DEGENERATE NONLINEAR PARABOLIC EQUATIONS WITH DISCONTINUOUS DIFFUSION COEFFICIENTS

DOHYUN KWON AND ALPÁR RICHÁRD MÉSZÁROS

Abstract. This paper is devoted to the study of some nonlinear parabolic equations with discontinuous diffusion intensities. Such problems appear naturally in physical and biological models. Our analysis is based on variational techniques and in particular on gradient flows in the space of probability measures equipped with the distance arising in the Monge–Kantorovich optimal transport problem. The associated internal energy functionals in general fail to be differentiable and geodesically $\lambda$-convex, therefore classical results do not apply in our setting. We study the combination of both linear and porous medium type diffusions and we show the existence and uniqueness of the solutions in the sense of distributions in suitable Sobolev spaces. Our notion of solution allows us to give a fine characterization of the emerging critical regions, observed previously in numerical experiments. A link to a three phase free boundary problem is also pointed out.

1. Introduction

In this paper we investigate a class of degenerate nonlinear parabolic equations, with discontinuous diffusion intensities. These can be written formally as the Cauchy problem

$$\begin{cases}
\partial_t \rho - \Delta \varphi(\rho) - \nabla \cdot (\nabla \Phi \rho) = 0, & \text{in } (0, T) \times \Omega, \\
(\nabla \varphi(\rho) + \nabla \Phi \rho) \cdot \mathbf{n} = 0, & \text{on } (0, T) \times \partial \Omega, \\
\rho(\cdot, 0) = \rho_0, & \text{in } \Omega,
\end{cases}
$$

(1.1)

Date: July 29, 2019.
for the unknown \( \rho : [0, T] \times \Omega \to [0, +\infty) \), where \( T > 0 \) is a given time horizon, \( \Omega \subset \mathbb{R}^d \) is the closure of a bounded convex open set with smooth boundary, \( \Phi : \Omega \to \mathbb{R} \) is a given Lipschitz continuous potential function, \( \rho_0 \in \mathcal{P}(\Omega) \) is a nonnegative Borel probability measure and the diffusion intensity function \( \Phi : [0, +\infty) \to \mathbb{R} \) is supposed to have a discontinuity at \( \rho = 1 \). The choice of \( \rho = 1 \) where the discontinuity happens has no particular significance and our results may be generalized for nonlinearities \( \Phi \) having finitely many singularities, without too much effort. Therefore, \( \Phi \) is extended to be a multi-valued function at the discontinuity and in addition, it is supposed to be monotone in the sense that if \( \eta^i \in \Phi(\rho^i) \), then

\[
(\eta^1 - \eta^2)(\rho^1 - \rho^2) \geq 0.
\]

Our aim is to identify a large class of potentials \( \Phi \), nonlinearities \( \Phi \) and initial data \( \rho_0 \), for which we show the well-posedness of (1.1) in a suitable distributional sense. Furthermore, we aim to describe some fine properties of the solutions.

Such problems appear naturally in physical and biological models. Let us briefly describe two of these. In [BJ92], the authors study so-called phenomena of self-organized criticality. These arise typically in sandpile models, in which the sand particles are subject to a constant diffusion only at regions where their density is greater than a given threshold, otherwise they remain still. At the macroscopic level, in the cited reference such models were described by equations similar to (1.1), with \( \Phi = 0 \) and \( \Phi(\rho) = 0 \), if \( \rho < \rho_c \) and \( \Phi(\rho) = \text{const} \) if \( \rho \geq \rho_c \) (where \( \rho_c \) is a given threshold value). Via an approximation procedure and numerical investigations, the authors observe the growth (in time) of the critical region, where \( \rho = \rho_c \), therefore, they conclude that particles following this diffusion law ‘self-organize into criticality’. Our main results in this paper will rigorously confirm such phenomena.

In [CK13] the authors study diffusion models for biological organisms that increase their motility when food or other resource is insufficient. They refer to such phenomena as starvation driven diffusion. At the mathematical level, their model consists in a system of reaction-diffusion equations for two species, where the diffusion rates are discontinuous functions depending on the (food supply)/(food demand) ratio in the global population. In this model, a Lotka-Volterra type competition is implemented and a particular example is provided when one species follows the starvation driven diffusion and the other follows the linear diffusion. The authors conclude, by means of numerical simulations, that in heterogeneous environments the starvation driven diffusion turns out to be a better survival strategy than the linear one. Therefore, by this conclusion the authors would like to underline also the fact that in biological models, discontinuous diffusion rates might appear in a very natural way, resulting many times in a better description of competing biological systems.

Degenerate nonlinear parabolic problems like (1.1) received a lot of attention in the past couple of decades. For a non-exhaustive list of classical works on this subject we refer to [BBC75, BC81, BBH89, CE83, Car99] and the references therein. In majority of the literature, however, the nonlinearity \( \Phi \) is taken to be a continuous function.

To the best of our knowledge, except in particular cases involving linear type diffusions and/or bounded initial data (see for instance in [BRR10, BRR11, BR18]), our model problem in its full generality has not been addressed previously in the literature. The solution obtained in the aforementioned references heuristically can be written as pairs \((\rho, \eta_\rho)\) belonging to well-chosen function spaces, such that

\[
\partial_t \rho - \Delta(\eta_\rho) - \nabla \cdot (\nabla \Phi \rho) = 0
\]

is fulfilled either in the distributional or entropic sense and \( \rho(t, x) \in \eta_\rho(t, x) \) a.e.

In this paper, we rely on the gradient flow structure of (1.1) in the space of probability measures, when equipped with the distance \( W_2 \) arising in the Monge-Kantorovich optimal transport problem. To (1.1), we associate an entropy functional \( \mathcal{E} : \mathcal{P}(\Omega) \to \mathbb{R} \cup \{+\infty\} \), defined as

\[
\mathcal{E}(\rho) := \left\{ \begin{array}{ll}
\int_\Omega S(\rho(x)) \, dx + \int_\Omega \Phi(x) \, d\rho(x), & \text{if } S(\rho) \in L^1(\Omega), \\
+\infty, & \text{otherwise,}
\end{array} \right.
\]

where \( S : [0, +\infty) \to \mathbb{R} \) is a given function. At the formal level, the relationship between \( \Phi \) and \( S \) can be written as

\[
\Phi(\rho) = \rho S'(\rho) - S(\rho) + S(1) \quad \text{and} \quad \Phi'(\rho) = \rho S''(\rho), \quad \text{if } \rho \neq 1.
\]

We observe that the discontinuity of \( \Phi \) at \( \rho = 1 \) corresponds to the non-differentiability of \( S \). Furthermore, as \( \Phi \) is monotone, we impose that \( S \) is convex and the multiple values of \( \Phi \) can be represented by the
subdifferential of $S$. In this sense, throughout the paper we consider $S$ to be given which satisfies the following assumption.

**Assumption 1.1.** $S : [0, +\infty) \to \mathbb{R}$ is superlinear, continuous and strictly convex. Furthermore, $S$ is twice continuously differentiable in $\mathbb{R}^+ \setminus \{1\}$.

Let us underline the fact that even though in our models the convexity of the energy is assumed, in the standard sense, surprisingly the internal energy part of the functional $\mathcal{E}$ in general fails to be geodesically $\lambda$-convex (as we show in Subsection 2.3). Therefore the classical results from [AGS08] do not apply. The lack of geodesic $\lambda$-convexity in the context of Wasserstein gradient flows typically poses serious obstructions (as we can see for instance in [DFM14, MMS09, KM18]). In addition to this, in our setting the non-differentiability of $S$ poses further technical difficulties. So, the existence of the gradient flow of $\mathcal{E}$ in $(\mathcal{P}(\Omega), W_2)$ seems to be a non-trivial question, and the fine characterization of the density curves, their velocities and the critical region $\{\rho = 1\}$, in as general settings as possible, is also a challenging task. Because of the same reasons, an approach by maximal monotone operators as in [BR18] would not be satisfactory in our setting either. In this context, ours seems to be the first contribution which rigorously characterizes the gradient flows of a general class of non-differentiable and non-geodesically $\lambda$-convex internal energies in $(\mathcal{P}(\Omega), W_2)$.

In our analysis, we rely on the classical minimizing movements scheme of De Giorgi (see also [JK098] and [San117]). This, for a given $\rho_0 \in \mathcal{P}(\Omega)$ (and for a small parameter $\tau > 0$ and $N \in \mathbb{N}$ such that $N\tau = T$) iteratively constructs $(\rho_k)_{k=0}^N$ as

$$
\rho_{k+1} = \text{argmin} \left\{ \mathcal{E}(\rho) + \frac{1}{2\tau} W_2^2(\rho_k, \rho) : \rho \in \mathcal{P}(\Omega) \right\}, \quad k \in \{0, \ldots, N-1\}.
$$

In order to write down the first order necessary optimality conditions associated to (1.3), in Section 2 as our first contribution in this paper, we give a precise characterization of the subdifferential of $\mathcal{E}$ in $(\mathcal{P}(\Omega), W_2)$ (cf. [AGS08]) in various settings (depending on the growth condition of $S$ and the summability of $\rho_0$). Our analysis in this section relies on classical results from convex analysis, carefully adapted to (1.3). As an intermediate result, we show (see Lemma 2.10) that optimizers of the problem (1.3) enjoy higher summability estimates than the a priori ones coming from the growth condition of $S$ at $+\infty$. In this section, we show also that the internal energies considered in our setting, in general fail to be geodesically $\lambda$-convex.

