More Optimal Obstacle Placement Problems Inside a Disk

Anisa M. H. Chorwadwala

Abstract. In this paper, we deal with an obstacle placement problem inside a disk, that can be formulated as an energy minimization problem with respect to rotations of the obstacle about its center and also w.r.t the translations of the obstacle within the disk. Such problems find important applications in the design of liquid crystal devices, musical instruments and optimal accelerator cavities. We show that the extremal configurations correspond to the cases, where an axis of symmetry of the obstacle coincide with an axis of symmetry of the disk. We characterize the maximizing and minimizing configurations for the case, when the obstacle has a dihedral symmetry of even order. We also characterize the local and global maximizing and minimizing configurations for the case, when the obstacle has a dihedral symmetry of even order. For the case of odd order symmetry, we have partial results. We face exactly the same difficulties as in [1] in characterizing the optimal configurations for the odd order case completely. Finally, various numerical experiments validate the theoretical results obtained as well as the conjectures stated.

This article is a follow up of the paper [1]. The family of domains considered here is the same as the one considered in [1] but the boundary value problem is different from that of [1]. In [1], we had homogeneous boundary data while in the current paper we consider an inhomogeneous boundary data. Further, in the place of an eigenvalue problem considered in [1], we consider a Laplace equation here. We carry out the shape calculus analysis for the boundary value at hand and derive an expression for the Eulerian derivative of the energy functional. Once we have this expression, the proof for finding optimal configurations w.r.t. the rotations of the obstacle about its fixed center follows more or less from [1]. We also obtain results characterizing global maximizers/minimisers configuration of the obstacle inside the disk, w.r.t. both rotations and translations of the obstacle within the disk.

1 Introduction

A shape optimization problem typically deals with finding a shape, which is optimal in the sense that it minimizes a certain cost functional among all shapes satisfying some given constraints. For an introduction, motivation, generic model, origin, history, evolution, recent results, etc. of shape optimization problems, please refer to the introduction section of [1]. To be fair, we mention a list of relevant references here: [2–9] For a mini review of the kind of shape optimization problems that the author along with her collaborators have worked on one may also refer to [10]. Other interesting references include [11–16]. We once again request the reader to...
refer to [1] for an introduction to shape optimization problems for nematic liquid crystals in confined geometries and for its relevance to the optimal placement problem at hand.

In this paper, we consider the family of domains considered in [1], i.e., this family consists of doubly connected planar domains with specified boundary conditions on the inner and outer boundary component. We will consider a disk minus an obstacle with dihedral symmetry of even order. In this case, as seen in [1], the corresponding nematic profile, modeled as an energy minimizer, depends not only on the location of the center of the inner obstacle relative to the outer circle but also on the orientation of the obstacle w.r.t. the diameter of the outer disk passing through the center of the obstacle. We aim to find the optimal orientation of the inner obstacle about its fixed center inside the disk. For a motivation of placing an obstacle with dihedral symmetry inside a disk in Liquid Crystal context please refer to [1] again. The problem with homogeneous boundary conditions is not interesting from a liquid crystals point of view. Please see [17], [18], [19] and [20].

The work in [1] is inspired by [21]. For a short description of the main results of [21], their proofs and its comparison with the main results and the proof approach of [1] one could refer to the introduction section of [1] again.

Consider the following inhomogeneous Dirichlet Boundary Value Problem:

\[
\begin{align*}
\Delta u &= 0 & \text{in } \Omega := B \setminus P, \\
    u &= 0 & \text{on } \partial P, \\
    u &= g & \text{on } \partial B.
\end{align*}
\]  

(1)

For us \( g = M \), a nonzero constant.

We take the same family of admissible domains \( \Omega \) as in [1]. That is, we consider the case where the planar obstacle \( P \) is invariant under the action of a dihedral group \( D_n \), \( n \geq 3 \). It follows that the axes of symmetry of \( P \) intersect in a unique point in the interior of \( P \). We call this point the center of \( P \) and denote it by \( o \). Let \( B \) be a disk in \( \mathbb{R}^2 \) containing \( o \) away from its center. We place the obstacle \( P \) centered at the fixed point \( o \) inside \( B \). That is, the centers of \( P \) and \( B \) are distinct. The disk \( B \) obviously is invariant under the action of dihedral groups \( D_n \), for each \( n \geq 3 \). Therefore, in our case, we have the following: (0) the volume constraint on \( P \) and \( B \) both, (i) invariance of both \( B \) and \( P \) under the action of the same dihedral group, (ii) \( B \) and \( P \) need not be concentric, (iii) smoothness condition on both the boundaries, (iv) the monotonicity condition on the boundary \( \partial B \) of the obstacle \( P \) as in [1] and [21]. We recall a monotonicity condition on the boundary of the disk \( B \) derived in Lemma 4.1 of [1]. Therefore, for us condition (v) of [21] for \( B \) is replaced by the statement of Lemma 4.1 of [1]. By Theorem 8.14 on page 188 of [22] we get that the boundary value problem [1] admits a unique solution in \( C^\infty (\overline{D}) \).

In this setting, we investigate the extremal configurations of the obstacle \( P \) with respect to the disk \( B \) for the energy functional

\[
E(\Omega) := \int_\Omega \|\nabla u\|^2 \, dx
\]  

(2)

for [1] by rotating \( P \), inside \( B \), about the fixed center \( o \) of \( P \). We also study the behaviour of \( E \) w.r.t. the translation of \( P \) within \( B \).

We follow the same line of ideas as in [1] and [14]. A novelty, as compared to [1] and [14], is going to be the computation of (a) the shape derivative of the solution, and (b) the Eulerian derivative of the energy functional w.r.t. the variations of the domain under the action of a vector field. We characterize the global maximizers/minimisers w.r.t. both rotations and translations of the obstacle within the disk.

