha \text{Ext}^j_A(A/I_\ell, A) = (0) \), completing the proof. \( \square \)

For the rest of this section, we consider the following example, considered by Reisner in [14, Remark 3] and associated with a minimal triangulation of the real projective plane. Let \( A = \mathbb{Z}[x_0, \ldots, x_5] \) and let \( I \) be the ideal of \( A \) generated by the 10 monomials

\[
\{x_0x_1x_2, x_0x_1x_3, x_0x_2x_4, x_0x_3x_5, x_0x_4x_5, x_1x_2x_3, x_1x_3x_4, x_1x_4x_5, x_2x_3x_4, x_2x_3x_5\}.
\]

It is well-known that \( \text{cd}(I, A) \leq 4 \) (cf. [15]), i.e. \( H^j_I(A) = (0) \) for \( j \geq 5 \). As we will see in the next example \( H^j_I(A) \neq (0) \) and hence \( H^4_I(A) \) is a top local cohomology module. This allows us to give a negative answer to Question [14] as follows.

**Example 5.2.** Let \( A \) and \( I \) be as in the previous paragraph, and let \( m = (2, x_0, \ldots, x_5) \). It is straightforward to check that \( \text{Ext}^4_A(A/I, A) \cong A/m \), which is annihilated by 2. As in Proposition 5.1, for all \( \ell \geq 1 \), let \( I_\ell \) be the ideal generated by the \( \ell \)-th powers of the displayed monomial generators of \( I \). Since \( \text{Ext}^4_A(A/I, A) \cong A/m \), it follows from the proof of Proposition 5.1 that

\[
\text{Ext}^4_A(A/I_\ell, A) \cong A/(2, x_0^\ell, \ldots, x_5^\ell)
\]

for all \( \ell \geq 1 \). It follows from [13, Theorem 1] that the transition map \( \text{Ext}^4_A(A/I_\ell, A) \to \text{Ext}^4_A(A/I_{\ell+1}, A) \) is injective for each \( \ell \geq 1 \). Therefore \( H^4_I(A) \neq 0 \) and is supported only in the maximal ideal \( m \). It follows from Proposition 5.1 that \( 2 \cdot \text{Ext}^4_A(A/I_\ell, A) = (0) \) for all \( \ell \geq 1 \); and hence \( 2 \cdot H^4_I(A) = (0) \). Now consider the \( m \)-adic completion \( \hat{A}^m \) of \( A \), a complete unramified regular local ring. We again write \( I \) for the ideal \( I \hat{A}^m \subseteq \hat{A}^m \). (Concretely, the ring \( \hat{A}^m \) is isomorphic to \( \mathbb{Z}_2[[x_0, \ldots, x_5]] \), where \( \mathbb{Z}_2 \) denotes the ring of 2-adic integers, and \( I \hat{A}^m \) is generated by the same ten monomials.) Local cohomology commutes with the flat base change \( A \to \hat{A}^m \), so \( H^j_I(A) \neq (0) \) and \( H^j_I(I \hat{A}^m) = (0) \) for all \( j > 4 \). Consequently \( H^4_I(I \hat{A}^m) \) is a top local cohomology module that is annihilated by 2. In particular, \( \text{Ann}_{\hat{A}^m}(H^4_I(I \hat{A}^m)) = (2) \) by Theorem 3.1.

**Remark 5.3 (Arithmetic rank of the ideal \( I \)).** It follows from [15, Example 5]) that the ideal \( I \) can be defined up to radical by 4 elements

\[
\{x_0x_3x_5, x_0x_1x_3 + x_0x_4x_5 + x_2x_3x_5, x_0x_2x_4 + x_1x_2x_3 + x_1x_3x_4, x_0x_1x_2 + x_1x_4x_5 + x_2x_3x_4\}
\]

in both \( A \) and \( \hat{A}^m \). Since it is shown in Example 5.2 that \( H^4_I(A) \neq 0 \) and \( H^4_I(I \hat{A}^m) \neq 0 \), the arithmetic rank of \( I \) must be 4 in both \( A \) and \( \hat{A}^m \) and \( \text{cd}(A, I) = \text{cd}(\hat{A}^m, I) = 4 \).

---

2This can be seen directly from Hochster’s formula; alternatively, as indicated by Lyubeznik in [13], it can be computed using the Taylor resolution of \( A/I \).

3In Lyubeznik’s theorem, the ring was assumed to be a local ring containing a field. However, since each \( \text{Ext}^4_A(A/I_\ell, A) \) is annihilated by 2 and supported only in the maximal ideal \( m \), it is naturally a module over the local ring \( \hat{R} \); hence Lyubeznik’s theorem is applicable.
Remark 5.4. During the preparation of this paper, we learned that Hochster and Jeffries obtained the following result: Let \((R, \mathfrak{m})\) be a Noetherian local domain of characteristic \(p\). Assume that the arithmetic rank of an ideal \(I\) is the same as its cohomological dimension, which is denoted by \(\delta\). Then \(H^I_1(R)\) is faithful.

The combination of Example 5.2 and Remark 5.4 shows that the mixed-characteristic analogue of the aforementioned Hochster-Jeffries result does not hold.

Hernández, Núñez-Betancourt, Pérez, and Witt also studied the module \(H^I_1(\hat{A}^m)\), concluding [5, Theorem 6.3] that this module has zero-dimensional support while its injective dimension as an \(\hat{A}^m\)-module is equal to 1. We finish this section with a finer analysis of the structure of \(H^I_1(\hat{A}^m)\), that in particular recovers this result of [5].

Proposition 5.5. Let \((R, \mathfrak{m}) = \hat{A}^m\) denote the completion of \(A\) at the maximal ideal \(\mathfrak{m} = (2, x_0, \ldots, x_5)\) and let \(\hat{R}\) denote \(R/(2)\). Then \(H^I_1(R) \cong E_{\hat{R}}(\hat{R}/\mathfrak{m})\) as \(R\)-modules.

Proof. As we have seen in Example 5.2 that the transition map \(\text{Ext}^4_A(A/I_\ell, A) \to \text{Ext}^4_A(A/I_{\ell+1}, A)\) is injective for each \(\ell \geq 1\). Since \((x_0^{\ell+1}, \ldots, x_5^{\ell+1}) : (x_0^\ell, \ldots, x_5^\ell) = (x_0^\ell, \ldots, x_5^\ell, x_0 \cdots x_5)\) (which holds in both \(A\) and \(A/(2)\)), it is straightforward to check that this transition map is given by

\[
\begin{align*}
A &\xrightarrow{(2, x_0^\ell, \ldots, x_5^\ell)} A \\
&\cong \lim_{\ell \to \infty} \text{Ext}^4_A(A/I_\ell, A)
\end{align*}
\]

Therefore,

\[
H^I_1(A) \cong \lim_{\ell \to \infty} \text{Ext}^4_A(A/I_\ell, A)
\]

\[
\cong \lim_{\ell \to \infty} (\cdots \to A (2, x_0^\ell, \ldots, x_5^\ell) \xrightarrow{x_0 \cdots x_5} A (2, x_0^{\ell+1}, \ldots, x_5^{\ell+1}) \to \cdots)
\]

\[
\cong H^4_m(A/(2))
\]

\[
\cong H^4_m(\hat{R})
\]

Therefore \(H^I_1(R) \cong H^I_1(A) \otimes_A R \cong H^4_m(\hat{R}) \cong E_{\hat{R}}(\hat{R}/\mathfrak{m})\) as \(R\)-modules. This completes the proof. \(\square\)