In order to give a precise description of the optimality conditions associated to (1.3), we introduce a function $\rho_k$ which encodes the ‘transition’ between the phases $\{\rho_k < 1\}$ and $\{\rho_k > 1\}$ through the critical region $\{\rho_k = 1\}$. This is very much inspired by the derivation of the pressure variable in recent models studying crowd movements under density constraints (see in [MRC10], [DMS16], [MS16]). Because of this similarity, throughout the paper, we sometimes use the abused terminology of pressure to refer to the variable $p$. Numerical experiments suggest (see Figure 1) that interestingly the critical region emerges in general already after one minimizing movement iteration.

**Figure 1.** One minimizing movement step in 1D, for $\Phi(x) = 2x$, $\Omega = [0, 1]$ and $S$ in (1.7)

After obtaining the necessary compactness results, we pass to the limit with the time discretization parameter $\tau \downarrow 0$ and we recover a PDE (which precisely describes the weak distributional solutions of (1.1)) satisfied by the limit quantities $(\rho, p)$. This formally reads as

$$
\begin{cases}
\partial_t \rho - \Delta (L_S(\rho, p)) - \nabla \cdot (\nabla \Phi \rho) = 0, & \text{in } (0, T) \times \Omega, \\
\rho(0, \cdot) = \rho_0, & \text{in } \Omega, \\
(\nabla (L_S(\rho, p)) + \nabla \Phi \rho) \cdot n = 0, & \text{in } [0, T] \times \partial \Omega.
\end{cases}
$$

\begin{align}
&\qquad \text{(A) } \rho_0 \\
&\quad \text{(B) } \rho_1
\end{align}
Here, the operator $L_S$ is defined pointwisely for functions $(\rho, p) : [0, T] \times \Omega \to \mathbb{R}$ by
\begin{equation}
L_S(\rho, p)(t, x) := [\rho(t, x) S'(\rho(t, x)) - S(\rho(t, x)) + S(1)] \mathbb{1}_{\{\rho \neq 1\}}(t, x) + p(t, x) \mathbb{1}_{\{\rho = 1\}}(t, x)
\end{equation}
and the pressure variable $p : [0, T] \times \Omega \to \mathbb{R}$ satisfies
\begin{align}
\begin{cases}
p(t, x) = S(1-) & \text{if } 0 \leq \rho(t, x) < 1, \\
p(t, x) = \rho \log \rho, & \text{if } \rho(t, x) = 1, \\
p(t, x) = S'(1+) & \text{if } \rho(t, x) > 1.
\end{cases}
\end{align}

Formally, (1.4) and (1.6) correspond to the three phase free boundary problem
\[ \Delta p = -\Delta \Phi, \quad \text{in } \{\rho = 1\}, \quad p = S'(1-) \text{ in } \{\rho < 1\} \quad \text{and} \quad p = S'(1+) \text{ in } \{\rho > 1\}. \]

Throughout the paper we distinguish cases depending on the diffusion rates in the two phases $\{\rho < 1\}$ and $\{\rho > 1\}$. We consider the combination of linear and porous medium type diffusions, which correspond to a behavior as $S(\rho) \sim \rho \log(\rho)$ and $S(\rho) \sim \rho^m$ (for $m > 1$), in $\{\rho < 1\}$ and $\{\rho > 1\}$.

In order to emphasize the main ideas of the paper and to avoid the technical notations at the first glance, we present in details two toy problems. These turn out to be building blocks of our analysis in more general cases. Section 3 is devoted to the case when the entropy is of logarithmic type on both phases $\{\rho < 1\}$ and $\{\rho > 1\}$ and in particular $S$ is given by
\begin{equation}
S(\rho) := \begin{cases}
\rho \log \rho, & \text{if } \rho \in [0, 1], \\
2 \rho \log \rho, & \text{if } \rho \in (1, +\infty).
\end{cases}
\end{equation}
In this case, it turns out that the solution $(\rho, p)$ satisfies $p = 1$ in $\{\rho < 1\}$, $p \in [1, 2]$ in $\{\rho = 1\}$, $p = 2$ in $\{\rho > 1\}$ and we have the simplified expression $L_S(\rho, p) = pp$.

Similarly, Subsection 5.1 presents the analysis in the case when $S$ is given by
\begin{equation}
S(\rho) := \begin{cases}
\rho^m, & \text{for } \rho \in [0, 1], \\
2 \rho^m - \frac{1}{m - 1}, & \text{for } \rho \in (1, +\infty),
\end{cases}
\end{equation}
for some $m > 1$. For this energy, the first equation of (1.4) can be written as
\[ \partial_t \rho - \nabla \cdot \left( \rho \left[ \nabla (\rho^m \rho^1) + \nabla \Phi \right] \right) = 0, \quad \text{in } (0, T) \times \Omega. \]
Furthermore, $p = \frac{m}{m - 1}$ in $\{\rho < 1\}$, $p \in [\frac{m}{m - 1}, \frac{2m}{m - 1}]$ in $\{\rho = 1\}$ and $p = \frac{2m}{m - 1}$ in $\{\rho > 1\}$.

Starting with Section 4, we consider general entropies. Assumptions are made on the growth of $S$ in the two different phases $\{\rho < 1\}$ and $\{\rho > 1\}$. First, we impose

**Assumption 1.2.**
\begin{equation}
S : [0, +\infty) \to \mathbb{R} \text{ satisfies } \frac{\rho^{m-2}}{\sigma_2} < S''(\rho) \text{ if } \rho \in (0, 1) \text{ for some } m \geq 1 \text{ and } \sigma_2 > 0.
\end{equation}

The imposed summability assumption on the initial data $\rho_0 \in \mathcal{P}(\Omega)$ plays also a crucial role in our analysis. If $\rho_0 \in L^\infty(\Omega)$, it turns out that the entire iterated sequence $(\rho_k)_{k=1}^N$ obtained in the scheme (1.3) remains essentially uniformly bounded, provided the potential $\Phi$ is smooth enough. This fact does not depend on the differentiability of $S$ and it is well-known in the literature (see [San15]). In this case, imposing only the assumption (1.8) on $S$ is enough to obtain the well-posedness of (1.4)-(1.6).

The other ‘extreme’ case is when we only impose that $\rho_0$ has finite energy, i.e. $\mathcal{E}(\rho_0) < +\infty$. We show that the iterated sequence will have improved summability estimates for $k \in \{1, \ldots, N\}$ (see in Lemma 2.10), provided $S$ satisfies the additional growth condition (1.9b)-(1.9a) below. These summability estimates on the iterated sequence will be enough to obtain the necessary a priori estimates and pass to the limit as $\tau \downarrow 0$ to obtain a weak solution to (1.4)-(1.6).

As a consequence of these arguments, we will always distinguish two cases with respect to the previous two summability assumptions when stating our main results. Our main result in the case of $\rho_0 \in L^\infty(\Omega)$ reads as:

**Theorem 1.1** (Theorems 3.1, 4.2, 5.1, 5.6 and Theorem 6.1). Suppose that (1.8) holds and $\Phi$ satisfies (2.4). For $\rho_0 \in L^\infty(\Omega)$, there exists $\rho \in L^\infty([0, T] \times \Omega)$, $\rho^m \in L^2([0, T]; H^1(\Omega))$ and $p \in L^2([0, T]; H^1(\Omega)) \cap L^\infty([0, T] \times \Omega)$ such that $(\rho, p)$ is a unique solution of (1.4)-(1.6) in the sense of distributions.
For general initial data such that $\mathcal{E}(\rho_0) < +\infty$ we shall impose the following additional growth condition on $S$.

**Assumption 1.3.**

\begin{align}
(1.9a) &\quad S : [0, +\infty) \to \mathbb{R} \text{ satisfies } \frac{\rho^r - 2}{\sigma_1} \leq S''(\rho) \text{ if } \rho \in (1, +\infty) \text{ and } \\
(1.9b) &\quad S''(\rho) \leq \sigma_1 \rho^{r-2} \text{ if } \rho \in (1, +\infty) \text{ for some } r, \sigma_1 \geq 1.
\end{align}

Notice that under (1.9) and $r > 1$, $\mathcal{E}(\rho_0) < +\infty$ is equivalent to $\rho_0 \in L^r(\Omega)$. Similarly to Theorem 1.1, we can formulate the corresponding well-posedness result.

**Theorem 1.2** (Theorems 3.1, 4.2, 5.1, 5.6 and Theorem 6.1). Suppose that (1.8) and (1.9) are fulfilled and

\begin{equation}
(1.10) \quad m < r + \frac{\beta}{2}
\end{equation}

holds true for $\beta > 1$ (its precise value is given in (2.22)). For $\rho_0 \in \mathcal{P}(\Omega)$ such that $\mathcal{E}(\rho_0) < +\infty$, there exists $\rho \in L^3([0, T] \times \Omega)$ and $p \in L^2([0, T]; H^1(\Omega)) \cap L^\infty([0, T] \times \Omega)$ such that $(\rho, p)$ is a solution of (1.4)-(1.6) in the sense of distributions. Furthermore, we have

$$
\rho^{m - \frac{1}{2}} \in L^2([0, T]; H^1(\Omega)), \quad \text{if } m \leq r \quad \text{and} \quad \rho^{m - \frac{1}{2}} \in L^q([0, T]; W^{1,q}(\Omega)) \quad \text{if } r < m < r + \frac{\beta}{2}
$$

for some $q \in (1, 2)$. If in addition $\beta \geq 2r$, then the pair $(\rho, p)$ is unique.