The presentation of the paper is as follows. In order to identify the various different configurations in the family of domains under consideration we recall, in section 2 a few important dilutions from [1] through a sequence of illustrative images . In Section 3 we state our main theorem, viz., Theorem 3.1 describing the extremal configurations for the energy functional associated to [1] over the family of admissible domains. This theorem also characterises the maximising and the minimising configurations for it. It is worth emphasising here that Theorem 3.1 describes the behaviour of the energy functional w.r.t. the rotations of the obstacle about its fixed center. We further characterize the global maximizing and the minimizing configurations for \( E \) w.r.t. the rotations of the obstacle about its center, where the center is allowed to translate within the disk. We also state a result about the critical points for \( n \) odd too. In section 4 we carry out the shape calculus analysis for the boundary value at hand and derive an expression for the Eulerian derivative of the energy functional. In section 5 we give a proof of the extremal configurations for obstacles with even order dihedral symmetry. We prove a partial result for \( n \) odd. In section 6 we provide a proof for the global extremal configurations. Section 7 presents some numerical results that validate the extremal configurations obtained and also justify the conjectures formulated. In section 8 we summarize the important conclusions of the paper.
2 The ON and OFF configurations

Let $n$ be a positive integer, $n \geq 3$, even or odd. Let $P$ be a compact and simply connected subset of $\mathbb{R}^2$ satisfying assumptions 3.1 and 3.2 of [1]. We refer the reader to section 2 of [1] for definitions of centre $o$ of the obstacle $P$, sectors of the obstacle $P$, incircle $C_1(P)$ and circumcircle $C_2(P)$ of the obstacle $P$, vertices of $P$, opposite vertices of $P$, and inner vertices and outer vertices of $P$. Let $B$ be an open disk in $\mathbb{R}^2$ of radius $r_1$ such that $B \supset cl(conv(C_2(P)))$. Let $\Omega := B \setminus P$. Please refer to section 3.2 of [1] for the definitions of ON and OFF configurations of the obstacle w.r.t. the disk $B$. We only retain the pictures here as a quick recap. Without loss of generality we assume that the centre $o$ of the obstacle $P$ is at the origin $(0,0)$ of $\mathbb{R}^2$.

3 The Main Theorems

We recall that $P$ is a compact and simply connected subset of $\mathbb{R}^2$ satisfying assumptions 3.1 and 3.2 of [1] and that $B$ is an open disk in $\mathbb{R}^2$ of radius $r_1$ such that $B \supset \text{cl}(\text{conv}(C_2(P)))$. For $t \in \mathbb{R}$, let $\rho_t \in SO(2)$ denote the rotation in $\mathbb{R}^2$ about the origin $\mathbf{q}$ in the anticlockwise direction by an angle $t$, i.e., for $\zeta \in \mathbb{C} \cong \mathbb{R}^2$, we have $\rho_t \zeta := e^{i t \zeta}$. Now, fix $t \in [0, 2\pi]$. Let $\Omega_t := B \setminus \rho_t(P)$ and $\mathcal{F} := \{\Omega_t : t \in [0, 2\pi]\}$.

We now state the theorem for $n$ even, $n \geq 3$:

**Theorem 3.1 (Extremal configurations w.r.t. the rotations of the obstacle about its fixed center away from the center of the disk)** The energy functional $E(\Omega_t)$ for $\Omega_t \in \mathcal{F}$ is optimal precisely for those $t \in [0, 2\pi]$ for which an axis of symmetry of $P_t$ coincides with a diameter of $B$.

Among these optimal configurations, the maximizing configurations are the ones corresponding to those $t \in [0, 2\pi]$ for which $P_t$ is in an OFF position with respect to $B$; and the minimizing configurations are the ones corresponding to those $t \in [0, 2\pi]$ for which $P_t$ is in an ON position with respect to $B$.

Equation (11), Propositions 5.1 and 5.2 imply Theorem 3.1 for $n$ even, $n \geq 3$. Proposition 4.1 on page 119 of [24] says that for $n$ odd, we identify some of the extremal configuration for $E$. We prove that equation (11) and Proposition 5.1 hold true for $n$ odd too. We provide numerical evidence for $n = 5$ and conjecture that Proposition 5.2 and hence, Theorem 3.1 hold true for $n$ odd too.

Let $r_3^2$ and $r_2^2$ denote the radii of the incircle $C_3$ and the circumscribed circle $C_2$ of the obstacle $P$ respectively. Let $P(d,t)$ be the obstacle $P_t$ as in Theorem 3.1 with its center $\mathbf{q}$ at a distance $d < r_1 - r_2^2$ from the center of $B$. Please note that in Theorem 3.1 $d$ is fixed and is always $> 0$. This was because, for the case $d = 0$, $t \mapsto E(\Omega_t)$ is a constant map. This can be seen as follows. When $d = 0$ we have (a) $\Omega_t$ is isometric to $\Omega_s$ for each $t, s \in \mathbb{R}$, and (b) since the boundary data on each of the boundary component is radial w.r.t. the center of $B$ we get the solution $y$ of (11) satisfies $y(\Omega_t) = y(\Omega_s)$ for each $t, s \in \mathbb{R}$.

Since we want to study the behaviour of $E$ w.r.t. the translations of the obstacle too, we now allow $d$ to be 0. Let $\Omega_{(d,t)} := B \setminus P(d,t)$ for $d \in [0, r_1 - r_3^2]$, $t \in [0, 2\pi]$. Let $E((d,t)) := E(\Omega_{(d,t)})$. Let $\mathcal{G}$ be defined as $\{\Omega_{(d,t)} : (d,t) \in [0, r_1 - r_3^2] \times [0, 2\pi]\}$.

**Theorem 3.2 (Global extremal configurations, i.e., extremal configurations w.r.t. the translations and rotations of the obstacle within $B$)** Fix $n \geq 3$, even or odd. The concentric configurations, i.e., $\Omega_{(0,t)}$, for any $t \in [0, 2\pi]$, is the minimising configuration for $E((d,t))$ over $\mathcal{G}$. At a maximising configuration for $E((d,t))$ over $\mathcal{G}$, the circumscribed of the obstacle must intersect or touch $\partial B$.

