Semi-simple groups of compact 16-dimensional planes

by Helmut R. SALZMANN

Abstract

The automorphism group $\Sigma$ of a compact topological projective plane with a 16-dimensional point space is a locally compact group. If the dimension of $\Sigma$ is at least 29, then $\Sigma$ is known to be a Lie group. For the connected component $\Delta$ of $\Sigma$ the condition $\dim \Delta \geq 27$ suffices. Depending on the structure of $\Delta$ and the configuration of the fixed elements of $\Delta$ sharper bounds are obtained here. Example: If $\Delta$ is semi-simple and fixes exactly one line and possibly several points on this line, then $\Delta$ is a Lie group if $\dim \Delta \geq 11$. Any semi-simple group $\Delta$ which satisfies $\dim \Delta \geq 25$ is a Lie group.

1. Introduction

A compact connected topological projective plane has a point space $P$ of (covering) dimension $\dim P = d \mid 16$, provided $d < \infty$. For properties and results concerning 16-dimensional planes see the treatise [19] and a more recent update [17]. With the compact-open topology (the topology of uniform convergence), the automorphism group $\Sigma = \text{Aut} P$ of a compact 16-dimensional plane $P = (P, \mathcal{L})$ is a locally compact transformation group of $P$ as well as of the line space $\mathcal{L}$, see [19] 44.3. In the case of the classical plane $\mathcal{O}$ over the octonion algebra $\mathcal{O}$ the group $\Sigma$ is a simple Lie group of dimension 78 ([19] 18.19). If $P$ is not classical, then $\dim \text{Aut} P \leq 40$ ([19] 87.7). All planes with $\dim \Sigma \geq 35$ are known explicitly, provided $\Sigma$ does not fix exactly one incident point-line pair ([17]). If $\dim \Sigma \geq 27$, then the connected component $\Delta$ of $\Sigma$ is a Lie group ([10]). More detailed results can be found in [17]. For semi-simple groups sharper bounds will be obtained here.

2. Preliminaries

In the following, $\mathcal{P} = (P, \mathcal{L})$ will always mean a compact 16-dimensional projective plane if not stated otherwise; $\Delta$ denotes a connected closed subgroup of $\text{Aut} \mathcal{P}$.

Notation is more or less standard and agrees with that in the book [19]. A flag is an incident point-line pair, a double flag consists of two points, say $u, v$, their join $uv$, and a second line in the pencil $\mathcal{L}_v$. A 2-dimensional plane will also be called flat. Homeomorphism is indicated by $\approx$. The topological dimension $\dim$ of a set $M \subseteq P$ or a group, the covering dimension, coincides with the inductive dimension, see [19] §92, 93.5. As customary, $\text{Cs}_{\Delta} \Gamma$ or just $\text{Cs} \Gamma$ is the centralizer of $\Gamma$ in $\Delta$. Distinguish between the commutator subgroup $\Gamma'$ and the connected component $\Gamma^1$ of the topological group $\Gamma$. Local isomorphism of groups is symbolized by $\cong$. The coset space $\Delta / \Gamma = \{ \Gamma \delta \mid \delta \in \Delta \}$ has the dimension $\Delta : \Gamma = \dim \Delta - \dim \Gamma$. If $\Gamma$ is any subset of $\Delta$, then $\mathcal{F}_{\Gamma}$ denotes the configuration of all
fixed elements (points and lines) of $\Delta$. The group $\Delta_{[c, A]}$ consists of the axial collineations in $\Delta$ with axis $A$ and center $c$. A collineation group $\Gamma$ is said to be straight if each orbit $x^\Gamma$ is contained in some line. In this case a theorem of Baer [1] asserts that either $\Gamma = \Gamma_{[c, A]}$ is a group of axial collineations or $\mathcal{F}_\Gamma$ is a Baer subplane (cf. 2.2 below).

2.1 Topology. Each line $L$ of $\mathcal{P}$ is homotopy equivalent ($\cong$) to an 8-sphere $S_8$, see [19] 54.11. So far, no example with $L \not\cong S_8$ has been found. The Lefschetz fixed point theorem implies that each homeomorphism $\varphi: P \to P$ has a fixed point. By duality, each automorphism of $\mathcal{P}$ fixes a point and a line, see [19] 55.19, 45.

2.2 Baer subplanes. Each 8-dimensional closed subplane $\mathcal{B}$ of $\mathcal{P}$ is a Baer subplane, i.e., each point of $\mathcal{P}$ is incident with a line of $\mathcal{B}$ (and dually, each line of $\mathcal{P}$ contains a point of $\mathcal{B}$), see [14] §3 or [19] 55.5 for details. By a theorem of L"owen [8] Th. B, any two Baer subplanes of a compact connected projective plane of finite dimension have a point and a line in common. $(\mathcal{M})$ will denote the smallest closed subplane of $\mathcal{P}$ containing the set $\mathcal{M}$ of points and lines. We write $\mathcal{B} \lhd \mathcal{P}$ if $\mathcal{B}$ is a Baer subplane and $\mathcal{B} \leq \mathcal{P}$ if $8| \dim \mathcal{B}$.

2.3 Groups. Any connected subgroup $\Delta$ of $\Sigma = \mathrm{Aut} \mathcal{P}$ with $\dim \Delta \geq 27$ is a Lie group, see [10]. For $\dim \Delta \geq 35$, the result has been proved in [19] 87.1. In particular, $\Delta$ is then either semi-simple, or $\Delta$ has a central torus subgroup or a minimal normal vector subgroup $\Xi \cong \mathbb{R}^k$, see [19] 94.26.

2.4 Involutions. Each involution $\iota$ is either a reflection or it is planar ($\mathcal{F}_\iota \lhd \mathcal{P}$), see [19] 55.29. Commuting involutions with the same fixed point set are identical ([19] 55.32). Let $\mathbb{Z}_2^m \cong \Phi \leq \mathrm{Aut} \mathcal{P}$ and $\dim \mathcal{P} = 2^m$. Then $r \leq m + 1$; if $\Phi$ is generated by reflections, then $r \leq 2$, see [19] 55.34(c,b). If $r \geq m$ (>) 2, then $\Phi$ contains a reflection (a planar involution), cf. [19] 55.34(d,b). Any torus group in $\mathrm{Aut} \mathcal{P}$ has dimension at most $m$, see [19] 55.37, for $m = 4$ in particular, $\dim \Delta \leq 4$, see also [4]. The orthogonal group $\mathrm{SO}_8 \mathbb{R}$ cannot act non-trivially on $\mathcal{P}$ ([19] 55.40).

2.5 Stiffness refers to the fact that the dimension of the stabilizer $\Lambda$ of a (non-degenerate) quadrangle $\varepsilon$ cannot be very large. If $\mathcal{P}$ is the classical plane, then $\Lambda$ is the 14-dimensional exceptional compact simple Lie group $G_2 \cong \mathrm{Aut} \mathcal{O}$ for each choice of $\varepsilon$, cf. [19] 11.30–35. In the general case, let $\Lambda$ denote the connected component of $\Delta_\varepsilon$. Then the following holds:

(a) $\Lambda \cong G_2$ and $\mathcal{F}_\Lambda$ is flat, or $\dim \Lambda < 14$ ([19] 83.23, 24),
(b) $\Lambda \cong G_2$ or $\dim \Lambda \leq 11$ ([2] 4.1),
(b) if $\mathcal{F}_\Lambda$ is a Baer subplane, then $\Delta_\varepsilon$ is compact and $\dim \Lambda \leq 7$ ([19] 83.6),
(b) if $\mathcal{F}_\Lambda \lhd \mathcal{P}$ and $\Lambda$ is a Lie group, then $\Lambda \cong \mathrm{Spin}_3 \mathbb{R}$ or $\dim \Lambda \leq 1$ ([19] 83.22),
(c) if there exists a subplane $\mathcal{B}$ such that $\mathcal{F}_\Lambda \lhd \mathcal{B} \lhd \mathcal{P}$, then $\Lambda$ is compact ([12] 2.2, [19] 83.9),
(c) if $\Lambda$ contains a pair of commuting involutions, then $\Delta_\varepsilon$ is compact ([19] 83.10),
(d) if $\Lambda$ is compact or semi-simple or if $\mathcal{F}_\Lambda$ is connected, then $\Lambda \cong G_2$ or $\dim \Lambda \leq 10$ ([2] XI.9.8, [12] 4.1, [2] 3.5),
(d) if $\Lambda$ is compact, or if $\dim \mathcal{F}_\Lambda = 4$, or if $\Lambda$ is a Lie group and $\mathcal{F}_\Lambda$ is connected, then
Remark. The result [19] 53.2 depends on a theorem of Szenthe for which a correct proof has been given in the meantime by Hofmann and Kramer [6] 5.5 Corollary.

2.7 Lemma. If $\mathcal{F}_{\Delta} = \emptyset$, then $\Delta$ is semi-simple with trivial center, or $\Delta$ induces a centerfree semi-simple group on some connected proper closed subplane. In particular, $\mathcal{F}_{\Delta} \neq \emptyset$ whenever $\Delta$ is commutative.

Proof. As a flat plane does not have a proper closed subplane, the Lemma is true for flat planes by [19] 33.1, and each commutative connected subgroup fixes a point or a line. Suppose the Lemma has been shown for all planes of smaller dimension thane the plane on which $\Delta$ acts. If $\Delta$ contains a central element $\zeta \neq 1$, then $\Delta$ is not semi-simple and hence has a commutative normal subgroup $\Xi$, then there is a point $p$ such that $p^\Xi = p$ or $p^{\Xi^*} = p$ (up to duality). By assuption, $p^\Delta \neq p$ and $p^\Delta$ is not contained in a line. Obviously $\zeta|_{p^\Delta} = 1$, and normality of $\Xi$ implies $\Xi|_{p^\Delta} = 1$. Therefore $\mathcal{E} = \langle p^\Delta \rangle$ is a proper connected subplane and $\overline{\Delta} = \Delta|_{\mathcal{E}}$ satisfies $\mathcal{F}_{\overline{\Delta}} = \emptyset$. Now the Lemma can be applied to $\overline{\Delta}$. \hfill $\Box$

Note that the Lemma holds for all compact connected planes of finite dimension.

2.8 Addendum. If $\mathcal{F}_{\Delta} = \emptyset$ and if there is no $\Delta$-invariant proper subplane, then each involution in a proper simple factor of $\Delta$ is planar. This is true for each compact plane of dimension $d \mid 16$.

Proof. By 2.7 the group $\Delta$ is semi-simple with trivial center. Suppose that $\Delta = \Gamma \times \Psi$ is a product of two proper factors. If $\Gamma$ contains a reflection $\gamma \in \Gamma_{|c,A}$, then $\gamma^\Psi = c \neq c^\Gamma$ and $\Psi|_{c,A} = 1$. A line $L$ containing $c^\Gamma$ would be fixed by $\Gamma \Psi = \Delta$. Therefore $\langle c^\Gamma \rangle = \mathcal{E} \leq \mathcal{F}_\Psi$, and $\mathcal{E}^\Gamma = c^\Psi = c^\Delta$ contrary to the assumtion. Hence each involution in a proper factor is planar.