Let us comment on the additional technical assumption (1.10) in the previous theorem. While this condition has to be required for purely technical reasons and we do not claim anything about its sharpness, we believe that it could be physically motivated. This would just mean that for unbounded initial data, the diffusion rate on the region $\{\rho < 1\}$ cannot be ‘too much slower’ than the one on the region $\{\rho > 1\}$. With other words, ‘too fast’ diffusion rate on $\{\rho > 1\}$ and ‘too slow’ diffusion on $\{\rho < 1\}$ might result in unphysical phenomena and in non-existence of solutions.

It worth also noticing that the previous phenomenon is not expected for bounded solutions. Also, in particular from the definition of $\beta$ in (2.22), we see that $\beta = +\infty$ if $d = 1$ or $d = 2$. Therefore, in such cases the previous theorem holds true without the additional assumption (1.10). The same is true in the case when $1 \leq m \leq r$.

Let us make a brief comment also on the proof of the previous theorems. In the case when the diffusion rates are equal on the two phases $\{\rho < 1\}$ and $\{\rho > 1\}$, i.e. $m = r$, the derivation of the optimality conditions already gives us enough a priori estimates on gradients of suitable powers of the density variable. Then, these are enough to obtain the strong compactness of the interpolated curves connecting the discrete time densities raised on a carefully chosen ‘intermediate’ power (depending on both $m$ and $r$). This idea seems to be crucial in our analysis and this is one of the most technical parts of the paper.

It worth to comment also on the fact that in Theorem 1.2 we obtain improved summability estimates of the density variable, even if one merely imposes $L^r$ summability on $\rho_0$ and the diffusion rate in $\{\rho > 1\}$ is $r$, we obtain $\rho \in L^3([0, T] \times \Omega)$ (since $\beta$ given in (2.22) satisfies $\beta > r$; in particular $\beta = +\infty$ in $d = 1$ and $d = 2$). This improved summability estimate (w.r.t. the summability of the initial data) seems to be well-known in the case of standard porous medium equations (for instance in the case of $\Phi = 0$, this is a consequence of [Váz07, Theorem 8.7]). Our proof, which is based on purely optimal transport techniques, implies this estimate in particular also in the classical setting.

When studying the well-posedness of the system (1.4)-(1.6), one can ask the natural question whether these PDEs can be represented as continuity equations. Under suitable additional assumptions, this is always the case, as we can show in Theorem 4.9, Theorem 5.5 and Theorem 5.13 when (1.4) also reads as

\begin{equation}
(1.11) \quad \begin{cases}
\partial_t \rho - \nabla \cdot \left( \rho \nabla (S'(\rho) \mathbb{1}_{\{\rho \neq 1\}} + p \mathbb{1}_{\{\rho = 1\}}) \right) - \nabla \cdot (\rho \nabla \Phi) = 0, & \text{in } (0, T) \times \Omega, \\
\rho(0, \cdot) = \rho_0, & \text{in } \Omega, \\
\rho \left[ \nabla (S'(\rho) \mathbb{1}_{\{\rho \neq 1\}} + p \mathbb{1}_{\{\rho = 1\}}) + \nabla \Phi \right] \cdot n = 0, & \text{in } [0, T] \times \partial \Omega.
\end{cases}
\end{equation}

We underline that the required additional assumptions are needed to guarantee Sobolev estimates on $S'(\rho)$. We can summarize our results in this direction as follows.
Theorem 1.3 (Theorems 4.9 and 5.13). Let us suppose that we are in the setting of Theorem 1.2 and $(\rho, p)$ is the solution of (1.4)-(1.6). If we additionally assume

\begin{equation}
(1.12) \quad m < r + \frac{1}{2}
\end{equation}

and

\begin{equation}
(1.13) \quad \beta > 2 \text{ and } m < \frac{\beta}{2} + \frac{1}{2},
\end{equation}

then $(\rho, p)$ is a weak solution of (1.11) in the sense of distribution. The uniqueness of the solution holds under the same assumption as in Theorem 1.2. If in addition $\rho_0 \in L^\infty(\Omega)$ and $\Phi$ satisfies (2.4), we can drop (1.13) from the statement.

In the same way as in Theorem 1.2 (by the definition of $\beta$ in (2.22)), (1.13) holds for any $m, r \geq 1$ if $d = 1$ or $d = 2$. Moreover, when $r = m$, then the second inequality in (1.13) is satisfied for all $m \geq 1$ and $\beta > 2$ is equivalent to $m > \frac{2d - 2}{d - 1}$.

The attentive reader could observe that in the statements of Theorem 1.1 and 1.2 we included the corresponding uniqueness results as well. Indeed, Section 6 is entirely devoted to this issue and in particular we obtain an $L^1$ contraction result for the density variable $\rho$ (see in Theorem 6.1), implying its uniqueness. This will then imply the uniqueness of the corresponding $p$ variable as well. Our approach is inspired by [DMM16], Section 3 and [Váz07, Theorem 6.5], and as expected, the monotonicity of the operator $L_S$ (see Lemma 6.2) plays a crucial role in our argument. By the ‘double degeneracy’ of our problem, neither of the previously mentioned two approaches apply directly and a very careful combination of the two is required to obtain the desired $L^1$ contraction. Similarly as in [Váz07, Theorem 6.5], in this analysis an additional summability assumption is needed on the density variable. Due to the extra $L^\beta$ summability obtained in Theorem 1.2 or in the case of bounded solutions as in Theorem 1.1, this is automatically fulfilled in many cases. It is unclear whether it would be possible to obtain an $W_2$-type contraction in the spirit of [CMV03, CMV06] in our case. Let us notice that the results from [BC14] imply that the Wasserstein contraction is equivalent to the geodesic convexity of the internal energy. Since the energies considered in this article in general fail to be geodesically $\lambda$-convex, the question of the existence of a function $C: [0, +\infty) \to [0, +\infty)$ such that $W_2(\rho^1, \rho_0^2) \leq C(t)W_2(\rho_0^1, \rho_0^2)$ for $t \geq 0$ (along two solutions $\rho^1$ and $\rho^2$), seems highly nontrivial. These investigations represent the subject of current study.

Section 7 is devoted to further discussions on the models studied in this paper. In particular, we discuss examples where the emergence of the critical region $\{\rho = 1\}$ can be observed for positive times, even if that was not present in the case of the initial data, i.e. $\mathcal{L}_d(\{\rho_0 = 1\}) = 0$. We illustrate this in dimension one and we describe stationary solutions (minimizers of the free energy) corresponding to suitable potential functions $\Phi$, where the critical region is present. As we mentioned before, our problems can be linked to three phase free boundary problems, and in this section we also derive these ones formally.

We end our paper with three small appendices, where we collected some well-known facts (or consequences of well-known results) from the theory of optimal transport and convex analysis. Here, we present also a suitable version of the classical Aubin-Lions lemma, which is repeatedly used throughout the paper to obtain compactness of families of time dependent functions in Lebesgue spaces.

2. THE MINIMIZING MOVEMENT SCHEME, OPTIMALITY CONDITIONS AND PROPERTIES OF THE ENERGY

Throughout the paper $\Omega \subset \mathbb{R}^d$ is given, as the closure of a bounded, convex open set with smooth boundary. $\mathcal{P}(\Omega)$ denotes the space of Borel probability measures on $\Omega$ and $\mathcal{L}^d$ stands the Lebesgue measure on $\mathbb{R}^d$. We also use the notation $\mathcal{P}^m(\Omega) := \{\mu \in \mathcal{P}(\Omega) : \mu \ll \mathcal{L}^d|\Omega\}, T > 0$ is a fixed time horizon and we often use the notation $Q := [0, T] \times \Omega$.

As $S'$ is strictly increasing in $\mathbb{R}^+ \setminus \{1\}$ from Assumption 1.1, $S'(0+)$ and $S'(1\pm)$ are well-defined in $\mathbb{R} \cup \{-\infty\}$ and $\mathbb{R}$, respectively, as follows.

\begin{equation}
(2.1) \quad S'(0+) := \lim_{\varepsilon \to 0^+} S'(\varepsilon), \quad S'(1-) := \lim_{\varepsilon \to 1^-} S'(\varepsilon) \text{ and } S'(1+) := \lim_{\varepsilon \to 1^+} S'(\varepsilon).
\end{equation}

In particular, we have that $S'(1-) < S'(1+)$. 

6
We define the corresponding internal energy \( J : \mathcal{P}(\Omega) \to \mathbb{R} \cup \{+\infty\} \) by
\[
J(\rho) := \begin{cases} 
\int_{\Omega} S(\rho(x)) \, dx & \text{if } \rho \in \mathcal{P}^c(\Omega), \\
+\infty & \text{otherwise}
\end{cases}
\] (2.2)

Furthermore, we suppose that there is given \( \Phi : \Omega \to \mathbb{R} \) a potential function in \( C^2(\overline{\Omega}) \) and the associated potential energy \( F : \mathcal{P}(\Omega) \to \mathbb{R} \) given by
\[
F(\rho) := \int_{\Omega} \Phi(x) \, d\rho(x).
\]

Let \( \rho_0 \in \mathcal{P}(\Omega) \) be given and consider a time discretization parameter \( \tau > 0 \) and \( N \in \mathbb{N} \) such that \( N \tau = T \). We define the minimizing movements \( (\rho_k)_{k=1}^N \) of \( J + F \) as follows: for \( k \in \{1, \ldots, N\} \) set,
\[
(2.3) \quad \rho_k := \arg \min_{\rho \in \mathcal{P}(\Omega)} \left\{ J(\rho) + F(\rho) + \frac{1}{2\tau} W_2^2(\rho, \rho_{k-1}) \right\}.
\]

Note that the existence and uniqueness of the solutions in the minimization problems (2.3) follow from standard compactness, lower semicontinuity, and convexity arguments.