For $n$ even, $n \geq 3$, we further have that, at the maximizing configuration over $\mathcal{G}$, the obstacle must be in an OFF position w.r.t. $B$.

The concentric configurations are the global minimising configurations w.r.t. all the translations and all rotations of the obstacle within $B$, for $n \geq 3$, $n$ even or odd. The OFF configurations with an outer vertex touching $\partial B$ are the global maximising configurations w.r.t. all the translations and rotations of the obstacle within $B$, for $n \geq 3$, $n$ even.

4 Shape calculus

4.1 Existence of shape derivatives

Let $D$ be a given domain in $\mathbb{R}^N$. Assume that for any domain $\Omega$ of class $C^k$ in $D$. Let $V \in C(0,\varepsilon;\mathcal{D}^k(D;\mathbb{R}^N))$ be a vector field. Consider the following Dirichlet boundary value problem:

$$-\Delta y(\Omega) = h(\Omega) \quad \text{in} \quad L^2(\Omega),$$
$$y(\Omega) = z(\Gamma) \quad \text{on} \quad \Gamma.$$  \hspace{1cm} (3)

**Proposition 4.1** Let $(h(\Omega),z(\Gamma)) \in L^2(\Omega) \times H^{\frac{1}{2}}(\Gamma)$ be given elements such that there exists the shape derivatives $(h'(\Omega), z'(\Gamma))$ in $L^2(\Omega) \times H^{\frac{1}{2}}(\Gamma)$. Then the solution $y(\Omega)$ to the Dirichlet boundary value problem (3) has the shape derivative $y'(\Omega,V)$ in $H^1(\Omega)$ determined as the unique solution to the Dirichlet boundary value problem (4).

$$-\Delta y'(\Omega,V) = h'(\Omega,V) \quad \text{in} \quad \mathcal{D}'(\Omega),$$
$$y'(\Omega,V)|_{\Gamma} = -\frac{\partial y}{\partial n}(V(0),n) + z'(\Gamma,V) \quad \text{on} \quad \partial \Omega, \hspace{1cm} (4)$$
Please note that, for us the vector field $V$ is a function of $x$ and does not depend on $t$. Therefore, $V(0) = V$.

We observe that, for the Boundary value Problem 1 on $\Omega = B \setminus P$, the corresponding $(h,z)$ belongs to $L^2(\Omega) \times H^1(\Gamma)$. And hence there exists a solution $y(\Omega) \in H^1(\Omega)$ of the Dirichlet boundary value problem 1. We will prove that, for this choice of $h,z$ and for the solution $y$, the shape derivatives $h'(\Omega, V), z'(\Gamma, V)$ and $y'(\Omega, V)$ exist, and belong to $L^2(\Omega), H^1(\Gamma)$ and $H^1(\Omega)$ respectively, for any $\Omega \in C(0, c; D^k(D; R^N))$. We will also prove that both $h'$ and $z'$ are zero. Then, by the proposition 4.1 mentioned above, i.e., Proposition 3.1 on page 119 of [24] we would have proved that the shape derivative $y'(\Omega, V)$ satisfies boundary value problem 2.

In view of Definition 2.71 on page 98 of [24], the material derivative $h = h(\Omega, V)$ of the function $h(\Omega) \in C^\infty(\Omega)$ exists, belongs to $C^\infty(\Omega)$ and equals zero. Moreover, because $h \in C^\infty(\Omega), h(\Omega, V)$ is exactly equal to $\langle \nabla h, V \rangle$. Therefore, by Definition 2.85 on page 111 of [24], we get the shape derivative $h'$ of $h$ in the direction of $V$ exists and is an element of $C^\infty(\Omega)$ defined by $h'(\Omega, V) = h(\Omega, V) - \langle \nabla h, V \rangle$ is 0.

In view of Definition 2.74 on page 100 of [24], the material derivative $\dot{z} = \dot{z}(\Gamma, V)$ of $z(\Gamma) \in C^\infty(\Gamma)$ exists, belongs to $C^\infty(\Gamma)$ and equals zero. Moreover, because $z \in C^\infty(\Gamma), \dot{z}(\Gamma, V)$ is exactly equal to $\langle \nabla \Gamma \dot{z}, V \rangle$. Therefore, by Definition 2.88 on page 114 of [24], we get the shape derivative of $\dot{z}'$ in the direction of $V$ exists and is an element of $C^\infty(\Gamma)$ defined by $\dot{z}'(\Gamma, V) = \dot{z}(\Gamma, V) - \langle \nabla \Gamma \dot{z}, V \rangle = 0$.

Thus, (4) becomes
\[
-\Delta y'(\Omega, V) = 0 \quad \text{in } D'(\Omega),
\]
\[
y'(\Omega, V)|_{\Gamma} = -\frac{\partial y}{\partial n}(V, n) \quad \text{on } \partial \Omega.
\]

4.2 The energy functional

We recall here that $P$ is a compact and simply connected subset of $\mathbb{R}^2$ satisfying assumptions 3.1 and 3.2 of [1] and that $B$ is an open disk in $\mathbb{R}^2$ of radius $r_1$ such that $B \supset cl(conv(C_2(P)))$. For $s \in \mathbb{R}$, let $\rho_s \in SO(2)$ denote the rotation in $\mathbb{R}^2$ about the origin $\rho_s$ in the anticlockwise direction by an angle $s$, i.e., for $\zeta \in \mathbb{C} \cong \mathbb{R}^2$, we have $\rho_s \zeta := e^{is\zeta}$. Now, fix $s \in [0, 2\pi]$. Let $P_s := \rho_s(P), \Omega_s := B \setminus \rho_s(P)$ and $F := (\Omega_s : s \in [0, 2\pi])$.