Remark. The statement is not true if there is an invariant subplane: in the classical quaternion plane $\mathcal{H}$, the group $\Delta$ consisting of all collineations which map the real subplane onto itself is the direct product of the automorphism group $\Gamma \cong \text{SO}_3 \mathbb{R}$ of the quaternions and the group $\mathcal{P} \cong \text{SL}_3 \mathbb{R}$ of real collineations. The involutions in $\mathcal{P}$ are reflections of $\mathcal{H}$.

2.9 Fact. If $\mathcal{E} = \mathcal{E} < \mathcal{P}$, if $|\mathcal{E}|\mathcal{E} = \Delta/K$ is a semi-simple Lie group, and if $\Lambda = K^1$, then $\Delta$ contains a covering group $\Gamma$ of $\Delta/K$ such that $\Gamma|_{\mathcal{E}} \cong \Delta/K$ and $\Delta = \Gamma\Lambda$. In particular, $\Delta$ is a Lie group whenever $\Lambda$ is.

Proof. The first claim is a special case of [19] 94.27; the second follows from $\dim \Gamma = \Delta:K = \dim \Delta - \dim \Lambda$ because $\Delta$ is connected. \hfill $\Box$

3. No fixed elements
The following slightly improves results in [17]:

3.1. If $\Delta$ is semi-simple, $F_\Delta = \emptyset$ and if $\dim \Delta \geq 20$, then $\Delta$ is a Lie group. For $\dim \Delta \geq 21$ the assertion has been proved by different methods in [17] 3.0.

Proof. Suppose that $\Delta$ is not a Lie group.

(a) By the Lemma above, $\Delta$ is a direct product of simple groups with trivial center, or it induces such a group on some $\Delta$-invariant connected subplane $\mathcal{E}$. Choose $\mathcal{E}$ in such a way that the dimension of $\mathcal{E}$ is minimal. In the case $\mathcal{E} = \mathcal{P}$ the center of $\Delta$ is trivial and $\Delta$ is a Lie group. If $\mathcal{E}$ is flat, then $\Delta|_\mathcal{E} = \Delta/K$ is strictly simple of dimension 3 or $\Delta|_\mathcal{E} \cong SL_3\mathbb{R}$ (cf. [19] 33.6,7); by Stiffness, $\Lambda = K^1 \cong G_2$ is a Lie group and 2.9 applies, or $\dim K \leq 10$ and $\dim \Delta \leq 18$.

(b) Next, assume that $\mathcal{E} \nsubseteq \mathcal{P}$. All almost simple groups of dimension at least 10 acting on $\mathcal{E}$ have been determined by Stroppel [20]; for those satisfying $F_\Delta = \emptyset$ see also [16] 2.1. Suppose first that $\Delta^* = \Delta|_\mathcal{E} = \Delta/K = \Gamma \times \Psi$ is not simple, and that $\Gamma$ is a simple factor. By the addendum above, each involution in $\Gamma$ is planar. As the center of $\Gamma$ is trivial, there are distinct involutions $\alpha, \beta \in \Gamma$. Because of L"owen's theorem (see 2.2 above) there is some point $c \in F_{\alpha,\beta}$, and the point space $F_{\alpha,\beta}$ of $F_{\alpha,\beta}$ has dimension at most 2. If $c^\Psi = c$, then $\langle c^\Delta \rangle = \langle c^\Gamma \rangle \leq F_\Psi < \mathcal{E}$ contrary to the assumption. Similarly, if $c^\Psi \neq c$ is contained in a line $L$ of $\mathcal{E}$, then $L = L^\Psi$ induces a line of $F_\alpha$ and of $F_\beta$, a contradiction dual to the previous one. Hence $\langle c^\Psi \rangle$ is a flat subplane, and $\Psi$ is simple of dimension 3 or 8. Moreover, $\Lambda = K^1$ is a compact normal, hence semi-simple subgroup, in fact a Lie group (see [19] 93.11). Stiffness implies $\dim \Lambda \leq 6$. Interchanging the rôles of $\Gamma$ and $\Psi$, it follows that both $\Gamma$ and $\Psi$ have dimension 8, in fact, $\Gamma \cong \Psi \cong SL_3\mathbb{R}$, and $\Delta$ is a Lie group by 2.9.

(c) According to [16] 2.1,2, the induced group $\Delta^* = \Delta|_\mathcal{E}$ is a motion group of the classical quaternion plane or $\Delta^* \cong SL_3\mathbb{C}$ acts on a Hughes plane and fixes a proper subplane of $\mathcal{E}$. We will have to deal with this group in the case $\dim \mathcal{E} = 4$. If $\Delta^* \cong PU_3(H, r)$, then $\dim \Delta^* = 21$. Recall that $\Delta$ is semi-simple. The kernel $K$ is compact and $\Lambda = K^1$ is semi-simple; $\Delta/K$ is locally isomorphic to $U_3(H, r)$. By [10] only the cases $\dim \Delta < 27$ must be considered. Then $\dim \Lambda \mid 6$ and $\Lambda$ is a compact Lie group. For $\Delta^* \cong PSU_4(\mathbb{C}, 1)$ as a motion group of the quaternion plane cf. [19] 18.32. A maximal compact subgroup of $\Delta^*$ is isomorphic to $U_3\mathbb{C}$ and may be the image of a non-Lie group. Again $K$ is compact by stiffness, it is a finite extension of the semi-simple group $\Lambda = K^1$, and $\Lambda$ is a Lie group, see [19] 93.11. Thus $\Delta$ is a Lie group.

Note that in steps (a–c) the smaller bound $\dim \Delta \geq 19$ suffices; the assumption $\dim \Delta \geq 20$ will only be needed in the next step.

(d) Finally, let $\dim \mathcal{E} = 4$. Suppose that $\dim \Delta|_\mathcal{E} > 3$. According to [19] 71.8 the induced group $\Delta|_\mathcal{E}$ is an almost simple Lie group, and $\Delta|_\mathcal{K} \leq 8$ or $\Delta|_\mathcal{K} = 16$. In this step, the first case will be considered. Then $\dim K \geq 12$ and $\Lambda = K^1 \cong G_2$. Therefore $\Delta/K \geq 6$, and 2.9 shows that $\Delta$ is a Lie group.

(e) In the second case, $\Delta|_\mathcal{E} \cong PSL_3\mathbb{C}$ by [19] 71.8. This includes the possibility that there is a Hughes plane $H^\Delta = H$ such that $\mathcal{E} < H < \mathcal{P}$. The plane $\mathcal{E}$ is the classical complex plane ([19] 72.8), and $4 \leq \dim K \leq 8$. The normal subgroup $\Lambda = K^1$ is semi-simple and hence
\[ \dim \Lambda \in \{6, 8\}. \] Consequently \( \dim \Delta \geq 22 \). Choose a line \( L \) of \( \mathcal{E} \), a point \( z \in L \setminus \mathcal{E} \), and two points \( a, b \in \mathcal{E} \), \( a, b \notin L \). If \( \langle \mathcal{E}, z \rangle \triangleleft \mathcal{P} \), then \( \Lambda \) would be a compact Lie group by 2.5(c).

Hence \( \Delta_z \) acts effectively on \( \mathcal{E} \). The stabilizer \( \Gamma = \Delta_z \cap \mathcal{G} \) fixes each point of \( \mathcal{E} \) on the line \( ab \), and \( \dim \Gamma \geq 3 \) because of 2.6. Let \( \mathbb{N} \) be a compact central subgroup of \( \Lambda \), so that \( \mathbb{N} \subset \mathcal{F} = \mathcal{F}_\Gamma \). As \( \mathbb{N} \) is not a Lie group and \( \mathbb{N} \geq \mathbb{1} \), it follows from [19] 71.2 that \( \mathcal{F} \triangleleft \mathcal{P} \).

Now \( \Gamma \) is compact by 2.5(b). On the other hand, \( \Gamma \) is a group of axial collineations in \( \Delta_z \). These form a group \( \mathbb{C}^2 \times \mathbb{C}^x \) and do not contain a compact subgroup of dimension 3, a contradiction.

\[ \square \]

3.2 Theorem. If \( \mathcal{F}_\Delta = \emptyset \) and \( \dim \Delta \geq 22 \), then \( \Delta \) is a Lie group.

Proof. (a) Suppose that \( \Delta \) is not a Lie group. Then \( \dim \Delta < 27 \) by [16], and there are arbitrarily small compact, 0-dimensional central subgroups \( \mathbb{N} \) such that \( \Delta/\mathbb{N} \) is a Lie group, cf. [19] 93.8. Choose a fixed point \( x \) of some element \( \zeta \in \mathbb{N} \setminus \{\mathbb{1}\} \). From \( \zeta|_{\Delta} = \mathbb{1} \) and \( \mathcal{F}_\Delta = \emptyset \) it follows that \( \Delta = \langle p^\Delta \rangle \) is a proper connected subplane. Put \( \Delta|_D = \Delta/\mathbb{K} \). If \( \mathcal{D} \) is flat, then \( \Delta/\mathbb{K} = 8 \) and \( \mathbb{K} = 1 \leq G_2 \) by stiffness, so that \( \Delta|_D \triangleq \text{SL}_3\mathbb{R} \) and 2.9 applies.

If \( \dim \mathcal{D} = 4 \), then \( \Delta/\mathbb{K} \) is a Lie group by [19] 71.2, and stiffness 2.5(e) shows that \( \dim \mathbb{K} < 8 \) or \( \mathbb{K} = 1 \triangleq \text{SU}_3\mathbb{C} \). Hence \( \Delta/\mathbb{K} \geq 14 \), and then \( \Delta/\mathbb{K} \triangleq \text{PSL}_3\mathbb{C} \) by [11] 5.6. Now \( 6 \leq \dim \Lambda \leq 8 \), and the same arguments as at the end of step (e) of the previous proof show that this is impossible. Consequently \( \dim \mathcal{D} = 8 \).

(b) Let \( \mathcal{D} \triangleleft \mathcal{P} \) and note that \( \Delta \) acts on \( \mathcal{D} \) without fixed elements. By [16] 2.1 the following holds for \( \Delta|_D = \Delta/\mathbb{K} \): either \( \mathcal{D} \) is the classical quaternion plane, \( \Delta/\mathbb{K} \) is a motion group of \( \mathcal{D} \) and \( \Delta/\mathbb{K} \in \{21, 15\} \), or \( \mathcal{D} \) is a Hughes plane and \( \Delta|_D \triangleq \text{SL}_3\mathbb{C} \). Moreover \( \Delta/\mathbb{K} \) is a Lie group and we may assume that \( \mathbb{N}|_D = \mathbb{1} \). The kernel \( \mathbb{K} \) is compact of dimension at most 7.

(c) In the first case, the motion group \( \Delta/\mathbb{K} \) is covered by a subgroup \( \mathbb{T} \triangleq \text{U}_3(\mathbb{H}, r) \) of \( \Delta \) (see 2.9), and \( \dim \mathbb{K} \leq 5 \). The representation of \( \mathbb{T} \) on \( \mathbb{K}/\mathbb{N} \) shows that \( \mathbb{K} \leq \text{Cs} \mathbb{T} \). We may assume that \( \mathbb{K} \) is connected, since \( \dim \mathbb{K} \mathbb{T} = \dim \Delta \) and \( \Delta \) is connected. Moreover, the center \( \mathbb{Z} \) of \( \mathbb{K} \) has positive dimension: because \( \mathbb{K} \) is not a Lie group, the claim follows from the structure of compact groups as described in [19] 93.11. The stabilizer \( \Pi = \Delta_\rho \) of a non-absolute point \( p \in \mathcal{D} \) fixes also the polar \( L \) of \( p \), and \( \Pi|/\mathbb{K} = \text{U}_2\mathbb{H} \times \text{U}_1\mathbb{H} \). In particular, \( \Pi \) is compact and \( \dim \Pi \geq 14 \).