In what follows, in our analysis we differentiate two cases with respect to the summability assumption on \( \rho_0 \). Since these need slightly different arguments, we separate them in two different subsections. In particular, if one assumes \( L^\infty \) summability on \( \rho_0 \), the presented results will hold true under no additional assumptions on \( S \) (other than in Assumption 1.1). However, in (2.3) we can allow general measure initial data, in which case an additional growth condition (see (1.9)) has to be imposed on \( S \) in order to obtain the same optimality conditions.

2.1. Optimality conditions for \( \rho_0 \in L^\infty(\Omega) \).

**Lemma 2.1.** If \( \Phi \) is non-constant, let us assume that \( \Phi \in C^2(\overline{\Omega}) \) is such that
\[
\nabla \Phi(x_0) \cdot n(x_0) > 0, \quad \forall x_0 \in \partial \Omega,
\]
where \( n \) stands for the outward normal vector to \( \partial \Omega \). Let \( (\rho_k)_{k=1}^N \) be constructed via the scheme (2.3). Then we have
\[
\|\rho_k\|_{L^\infty} \leq \|\rho_{k-1}\|_{L^\infty} (1 + \tau \|\Delta \Phi\|_{L^\infty})^d \leq \|\rho_0\|_{L^\infty} (1 + \tau \|\Delta \Phi\|_{L^\infty})^{kd} \leq \|\rho_0\|_{L^\infty} e^{d\tau \|\Delta \Phi\|_{L^\infty}}, \quad \forall k \in \{1, \ldots, N\}.
\]

**Proof.** The proof of this result in the case when \( \Phi \equiv 0 \) is essentially the same as the proof of [San15, Proposition 7.32] (since that proof is not assuming any differentiability on \( S \)).

For general \( \Phi \), we use some ideas from the proof of [CS18, Theorem 1]. Let us approximate \( S \) with a sequence \( (S_\varepsilon)_{\varepsilon > 0} \) of smooth convex functions such that \( S_\varepsilon'' \geq c_\varepsilon > 0 \) for any \( \varepsilon > 0 \) with \( S_\varepsilon''(0^+) = -\infty \). Let \( \rho_k^\varepsilon \) be the unique solution of (2.3), when we replace \( S \) with \( S_\varepsilon \). Writing down the optimality conditions we obtain
\[
S_\varepsilon'(\rho_k^\varepsilon) + \Phi + \frac{\phi_k^\varepsilon}{\varepsilon} = C \quad \text{a.e.,}
\]
where \( \phi_k^\varepsilon \in K(\rho_k^\varepsilon, \rho_{k-1}) \). Let us suppose that \( \phi_k^\varepsilon \in C^{2,0,\alpha}(\Omega) \), otherwise we approximate \( \rho_{k-1} \) by strictly positive \( C^{0,\alpha} \) measures (and \( \rho_k^\varepsilon \) is Lipschitz continuous and strictly positive), and we use Caffareli’s regularity theory to deduce the desired regularity for the potential.

Now, let \( x_0 \) a maximum point of \( \phi_k^\varepsilon \). From the previous equality, since \( S_\varepsilon' \) is strictly increasing, we certainly have that \( x_0 \) is a minimum point of \( \Phi + \frac{\phi_k^\varepsilon}{\varepsilon} \).

We claim that \( x_0 \notin \partial \Omega \). Indeed, if \( x_0 \) would belong to \( \partial \Omega \), we would have that
\[
(\nabla \phi_k^\varepsilon(x_0) + \varepsilon \nabla \Phi(x_0)) \cdot n(x_0) \leq 0.
\]
However, by the convexity of \( \Omega \), we have that \( (x_0 - \nabla \phi_k^\varepsilon(x_0)) \cdot n(x_0) \leq 0 \), from where \( \nabla \phi_k^\varepsilon(x_0) \cdot n(x_0) \geq 0 \).

This fact together with the assumption (2.4) yields a contradiction.

Therefore, the maximum point \( x_0 \) of \( \rho_k^\varepsilon \) belongs to the interior of \( \Omega \). This implies that \( \Delta \phi_k^\varepsilon(x_0) + \varepsilon \Delta \Phi(x_0) \geq 0 \). Using the Monge-Ampère equation we find
\[
\|\rho_k^\varepsilon\|_{L^\infty} = \rho_k^\varepsilon(x_0) = \rho_{k-1}(x_0 - \nabla \phi_k^\varepsilon(x_0)) \cdot (I_d - D^2 \phi_k^\varepsilon(x_0)) \leq \|\rho_{k-1}\|_{L^\infty} (1 - \Delta \phi_k^\varepsilon(x_0))^d
\]
\[
\leq \|\rho_{k-1}\|_{L^\infty} (1 + \tau \|\Delta \Phi\|_{L^\infty})^d \leq \|\rho_0\|_{L^\infty} (1 + \tau \|\Delta \Phi\|_{L^\infty})^{kd} \leq \|\rho_0\|_{L^\infty} e^{d\tau \|\Delta \Phi\|_{L^\infty}},
\]
where in the first inequality we have used the inequality between the arithmetic and geometric means. Since the last three bounds depend only on the data, these will also remain valid also in the limit \( \varepsilon \downarrow 0 \) (since the minimizers of both the approximated and the original problems are unique). Therefore the thesis of the lemma follows.

Now, we state the main result of this subsection on the first order necessary optimality conditions for the problems in (2.3).

**Theorem 2.2.** Suppose that \( \rho_0 \in L^\infty(\Omega) \). For all \( k \in \{1, \ldots, N\} \), there exists \( C = C(k) \in \mathbb{R} \) and \( \bar{\phi}_k \in \mathcal{K}(\rho_k, \rho_{k-1}) \) such that

\[
\begin{aligned}
C - \phi_k &\leq S'(0^+) &\text{in } \{\rho_k = 0\}, \\
C - \phi_k &\in [S'(1^-), S'(1^+)] &\text{in } \{\rho_k = 1\}, \\
C - \phi_k &\geq S' \circ \rho_k &\text{otherwise}.
\end{aligned}
\]

(2.5)

Here, \( \mathcal{K}(\rho_k, \rho_{k-1}) \) is given in Definition A.1. Also, \( S'(0^+) \) and \( S'(1^\pm) \) are given in (2.1). Note that \( \rho_k > 0 \) a.e. (See Lemma A.4) if \( S'(0^+) = -\infty \), and in this case the first inequality in (2.5) is not present.

The proof of the previous results relies on the precise derivation of the subdifferential of the corresponding objective functional in (2.3). Let us point out that the subdifferential of sum is not always the sum of subdifferentials (see for instance [San15, Example 7.22]). Therefore, we need to carefully choose the domain of definition of \( \mathcal{J} \). In the spirit of Lemma 2.1, we consider it as a functional on \( L^\infty(\Omega) \) instead of \( \mathcal{P}(\Omega) \). The additive property of subdifferentials on \( L^\infty(\Omega) \) holds under suitable conditions (cf. [ET76]).

**Proposition 2.3.** For all \( k \in \{1, \ldots, N\} \) we have

\[
\partial \left( \mathcal{J}(\rho) + \mathcal{F}(\rho) + \frac{1}{2\tau} W^2_1(\rho, \rho_{k-1}) \right) \bigg|_{\rho=\rho_k} = \partial \mathcal{J}(\rho_k) + \Phi + \frac{1}{2\tau} \partial (W^2_1(\rho, \rho_{k-1})) \bigg|_{\rho=\rho_k}
\]

(2.6)

\[
\partial \left( \mathcal{J}(\rho) + \mathcal{F}(\rho) + \frac{1}{2\tau} W^2_1(\rho, \rho_{k-1}) \right) \bigg|_{\rho=\rho_k} = \partial \mathcal{J}(\rho_k) + \Phi + \frac{1}{2\tau} \partial (W^2_1(\rho, \rho_{k-1})) \bigg|_{\rho=\rho_k}
\]

**Proof.** To simplify the writing, we consider only the case \( k = 1 \). Let us check that \( \mathcal{J} \) and \( W^2_1(\cdot, \rho_0) \) satisfy the assumptions in Lemma B.2. The convexity of \( S \) implies that of \( \mathcal{J} \). Also, the continuity of \( \mathcal{J} \) in \( L^\infty(\Omega) \) follows from the continuity of \( S \). From Lemma B.1, we conclude \( \mathcal{J} \in \Gamma(L^\infty(\Omega)) \). We have the same conclusion for the functional \( \mathcal{F} \) (which is actually linear in \( \rho \)).