When $g = M$, a constant, then by Theorem 8.14 on page 188 of [22] we get that the solution $u_s$ of (1) on $\Omega_s$ belongs to $C^\infty(\Omega_s)$. Therefore, by Green’s identity we get $E(s) := E(\Omega_s) = \int_{\Omega_s} \langle \nabla u_s \rangle^2 \, dx = \int_{\Omega_s} (\Delta u_s) u_s \, dx + \int_{\partial \Omega_s} u_s \frac{\partial u_s}{\partial n} \, d\Sigma$, where $d\Sigma$ is the line element on $\partial \Omega_s$ and $n$ is the outward unit normal vector to $\Omega_s$ at $x \in \partial \Omega_s$.

From (4), $E(s)$ reduces to the following $E(s) = \int_{\partial \Omega} u_s \frac{\partial u_s}{\partial n} \, d\Sigma = \int_{\partial \Omega} g \frac{\partial u_s}{\partial n} \, d\Sigma = M \int_{\partial \Omega} \frac{\partial u_s}{\partial n} \, d\Sigma.$

4.3 Formal deduction of the Eulerian derivative of the energy functional

By the arguments similar to the one given in section 4.1, one can prove that, for each $s$ such that $s \in [0, 2\pi]$, the shape derivative of $u_s$ w.r.t. the perturbation vector field $V$ exists and satisfies the following boundary value problem:
\[
\Delta w = 0 \quad \text{in } \Omega_s := B \setminus \overline{P_s},
\]
\[
w = -\frac{\partial u_s}{\partial n}(V, n) \quad \text{on } \partial P_s,
\]
\[
w = 0 \quad \text{on } \partial B.
\]

We denote the shape derivative of $u_s$ as $u_s'$.

Since $u_s \in C^\infty(\Omega)$ and $V \in C^\infty(D)$, Theorem 8.14 on page 188 of [22] implies that the weak solution $u'_s \in H^1(\Omega)$ of (6) is in fact in $C^\infty(\Omega)$. Therefore, by Green’s identity applied to $u_s$ and $u'_s$ we get, $\int_{\Omega} u_s \Delta u'_s \, dx = \int_{\partial \Omega} u'_s \frac{\partial u_s}{\partial n} \, d\Sigma - \int_{\Omega} u'_s \Delta u_s \, dx = \int_{\partial \Omega} u'_s \frac{\partial u_s}{\partial n} \, d\Sigma - \int_{\Omega} u'_s \frac{\partial u_s}{\partial n} \, d\Sigma$. In view of (1) and (6), we then get
\[
\int_{\partial \Omega} u'_s \frac{\partial u_s}{\partial n} \, d\Sigma = \int_{\partial P} u'_s \frac{\partial u_s}{\partial n} \, d\Sigma = \int_{\partial P} \left(\frac{\partial u_s}{\partial n}\right)^2 (V, n) \, d\Sigma.
\]

Since $E(s) = \int_{\partial \Omega} u_s \frac{\partial u_s}{\partial n} \, d\Sigma$, we refer to section 2.33 titled ‘Derivatives of boundary integrals’ on page 115 of [24] to derive the expression of the Eulerian derivative of $E(\Omega)$: Let $D$ be a given domain in $\mathbb{R}^N$. Let $Z_s := Z(\partial \Omega_s) := u_s \frac{\partial u_s}{\partial n} \in L^1(\partial \Omega_s)$. From section 4.1 it follows that for every vector field $V \in C(0, c; D^k(D; \mathbb{R}^N))$,
$u_s$ has a strong material derivative in $L^1(\partial \Omega_s)$ and a shape derivative in $L^1(\partial \Omega_s)$. Now since $u_s \in C^\infty(\mathbb{R})$, it is easy to see that $Z_s$ has a strong material derivative in $L^1(\partial \Omega_s)$ and a shape derivative in $L^1(\partial \Omega_s)$, for any vector field $V \in C(0, \mathbb{R}; \mathbb{R}^N)$. By equation (2.173) on page 116 of [24], it follows that the Eulerian derivative $dE(\Omega, V) = \int_{\partial \Omega} \left[ Z'(\partial \Omega, V) + \kappa Z(V, n) \right] d\Sigma$, where $\kappa$ is the mean curvature on the manifold $\partial \Omega$. It’s not difficult to see that $Z'(\partial \Omega, V) = u \frac{\partial u'}{\partial n} + u \frac{\partial u}{\partial n}$ Therefore,

$$dE(\Omega, V) = \int_{\partial \Omega} u \frac{\partial u'}{\partial n} d\Sigma + \int_{\partial B} u \frac{\partial u}{\partial n} \langle V, n \rangle d\Sigma = \int_{\partial B} u \frac{\partial u'}{\partial n} d\Sigma - \int_{\partial B} \left( \frac{\partial u}{\partial n} \right)^2 \langle V, n \rangle d\Sigma.$$

Now, from (7) it follows that $dE(\Omega, V) = -\int_{\partial P} \left( \frac{\partial u}{\partial n} \right)^2 \langle V, n \rangle d\Sigma - \int_{\partial P} \left( \frac{\partial u}{\partial n} \right)^2 \langle V, n \rangle d\Sigma$. Therefore,

$$dE(\Omega, V) = -2 \int_{\partial P} \left( \frac{\partial u}{\partial n} \right)^2 \langle V, n \rangle d\Sigma. \tag{8}$$

In a similar way one can prove that the Eulerian derivative of $E$ at $\Omega_s$ in the direction $V$ exists for each $s \in [0, 2\pi]$. We denote this Eulerian derivative by $dE(\Omega_s; V)$. Thus, for each $s \in [0, 2\pi]$, $dE(\Omega_s, V) = -2 \int_{\partial P_s} \left( \frac{\partial u}{\partial n} \right)^2 \langle V, n \rangle d\Sigma. \tag{9}$

5 Proof of Theorem 3.1

In this section, we prove our main theorem, viz., Theorem 3.1 for $n \geq 3$, $n$ even. We prove that equation (11) and Proposition 5.1 hold true for any $n \geq 3$, even or odd.