Choose \( z \in L \setminus \mathcal{D} \) and note that \( \Pi_z \cap \mathbb{K} = 1 \) because \( \langle \mathcal{D}, z \rangle = \mathcal{P} \). Hence \( \Pi_z = \Delta_z \) is a Lie group. From [19] 96.11 it follows that \( \Pi : \Pi_z \leq 7 \) and \( \dim \Delta_z \geq 7 \). The group \( \Delta_z \) acts faithfully on \( \mathcal{D} \), it is isomorphic to a subgroup of \( \text{U}_2\mathbb{H} \times \text{U}_1\mathbb{H} \). We apply Richardson’s theorem [19] 96.34 to the action of \( \Delta_z \) on \( S := L \cap \mathcal{D} \approx \mathbb{S}_4 \) (cf. [19] 96.22). Put \( \Phi = \Delta_z|_S = \Delta_z/\mathbb{H} \) and note that \( \mathbb{H} \) is isomorphic to a subgroup of \( \text{U}_1\mathbb{H} \), so that \( \dim \Phi \geq 4 \).

(d) There are the following possibilities:

1) \( \Phi \triangleq \text{SO}_3\mathbb{R} \times \text{SO}_2\mathbb{R} \) and \( \Phi \) has a one-dimensional orbit, 2) \( \Phi \) has two fixed points \( u, v \in S \),

3) \( \Phi \triangleq \text{SO}_3\mathbb{R} \) is transitive on \( S \) and \( \dim \Phi \geq 10 \). In the first two cases, there are points \( u, v, w \in S \) and \( q \in pv \) such that \( \Delta_{z,u,v,w,q} \) has dimension \( > 0 \), but this group fixes \( S \) pointwise and is trivial on \( \mathcal{D} \). In the third case, \( \Delta_{z,v} \) fixes a second point \( u \in S \). Let
Then $\Gamma = \Delta_{z,q}$ fixes each point of $J \approx S_4$, and $\dim \Gamma \geq 3$. Hence $\mathcal{F}_\Gamma \triangleleft \mathcal{P}$, and $J$ is contained in a line of $\mathcal{F}_\Gamma$. By the open mapping theorem [19] 51.19,20 we conclude that $J$ is in fact a line of $\mathcal{F}_\Gamma$. Therefore $M = L \cap \mathcal{F}_\Gamma \approx S_4$, and Richardson’s theorem [19] 96.34 shows that $\Gamma K$ induces a Lie group on $M$. As $K_z = 1$, both $K$ and $\Delta$ would be Lie groups.

(e) If $\Delta/K \cong \text{PSU}_4(\mathbb{C},1)$ is the 15-dimensional motion group of the planar polarity, then $\Delta$ is doubly transitive on the absolute $L$ on $C$. Theorem [19] 96.34 shows that $\Gamma K$ induces a Lie group on $M$. As $K_z = 1$, both $K$ and $\Delta$ would be Lie groups.

(f) Of the possibilities listed in step (b), only the following remains: $\mathcal{D}$ is a Hughes plane (cf. [19] § 86, in particular, 86.33,34), $\dim \Delta = 17$, and there is an invariant subplane $\mathcal{C}$ isomorphic to the classical complex plane. The commutator group $\Upsilon = \Delta' \cong \text{SL}_3 \mathbb{C}$ induces on $\mathcal{C}$ the full automorphism group $\text{PSL}_3 \mathbb{C}$. The center of $\Upsilon$ is generated by an element $\xi$ of order 3. The kernel $K$ is compact by stiffness, and $\dim K \geq 5$. Moreover, $\Upsilon$ acts trivially on $K$, and $K \leq C \Upsilon$. Choose a point $z$ which is not incident with any line of $\mathcal{C}$. As $\mathcal{D}$ is a Baer subplane, there is a unique line $L$ of $\mathcal{D}$ with $z \in L$, and $\mathcal{F}_z = \mathcal{C}$ implies $L^\xi \neq L$. The stabilizer $\Upsilon_z$ fixes each point of $z^K \subset L$ and of $z^\xi \subset L^\xi$. Both orbits of $z$ are homeomorphic to $K$; their dimension is at least 5. Hence $(z^K, z^\xi) = \mathcal{P}$ and $\Upsilon_z = 1$. It follows that $z^\Upsilon$ is open in $P$, and $\Delta$ would be a Lie group by 2.6.

4. Exactly one fixed element

Throughout this section, $\Delta$ fixes a line $W$ but no point.

4.0. If $\mathcal{F}_\Delta = \{W\}$ and if $\dim \Delta \geq 22$, then $\Delta$ is a Lie group.

Proof. According to [17] the assertion is true for $\dim \Delta \geq 23$. Thus we may assume that $\dim \Delta = 22$ and that $\Delta$ is not a Lie group. Steps (a,b) are the same as in [17].

(a) There exist arbitrarily small compact central subgroups $N \leq \Delta$ of dimension 0 such that $\Delta/N$ is a Lie group, cf. [19] 93.8. If $N$ acts freely on $P \setminus W$, then each stabilizer $\Delta_z$...
with \( x \notin W \) is a Lie group because \( \Delta_x \cap N = \mathbb{I} \). By \([19]\) 51.6 and 8 and 52.12, the one-point compactification \( X \) of \( P \setminus W \) is homeomorphic to the quotient space \( P/W \), and \( X \) is a Peano continuum (i.e., a continuous image of the unit interval); moreover, \( X \) is homotopy equivalent to \( S_{16} \), and \( X \) has Euler characteristic \( \chi(X) = 2 \). According to a theorem of Löwen \([7]\), these properties suffice for \( \Delta \) to be a Lie group.

(b) Suppose now that \( x^c = x \) for some \( x \notin W \) and some \( \zeta \in \mathbb{N} \setminus \mathbb{I} \). By assumption, \( x^\Delta \) is not contained in a line and hence generates a \( \Delta \)-invariant subplane \( D = \langle x^\Delta, W \rangle \leq F_\zeta < P \).

Put \( \Delta^* = \Delta|_D \) and write \( \Delta|_D = \Delta/K \). If \( D \) is flat, then \( \dim \Delta \leq 6 + 14 \) by Stiffness; similarly, \( \dim D = 4 \) implies \( \dim \Delta \leq 12 + 8 \). Hence \( D < P \), \( K \) is compact, \( \dim K < 8 \), \( \dim \Delta^* \geq 15 \), \( \Delta^* \) is a Lie group \([19]\), and we may assume that \( \mathbb{I} \neq N \leq K \). If even \( \dim \Delta^* > 16 \), then \([18]\) 1.10 shows that \( \mathcal{D} \) is the classical quaternion plane, because \( \Delta^* \) does not fix a flag.

(c) If \( \Delta \) is not transitive on \( S = W \setminus \mathcal{D} \), then there are points \( u, v, w \in S \) such that \( \Delta : \Delta^* \leq 9 \). Choose a line \( L \) of \( \mathcal{D} \) in the pencil \( \mathcal{L} \setminus \{W\} \) and a point \( x \in L \setminus \mathcal{D} \), so that \( \langle \mathcal{D}, x \rangle = P \), \( \Delta_x \cap K = \mathbb{I} \), and \( \Delta_x \) acts faithfully on \( \mathcal{D} \). In particular, \( \Delta_x \) fixes \( L \) and \( \Delta_x \) is a Lie group. Moreover, \( \dim z^{\Delta_x} < 8 \) (or else \( K \) would be a Lie group by 2.6 above. Therefore \( \Delta : \Delta_x \leq 3 + 4 + 7 = 14 \) and \( \Lambda = (\Delta_x^* u, w) \) satisfies \( \dim \Lambda \geq 2 \). The stiffness result 2.5(b) shows that \( \Lambda \cong \text{Spin}_3 \mathbb{R} \). From \([19]\) 55.32 and the structure of compact groups \([19]\) 93.11 it follows that \( K \) is commutative or an almost direct product of \( \text{Spin}_3 \mathbb{R} \) with a connected commutative group. By \([19]\) 93.19 the group \( \Lambda \) acts trivially on the commutative factor \( A \) of \( K \). As \( K/NK \) is finite and \( K \cap A = \mathbb{I} \), the group \( \Lambda \) centralizes also a non-commutative factor of \( K \), and hence \( \Lambda \leq \text{Cs} K \). In the cases \( \dim K \leq 5 \), \( \dim \Delta^*_D \geq 17 \), the plane \( \mathcal{D} \) is classical and \( \Lambda \) fixes all points of a circle in \( S \) containing \( u, v, w \). If, on the other hand, \( \dim K > 0 \), then \( z^K \subseteq \mathcal{F}_A \) has positive dimension. In any case, \( \mathcal{F}_A \) is connected. Because \( N \) acts freely on \( L \setminus \mathcal{D} \) and groups of planes of dimension \( \leq 4 \) are Lie groups (cf. \([19]\) 32.21 and 71.2), it follows that \( \mathcal{F}_A < \mathcal{P} \).

We have \( K = \mathbb{I} \), \( \dim z^K = \dim K \), \( z^K \subseteq \mathcal{F}_A \), and therefore \( \dim K \leq 4 \), in fact even \( \dim K < 4 \) because of 2.6. Now \( \dim \Delta^*_D \geq 19 \), and \( \mathcal{D} \) is the classical quaternion plane, see \([19]\) 84.28 or \([16]\) 1.10. In particular, \( S \cong \mathbb{S}_4 \). Recall that \( \dim u + \dim v^\Delta + \dim w^\Delta^* \geq 8 \). It follows that \( \Delta \) is doubly transitive on the 3-dimensional orbit \( V = v^\Delta \). Similarly, \( \Delta_x \) is doubly transitive on \( V \), and \( \dim w^\Delta^* \geq 2 \). The doubly transitive groups have been determined by Tits, see \([19]\) 96.16. The large orbit of \( w \) excludes the possibility that \( V \approx \mathbb{R}^3 \). Hence \( V \) is compact and \( \Delta_x |_V \) is simple, in fact one of the groups \( \text{PU}_2(\mathbb{H}, 1) \) or \( \text{PSU}_3(\mathbb{C}, 1) \). In the first case, \( \Lambda \) would be 4-dimensional. In the second case, we obtain \( \dim \Lambda = 2 \), contradicting stiffness.