Let us show that \( W^2_1(\cdot, \rho_0) \in \Gamma(L^\infty(\Omega)) \). Define \( H : L^1(\Omega) \to \mathbb{R} \cup \{+\infty\} \) by

\[
H(\phi) := -\int_\Omega \phi \, d\rho_0.
\]

(2.7)

Proposition A.3 implies that \( H^* : L^\infty(\Omega) \to \mathbb{R} \cup \{+\infty\} \) is given (in the sense of (B.1)) by

\[
H^* = \frac{1}{2} W^2_1(\cdot, \rho_0) \text{ on } L^\infty(\Omega).
\]

We conclude \( W^2_1(\cdot, \rho_0) \in \Gamma(L^\infty(\Omega)) \).

Lastly, choose \( A \subseteq \Omega \) a Borel set such that \( \mathcal{L}^d(A) \neq 1 \) and define

\[
\hat{\mu} := \frac{1}{\mathcal{L}^d(A)} \mathbb{1}_A.
\]

(2.8)

\[
\mathcal{J}(\hat{\mu}), \mathcal{F}(\hat{\mu}) \text{ and } W^2_1(\hat{\mu}, \rho_0) \text{ are finite. Furthermore, by the continuity of } S \text{ in } \mathbb{R}^+, \mathcal{J} \text{ is continuous at } \hat{\mu}. \text{ In the same way } \mathcal{F} \text{ is also continuous at } \hat{\mu}. \text{ Thus, we conclude (2.6) from Lemma B.2.}
\]

Next, let us find the subdifferential of \( W^2_1(\cdot, \rho_{k-1}) \). While this subdifferential is expected to be the set of Kantarovich potentials \( \mathcal{K}(\rho_{k-1}) \), it is not straightforward to conclude about this as we consider the subdifferential for the functional on \( L^\infty(\Omega) \). We rely on the ideas from [San15, Proposition 7.17], tailored to our setting.

**Lemma 2.4.** [San15, Lemma 7.15] Let \( X \) be a Banach space and \( H : X \to \mathbb{R} \cup \{+\infty\} \) be convex and lower semicontinuous. Set \( H^*(y) = \sup_{x \in X} \{\langle x, y \rangle_X, x^* - H(x)\} \). Then, we have

\[
\partial H^*(y) = \arg \max_{x \in X} \{\langle x, y \rangle_X, x^* - H(x)\}.
\]

(2.9)

**Lemma 2.5.** \( H : L^1(\Omega) \to \mathbb{R} \cup \{+\infty\} \) given in (2.7) is convex and l.s.c.
Proof. The proof of convexity of $H$ is the same as in [San15, Proposition 7.17], where one needs to change only the definition of $\varphi^c$ using essential infima.

Let us show now that $H$ is l.s.c. For this, let $\varphi \in L^1(\Omega)$ and $(\varphi_n)_{n \in \mathbb{N}}$ a sequence in $L^1(\Omega)$ such that $\varphi_n \to \varphi$ strongly in $L^1(\Omega)$ as $n \to +\infty$.

Notice first that by definition,
\[-\varphi^c(y) \geq \varphi(y), \text{ a.e. in } \Omega,\]
from where we have that $H(\varphi) > -\infty$. Because of the strong $L^1$ convergence, we know that there exists a subsequence of $(\varphi_n)_{n \in \mathbb{N}}$ (that we do not relabel), which is converging pointwise a.e. in $\Omega$ to $\varphi$. We shall work with this sequence from now on.

Writing the previous inequality for $\varphi^c_n$ and $\varphi_n$, we have that
\[
\liminf_{n \to +\infty} -\varphi^c_n(y) \geq \liminf_{n \to +\infty} \varphi_n(y) = \varphi(y), \text{ a.e. in } \Omega,
\]
where we used the fact that $\liminf$, there exists a subsequence $(\varphi_n)_{n \in \mathbb{N}}$ such that
\[
\exists \hat{\varphi}_n \text{ with } \hat{\varphi}_n \to \varphi \text{ strongly in } L^1(\Omega) \text{ as } n \to +\infty.
\]

Proof of the claim. Actually the first inequality was shown before, thus we show only the second one. Thus, by Egorov’s theorem, we have that for any $\delta > 0$ there exists a measurable set $B_\delta \subseteq \Omega$ such that $\mathcal{L}^d(B_\delta) < \delta$ and $(\varphi_n)_{n \in \mathbb{N}}$ converges uniformly to $\varphi$ as $n \to +\infty$ on $\Omega \setminus B_\delta$. Let us fix a small $\delta > 0$. We have furthermore that for any $\varepsilon > 0$ there exists $N_\varepsilon \in \mathbb{N}$ such that
\[
\varphi(x) - \varepsilon \leq \varphi_n(x) \leq \varphi(x) + \varepsilon
\]
for a.e. $x \in \Omega \setminus B_\delta$ and $n \geq N_\varepsilon$. Because of this, we have the following chain of inequalities for all $n \geq N_\varepsilon$
\[
-\varphi^c_n(y) = \sup_{x \in \Omega} \{ \varphi_n(x) - |x-y|^2 \} \geq \sup_{x \in \Omega \setminus B_\delta} \{ \varphi_n(x) - |x-y|^2 \} \geq \sup_{x \in \Omega \setminus B_\delta} \{ \varphi(x) - \varepsilon - |x-y|^2 \}.
\]
Taking $\liminf_{n \to +\infty}$ of both sides, one obtains
\[
g(y) \geq \sup_{x \in \Omega \setminus B_\delta} \{ \varphi(x) - \varepsilon - |x-y|^2 \}
\]
for a.e. $y \in \Omega$. By the arbitrariness of $\varepsilon$ and $\delta$ (in this order), one gets that
\[
g(y) \geq \sup_{x \in \Omega} \{ \varphi(x) - |x-y|^2 \} = -\varphi^c(y),
\]
as we claimed.

Notice that we have proved the following: if $(\varphi_n)_{n \in \mathbb{N}}$ is converging to $\varphi$ in $L^1(\Omega)$, then there exists a subsequence $(\varphi_{n_j})_{j \in \mathbb{N}}$ of the original sequence such that
\[
H(\varphi) \leq \liminf_{j \to +\infty} H(\varphi_{n_j}).
\]
This statement actually implies the l.s.c. of $H$ on the full sequence. Indeed, observe that by the definition of $\liminf$, there exists a subsequence $(\varphi_{n_k})_{k \in \mathbb{N}}$ of the original sequence such that
\[
\liminf_{n \to +\infty} H(\varphi_n) = \lim_{k \to +\infty} H(\varphi_{n_k}).
\]
We have shown previously that there exists a subsequence $(\varphi_{n_{k_j}})_{j \in \mathbb{N}}$ of $(\varphi_{n_k})_{k \in \mathbb{N}}$ such that
\[
H(\varphi) \leq \liminf_{j \to +\infty} H(\varphi_{n_{k_j}}).
\]
On the other hand
\[
\liminf_{j \to +\infty} H(\varphi_{n_{k_j}}) = \lim_{j \to +\infty} H(\varphi_{n_{k_j}}) = \lim_{k \to +\infty} H(\varphi_{n_k}) = \liminf_{n \to +\infty} H(\varphi_n),
\]
thus the l.s.c. of $H$ follows. 

Proposition 2.6. For all $k \in \{1, \ldots, N\}$ we have
\begin{equation}
\frac{1}{2} \partial(W_2^2(\rho, \rho_{k-1}))|_{\rho = \rho_k} = \mathcal{K}(\rho_k, \rho_{k-1})
\end{equation}

Proof. To simplify the notation, we set $k = 1$. Recall from Proposition A.3 that
\begin{equation}
\frac{1}{2} \partial(W_2^2(\rho, \rho_0))|_{\rho = \rho_1} = \partial H^*(\rho_1)
\end{equation}

for $H$ given in (2.7). From Lemma 2.4 and Lemma 2.5, it holds that
\begin{equation}
\partial H^*(\rho_1) = \operatorname{argmax}_{\phi \in L^1(\Omega)} \left\{ \int_{\Omega} \phi d\rho_1 + \int_{\Omega} \phi^c d\rho_0 \right\}.
\end{equation}

From Definition A.1, we conclude.

Lastly, let us compute the subdifferential of $\mathcal{J}$ based on [Roc71]. Before, we need the following preparatory result.

Lemma 2.7. [Roc71, Corollary 1B] Let $\psi$ and $\Psi$ be given as in (B.2). Assume that $\psi(\mu(x))$ is majorized by a summable function of $x$ for at least one $\mu \in L^\infty(\Omega)$ and that $\psi^*(\zeta(x))$ is majorized by a summable function of $x$ for at least one $\zeta \in L^1(\Omega)$. Then, an element $\xi \in L^\infty(\Omega)^*$ belongs to $\partial \Psi(\mu)$ given in (B.3) if and only if $\xi^a(x) \in \partial \psi(\mu(x))$ for a.e. $x \in \Omega$ where $\xi^a$ is the absolutely continuous component of $\xi$, and the singular component $\xi^s$ of $\xi$ attains its maximum at $\mu$ over
\begin{equation}
\{ \nu \in L^\infty(\Omega) : \Psi(\nu) < +\infty \}.
\end{equation}

Proposition 2.8. For $\rho_k$ is given in (2.3), if $\xi \in \partial \mathcal{J}(\rho_k) \cap L^1(\Omega)$, then it holds that
\begin{equation}
\xi \in \begin{cases}
[-\infty, S'(0+)] & \text{a.e. in } \{\rho_k = 0\}, \\
[S'(1-), S'(1+)] & \text{a.e. in } \{\rho_k = 1\}, \\
S' \circ \rho_k & \text{a.e. in } \{\rho_k \neq 1\}.
\end{cases}
\end{equation}

Proof. Let us show that $S$ and $S^*$ satisfies assumptions on Lemma 2.7. Let $\mu = \xi - \frac{1}{2}(1 + \mathbb{1}_\Omega)$, then $S(\mu)$ is finite, and thus in $L^1(\Omega)$. On the other hand, as $S$ is superlinear, $S^* < +\infty$ in $[0, +\infty)$. Therefore, for any constant $c \in \mathbb{R}$, $S^*(c) \in L^1(\Omega)$.