We first justify that, for any $n \geq 3$, even or odd, the energy functional $E$ for the family of domains under consideration is a function of just one real variable, and that it is an even, differentiable and periodic function of period $2\pi/n$. This helps in identifying the critical points of $E$. Therefore, in order to determine the extremal configuration/s for $E$ we study its behavior on the interval $[0, \frac{\pi}{n}]$. The expression (9) for its derivative, that we derived in section 4.3, becomes useful in this analysis. We identify some of critical points of $E$ in Proposition 5.1 for $n \geq 3$, even or odd.

We prove Proposition 5.2 for $n$ even, $n \geq 3$. In view of equation (11), Propositions 5.1 and 5.2 imply that, for $n$ even, $n \geq 3$, (a) these are the only critical points for $E$, and that, (b) between every pair of consecutive critical points, $E$ is a strictly monotonic function of the argument. We use a ‘sector reflection technique’ and a ‘rotating plane method’, which were introduced in [1], for the analysis.

5.1 Sufficient Condition for the Critical Points of $E(B \setminus P_t)$, $t \in [0, 2\pi]$

Fix $n \geq 3$, even or odd. Let $E(t)$ be as in [2] which denotes the energy functional associated to the Boundary value problem [1] on $\Omega_t$, i.e., $E(t) := E(\Omega_t)$. In this section, we establish a sufficient condition for the critical points of the $C^2$ function $E : \mathbb{R}^+ \to [0, \infty]$.

Recall from [1] $B = \{ re^{i\phi} : \phi \in [0, 2\pi], 0 \leq r < g(\phi) \}$, where $g : [0, 2\pi] \to [0, \infty]$ is a $C^2$ map with $g(0) = g(2\pi)$. Here, $(r, \phi)$ is measured with respect to the origin $\tilde{\alpha} = (0, 0)$ of $\mathbb{R}^2$.

5.1.1 The Initial Configuration

We start with the following initial configuration $\Omega_{\text{init}}$ of a domain $\Omega \in \mathcal{F}$. Let $P$ and $B$ be as described in section 3. Let $\Omega_{\text{init}}$ denote the domain $B \setminus P \in \mathcal{F}$, where $P$ is in an OFF position with respect to $B$. Recall that we assumed, without loss of generality, that (a) The centers of $B$ and $P$ are on the $x_1$-axis, (b) the center of $P$ is at the origin, and (c) the center of $B$ is on the negative $x_2$-axis. Let $\tilde{x}^0 := (-x^0, 0)$ be the center of the disk $B$, where $0 < x^0 < r_1$. The initial configurations for obstacles with $D_2$, $S_2$, $C_2$ and $Z_2$ symmetry are shown in Figure 5.
Therefore, it suffices to study the behavior of $E$. Because of the initial configuration assumptions on $B$, $f$ is an increasing function of $\phi$ on $[0, \frac{\pi}{2}]$ for $n$ even, and is a decreasing function of $\phi$ on $[0, \frac{\pi}{2}]$ for $n$ odd. The condition that the obstacle $P$ can rotate freely about its center $\phi$ inside $B$, that is, $\rho(P)$ is contained in $B \forall \rho \in SO(2)$ is guaranteed by assuming that the closure of the convex hull of the circumcircle $C_2(P)$ is contained in $B$.

**5.1.2 Configuration at Time $t$**
Now, fix $t \in [0, 2\pi]$. We set $P_t := \rho_t(P), \Omega_t := B \setminus P_t$. Then, in polar coordinates, we have $\partial P_t := \{f(\phi-t)e^{i\phi} | \phi \in [0, 2\pi]\}$.

**5.1.3 Expression for the Eulerian Derivative of the energy functional $E$**
We recall, from section 4.3, that the Eulerian derivative $dE(\Omega, V)$ of $E$ at $\Omega$ in the direction $V$ exists, and is given by \[ E'(t) = -2 \int_{x \in \partial \Omega_t} \left| \frac{\partial y(t)(x)}{\partial \eta_t} \right|^2 \langle \eta_t, v \rangle (x) \, d\Sigma(x), \] where $d\Sigma$ is the line element on $\partial \Omega_t$, $\eta_t(x)$ is the outward unit normal vector to $\Omega_t$ at $x \in \partial \Omega_t$, and $v \in C^\infty(\Omega_t)$ is the deformation vector field defined as $v(\zeta) = \rho(\zeta) i\eta$, $\forall \zeta \in C \cong \mathbb{R}^2$. Here, $\rho : \mathbb{R}^2 \to [0, 1]$ is a smooth function with compact support in $B$ such that $\rho \equiv 1$ in a neighborhood of $cl(conv(C_2(P)))$.

**5.1.4 The Energy Functional $E$ is an Even and Periodic Function with Period $\frac{2\pi}{n}$**
Recall that $n \geq 3$ is a fixed integer, even or odd. Let $R_0 : \mathbb{R}^2 \to \mathbb{R}^2$ denote the reflection in $\mathbb{R}^2$ about the $x_1$-axis. Then, as in 4.3, we get $\Omega_{-t} = R_0(\Omega_t)$ for all $t \in \mathbb{R}$ and $\Omega_{\frac{2\pi}{n} + t} = \Omega_t$ for all $t \in \mathbb{R}$. Further, since the boundary data is constant on each boundary component, the solution $y$ of (1) satisfies $y(\Omega_{\frac{2\pi}{n} + t}) = y(\Omega_t)$ for all $t \in \mathbb{R}$. This implies that $E : \mathbb{R} \to (0, \infty)$ is an even and periodic function with period $\frac{2\pi}{n}$. Thus we have,

\[
E \left( t + \frac{2\pi}{n} \right) = E(t), \quad \text{and} \quad E(-t) = E(t) \quad \forall t \in \mathbb{R}.
\] (11)

Therefore, it suffices to study the behavior of $E(t)$ only on the interval $[0, \frac{2\pi}{n}]$.

**5.1.5 Sufficient Condition for the Critical Points of $E$**
The following theorem states a sufficient condition for the critical points of the function $E : \mathbb{R} \to (0, \infty)$.