(d) The previous step shows that \( \Delta \) is transitive on \( S = W \setminus \mathcal{D} \). Hence \( S \cong \mathbb{S}_4 \), and \( \Delta \) has a subgroup \( \mathcal{O} \cong \mathcal{U}_3 \mathbb{H} \cong \text{Spin}_3 \mathbb{R} \), see \([19]\) 53.2, 96.19–22, 55.40, and 94.27. The central involution \( \sigma \) of \( \mathcal{O} \) induces on \( \mathcal{D} \) a reflection with axis \( S \). As its center is not fixed by \( \Delta \), it follows from \([19]\) 61.13 that \( \Delta^* \) contains a transitive translation group with axis \( S \). Therefore \( \Delta : \mathcal{K} \geq 18 \) and \( \mathcal{D} \) is classical (cf. \([19]\) p. 500, Theorem or \([16]\) 1.10). By \([19]\) 55.40 the group \( \text{SO}_6 \mathbb{R} \) does not act on any compact plane. Hence the involution \( \sigma \) is even a reflection of \( \mathcal{P} \), and \( \sigma^\Delta \sigma = T \cong \mathbb{R}^8 \) is normal in \( \Delta \). The group \( \Delta|_D \) is contained in
SL₂\mathbb{H} \times \mathbb{R}^8. Either \Delta|_S is compact, or \Delta has a subgroup \mathcal{T} \cong SL₂\mathbb{H} \ (use \ [19] 94.34). In the first case, \Delta|_S = \mathcal{I}O|_S \cong SO_5\mathbb{R}. For v, w ∈ S, the stabilizer \Delta_v fixes a second point u ∈ S, and \Delta: \Delta_{u,v,w} = 4+3. Choose a line L of D in the pencil \mathcal{L}_v \setminus \{W\}, a point z ∈ L \setminus D, and put Γ = \Delta_{u,w}. Again we may assume that N ≤ K. By 2.6 we have dim zΓ < 8. The dimension formula yields \Delta: Γ ≤ 11. Let Λ = (F_z)^1. Then \dim Λ ≥ 4. Again Λ is a Lie group since N acts freely on L \setminus D. As D is the classical quaternion plane, any collineation which fixes 3 collinear points of D even fixes all points of a circle. Hence \mathcal{F}_Λ is connected. By [19] 32.21 and 71.2, we have \mathbb{Z}^N ≤ \mathcal{F}_Λ. Now Stiffness would imply \dim Λ ≤ 3 contrary to what has been stated before.

(e) If \Delta has a subgroup \mathcal{T} \cong SL₂\mathbb{H}, then the arguments in step (d) imply \Delta: K ≥ 15+8. A maximal compact subgroup of \Delta is connected and properly contains \mathcal{I}O. Consequently \dim Δ ≥ 24, and \Delta is a Lie group by [17] 4.0.

For 8-dimensional planes the following has been proved in [16] 3.1:

**4.1.** Suppose that \mathcal{F}_Δ consists of a unique line in an 8-dimensional plane and that \Delta is a semi-simple group of dimension > 3. Then \Delta is a Lie group and \dim Δ ≤ 10. In the case of equality, \Delta is isomorphic to O_15(\mathbb{R}, 1) or to some covering group of O_15(\mathbb{R}, 2).

**4.2.** Let \mathcal{F}_Δ = \{W\}. If \Delta is semi-simple and if \dim Δ ≥ 11, then \Delta is a Lie group.

**Proof.** As in steps (a,b) of the previous proof we may consider a subplane \mathcal{D} = \langle xΔ, W \rangle < \mathcal{P}. Both groups \Delta^* = \Delta^{|D} = Δ/K and Λ = K^1 are semi-simple. If \mathcal{D} is flat and \Delta^* ≠ 1, then \Delta^* \cong SL₂\mathbb{R} and either contains a central reflection or acts as hyperbolic motion group without fixed element. Hence \Delta^* = 1 and \Delta = Λ = G_2 or \dim Δ ≤ 10 by stiffness. If \dim \mathcal{D} = 4, then [17] 2.14 shows that \dim Δ ≤ 3 and Λ ≤ SU_3\mathbb{C} or \dim Λ ≤ 8 by stiffness. Thus \Delta is a Lie group by 2.9 or \dim Δ ≤ 10. In the case \mathcal{D} < \mathcal{P} the kernel K is compact and then \Lambda \cong Spin_5\mathbb{R} and \dim Δ^* ≥ 8. By the result 4.1 the group Δ^* is a Lie group and \dim Δ^* ≤ 10. From 2.9 it follows that \Delta is a Lie group.

**5. Fixed flag**

For 8-dimensional planes, the following results have been proved in [15] Theorem 1.3 and in [18] 5.1:

**5.0.** If the semi-simple group \Delta of an 8-dimensional plane fixes exactly one line and possibly some points on this line, and if \dim Δ ≥ 3, then \Delta is a Lie group.

**5.1.** Let \mathcal{F}_Δ = \{v, W\} be a flag in an 8-dimensional plane. If \dim Δ ≥ 10, then \Delta is a Lie group.

**5.2.** If \Delta fixes a flag \{v, W\} and possibly one or two further points on W, but no other line, if \Delta is semi-simple, and if \dim Δ ≥ 11, then \Delta is a Lie group.

**Proof.** The first arguments are the same as in steps (a,b) of the proof of 4.0 above. Thus there is a connected proper subplane \mathcal{D} = \langle xΔ, v, W \rangle of \mathcal{P}. Put Δ⋆ = Δ^{|D} = Δ/K, and note that both Δ⋆ and Λ = K^1 are semi-simple. If \mathcal{D} is flat, then Δ⋆ is trivial by [19] 33.8, the kernel K is isomorphic to the Lie group G_2 or \dim K ≤ 10 by stiffness 2.5(d). If \dim \mathcal{D} = 4,
then \( \dim \Delta^* \leq 3 \) (see \[17\] 2.14 or \[19\] 71.8,10 and 72.1–4), and stiffness 2.5(a,e) shows that \( \dim \Lambda < 8 \) or \( \Lambda \cong \text{SU}_3\mathbb{C} \) and 2.9 applies.

Finally, let \( \mathcal{D} < \mathcal{P} \). Then \( \dim \Delta^* \leq 3 \) or \( \Delta^* \) is a Lie group by 5.0 above. Moreover, \( \Lambda \) is compact and semi-simple, hence a Lie group, and then \( \Lambda \cong \text{Spin}_3\mathbb{R} \) by 2.5(\( \hat{b} \)) and \( \dim \Delta^* > 3 \). Therefore \( \Delta \) is a Lie group by 2.9.

\( \square \)

6. Two non-incident fixed elements

It has been stated in 2.3 above that \( \Delta \) is a Lie group whenever \( \dim \Delta \geq 27 \). In the case \( \mathcal{F}_\Delta = \{a,W\}, \ a \notin W \), no improvement of this result has been found in general; for semi-simple groups it has been proved in \[10\] (a) that \( \dim \Delta \geq 26 \) suffices.

Suppose that \( \mathcal{Z} = \text{Cs} \Delta \) is not a Lie group. If \( \mathcal{Z}|_W \neq \mathbb{I} \), then there is a point \( p \) such that \( \Lambda = (\Delta_p)^1 \) fixes a quadrangle, and stiffness implies \( \dim \Lambda \leq 11 \). On the other hand \( \Delta: \Delta_p \leq 16 \) by 2.6. Thus \( \dim \Delta \leq 26 \).

Throughout section 6, assume that \( \Delta \) fixes a line \( W \) and a point \( a \notin W \).

6.1 Proposition. If \( \Delta \) is semi-simple, and if there is some planar element \( \zeta \in \mathcal{Z} \) (so that \( \mathcal{F}_\zeta \) is a subplane of \( \mathcal{P} \)), then \( \dim \Delta \leq 19 \).

Proof. Assume that \( \dim \Delta > 19 \), and let \( x^\zeta = x \in \mathcal{F}_\zeta \). Then \( x^\Delta \neq x \) by assumption, \( x^\Delta \subseteq \mathcal{F}_\zeta \), and \( \mathcal{F}_\zeta \) is connected. Note that \( \Delta|_{\mathcal{F}_\zeta} = \Delta/K \) and \( K^1 \) are semi-simple. If \( \mathcal{F}_\zeta \) is flat or if \( \dim \mathcal{F}_\zeta = 4 \), then stiffness yields \( \dim K \leq 14 \), and \( \Delta:K \leq 3 \) (see \[17\] 2.14 or \[19\] 71.8–72.4). If \( \mathcal{F}_\zeta < \mathcal{P} \), then \( K^1 \) is compact and semi-simple, hence a Lie group, and \( K^1 \cong \text{Spin}_3\mathbb{R} \) by 2.5(\( \bar{b} \)). The classification of all planes such that \( \Delta:K > 16 \) as summarized in \[16\] 1.10 shows that \( \mathcal{F}_\zeta \) is the classical quaternion plane, and then \( \Delta/K \cong \text{SL}_2\mathbb{H} \cdot \text{Spin}_3\mathbb{R} \). It follows that a maximal compact subgroup of \( \Delta \) is locally isomorphic to \( \text{Spin}_3\mathbb{R} \cdot (\text{Spin}_3\mathbb{R})^2 \), and \( \Delta \) would be a Lie group. Thus \( \dim \Delta \leq 16+3 \).

\( \square \)

6.2 Proposition. Suppose that \( \Delta \) is semi-simple and that \( \dim \Delta \geq 25 \). If the center \( \mathcal{Z} \) of \( \Delta \) acts non-trivially on \( W \), then \( \Delta \) is a Lie group.

Proof. Because of \[10\] (a) we may assume that \( \dim \Delta = 25 \). Assume that \( \mathcal{Z} \) is not a Lie group. There are several possibilities:

(a) \( \Delta \) has an almost simple factor \( \Psi \) of dimension 16. Then \( \Psi \) is locally isomorphic to \( \text{SL}_3\mathbb{C} \) and \( \Psi \) is a Lie group. Denote the product of the other factors of \( \Delta \) by \( \Gamma \). Let \( v^2 \neq v \in W \) and \( p \in K := av\setminus\{a,v\} \). Then \( \Lambda = (\Psi_p)^1 \) has positive dimension by 2.6, and \( D = \mathcal{F}_\Lambda \) is a proper subplane. In particular, \( \dim D \in \{0,2,4,8\} \). Put \( \Xi = (\Gamma_p)^1 \) and note that \( p^\Gamma \) is contained in \( D \). It follows that \( \dim \Xi > 0 \). Hence \( \mathcal{E} = \mathcal{F}_\Xi \) is also a proper subplane. Now \( \mathcal{E}^\Psi = \mathcal{E} \) and \( \dim \Lambda \geq 8 \). Stiffness implies \( \dim D \leq 4 \). If \( D \) is connected, then \( \mathcal{Z} \) induces a Lie group on \( D \) and there is some \( \delta \in \mathcal{Z} \) such that \( D \leq \mathcal{F}_\delta = \mathcal{F} = \mathcal{F}_\Delta < \mathcal{P} \).

The factor \( \Psi \) acts almost effectively on \( \mathcal{F} \). Hence \( \mathcal{F} < \mathcal{P} \) (use \[19\] 71.8 and 72.8). Let \( \Delta|_{\mathcal{F}} = \Delta/K \). As \( K^1 \) is semi-simple, stiffness shows \( \dim K \leq 6 \) and \( \Delta:K = 19 \). By the classification of 8-dimensional planes as summarized in \[16\] 1.10 (cf. also \[19\] 84.28), the plane \( \mathcal{F} \) is the classical quaternion plane and \( \Delta|_{\mathcal{F}} \cong \text{SL}_2\mathbb{H} \cdot \mathbb{H}^* \) in contradiction to the action of \( \Psi \) on \( \mathcal{F} \).