By Lemma 2.7, $\xi^a(x) \in \partial S(\rho_k(x))$ a.e., where $\xi^a$ is the absolutely continuous part of $\xi$. From the direct computation of $\partial S(\rho_k(x))$, we conclude that $\xi^a$ satisfies the right hand side of (2.11). As $\xi \in L^1(\Omega)$, the singular part of $\xi$ is zero, $\xi^s = \xi$ and we conclude (2.11).

Proof of Theorem 2.2. We only consider the case that $k = 1$. By the optimality of $\rho_1$ in (2.3), it holds that
\begin{equation}
0 \in \partial \left( \mathcal{J}(\rho_1) + \mathcal{F}(\rho) + \frac{1}{2r} W_2^2(\rho_1, \rho_0) \right)
\end{equation}

From Proposition 2.3 and Proposition 2.6, there exists $\xi \in \partial \mathcal{J}(\rho_1)$, $\overline{\phi}_1 \in \mathcal{K}(\rho_1, \rho_0)$ and $C \in \mathbb{R}$ such that
\begin{equation}
\xi + \frac{\overline{\phi}_1}{\tau} + \Phi - C = 0 \text{ a.e. on } \Omega.
\end{equation}

As $\overline{\phi}_1, \Phi \in L^1(\Omega), \xi \in \partial \mathcal{J}(\rho_1) \cap L^1(\Omega)$, Proposition 2.8 implies (2.5).

2.2. Optimality conditions for $\rho_0 \in \mathcal{P}(\Omega)$ having finite energy. In this subsection we are imposing (1.9). Let us show first that $\mathcal{J}$ satisfying the additional assumption in (1.9) defines a continuous functional on $L^s(\Omega)$. In the previous subsection, the continuity of $\mathcal{J}$ in $L^\infty(\Omega)$ directly follows from the continuity of $S$.

Lemma 2.9. Let $\mathcal{J}$ be given in (2.2) satisfying (1.9b). Then $\mathcal{J}$ is continuous in $L^s(\Omega)$ for all
\begin{equation}
s > r \text{ if } r = 1, \text{ and } s \geq r \text{ if } r > 1.
\end{equation}

Proof. From (1.9b), there exists $c > 0$ such that for all $\rho \in [0, +\infty)$ (since $S$ is also continuous, hence uniformly bounded on $[0, 1]$)
\begin{equation}
|S(\rho)| \leq c(\rho^s + 1).
\end{equation}

for all $s$ satisfying (2.12).
Consider a sequence \( \{\mu_i\}_{i \in \mathbb{N}} \subset L^s(\Omega) \) such that
\[
\mu_i \rightarrow \mu \text{ in } L^s(\Omega) \text{ as } i \rightarrow \infty.
\]
These exists a subsequence \( \{\mu_{i_j}\}_{j \in \mathbb{N}} \subset \{\mu_i\}_{i \in \mathbb{N}} \) such that
\[
\mu_{i_j} \rightarrow \mu \text{ a.e. as } j \rightarrow \infty.
\]
From (2.13), it holds that for all \( j \in \mathbb{N} \)
\[
0 \leq c(|\mu_{i_j}|^s + 1) + |S(\mu_{i_j})| \leq c(|\mu_{i_j}|^s + 1) \pm S(\mu_{i_j}).
\]
Let us apply Fatou’s lemma into \( c(|\mu_{i_j}|^s + 1) + S(\mu_{i_j}) \). From (2.14), (2.15) and the continuity of \( S \), it holds that
\[
\int_{\Omega} c(|\mu(x)|^s + 1) + S(\mu(x)) dx \leq \liminf_{j \rightarrow \infty} \int_{\Omega} c(|\mu_{i_j}(x)|^s + 1) + S(\mu_{i_j}(x)) dx,
\]
and we have
\[
\mathcal{J}(\mu) \leq \liminf_{j \rightarrow \infty} \mathcal{J}(\mu_{i_j}).
\]
Similarly to the argument at the end of the proof of Lemma 2.5, we conclude the lower semicontinuity along the full sequence, therefore
\[
\mathcal{J}(\mu) \leq \liminf_{i \rightarrow \infty} \mathcal{J}(\mu_i).
\]
Applying Fatou’s lemma again into \( c(|\mu_{i_j}|^s + 1) - S(\mu_{i_j}) \), we get
\[
\mathcal{J}(\mu) \geq \limsup_{j \rightarrow \infty} \mathcal{J}(\mu_{i_j}),
\]
and as before, we deduce the upper semicontinuity along the full sequence. Therefore (2.17) and (2.18) imply that \( \mathcal{J}(\mu) = \lim_{j \rightarrow \infty} \mathcal{J}(\mu_{i_j}) \) and \( \mathcal{J} \) is continuous in \( L^t(\Omega) \).

In what follows, we show that the minimizers of the of the minimizing movements scheme (2.3) enjoy higher order summability estimates (which are independent of \( \rho_0 \), but depend on \( \tau \)). These will play a crucial role later when deriving the optimality conditions.

**Lemma 2.10.** Suppose that \( S \) satisfies Assumption 1.1 and (1.9a). Let \( \rho_k \in \mathcal{P}(\Omega) \) be the minimizer in (2.3). Then \( \rho_k \in L^t(\Omega) \), where \( \beta := (2r - 1)d/(d - 2) \), if \( d \geq 3 \). If \( d = 2 \) then the statement is true for any \( \beta < +\infty \) and \( \beta = +\infty \) if \( d = 1 \).

**Remark 2.1.** Let us notice that the previous lemma gives an improvement on the summability of \( \rho_k \). Indeed, in case when the internal energy is of logarithmic entropy type, we know a priori that \( \rho_k \in L^1(\Omega) \), while in the case of power like entropies, we have a priori \( \rho_k \in L^t(\Omega) \). In contrast to these, we clearly improve the summability exponents in both cases.

**Proof of Lemma 2.10.** For \( \varepsilon > 0 \) let \( S_\varepsilon : [0, +\infty) \rightarrow \mathbb{R} \) smooth, strictly convex such that \( S_\varepsilon'' \geq \varepsilon \) (for some \( \varepsilon > 0 \)), \( S_\varepsilon'(0+) = -\infty \) and \( S_\varepsilon \rightarrow S \) uniformly as \( \varepsilon \rightarrow 0 \). Let \( \rho_{k,\varepsilon} \) be the unique minimizer of the problem
\[
\inf_{\rho \in \mathcal{P}(\Omega)} \left\{ E_\varepsilon(\rho) := \int_{\Omega} S_\varepsilon(\rho) dx + \mathcal{F}(\rho) + \frac{1}{2\tau} W_2^2(\rho, \rho_{k-1}) \right\}.
\]
By the assumptions on \( S_\varepsilon \), classical results imply that \( \rho_{k,\varepsilon} \) is Lipschitz continuous.

Without loss of generality, we can assume that \( S_\varepsilon \) satisfies the growth (1.9a) if \( \rho > 2 \). We can write the optimality condition
\[
S_\varepsilon''(\rho_{k,\varepsilon}) \nabla \rho_{k,\varepsilon} + \nabla \Phi + \frac{\nabla \varphi_{k,\varepsilon}^\tau}{\tau} = 0 \text{ a.e.,}
\]
where \( \varphi_{k,\varepsilon}^\tau \) is a Kantorovich potential in the transport of \( \rho_{k,\varepsilon} \) onto \( \rho_{k-1} \). From here, there exists a constant \( C > 0 \) (depending only on \( r \) and \( \tau_1 \)) such that
\[
\int_{\Omega} |S_\varepsilon''(\rho_{k,\varepsilon}) \nabla \rho_{k,\varepsilon} |^2 dx \leq C \left( \|\nabla \Phi\|_{L^\infty}^2 + \frac{1}{\tau_2} W_2^2(\rho_{k,\varepsilon}, \rho_{k-1}) \right).
\]
And in particular, for any $\ell > 2$, we have by setting $\Omega_{\ell} := \{ \rho_k^\ell > \ell \}$, 

\begin{equation}
\int_{\Omega_{\ell}} \| \nabla (\rho_k^\ell)^{-1/2} \|^2 \, dx \leq C \left( \| \nabla \Phi \|^2_{L^\infty} + \frac{1}{\tau^2} W_2^2 (\rho_k^\ell, \rho_{k-1}) \right).
\end{equation}

We know that the optimizers $\rho_k^\ell$ are Lipschitz continuous on their supports, therefore the super-level sets $\Omega_{\ell}$ are open.