**Proposition 5.1** (Sufficient condition for critical points of $E$) Let $n \geq 3$ be a fixed integer, even or odd. For each $k = 0, 1, 2, \ldots, 2n - 1$, $E'(k \frac{2\pi}{n}) = 0$. 

Fix $k \in \{0, 1, 2, \ldots, 2n - 1\}$. Let $t_k := k \frac{\pi}{n}$. Then, the domain $\Omega_{tk}$ is symmetric with respect to the $x_1$ axis. And, because of the nice boundary conditions in $[1]$, the solution $y(t_k)$ satisfies $u \circ R_0 = u$, where $R_0$ is as in section 5.1.4. The proof now follows, as in $[1]$, from property (iii) of Lemma 4.2 of $[1]$ and the expression (10) by observing that $\frac{\partial (y(t_k) \circ R_0)}{\partial \eta}(x) = \frac{\partial (y(t_k))}{\partial \eta}(R_0(x))$ for each $x$ on $\partial P_{tk}$ where the normal derivative makes sense.

5.2 The Sectors of $\Omega_t$

We recall the definition of sectors of $\Omega_t$ from $[1]$. Fix $n \geq 3$, even or odd. For a fixed $t \in \mathbb{R}$ and $a, b \in \mathbb{Z}, a < b$, let $\sigma(a, b) := \{ r e^{i \phi} \in \mathbb{R}^2 : \phi \in (t + \frac{an}{2}, t + \frac{bn}{2}) \}$, $r \in \mathbb{R}$. Then, as in $[1]$, equation (10) can be written as

$$E'(t) = -2 \sum_{k=0}^{n-1} \int_{\partial P_t \cap \sigma(k,k+1)} \left| \frac{\partial y(t)}{\partial \eta} (x) \right|^2 \langle \eta, v \rangle (x) \ d\Sigma(x)$$

$$-2 \sum_{k=n}^{2n-1} \int_{\partial P_t \cap \sigma(k,k+1)} \left| \frac{\partial y(t)}{\partial \eta} (x) \right|^2 \langle \eta, v \rangle (x) \ d\Sigma(x).$$

Please refer to Figure 7 of $[1]$ for a pictorial illustration of sectors of $\Omega_t$.

5.3 A Sector Reflection Technique

Here onwards, we fix $n \geq 3$, $n$ even. For $\alpha \in [0, 2\pi]$, the set $z_\alpha := \{ r e^{i \alpha} \mid r \in \mathbb{R} \}$ denotes the line in $\mathbb{R}^2$ corresponding to angle $\phi = \alpha$, represented in polar coordinates. Let $R_\alpha : \mathbb{R}^2 \rightarrow \mathbb{R}^2$, $\alpha \in \mathbb{R}$, denote the reflection map about the $z_\alpha$-axis. For each $t \in \mathbb{R}$, the obstacle $P_t$ is symmetric with respect to the line $z_{t+\frac{(k+1)\pi}{n}}$. We have, for $k = 0, 1, 2, \ldots, 2n - 1$,

$$R_{t+\frac{(k+1)\pi}{n}}(\partial P_t \cap \sigma(k,k+1)) = \partial P_t \cap \sigma(k+1,k+2).$$

For $k = 0, 1, 2, \ldots, 2n - 1$, let $H^k_t := \Omega_t \cap \sigma(k,k+1)$. Now, let $\bar{H}^k_t := cl(\Omega_t) \cap \sigma(k,k+1)$.

5.4 The Rotating Plane Method

Recall here that $n \geq 3$ is a fixed even integer. As in $[1]$ we have the following:

For each $k = 0, 2, 4, \ldots, n - 2$,

$$\int_{\partial P_t \cap \sigma(k,k+1)} \left| \frac{\partial y(t)}{\partial \eta} (x) \right|^2 \langle \eta, v \rangle (x) \ d\Sigma + \int_{\partial P_t \cap \sigma(k+1,k+2)} \left| \frac{\partial y(t)}{\partial \eta} (x) \right|^2 \langle \eta, v \rangle (x) \ d\Sigma$$

$$= \int_{\partial P_t \cap \sigma(k,k+1)} \left( \left| \frac{\partial y(t)}{\partial \eta} (x) \right|^2 - \left| \frac{\partial y(t)}{\partial \eta} (x') \right|^2 \right) \langle \eta, v \rangle (x) \ d\Sigma.$$

$$\langle \eta, v \rangle > 0 \quad \text{on} \quad \partial P_t \cap \sigma(k,k+1) \quad \text{for each} \quad k = 0, 2, 4, \ldots, n - 2. \quad (15)$$

For each $k = n, n + 2, \ldots, 2n - 2$,

$$\int_{\partial P_t \cap \sigma(k,k+1)} \left| \frac{\partial y(t)}{\partial \eta} (x) \right|^2 \langle \eta, v \rangle (x) \ d\Sigma + \int_{\partial P_t \cap \sigma(k+1,k+2)} \left| \frac{\partial y(t)}{\partial \eta} (x) \right|^2 \langle \eta, v \rangle (x) \ d\Sigma$$

$$= \int_{\partial P_t \cap \sigma(k+1,k+2)} \left( \left| \frac{\partial y(t)}{\partial \eta} (x) \right|^2 - \left| \frac{\partial y(t)}{\partial \eta} (x') \right|^2 \right) \langle \eta, v \rangle (x) \ d\Sigma,$$

$$\langle \eta, v \rangle > 0 \quad \text{on} \quad \partial P_t \cap \sigma(k+1,k+2) \quad \text{for each} \quad k = n, n + 2, \ldots, 2n - 2. \quad (17)$$

Here, $x' := R_{t+\frac{(k+1)\pi}{n}}(x)$. 
5.5 Necessary Condition for the Critical Points of $E$

Recall here that $n \geq 3$ is a fixed even integer. We finally show that $\{ \frac{k\pi}{n} \mid k = 0, 1, \ldots n - 1 \}$ are the only critical points of $E$, and that, between every pair of consecutive critical points of $E$, it is a strictly monotonic function of the argument. In view of Proposition 5.1 and equation (11), it now suffices to study the behavior of $E$ only on the interval $\left(0, \frac{\pi}{n}\right)$.