Consequently \( \dim D = 0 \), \( \dim \Xi = 9 \), and \( \dim \mathcal{E} \leq 4 \) by stiffness, but then \( \Psi|_{\mathcal{E}} = \mathbb{I} \),
which is impossible.  

(b) $\Delta$ has an almost simple factor $\Psi$ of dimension 15, and $\Psi$ is locally isomorphic to one of the groups $SU_4\mathbb{C}$, $SL_2\mathbb{H}$, $SL_4\mathbb{R}$, or $\Psi$ maps onto a group $PSU_4(\mathbb{C}, r)$, $r = 1, 2$. Then there is a second almost simple factor $\Gamma$ of dimension 10. This situation can be treated in a similar way as case (a), but a few more arguments are needed.  

(i) $\Delta$ is not transitive on $W$. In fact, transitivity implies $W \approx \mathbb{S}_8$ by 2.6, a maximal compact subgroup $\Phi$ of $\Delta|_W$ is also transitive ([19] 96,19), and $\Phi \cong SO_9\mathbb{R}$ would be too big (cf. [19] 96.23).  

(ii) There are points $v \in W$ and $p \in K := av \setminus \{a, v\}$ such that $\dim v^\Delta < 8$ and $\Psi_p \neq 1$. The first claim follows from (i), and $\dim \Psi_v \geq 8$. If $\Psi_v$ acts freely on $K$, then $\Psi_v$ is transitive on $K$ by [19] 96.11, lines are homeomorphic to $\mathbb{S}_8$ by 2.6, and $\Psi_v \approx K \simeq \mathbb{S}_7$ (see [19] 52.5). A maximal compact subgroup $\Phi$ of $\Psi_v$ is at most 7-dimensional and has the homotopy of $\mathbb{S}_7$, but $\pi_\nu S_7 = 0$ for $\nu < 7$ and $\pi_\nu \Phi \neq 0$ for $\nu = 1$ or $3$, see [19].  

(iii) One of $D = \mathcal{F}_\Psi$ or $\mathcal{E} = \mathcal{F}_{\Psi}$ is a connected proper subplane. Note that $p^\Gamma \subseteq D$. If $v^\Gamma = v$, then $D$ contains a quadrange and a connected orbit of $\Gamma$; thus $D < \mathcal{P}$. If $v^\Gamma = v$, however, then $v^\Psi \neq v$, and $\Gamma$ fixes each point of the connected orbit $v^\Psi \subseteq W$; moreover, $\dim \Gamma_p > 1$, and $\mathcal{E} < \mathcal{P}$.  

(iv) If $v^\Gamma = v$, then $\dim \Gamma|_D = 10$, $\mathcal{D} \triangleleft \mathcal{P}$, and $\dim \Gamma_p \geq 2$. We have $\mathcal{E}^\Psi = \mathcal{E}$. Either $\mathcal{E} < \mathcal{P}$ or $v^\Psi = v$. In the latter case, $\Psi_p|_D = 1$, $\dim \Psi_p = 7$ by stiffness, and $\Psi$ is transitive on $K$. Hence $\Gamma_p \leq \Delta_{\{av\}}$, and $\Gamma_p \triangleleft \Gamma$ would be a proper normal subgroup. Consequently $\dim \Psi|_\mathcal{E} = 15$, and $\mathcal{E} \triangleleft \mathcal{P}$.  

(v) If $v^\Gamma = v$, then $v^\Psi = v$, $\mathcal{E} < \mathcal{P}$, $\dim \Psi|_\mathcal{E} = 15$, and $\mathcal{E} \triangleleft \mathcal{P}$. From [15] 3.3 and $\dim \Psi > 10$ it follows that $\mathcal{E}$ is the classical quaternion plane. In particular, $\Psi \cong SL_2\mathbb{H}$. Moreover $\mathbb{Z}|_\mathcal{E}$ is a Lie group and there is some $\zeta \in \mathbb{Z}$ such that $\mathcal{E} = \mathcal{F}_\zeta$ is $\Delta$-invariant and $\dim \Delta|_\mathcal{E} = 25$. This is impossible.  

(vi) Corollary. Both $\mathcal{D}$ and $\mathcal{E}$ are Baer subplanes.  

Again $\mathcal{E}$ is classical by 2.11. As in the previous step, $\mathcal{E}^\Delta = \mathcal{E}$ and $\dim \Delta|_\mathcal{E} = 25$, a final contradiction.  

(c) $\Delta$ has an almost simple factor $\Psi$ of dimension 14. In this case, $\Psi$ is a Lie group, there are two other factors $\mathcal{B}$ and $\mathcal{A}$ of dimension 8 and 3, respectively, and $\mathcal{B}$ is a a Lie group or maps onto $PSU_3(\mathbb{C}, 1)$.  

(i) If $\Psi \cong G_2$ is compact or, more generally, whenever $\Psi$ has a subgroup $\Phi \cong SO_9\mathbb{R}$, then any two conjugate commuting involutions $\iota$, $\kappa \in \Phi$ are planar (use [19] 55.35), and $\mathcal{F}_\iota$ is a Baer subplane. (For involutions in $G_2$ see [19] 31-35 or [17] 2.5.) Choose a point $x$ in $\mathcal{F}_\iota$, $a \neq x \notin W$, and put $v = ax \cap W$ and $\Gamma = BA$. Either $\mathcal{F}_{\iota, \kappa}$ is a 4-dimensional subplane or $\kappa$ induces on $\mathcal{F}_\iota$ a reflection with center $v$, say. In the first case, $\mathbb{Z}|_{\mathcal{F}_{\iota, \kappa}}$ is a Lie group by [19] 71.2, and there is some $\zeta \in \mathbb{Z}$ such that $\mathcal{F}_\zeta$ is a connected proper subplane, but then $\Delta|_{\mathcal{F}_\zeta}$ is too big. In the second case, $v^\Gamma = v$, $V = v^\Psi \neq v$, and $\Gamma|_V = 1$. It follows that $\dim \Gamma_x \geq 3$ and that $\mathcal{E} = \mathcal{F}_{\xi} = \mathcal{E}^\Psi$ is a connected proper subplane. The simple group $\Psi$ acts effectively on $\mathcal{E}$. Consequently $\iota|_{\mathcal{E}}$ is planar and $\dim(\mathcal{E} \cap \mathcal{F}_\iota) = 4$. Again this is impossible, cf. also [19] 84.8.
(ii) Similar arguments apply if \( B \) has a subgroup \( \Phi \cong \text{SO}_3 \mathbb{R} \), in particular, if \( B \) is compact. Again involutions \( \iota, \kappa \in \Phi \) are planar and \( \mathcal{F}_{\iota, \kappa} \) is a triangle. The factor \( \Psi \) fixes all points of some \( B \)-orbit \( V = v^B \subseteq W \), and \( \dim \Psi_x \geq 6 \). The center \( Z \) acts effectively on \( D = \mathcal{F}_{\Psi_x} \), and \( D \triangleleft \mathcal{P} \). Now stiffness 2.5(b) shows \( \dim \Psi_x \leq 3 \) because \( \Psi \) is Lie group, a contradiction. Therefore \( B \) has no subgroup \( \text{SO}_3 \mathbb{R} \).

(iii) Therefore \( \Psi \) is isomorphic to the twofold covering \( \tilde{G} \) of \( G_2(2) \); a maximal compact subgroup \( \Phi \) of \( \Psi \) is isomorphic to \( \text{Spin}_3 \mathbb{R} \). The center of \( \Psi \) is generated by a reflection \( \omega \) with axis \( W \). There are two other central involutions \( \iota, \kappa \in \Phi \), these may be planar or they are reflections with centers \( u, v \in W \). In the first case the argumentation is the same as in step (i). If \( \iota \in \Delta_{[u, av]} \), then \( \iota^\mathcal{F} = v \neq \iota^\Psi = V = \Gamma | V = 1 \). For the same reasons as in step (b)(ii) the group \( B \) does not act freely on \( K = av \backslash \{ a, v \} \) for a suitable \( x \in K \). It follows that \( \mathcal{E} = \mathcal{F}_B = \mathcal{E}^\Psi \) is a proper connected sub plane. Because \( \omega \) is a reflection of \( \mathcal{P} \), the group \( \Psi \) acts effectively on \( \mathcal{E} \). The arguments can now be repeated for \( \Psi|_\mathcal{E} \). Hence \( \iota \) and \( \kappa \) induce reflections on \( \mathcal{E} \), and \( \Gamma \) fixes all points of \( V \subseteq W \). Moreover, \([19] \) 96.13, applied to \( \Phi|_V \), shows that \( \dim V \geq 3 \), so that \( \mathcal{E} \triangleleft \mathcal{P} \). If \( \dim(\Psi \mathcal{A})|_\mathcal{E} = 17 \), the classification as summarized in \([19] \) 84.28 or \([16] \) 1.10 would imply that \( \mathcal{E} \) is a translation plane. Therefore \( \mathcal{A}|_\mathcal{E} = 1 \) and \( \mathcal{E} = \mathcal{F}_\mathcal{A} \) is \( \Psi \mathcal{B} \)-invariant. By stiffness \( \dim(\Psi \mathcal{B})|_\mathcal{E} = 22 \) is too big. Thus case (c) is impossible.

(d) An almost simple factor \( \Psi \triangleleft \Delta \) of maximal dimension satisfies \( \dim \Psi = 10 \); all other factors have dimension 3 or 6. Write \( \Delta \) as an almost direct product \( BA \) with \( \dim A = 3 \), and choose \( v \in W \) such that \( v^Z \neq v \). Let \( a, v \neq x \in av \). Then \( \dim B_Z > 6 \) (by 2.6), and \( \mathcal{E} = \mathcal{F}_{B_Z} = \mathcal{E}^A \) is a proper subplane. If \( \dim \mathcal{E} \) is 2 or 4, then \( Z|_\mathcal{E} \) is a Lie group, and there is some \( \zeta \in Z \) such that \( \mathcal{E} \leq \mathcal{F} = \mathcal{F}_\zeta = \mathcal{F}^\Delta \triangleleft \mathcal{P} \). By stiffness \( \dim \Delta|_{\mathcal{F}} = 19 \), \( \mathcal{F} \) is the classical quaternion plane (cf. \([19] \) 84.28 or \([16] \) 1.10), and then \( \Delta|_\mathcal{F} \cong \text{SL}_2 \mathbb{H} \cdot \mathbb{H}^\times \) is not semi-simple. Therefore \( \dim \mathcal{E} \in \{0, 8\} \). If \( \mathcal{E} \) is not connected, then \( \mathcal{A}|_\mathcal{E} = 1 \) and \( D = \mathcal{F}_\mathcal{A} = D^B = D^\Delta \). By stiffness, the semi-simple kernel of \( \Delta|_D \) has dimension at most 6 and contains \( A \). Hence \( \dim \Delta|_D \geq 19 \), but again this is impossible. Thus \( \mathcal{E} = \mathcal{E}^\mathcal{Z} \triangleleft \mathcal{P} \), and \( Z \) acts effectively on \( \mathcal{E} \) (or else \( \mathcal{E} = \mathcal{F}_\zeta \) for some \( \zeta \in Z \), \( \mathcal{E}^\Delta = \mathcal{E} \), \( \dim \Delta|_\mathcal{E} = 19 \), a contradiction.) Now \( B_x \cap Z = 1 \), \( B_x \) is a Lie group, and \( \dim B_x \leq 3 \) by stiffness, in contrast to what has been stated above.