Moreover, once again using the fact that $\rho_k^\ell$ is Lipschitz, we have that there exists $\delta > 0$ such that 

$$\text{dist} (\partial \Omega_{\ell}, \overline{\Omega_{\ell}}) \geq 2\delta.$$ 

Indeed, otherwise if one supposes the contrary, then for any $n \in \mathbb{N}$, there exist $x_n \in \partial \Omega_{\ell}$ and $y_n \in \Omega_{2\ell}$ such that $\text{dist}(x_n, y_n) < \frac{1}{2\delta}$, then one would have that $|\rho_k^\ell(x_n) - \rho_k^\ell(y_n)| \leq \frac{1}{n} \| \nabla \rho_k^\ell \|_{L^\infty} \to 0$, as $n \to +\infty$. However, this would be a contradiction since $\rho_k^\ell(x_n) = \ell$ and $\rho_k^\ell(y_n) \geq 2\ell$.

Now, by defining $\Omega_{\ell, \delta} := \{ \chi_{\Omega_{\ell}} \ast \eta_k > s \}$ for some $s \in (0, 1/2)$ to be set later (where $\eta_k : \mathbb{R}^d \to \mathbb{R}$ is a mollifier obtained from a smooth even kernel $\eta : \mathbb{R}^d \to \mathbb{R}$ such that $\int_{\mathbb{R}^d} \eta \, dx = 1$, $\eta \geq 0$ and $\text{spt}(\eta) \subset B_1(0)$ – by $\eta_k := \eta(\cdot / \delta)$), we have that $\Omega_{2\ell} \subset \overline{\Omega_{\ell, \delta}} \subset \Omega_{\ell}$, $\Omega_{\ell, \delta}$ is an open set, and by Sard’s theorem it has smooth boundary for $L^2$-a.e. $s \in (0, 1/2)$. We choose such an $s$.

We have in particular from (2.21) that 

\begin{equation}
\int_{\Omega_{\ell, \delta}} \| \nabla (\rho_k^\ell)^{-1/2} \|^2 \, dx \leq C \left( \| \nabla \Phi \|^2_{L^\infty} + \frac{1}{\tau^2} W_2^2 (\rho_k^\ell, \rho_{k-1}) \right),
\end{equation}

and so the Sobolev embedding theorem implies (since $\rho_k^\ell$ is only uniformly bounded in $L^r(\Omega)$) that $(\rho_k^\ell)^{-1/2} \in L^{2^*(r-1)/2}(\Omega_{\ell, \delta})$ from where $\rho_k^\ell \in L^\beta(\Omega_{\ell, \delta})$, where $\beta := 2^*(r-1)/2$, if $d \geq 3$ and $\beta < +\infty$ arbitrary if $d = 2$ and $\beta$ can be taken $+\infty$ if $d = 1$. Here we use the notation $2^* = 2d/(d-2)$.

From the above construction we can claim that $\rho_k^\ell \in L^\beta(\Omega)$. Indeed, we have 

\begin{equation}
\int_\Omega (\rho_k^\ell)^3 \, dx = \int_{\{\rho_k^\ell \leq \ell\}} (\rho_k^\ell)^3 \, dx + \int_{\Omega_{\ell, \delta}} (\rho_k^\ell)^3 \, dx + \int_{\Omega \setminus \Omega_{\ell, \delta}} (\rho_k^\ell)^3 \, dx 
\leq (2^* + 1)\delta^\beta L^d(\Omega) + C \left( \| \nabla \Phi \|^2_{L^\infty} + \frac{1}{\tau^2} W_2^2 (\rho_k^\ell, \rho_{k-1}) \right).
\end{equation}

Let us underline that this bound only depends on $W_2^2(\rho_k^\ell, \rho_{k-1})$.

Now, it is easy to see that because $S_\varepsilon \to S$ uniformly, we have that the objective functional in (2.19) $\Gamma$-converges to the objective functional in the original problem as $\varepsilon \downarrow 0$, w.r.t. the weak-$*$ convergence of probability measures. Indeed, take a sequence $(\rho^\varepsilon)_{\varepsilon > 0}$ and $\rho$ in $P(\Omega)$ such that $\rho^\varepsilon \rightharpoonup^* \rho$ as $\varepsilon \downarrow 0$. Notice that by the construction of the approximation $S_\varepsilon$, if $E_\varepsilon(\rho^\varepsilon) \leq C$ (for a constant independent of $\varepsilon$), then we have that $(\rho^\varepsilon)_{\varepsilon > 0}$ is uniformly bounded in $L^r(\Omega)$. By the uniform convergence $S_\varepsilon \to S$, we have that for any $\delta > 0$ there exists $\varepsilon_0$ such that 

$$S(\rho^\varepsilon) \leq S_\varepsilon(\rho^\varepsilon) + \delta, \quad \forall \varepsilon < \varepsilon_0.$$ 

Therefore 

$$E(\rho) \leq \liminf_{\varepsilon \downarrow 0} E(\rho^\varepsilon) \leq \liminf_{\varepsilon \downarrow 0} E_\varepsilon(\rho^\varepsilon) + \delta L^d(\Omega),$$

so the $\Gamma$-liminf inequality follows by the lower semicontinuity of the energy $E$ and the arbitrariness of $\delta > 0$. For the $\Gamma$-limsup inequality, we use a constant sequence $\rho^\varepsilon = \rho$ as a recovery sequence such that $E_\varepsilon(\rho)$ is finite for all $\varepsilon > 0$. Clearly $\lim_{\varepsilon \downarrow 0} E_\varepsilon(\rho) = E(\rho)$.

Finally, since both $\rho_k$ and $\rho_k^\ell$, the solutions of the original and the approximated problems, respectively are unique, when $\varepsilon \downarrow 0$ we find that $\rho_k$ also has the $L^\beta(\Omega)$ bound. The thesis of the lemma follows.
Lemma 2.11. Suppose that $\rho_0 \in \mathcal{P}(\Omega)$ with $\mathcal{J}(\rho_0) < +\infty$ and (1.9) hold. The curves $(\rho^*)_{t>0}$ are uniformly bounded in $L^3(\Omega)$ for $\beta$ given in

\begin{equation}
\beta := \begin{cases} 
(2r - 1) \frac{d}{d^2} & \text{if } d \geq 3, \\
(0, \infty) & \text{if } d = 2, \\
+\infty & \text{if } d = 1.
\end{cases}
\end{equation}

Proof. Let $\beta$ as in the statement of the lemma and let $(\rho^*)_{t>0}$ stand for the piecewise constant interpolations as defined in (3.9). Then, Lemma 2.10 implies that

$$
\int_0^T \int_\Omega (\rho^*)^\beta \, dx \, dt = \tau \sum_{k=1}^N \int_\Omega (\rho^*)^\beta \, dx \leq \tau NC + C \sum_{k=1}^N \frac{1}{\tau} W_2^2(\rho_k, \rho_{k-1}),
$$

where $C > 0$ depends only on the data and $\Omega$. Since $\tau N = T$ and $\sum_{k=1}^N \frac{1}{\tau} W_2^2(\rho_k, \rho_{k-1})$ is uniformly bounded (see Lemma 3.4), we conclude.

Under the above assumption, we show a result parallel to Theorem 2.2.

Theorem 2.12. Suppose that $\rho_0 \in \mathcal{P}(\Omega)$ such that $\mathcal{E}(\rho_0) < +\infty$ and (1.9) hold. Then, for all $k \in \{1, \ldots, N\}$ there exists $C = C(k) \in \mathbb{R}$ and $\overline{\phi}_k \in \mathcal{K}(\rho_k, \rho_{k-1})$ satisfying (2.5). Here, $\mathcal{K}(\rho_k, \rho_{k-1})$ and $\rho_k$ are given in Definition A.1 and (2.3), respectively.

We recall the following lemma from [Roc68] and [Roc71] and compute the subdifferential of $\mathcal{J}$ explicitly. In comparison to the previous subsection, it holds that $(L^r(\Omega))^* \equiv L^{r'}(\Omega)$ for $r \in (1, +\infty)$ where $r' := \frac{1}{r-1}$ and thus the argument below is simpler than Lemma 2.7.

Lemma 2.13. [Roc68, Theorem 2], [Roc71, Equations (1.11) & (1.12)] Let $\psi$ and $\Psi$ be given as in (B.2). Assume that $\psi(\mu(x))$ is majorized by a summable function of $x$ for at least one $\mu \in L^\infty(\Omega)$ and that $\psi^\ast(\zeta(x))$ is majorized by a summable function of $x$ for at least one $\zeta \in L^1(\Omega)$. Then, an element $\xi \in L^r(\Omega)^*$ belongs to $\partial \Psi(\mu)$ given in (B.3) if and only if $\xi(x) \in \partial \psi(\mu(x))$ for a.e. $x \in \Omega$.

Proof of Theorem 2.12. Let us set $k = 1$. The first part of the proof is parallel to Proposition 2.3 and Proposition 2.6. Let us show

\begin{equation}
\partial \left( \mathcal{J}(\rho) + \mathcal{F}(\rho) + \frac{1}{2r} W_2^2(\rho, \rho_0) \right) \bigg|_{\rho = \rho_1} = \partial \mathcal{J}(\rho_1) + \Phi + \frac{1}{\tau} \mathcal{K}(\rho_1, \rho_0)
\end{equation}

where $\mathcal{K}$ is given in Definition A.1 and the subdifferential is defined in Definition B.1. Recall $\Gamma(\cdot)$ from Definition B.2 and its equivalent property in Lemma B.1. Note that $\mathcal{J} \in \Gamma(L^r(\Omega))$ follows from the convexity of $S$ and Lemma 2.9. The same is true for $\mathcal{F}$.