Proposition 5.2 (Necessary condition for critical points) Fix $n \geq 3$, $n$ even. For each $t \in \left]0, \frac{\pi}{n}\right]$, $E'(t) < 0$.

Proof Notice here that if $u$ is a solution of (1) for $g = M > 0$, then $-u$ will be a solution of (1) for $g = -M$. And hence, the energy for the case $g = M > 0$ and $g = -M < 0$ are the same. Therefore, it is enough to consider the case $g = M > 0$.

Fix $t \in \left]0, \frac{\pi}{n}\right]$. Using (14) and (16), equation (12) can be written as

$$E'(t) = -2 \sum_{0 \leq k \leq n-2 \atop k \text{ even}} \int_{\partial P_t \cap \sigma(k+1,k+1)} \left( \left| \frac{\partial y(t)}{\partial \eta} \right|^2 - \left| \frac{\partial y(t)}{\partial \eta} \right|^2 \right) \langle \eta, v \rangle (x) \, d\Sigma(x)$$

(18)

Let $H(t) := \bigcup_{0 \leq k \leq n-2 \atop k \text{ even}} H^k(t)$. Let $w(x) := y(t)(x) - y(t)(x')$. By Lemma 6.1 of [1], the real valued function $w$ is well-defined on $H(t)$. Moreover, $w \equiv 0$ on $\partial P_t \cap \partial H(t)$ and also on $\partial H(t) \cap z_{t+\frac{k\pi}{n}}$ for each $k = 1, 3, \ldots n - 1$. That is, $w(x) = 0 \forall x \in \partial H(t) \cap \left( \partial P_t \bigcup_{k \text{ odd}} \frac{\pi}{n} z_{t+\frac{k\pi}{n}} \right)$. Moreover, since $y(t) = M > 0$ on $\partial B$ and $y(t) \in (0, M)$ inside $\Omega(t)$, and since for each $k = 0, 2, \ldots n - 2$, the reflection of $\partial H^k(t) \cap \partial B$ about the axis $z_{t+\frac{k\pi}{n}}$ lies completely inside $H^k(t) \subset \Omega(t)$, we obtain $w(x) > 0$ for each $x$ in $\partial H(t) \cap \partial B \setminus \left( \bigcup_{0 \leq k \leq n-2 \atop k \text{ odd}} \frac{\pi}{n} z_{t+\frac{k\pi}{n}} \right)$. Now, with arguments similar to the ones in the proof of Proposition 6.2 of [1], it can be shown that $w(x) > 0 \forall x \in \partial H(t) \cap \bigcup_{0 \leq k \leq n-2 \atop k \text{ even}} \frac{\pi}{n} z_{t+\frac{k\pi}{n}}$. This is equivalent to saying that for each $k$, $0 \leq k \leq n - 2$, even, $w(x) > 0$ for all $x \in \partial H^k(t) \cap z_{t+\frac{k\pi}{n}}$. Therefore, the non-constant function $w$ satisfies $-\Delta w = 0$ in $H(t)$, $w \geq 0$, on $\partial H(t)$. Hence, by the maximum principle, $w$ is non-negative on the whole of $H(t)$. Since $w$ achieves its minimal value zero on $\bigcup_{0 \leq k \leq n-2 \atop k \equiv 0 \text{ mod } 2} \left( \partial P_t \cap \sigma(k+1,k+1) \right)$, by the Hopf maximum principle, one has $\frac{\partial w}{\partial \eta}(x) < 0 \forall x \in \bigcup_{0 \leq k \leq n-2 \atop k \equiv 0 \text{ mod } 2} \left( \partial P_t \cap \sigma(k+1,k+1) \right)$. Also, by the application of the Hopf maximum principle to problem (1) for $g = M > 0$, it follows that

$$\frac{\partial y(t)}{\partial \eta}(x) < 0 \forall x \in \partial P_t, \quad \text{and} \quad \frac{\partial y(t)}{\partial \eta}(x) > 0 \forall x \in \partial B.$$

Thus,

$$\left| \frac{\partial y(t)}{\partial \eta}(x) \right|^2 - \left| \frac{\partial y(t)}{\partial \eta}(x') \right|^2 > 0 \forall x \in \bigcup_{0 \leq k \leq n-2 \atop k \equiv 0 \text{ mod } 2} \left( \partial P_t \cap \sigma(k+1,k+1) \right).$$

(19)

Now, from (19) and (15), it follows that the first term in (18) is strictly negative. Similarly, one can prove using (17) that the second term in (18) is also strictly negative. This proves the proposition for $n$ even. \qed

5.6 Proof of Theorem 3.1

Theorem 3.1, for $n$ even, now follows from Propositions 5.1 5.2 and equation (11).
5.7 The $n$ Odd Case

We face exactly the same difficulties as in [1] in characterizing the optimal configurations for the odd order case completely. Please refer to section 6.7 of [1] for details. Nevertheless, we provide some numerical evidence that enables us to make a conjecture that Theorem 3.1 holds true for $n$ odd too.

6 Proof of Theorem 3.2

Let $d \geq 0$ denote the distance between the center of the disk and the center of the obstacle having the dihedral symmetry. Let $t \in [0, 2\pi]$ denote the angle by which the obstacle is rotated about its center in the anticlockwise direction starting from the initial configuration as described in Sec. 5.1.1. Clearly, $E$ is a function of both $d$ and $t$. Please recall that when $d = 0$, the map $t \mapsto E(t)$ is constant as the domains remain isometric and because of the suitable boundary conditions the solution remains unaltered. For a fixed $d > 0$, it is interesting to study the behavior of the map $t \mapsto E(t)$. This is what we have studied in Theorem 3.1.