(e) \( \Delta \) has exactly two factors of dimension 8; all other factors have dimension 3 or 6. This is the last possibility, it can be treated exactly in the same way as (d).

**Remark.** The cases (a) and (c) can also be exclude as in step (d).

**6.3 Proposition.** Suppose that \( \Delta \) is semi-simple and that \( \dim \Delta \geq 25 \). If the center \( Z \) of \( \Delta \) acts trivially on \( W \), then \( \Delta \) is a Lie group.

**Proof.** Again we may assume that \( \dim \Delta = 25 \). Suppose that \( Z \) is not a Lie group. There are the same possibilities as in 6.2.

(a) \( \Delta \) has an almost simple factor \( \Psi \) of dimension 16. Then \( \Psi \) is locally isomorphic to \( \text{SL}_3 \mathbb{C} \) and \( \Psi \) is a Lie group. Denote the product of the other factors of \( \Delta \) by \( \Gamma \). The factor \( \Psi \) has a subgroup \( \Phi \cong \text{SO}_3 \mathbb{R} \). As before, the involutions in \( \Phi \) are necessarily planar. Let \( \iota, \kappa \) be two commuting involutions in \( \Phi \). If \( \kappa \) induces a planar involution on \( \mathcal{F}_\iota \), then \( Z \) acts freely on the 4-dimensional plane \( \mathcal{F}_{\iota, \kappa} \), and \( Z \) would be a Lie group. Therefore
factors have dimension 3. Choose \( x \in \mathcal{F}_i \) not incident with the three fixed lines. Then \( \dim x^r < 8 \) because of 2.6, and \( \dim \Gamma_x \geq 2 \). The group \( \Gamma_x \) fixes a quadrangle and \( \mathcal{E} = \mathcal{F}_{\Gamma_x} = \mathcal{E}^\Psi \) is a proper subplane. We have \( \dim \psi|_{\mathcal{E}} = 16 \) and \( \mathcal{E} \triangleleft \mathcal{P} \).

Hence \( \mathcal{E} \) is the classical quaternion plane by 2.11. But then \( \text{SL}_3 \mathbb{C} \) does not act on \( \mathcal{E} \) and the group \( Z \) would be a Lie group.

**Remark.** The proof of (a) shows that a factor \( \Psi \) of dimension > 10 does not have a subgroup \( \text{SO}_3 \mathbb{C} \).

(b) \( \Delta \) is an almost direct product \( \Psi \Delta \) of two factors of dimension 15 and 10, respectively. As in 6.2(b)(i,ii), \( \Delta \) is not transitive on \( W \), and there is a point \( x \) on a line \( av \) such that \( \psi_x \neq 1 \).

If \( V = v^r \neq v \), then \( \mathcal{D} = \mathcal{F}_{\Psi} = \mathcal{D}^\Gamma \) is a connected proper subplane, \( Z \) acts freely on \( \mathcal{D} \), and \( \mathcal{D} \triangleleft \mathcal{P} \). Because of 2.6 it follows that \( \dim x^r < 8 \) and \( \dim \Gamma_x \geq 3 \). As \( \Gamma \) acts almost effectively on \( V \) and \( \Gamma \) has a compact subgroup of dimension at least 4, Mann’s theorem 96.13 shows that \( \dim V \geq 3 \). Suppose that \( v^\Psi = v \). Then \( \psi|_V = 1 \), \( \dim x^\Psi < 8 \) by 2.6, and \( \dim \psi_x \geq 8 \), but \( \mathcal{F}_{\Psi} \triangleleft \mathcal{P} \), and \( \dim \psi_x \leq 7 \) by stiffness. Therefore \( v^\Psi \neq v \) and \( \mathcal{E} = \mathcal{F}_{\Gamma_x} = \mathcal{E}^\Psi \triangleleft \mathcal{P} \). In fact, \( \mathcal{E} \) is classical by 2.11. As a group of homologies \( Z \) acts freely on \( \mathcal{E} \), and \( \mathcal{Z} \) would be a Lie group. Consequently \( v^\Gamma = v \) whenever \( \dim v^\Delta < 8 \). Moreover \( \dim \Gamma_x > 1 \) and \( \mathcal{E} = \mathcal{E}^\Psi \triangleleft \mathcal{P} \). Again \( \mathcal{E} \) is classical by 2.11, but then \( Z \) would be a Lie group, a contradiction.

(c) \( \Delta \) has an almost simple factor \( \Psi \) of dimension 14. In this case, \( \Psi \) is a Lie group, there are two other factors \( B \) and \( A \) of dimension 8 and 3, respectively, and \( B \) is a Lie group or maps onto \( \text{PSU}_3(\mathbb{C}, 1) \). This case is similar to the previous one. Put \( \mathcal{T} = \Psi A \).

Again \( \Delta \) is not transitive on \( W \), and \( \dim \Delta < 8 \) for some \( v \in W \). Let \( a, v \neq x \in av \).

Then \( \dim \mathcal{T}_x > 1 \). If \( v^B \neq v \), then \( \mathcal{D} = \mathcal{F}_{\mathcal{T}_x} = \mathcal{D}^\mathcal{B} \triangleleft \mathcal{P} \), and \( \dim \mathcal{B}_x > 0 \) because of 2.6. It follows that \( v^T \neq v \) (or else \( \dim \mathcal{T}_x > 8 \) and \( \mathcal{T}_x|_{\mathcal{D}} = 1 \), which contradicts stiffness). Hence \( \mathcal{E} = \mathcal{F}_{\mathcal{B}_x} = \mathcal{E}^T \triangleleft \mathcal{P} \). The kernel of \( \mathcal{T} \big|_{\mathcal{E}} \) has dimension at least 3, and \( \dim \psi|_{\mathcal{E}} = 14 \). Now \( \mathcal{E} \) is classical by 2.11, and \( Z \) would be a Lie group. If \( v^B = v \), however, then \( \mathcal{B}_x|_{\psi^\Delta} = 1 \), and \( \dim x^\mathcal{B}_x < 8 \) (use 2.6). Again \( \dim \mathcal{B}_x > 0 \), and \( \mathcal{E} \) is the classical quaternion plane by 2.11.

As before, \( Z \) is a Lie group in contrast to the assumption.

(d) An almost simple factor \( \Psi \triangleleft \Delta \) of maximal dimension satisfies \( \dim \Psi = 10 \); all other factors have dimension 3 or 6. Write \( \Delta \) as an almost direct product \( \mathcal{T} \mathcal{G} \) with \( \dim \mathcal{T} = 16 \). The arguments in 6.2(b)(i,ii) show that \( \Delta \) is not transitive on \( W \). Choose \( v \) and \( x \) as in step (c). By 2.6 we conclude that \( \dim \mathcal{T}_x > 1 \). If \( v^r \neq v \), then \( \mathcal{D} = \mathcal{F}_{\mathcal{T}_x} = \mathcal{D}^\mathcal{F} \triangleleft \mathcal{P} \) and \( \mathcal{T}_x|_{\mathcal{D}} = 1 \). Stiffness implies \( \dim \mathcal{T}_x \leq 7 \) and \( \dim x^T \geq 9 \). As \( x^r \) is contained in \( \mathcal{D} \), we have \( \dim \Gamma_x > 0 \). Therefore \( \mathcal{E} = \mathcal{F}_{\Gamma_x} = \mathcal{E}^T \triangleleft \mathcal{P} \) and \( \dim x^T \leq 8 \). This contradiction shows that \( v^r = v \) and \( \Gamma_x|_{\psi^\Delta} = 1 \). Consequently again \( \mathcal{E} = \mathcal{F}_{\Gamma_x} = \mathcal{E}^r \triangleleft \mathcal{P} \). Let \( \mathcal{T}_x|_{\mathcal{E}} = \mathcal{T} / \mathcal{K} \). Then \( \mathcal{K} = \mathcal{K}^1 \) is compact and semi-simple, hence a Lie group, and stiffness 2.5(b) shows \( \dim \lambda \leq 3 \). As \( Z \) acts effectively on \( \mathcal{E} \), the plane \( \mathcal{E} \) is not classical. We have \( \dim \mathcal{T}_x \geq 13 \), and 2.11 implies that \( \mathcal{T} / \mathcal{K} \cong U_2(\mathbb{H}, \rho) \cdot \text{SU}_2 \mathbb{C} \). The complement of \( \Psi \) in \( \mathcal{T} \) can be chosen arbitrarily among the factors of dimension 3 or 6. Hence all these factors are compact and 3-dimensional. Therefore \( \Delta \) is a Lie group.
(e) $\Delta$ has exactly two factors of dimension 8; all other factors have dimension 3 or 6. The first part of the proof is identical to the previous one, and there is a Baer subplane $E = F_T = E^T_\delta$. As $T$ has two 8-dimensional factors, $\dim T|_E = 16$, and 2.11 implies that $E$ is the classical quaternion plane, but then $Z$ is a Lie group contrary to the assumption. □

Combined, Propositions 6.2 and 6.3 yield

**6.4 Theorem.** If $F_\Delta = \{a, W\}$, $a \notin W$, if $\Delta$ is semi-simple, and if $\dim \Delta \geq 25$, then $\Delta$ is a Lie group.

**7. Fixed double flag**

**7.1.** Let $F_\Delta$ be a double flag $\{u, v, uv, ov\}$. If $\Delta$ is semi-simple and if $\dim \Delta \geq 25$, then $\Delta$ is a Lie group.

**Proof.** For $\dim \Delta \geq 26$, this has been proved in [17] 8.0. It suffices, therefore, to consider the case $\dim \Delta = 25$. The arguments are similar to those in [17]. Let $\Psi$ be an almost simple factor of $\Delta$ of maximal dimension. Then $\dim \Psi \in \{16, 15, 14, 10, 8\}$. The product of the other factors of $\Delta$ will be denoted by $\Gamma$, the center of $\Delta$ by $Z$.

(a) If $p \notin uv \cup ov$, then $Z_p = 1$: suppose that $p^\circ = p$ for some $\zeta \in Z \setminus \{1\}$. Then $\zeta|_\rho \Delta = 1$ and $D = \langle p^\Delta \rangle < P$. With $\Delta|_D = \Delta/K$ we get $\Delta: K \leq \dim K \leq 7$, a contradiction.

(b) Each reflection $\sigma \in \Psi$ is in $\Psi_{[uv, ov]}$, and each non-central involution $\beta \in \Psi$ is planar. In fact, $\sigma \in \Psi_{[uv]}$ would imply that $\sigma^\Delta \sigma \cong \mathbb{R}^k$ is normal in $\Psi$. If $\beta$ is a reflection, then $\langle \beta^\Delta \rangle = \Psi$ is a compact group of homologies by [19] 61.2, and $\dim \Psi = 3$.

(c) Let $\beta$ be a planar involution in $\Psi$, and let $T$ be a semi-simple subgroup of the centralizer $C_\Delta \beta$. Then $\dim T \leq 13$: Write $T|_{F_\beta} = T/K$ and $\Lambda = K^1$. The kernel $\Lambda$ is compact and semi-simple, hence a Lie group, and then $\Lambda$ is contained in $\text{Spin}_3\mathbb{R}$ by stiffness. In [19] 6.1 it has been shown that $T: K \leq 10$.