It also makes sense to study the behavior of the map $d \mapsto E(d)$ for a fixed $t \in [0, 2\pi]$. By arguments similar to the proof of Theorem 2.1 on page 244 of [14], we get the following result with just the assumption that the set $P$ is convex as well as piecewise smooth and that it be reflection-symmetric about some line $L$.

**Theorem 6.1** Assume that $\Omega$ has the interior reflection property with respect to a line $L$ about which the set $P$ is reflection-symmetric. Suppose that $P$ is translated in the direction of a unit vector $v$ perpendicular to $L$ and pointing from the small side to the big side. Then, $\frac{dE}{dv} < 0$.

From Theorem 6.1, we get the following Corollary:

**Corollary 6.1** Fix $n \geq 3$, even or odd. Fix $t \in [0, 2\pi]$. Let $x$ denote the center of the obstacle $P_{(d, t_0)}$. Then, at any minimizing $x$,

a) $\Omega = B \setminus P_{(d, t_0)}$ has no hyperplane of interior reflection containing $x$. Moreover, at any maximizing $x$, either statement (a) above is true, or else

b) the circumcircle $C_2$ of $P_{(d, t_0)}$ intersects the small side of $\partial B$.

Clearly, the domain $\Omega_{(d, t_0)}$ enjoys the interior reflection property w.r.t. its axes of symmetry of $P_{(d, t_0)}$ that are not the diameters of $B$. Therefore, as in [14], we immediately get that

**Corollary 6.2** Fix $n \geq 3$, even or odd and $t \in [0, 2\pi]$. Then, (a) the concentric configuration, i.e., $d = 0$, is the only candidate for the minimiser of the map $d \mapsto E(d)$, and (b) at any maximising configuration of the map $d \mapsto E(d)$, the circumcircle $C_2$ of the obstacle $P_{(d, t_0)}$ must intersect $\partial B$.

Since $\Delta$ is invariant under the isometries of the domain, and since the boundary data in [1] is nice, it follows that for a fixed $t \in [0, 2\pi]$, in order to study the behavior of $d \mapsto E(d)$, it is enough to translate the center of the obstacle $P_{t}$ along the positive $x_1$-axis. Since $E$ is an even function, it follows by Theorem 6.1 that, $d \mapsto E(d)$ is minimum for $d = 0$ and is a strictly increasing function of $d$ in $[0, r_1 - r_0^2]$. Then, Corollary 6.2 along with Theorem 3.1 imply Theorem 3.2 that characterises the maximising and the minimising configurations over the family of domains $G$. Applying the idea from [14] to the candidates for the minimising configurations over $G$ for $n$ even, $n \geq 3$, we get that, when $g = K > 0$, at the global maximising configurations, w.r.t. both the translations of the obstacle within $B$ as well as the rotations of the obstacle about its center, the obstacle must be in an OFF position w.r.t. $B$ with its outer vertex touching $\partial B$. The global minimiser for $n \geq 3$, even or odd, remains to be the concentric configuration.

7 Numerical Results

We give some numerical evidence supporting Theorem 3.1. We provide numerical evidence for $n = 5$ and conjecture that Proposition 5.2 and hence, Theorem 3.1 hold true for $n$ odd too. Therefore, we choose two obstacles, a square and a pentagon, with dihedral symmetry of order $n = 4, 5$. We solve the boundary value problem in the domain $\Omega = B \setminus P$ using finite element method with $P^1$ elements (see e.g., [25, 26]) on a mesh with element size $h = 0.018$. The result for the square obstacle are shown in Figure 7.
Figures 7a-7c shows the OFF, intermediate and ON configurations. The OFF and the ON configurations are the maximizer and the minimizer for the energy $E$, which is also reflected in Table 1.

We next conjecture that Theorem 3.1 is true for odd $n$ too by demonstrating quantitative and qualitative results for an obstacle having pentagonal shape. The observations for obstacle having a pentagonal shape are shown in Figure 8.

Fig. 8: Simulations of extremal configurations for a pentagon obstacle
Figures 8a-8d shows the OFF, intermediate and ON configurations. The OFF and the ON configurations are the maximizer and the minimizer for the energy $E$, which is also reflected in Table 2.

8 Conclusions

In this paper, we considered an obstacle placement problem, where the planar obstacle is invariant under the action of a dihedral group. We considered an open disk in the Euclidean plane containing the obstacle such that the centers of the enclosing disk and the obstacle are non-concentric. This article is a follow up of the paper [1]. The family of domains considered here is the same as the one considered in [1], but the boundary value problem is different from that of [1]. In [1], we had homogeneous boundary data while in the current paper we consider an inhomogeneous boundary data. Further, in the place of an eigenvalue problem considered in [1], we consider a Laplace equation here. We carry out the shape calculus analysis for the boundary value problem at hand and derive an expression for the Eulerian derivative of the energy functional. Once we have this expression, the proof for finding optimal configurations w.r.t. the rotations of the obstacle about its fixed center follows more or less from [1]. We prove this result for the case where the obstacle has an even order dihedral symmetry. For the case of odd order symmetry, we have partial results. We face exactly the same difficulties as in [1] in characterizing the optimal configurations for the odd order case completely. We thereby formulate conjectures about such configurations based on numerical evidence.

We further characterize the global maximizing and the global minimizing configurations w.r.t. the rotations of the obstacle about its center as well as the translations of the obstacle within the disk. For the odd order case, we identify the global minimizing configuration and partially identify the global maximizing configurations as opposed to the even order case, where we completely characterize them. Finally, we provide some numerical evidences to support our theoretical findings and the conjectures.

9 Acknowledgments

We thank Dr. Apala Majumbar, University of Bath, UK for suggesting the boundary value problem which has applications in some liquid crystal context. We thank Dr. Rajesh Mahadevan, Universidad de Concepcion, Chile for suggesting a reference for the shape calculus part. We thank Dr. Souvik Roy, University of Texas, Arlington for his help in coming up with numerical evidence supporting our results and conjectures. We also thank University of Bath and Universidad de Concepcion for their support.