(d) If $\dim \Psi = 16$, then $\Psi \cong (P)\text{SL}_3\mathbb{C}$. The centralizer of the involution $\beta = \text{diag}(1, -1, -1)$ contains a group $\text{SL}_2\mathbb{C} \times \Gamma$ of dimension 6+9 and is too large.

(e) Each group $\Psi$ of type $A_3$ contains a planar involution $\beta$ centralizing a 6-dimensional semi-simple subgroup of $\Psi$. This is easy in the cases $\text{SU}_4\mathbb{C}$, $\text{SL}_2\mathbb{H}$, $\text{SL}_4\mathbb{R}$ and its universal covering group; it is less obvious for the groups related to $\text{SU}_4(\mathbb{C}, r)$, $r = 1, 2$, which are not necessarily Lie groups. In both cases, a suitable involution $\beta$ is determined by $\text{diag}(-1, -1, 1, 1)$; then $C_\Psi \beta$ contains a group locally isomorphic to $\text{SU}_2\mathbb{C} \times \text{SL}_2\mathbb{R}$ or to $\text{SU}_2(\mathbb{C})^2$, respectively, and $C_\Psi \beta$ is too large.

(f) Each involution of the compact group $G_2$ is centralized by $\text{SO}_4\mathbb{R}$, see [19] 11.31. The non-compact groups of type $G_2$ contain either $\text{SO}_4\mathbb{R}$ or $\text{Spin}_4\mathbb{R}$. In any case, the centralizer of a non-central involution is too large.

(g) If $\Psi$ is locally isomorphic to a group $U_2(\mathbb{H}, r)$ of dimension 10, then $\beta = \text{diag}(1, -1)$ describes a planar involution centralized by a semi-simple group of dimension 6+15, which is too large.

(h) If $\dim \Psi = 10$, then $\Psi$ maps onto $\text{Sp}_4\mathbb{R}$ or $O'_4(\mathbb{R}, 2)$. In the latter case, the diagonal element $\text{diag}(-1, 1)$ corresponds to a planar involution $\beta$ such that $C_\Psi \beta \cong O'_4(\mathbb{R}, 1) \cong \text{SO}_3\mathbb{C}$, again a contradiction.
(i) Finally, let $\Psi/(Z \cap \Psi) \cong \text{Sp}_4 \mathbb{R}$. Conceivably, $\Psi$ is not a Lie group. Again $\Psi$ cannot contain a planar involution. Hence the unique involution in $\Psi$ is a reflection $\sigma \in \Psi_{[u,v]} := H$. As $\dim H \leq 8$, there is a point $p$ such that $G = \langle p^\Psi \rangle$ is a connected subplane, and $G \leq P$, or else $\dim \Psi \mid G \leq 6$. We have $\Gamma_p \mid G = 1$, and $\Gamma_p$ is a compact Lie group by step (a). Stiffness 2.5(b) shows $\dim \Gamma_p \leq 3$ and $\dim p^\Gamma \geq 12$. Consequently $\langle p^\Gamma \rangle = P$ and $\Psi_p = 1$. It follows that $G = P$ and $\Gamma_p = 1$. Split $\Gamma$ into an almost direct product $AB$ with $\dim A = 6$. Then $\dim p^B > 8$, $\langle p^B \rangle = P$, and $\langle \Psi A \rangle_p = 1$. Hence $p^\Psi A$ is open in $P$ by [19] 53.1, and $p^\Delta$ is also open. This implies that $\Delta$ is a Lie group, see 2.6.

(j) The cases $\dim \Psi = 8$ can be treated similarly. Again there is a point $p$ such that $G = \langle p^\Psi \rangle \leq P$, $\Gamma_p \mid G = 1$, $\dim p^\Gamma \geq 14$, $\langle p^\Gamma \rangle = P$, and $\Psi_p = 1$. Let $B$ be the other 8-dimensional factor of $\Delta$ and denote the product of the remaining factors by $\Upsilon$. Then $\langle p^B \Upsilon \rangle = P$, or else an action of $B^\Psi \Upsilon$ on $G$ would have a kernel of dimension 0. Now $\Upsilon_p = 1$, $\langle p^\Upsilon \rangle = P$, $\langle B^\Psi \Upsilon \rangle_p = 1$, $p^\Delta$ is open in $P$, and $\Delta$ is a Lie group by 2.6.

$\square$

8. Fixed triangle

8.1. If $F_\Delta = \langle o, u, v \rangle$ is a triangle, if $\Delta$ is semi-simple, and if $\dim \Delta \geq 21$, then $\Delta$ is a Lie group.

Proof. For groups of dimension $\geq 22$, the claim is true by [17] 9.2 Corollary. Hence we may suppose that $\dim \Delta = 21$. Then $\Delta$ is almost simple or one of the following holds: (i) $\Delta$ has a 15-dimensional factor, (ii) $\Delta$ is a product of 3 factors of dimensions 10, 8, 3, (iii) each factor of $\Delta$ has dimension 3 or 6. Let again $Z = \text{Cs} \Delta$ be the center of $\Delta$ and suppose that $Z$ is not a Lie group. Note that $Z$ acts freely on the complement $D$ of $ou \cup ov \cup uv$; in fact, $p^\zeta = p$, $1 \neq \zeta \in Z$ implies $D = \langle p^\Delta, o, u, v \rangle < P$. Put $\Delta|_D = \Delta/K$. Then $\Delta : K \leq 11$ (see [19] 83.26), $\dim K \geq 10$, $D$ is flat by stiffness, $\Delta|_D$ is trivial, and $K$ is too large.

(a) If $\Delta$ is almost simple, then $\Delta$ is a Lie group, or $\Delta = \Delta/Z$ is isomorphic to $O_7^+(\mathbb{R}, 2)$ or to $\text{PSp}_6 \mathbb{R}$.

(b) In the first case, $\Delta$ has a subgroup $\text{SO}_3 \mathbb{R}$; it can be lifted to a group $\Theta \cong U_2 \mathbb{H} \leq \Delta$, see [19] 94.27 or 2.9, and note that by 2.4 there is no subgroup $\text{SO}_3 \mathbb{R}$ in $\Delta$. The central involution $\iota$ of $\Theta$ is not planar (or else $\Theta|_{F_\iota} \cong \text{SO}_3 \mathbb{R}$ contrary to 2.4). Therefore $\iota$ is a reflection; it is in the kernel of the action of $\Delta$ on one side of the fixed triangle and hence $\iota \in Z$; but then $\iota = \tau$ would be trivial.

(c) In the second case, the subgroup $\text{SU}_3 \mathbb{C}$ of $\Delta$ can be lifted to an isomorphic copy $\Omega < \Delta$, and $\Omega$ is contained in a maximal compact subgroup $\Xi < \Delta$; moreover $\dim \Xi = 7$ and $\Xi = \Theta \Omega$ is connected, $\Theta$ is commutative and $\Theta \leq \text{Cs} \Omega$ ([19] 93.10,11). Let $x$ be an arbitrary point in $D$ (the complement of the fixed lines). Then $Z$ acts freely on the subplane $D = F_{\Delta_x}$, and $\Delta_x$ is a Lie group because $\Delta_x \cap Z = 1$. If $\Delta$ has an 8-dimensional orbit on two sides of the fixed triangle, then $\Delta$ induces a Lie group on these orbits (see 2.6), and $\Delta$ itself would be a Lie group. Consequently $\dim \xi^{\Delta} \leq 14$ and $\dim \Delta_x \geq 7$. As $Z$ is not a Lie group, 2.12 implies $\dim D \in \{0, 8\}$. In the second case, Stiffness 2.5(b) shows that $\Delta_x = \text{Spin}_3 \mathbb{R}$. Hence $\dim D = 0$ for each $x \in D$. There are 3 pairwise commuting conjugate involutions in $\Omega$; these are planar because axes of reflections are fixed by $\Delta$. 

14
An involution \( \iota \in \Omega \) is centralized in \( \Omega \) by a group \( \Phi \cong SU_2 \mathbb{C} \). In the case \( \Phi|_{\mathcal{F}_i} \neq 1 \) there would exist planar involutions on \( \mathcal{F}_i \), and \( Z \) would be a Lie group. Hence \( \mathcal{F}_i = \mathcal{F}_\Phi \). All involutions \( \kappa \in \Omega \) such that \( \iota \kappa = \kappa \iota \) generate a subgroup \( \Psi \cong SU_3 \mathbb{C} \). As there are no 4-dimensional subplanes, \( \kappa \) and its conjugates induce reflections on \( \mathcal{F}_i \). Therefore \( \Psi|_{\mathcal{F}_i} \) is a group of homologies, say with center \( \iota \).

On the other hand, there is a product \( \mathcal{G} \), corresponding to \( Sp_3 \mathbb{R} \times Sp_4 \mathbb{R} \) in a double covering of \( \mathcal{A} \) (use \[19\] 94.27). Note that \( Sp_3 \mathbb{R} = SL_2 \mathbb{R} \) and that \( Sp_4 \mathbb{R} \) has a subgroup \( SU_3 \mathbb{C} \). Suppose that the latter group is mapped onto a group \( SO_3 \mathbb{R} \) in \( \mathcal{G} \). The arguments above show that \( \mathcal{G} \) contains a circle group of homologies, but this is impossible, since \( \mathcal{G} \) is almost simple. Therefore \( \mathcal{G} \) contains a central involution. Up to conjugacy, \( \iota \in \mathcal{C} \mathcal{G} \), and \( \dim(\Theta \mathcal{G})|_{\mathcal{F}_i} \geq 10 \). According to \[18\] 8.0, it follows that \( (C_\mathcal{G} \iota)^1|_{\mathcal{F}_i} \) is a Lie group. Recall that \( Z \) acts freely on \( D \). Hence \( Z \) is a Lie group, and so is \( \Delta \).

(i) A 15-dimensional factor \( \mathcal{G} \) is a Lie group or \( \mathcal{G}/Z \) is locally isomorphic to \( SU_4(\mathbb{C}, r) \), \( r = 1, 2 \). The group \( \Delta \) is an almost direct product \( \mathcal{G} \Gamma \). By stiffness, \( p^p \neq p \) for each \( p \in D \), and then \( \langle p^p, o, u, v \rangle = \mathcal{P} \). Consequently, \( \Gamma \) acts freely on \( D \) and \( \langle p^p, o, u, v \rangle \leq \mathcal{P} \) by 2.12.

(d) Suppose in case (i) that \( r = 1 \). Then \( \mathcal{G}/Z \) has a subgroup \( SU_3 \mathbb{C} \). As in step (c) there is a group \( \Omega \cong SU_3 \mathbb{C} \) in \( \mathcal{G} \), and all involutions in \( \Omega \) are planar. Choose some involution \( \iota \in \Omega \). Using the arguments and notation of step (c), we obtain the following: \( SU_2 \mathbb{C} = \Phi \leq C_\mathcal{G} \iota \), \( \mathcal{F}_i = \mathcal{F}_\Phi \), \( SU_2 \mathbb{C} \cong \Psi \leq C_\mathcal{G} \iota \), and \( \Psi|_{\mathcal{F}_i} \) is a group of homologies. The center \( Z \) acts freely on \( D \cap \mathcal{F}_i \). Hence the kernel of \( \Gamma|_{\mathcal{F}_i} \) is a compact Lie group; by stiffness \( \dim \Gamma|_{\mathcal{F}_i} = 6 \), and \( \Theta \Psi \Gamma \) induces a 10-dimensional group on \( \mathcal{F}_i \). According to \[18\] 8.0 the induced group is a Lie group. Therefore \( Z \) and \( \Delta \) are Lie groups.

(e) If \( r = 2 \), then \( \mathcal{G}/Z \cong O_6(\mathbb{R}, 2) \) has a subgroup \( SO_4 \mathbb{R} \). By 2.9 there is a subgroup \( X < \mathcal{G} \) which is isomorphic to \( SO_4 \mathbb{R} \) or to \( Spin_3 \mathbb{R} \). If \( X \) contains a reflection, say \( \iota \in D_{[0,uv]} \), then \( \iota \in Z \) (or else \( \langle \iota^T \rangle = \mathcal{G} \leq D_{[0,uv]} \), which is impossible). Recall that \( \Gamma \) acts freely on \( D \). Suppose first that \( X \cong SO_3 \mathbb{R} \). Then all involutions in \( X \) are planar. Let \( \beta \) denote the central involution in \( X \). There is a subgroup \( \Phi \cong SO_3 \mathbb{R} \) in \( X \). The kernel of \( X|_{\mathcal{F}_\beta} \) is a compact Lie group; by stiffness it is contained in \( Spin_3 \mathbb{R} \). Therefore \( \Phi \) acts faithfully on \( \mathcal{F}_\beta \), and \( C = C_{\alpha, \beta} < \mathcal{F}_\beta \) for each involution \( \alpha \in \Phi \), but \( C^\mathcal{G} = C \), and orbits of \( \Gamma \) on \( D \cap C \) are 6-dimensional, a contradiction. Consequently \( X \cong Spin_4 \mathbb{R} \). Only one of the 3 involutions in \( X \) can be contained in the center \( Z \). Let \( \beta \) be a planar involution in \( X \) such that \( 0 \neq \beta \). \( X/(\beta) \cong SO_3 \mathbb{R} \times Spin_3 \mathbb{R} \). If \( \iota \) is any involution in the facor \( \Phi \cong SO_3 \mathbb{R} \), then \( \iota|_{\mathcal{F}_\beta} = 1 \) and, as \( \Phi \) is simple, even \( \Phi|_{\mathcal{F}_\beta} = 1 \), but this contradicts stiffness 2.5(b).

(ii) \( \Delta \) has 3 almost simple factors \( \mathcal{G}, \Psi, \Gamma \) of dimensions 10, 8, 3, respectively. Recall that a semi-simple group of a 8-dimensional plane with a triangle of fixed elements has dimension at most 9 (\[15\] 6.1 = (†)). By stiffness it follows that \( \langle p^\mathcal{A}, o, u, v \rangle = \mathcal{P} \). If \( p^p = p \), then \( \langle p^\Psi \Gamma \rangle = \mathcal{P} \), \( \Gamma_p = 1 \), and \( p^p \neq p \). By (†) we have \( \langle p^\mathcal{G} \rangle = \mathcal{P} \). If \( \mathcal{D} = \langle p^\Psi \Gamma \rangle \subset \mathcal{P} \), then (†) implies \( \Gamma|_{\mathcal{D}} = 1 \), and \( \Gamma \) is a compact Lie group. Stiffness shows \( \Gamma \cong Spin_3 \mathbb{R} \). The involution \( \iota \in \Gamma \) is planar, and \( \mathcal{F}_\iota^\mathcal{A} = \mathcal{F}_i \), a contradiction. Therefore \( \langle p^\Psi \Gamma \rangle = \mathcal{P} \), and hence \( \Gamma_p = \Psi_p = 1 \). The different possibilities will be treated separately.

(f) If \( \mathcal{G} \) is the compact group \( U_2 \mathbb{H} \), then each non-central involution \( \iota \) in \( \mathcal{G} \) is planar,
since \((f^*)^T = \mathcal{T}\) is not axial. But then \(n \in \mathcal{T}_p\) for each fixed point \(p\) of \(n\). This contradicts the statements at the end of (ii). Analogous arguments show that \(\Psi\) is not compact.

(g) If \(\mathcal{T}\) is locally isomorphic to \(U_2(\mathbb{H}, 1)\), then \(\mathcal{T}\) is simply connected, because \(O'_4(\mathbb{R}, 1)\) has a subgroup \(\Phi \cong SO_3\mathbb{R}\) and \(\mathcal{F}_\Phi\) is flat. Therefore \(\mathcal{T}\) has a maximal compact subgroup \(X \cong Spin_3\mathbb{R}\). Again a non-central involution \(\beta\) is planar, which contradicts (ii).

(h) Only the possibility \(\mathcal{T}/Z \cong (\mathbb{P})Sp_4\mathbb{R}\) remains. Again \(\Delta\) has no subgroup \(SO_3\mathbb{R}\). Either \(\Psi/Z\) is locally isomorphic to \(SU_3(\mathbb{C}, 1)\) or \(\Psi\) is a double covering \(\Pi\) of \(SL_3\mathbb{R}\). A subgroup \(SU_2\mathbb{C}\) of the unitary group can be lifted to an isomorphic copy \(\Phi < \Psi\); the involution \(n \in \Phi\) is not central and hence it is planar, which contradicts (ii). Thus \(\Psi \cong \Pi\). Both factors \(\mathcal{T}\) and \(\Psi\) have a subgroup \(Spin_3\mathbb{R}\). The central involutions of these subgroups are reflections (because \(\Upsilon_p = \Psi_p = \mathbb{I}\)), and these are distinct, or else there would exist a subgroup \(\Omega \cong SO_3\mathbb{R}\). A maximal compact subgroup of \(\mathcal{T}\Psi\) is at most 7-dimensional. It contains a subgroup \(X \cong Spin_3\mathbb{R}\) without any planar involution.

(i) \(\mathcal{G} = \langle p^\Gamma, o, u, v \rangle < \mathcal{P}\) for any \(p \in D\): if \(p^\Gamma = p\), then \(p^\Delta \subseteq \mathcal{F}_\Gamma < \mathcal{P}\) and \(\dim \Delta_p \geq 13\). Stiffness would imply \(\Delta^1_k \cong G_2\), which is not true. Hence \(\Gamma\) acts almost effectively on \(\mathcal{G}\) and \(\mathcal{G} \trianglelefteq \mathcal{P}\). Equality is impossible, since \(\dim(\mathcal{T}\Psi_p) > 1\). Denote the connected component of \((\mathcal{T}\Psi)_p\) by \(\Lambda\). By 2.6 we may assume that \(\dim \Lambda \geq 3\). Note that \(\Lambda|_\mathcal{G} = \mathbb{I}\). Hence \(\Lambda\) is compact. It follows that \(\dim(\Lambda \cap \mathcal{X}) \geq 2\). Obviously, each involution in \(\Lambda \cap \mathcal{X}\) is planar. This contradicts the last statement in (h).

(iii) Each 6-dimensional factor of \(\Delta\) is locally and then even globally isomorphic to \(SL_2\mathbb{C}\). There is at least one factor \(\Gamma\) such that \(\dim \Gamma = 3\). We may assume that \(\Gamma\) is not a Lie group. Then a maximal compact subgroup \(\Theta\) of \(\Gamma\) is a 1-dimensional connected subgroup. Let \(\Xi\) denote the product of the other factors of \(\Delta\) and apply [17] 9.2 (B) to the group \(H = \Xi\Theta\). As \(\Theta\) is normal in \(H\), we obtain \(\dim H < 18\) and \(\dim \Delta \leq 19\). □

Summary

If \(\Theta\) denotes a compact connected 1-dimensional subgroup and if \(\dim \Delta \geq k\), the number in the table, then \(\Delta\) is a Lie group. Bold face entries improve corresponding results in [17].

1) \(\mathcal{F}_\zeta < \mathcal{P}\) \(\Rightarrow\) \(\dim \Delta \leq 19\) (6.1)
2) \(\text{or } \text{Cs } \Delta_{av} = \mathbb{I}\) (8.3 Remark)
References

[5.5 Corollary. Let $G$ be a locally compact group, with $G/G^1$ compact. If $X$ is a locally contractible, locally compact space and if $G \times X \rightarrow X$ is a transitive continuous faithful action, then $G$ is a Lie group and $X$ is a manifold.]
[9] Barbara Priwitzer, Large automorphism groups of 8-dimensional projective planes are Lie groups, Geom. Dedic. 52 (1994), 33–40
9.2. Assume that \( \Delta \) fixes a triangle \( a, u, v \).

(A) If \( \Delta \) is semi-simple and if \( \dim \Delta \geq 22 \), then \( \Delta \) is a Lie group.

(B) If \( \Delta \) has a 1-dimensional compact normal subgroup \( \Theta \) and if \( \dim \Delta \geq 18 \), then \( \Delta \) is a Lie group and \( \dim \Delta \leq 23 \).

(C) If \( \Delta \) has a minimal normal vector subgroup \( \Theta \cong \mathbb{R}^t \) and if \( \dim \Delta \geq 22 \), then \( \Delta \) is a Lie group.

(Proof of 9.2(B). All orbits on two sides of the fixed triangle have dimension \( <8 \), and \( \dim p^H \leq 14 \) for each point \( p \notin au \cup au \cup uv \). Put \( \Lambda = (H_p)^1 \). By the approximation theorem 93.8, there is a compact 0-dimensional central subgroup \( N \triangleleft H \) such that \( H/N \) is a Lie group. Note that \( \Theta \) is in the center of \( H \). If \( \Theta \neq e \), then \( \mathcal{F}_\Theta = \mathcal{F}_\Theta^H < \mathcal{P} \) and \( H:H_p = \dim p^H \leq \dim \mathcal{F}_\Theta = d \) with \( d \in \{0, 2, 4, 8\} \). Either \( d \leq 2 \), \( \Theta \triangleleft \Lambda = (H_p)^1 \neq G_2 \), \( \dim \Lambda \leq 11 \), and \( \dim H \leq 13 \), or \( d \geq 4 \), \( \dim \Lambda \leq 8 \), and \( \dim H \leq 16 \). If \( \Theta \neq e \), then \( \Theta \) acts non-trivially on the subplane \( \mathcal{E} = \langle p^N, a, u, v \rangle \), \( \mathcal{E} \) is not flat by 32.17, and \( \dim \mathcal{E} = 4 \) or \( \mathcal{E} \leq \mathcal{P} \). In the first case, \( N|_\mathcal{E} = N/K \) is a Lie group by 71.2, and \( K \neq 1 \). Hence \( \mathcal{F}_K = \mathcal{F}_K^H < \mathcal{P} \), \( p^H \subseteq \mathcal{F}_K \), \( H:H_p \leq 8 \), \( H_p|_\mathcal{E} = 1 \), \( \dim H_p \leq 8 \), and \( \dim H \leq 16 \). In the second case, we have \( N|_H = \mathbb{Z} \). Therefore \( H:H_p = \dim p^H \leq 8 \) or \( H_p \cap N = 1 \) and \( H_p \) is a Lie group. Stiffness implies \( \dim H_p \leq 7 \) or \( \dim H_p \leq 3 \), respectively, and \( \dim H \leq 17 \).)