Let us underline that it is crucial that we have a priori bounds on the optimizers of (2.3) in $L^\beta(\Omega)$ for some $\beta > 1$. Indeed, Lemma 2.10 yields that even if $r = 1$ (which corresponds to the logarithmic entropy type interaction energy), we have that the optimizers satisfy $\rho_k \in L^\beta(\Omega)$. In this case, without loss of generality, one considers the continuity of $\mathcal{J}$ and $\mathcal{F}$ in $L^\beta(\Omega)$. Otherwise, we gain $L^r(\Omega)$ bounds simply from the growth condition on $S$ at $+\infty$, hence we can also refer to the continuity of $\mathcal{J}$ in this space.

Furthermore, from Proposition A.3, we have

$$
H^* = \frac{1}{2} W_2^2(\cdot, \rho_0) \text{ on } L^\beta(\Omega)
$$

for $H : L^\beta(\Omega) \to \mathbb{R} \cup \{+\infty\}$ given in (2.7) and $\beta^* := \frac{2}{\beta - 1}$. Thus we get $W_2^2(\cdot, \rho_0) \in \Gamma(L^\beta(\Omega))$. Lastly, by the parallel argument in Lemma 2.5, $H$ is also in $\Gamma(L^{\beta'\ast}(\Omega))$. From Lemma B.2 and Lemma 2.4, we conclude (2.23).

The rest of the proof is parallel to that of Theorem 2.2. From (2.23) and Lemma 2.13, there exists $\xi \in \partial \mathcal{J}(\rho_1)$ satisfying (2.11), $\overline{\phi}_1 \in \mathcal{K}(\rho_1, \rho_0)$ and $C \in \mathbb{R}$ such that

$$
\xi + \frac{\overline{\phi}_1}{\tau} + \Phi - C = 0 \text{ a.e. on } \Omega.
$$

and we conclude (2.5).
2.3. **Non geodesic λ-convexity of \(J\).** Below, we discuss about the geodesic convexity of our internal energy. As we will see, in general \(J\) fails to be geodesically λ-convex. In this subsection we suppose that \(Ω\) is large enough, i.e. \(B_{r(d)}(0) \subset Ω\) for a radius \(r(d) > 0\) depending on the dimension, to be specified later.

**Theorem 2.14.** Let \(m, r > 1\) and \(c_0, c_1, a \in \mathbb{R}\) be given such that the function

\[
S(s) = \begin{cases} 
\frac{c_0}{m-1}s^m, & \text{s} \in [0,1), \\
\frac{c_1}{r} - 1 + a, & \text{s} \in [1, +\infty)
\end{cases}
\]

is convex and continuous on \([0, +\infty)\) and non-differentiable at \(s = 1\). With this choice of \(S\), let \(J\) be defined as in (2.2). Then \(J\) is not λ-convex along geodesics in \((\mathcal{P}(Ω), W_2)\) for any \(λ \in \mathbb{R}\).

**Proof.** First, from the convexity of \(S\) and its continuity non-differentiability at \(s = 1\), we have that \(S(1-) = S(1+)\) and \(S'(1-) < S'(1+)\), i.e.

\[
\text{(2.24)} \quad \frac{c_0}{m-1} = \frac{c_1}{r-1} + a \quad \text{and} \quad \frac{mc_0}{m-1} < \frac{rc_1}{r-1}.
\]

**Claim.** The function \(g : [0, +\infty) \to \mathbb{R}\) defined as \(g(s) = s^dS(s^{-d})\) fails to be λ-convex for any \(λ \in \mathbb{R}\).

**Proof of Claim.** By construction, we have

\[g(s) = \begin{cases} 
s^{d(1-m)c_0}, & s \in [0,1), \\
\frac{m}{r-1} - 
\end{cases}
\]

Since \(g\) is convex on \([0, 1)\) and on \([1, +\infty)\), we need to study \(g'(1-)\) and \(g'(1+)\). A direct computation yields

\[g'(1-) = -dc_0 \quad \text{and} \quad g'(1+) = -dc_1 + da,
\]

from where

\[g'(1-) - g'(1+) = -dc_0 + dc_1 - da = d\left(c_1 - c_0 - \frac{c_0}{m-1} + \frac{c_1}{r-1}\right) = d\left(\frac{rc_1}{r-1} - \frac{mc_0}{m-1}\right) > 0,
\]

where we have used (2.24). We conclude that \(g'(1-) > g'(1+)\), and therefore \(g\) cannot be λ-convex of any \(λ \in \mathbb{R}\).

Since \(g\) is not λ-convex for any \(λ \in \mathbb{R}\), Lemma 2.15 below implies that \(J\) cannot be λ-convex along geodesics for any \(λ \in \mathbb{R}\) and thus we conclude.

\[\square\]

**Lemma 2.15.** Let \(S : [0, +\infty) \to \mathbb{R}\) be a convex function such that \(S(0) = 0\) and it is superlinear at \(+\infty\). Let \(J : \mathcal{P}(Ω) \to \mathbb{R} \cup \{+\infty\}\) be defined as in (2.2). If \(J\) is geodesically λ-convex for some \(λ \in \mathbb{R}\), then one necessary has that \(g : (0, s(d)) \to \mathbb{R}\) defined as \(g(s) = s^dS(s^{-d})\) is \(θ\)-convex for some \(θ ∈ \mathbb{R}\) and for some \(s(d) > 1\) (depending on \(r(d)\)).

**Proof.** We follow essentially the same idea as highlighted in [Vil09, Exercise 17.22]. Let \((ρ_δ)_{δ ∈ (0,2)}\) be the curve given by \(ρ_δ := \frac{1}{\mathcal{L}^d(B_δ(0))} \mathbb{P}(B_δ(0))\). Let \(δ_0, δ_1 ∈ (0, r(d))\) such that \(δ_0 < δ_1\) be fixed, where \(r(d) > 0\) is the radius specified at the beginning of the subsection and the value of which we set below. Then \([0,1] ⊂ t → ρ_{(1-1)δ_0 + δ_1}\) is the geodesic between \(ρ_{δ_0}\) and \(ρ_{δ_1}\).

Let us notice that the optimal transport map in the transportation of \(ρ_{δ_0}\) onto \(ρ_{δ_1}\) is given by \(T(x) = (δ_1/δ_0)x\) and therefore

\[
W^2_2(ρ_{δ_0}, ρ_{δ_1}) = \frac{1}{\mathcal{L}^d(B_{δ_0}(0))} \int_{B_{δ_0}(0)} |x - T(x)|^2 \, dx = (δ_0)^{-d}(ω_d/d)^{-1}(δ_0 - δ_1)^2 \int_{B_{δ_0}} |x|^2 \, dx
\]

\[= (δ_0)^{-2-d(ω_d/d)^{-1}(δ_0 - δ_1)^2ω_d} \int_{0}^{δ_0} r^{d+1} \, dr = \frac{d}{d+2}(δ_0 - δ_1)^2,
\]

where we used the notation \(ω_d := \mathcal{L}^{d-1}(∂B_1(0))\).

**Direct computation** yields that

\[
J(ρ_δ) = \int_{B_δ(0)} S\left(\frac{1}{\mathcal{L}^d(B_δ(0))}\right) \, dx = (ω_d/d)δ^dS((d/ω_d)δ^{-d}) = (c_dδ)^dS((c_dδ)^{-d}),
\]

where \(c_d := (ω_d/d)^{1/2} .
\]

14
By the geodesic $\lambda$-convexity of $\mathcal{J}$ we have

$$\mathcal{J}(\rho_1) = \mathcal{J}(\rho_{(1-t)\delta_0 + t\delta_1}) \leq (1-t)\mathcal{J}(\rho_{\delta_0}) + t\mathcal{J}(\rho_{\delta_1}) - \frac{\lambda}{2}t(1-t)W_2^2(\rho_{\delta_0}, \rho_{\delta_1}).$$

This, by (2.25)-(2.26) implies furthermore

$$g(c_d((1-t)\delta_0 + t\delta_1)) \leq (1-t)g(c_d\delta_0) + tg(c_d\delta_1) - \frac{\lambda}{2}(1-t)\frac{d}{(cd)^2(d+2)}(c_d\delta_0 - c_d\delta_1)^2$$

Therefore, by setting $\theta := \lambda \frac{d}{(cd)^2(d+2)}$, we find that $g$ is $\theta$-convex on the interval $(0, s(d))$, with the choice of $s(d) := r(d)c_d$ and the value of $r(d) > 0$ is supposed to be large enough such that $s(d) > 1$.

**Remark 2.2.** The very same conclusion can be achieved for linear type diffusions, i.e. when $r = 1$ or $m = 1$. In such cases the corresponding branch of the energy functional has to be changed to a logarithmic entropy.

3. Linear diffusion with discontinuities – a cornerstone of our analysis

In this section we show the well-posedness of (1.4) in the most simple case considered in this paper, i.e. when the associated internal energy is an entropy of logarithmic type. We give a fine characterization of the ‘critical phase’ $\{\rho = 1\}$ via a scalar pressure field, inspired from recent works on crowd motion models with hard congestion effects (see for instance [MRC10, MS16]). In the next sections we shall see how the results and ideas from this sections will be important to build solutions for problems with more general nonlinearities.

In this section, we assume that $S : [0, +\infty) \to \mathbb{R}$ is defined by

$$S(\rho) := \begin{cases} \rho \log \rho, & \text{for } \rho \in [0, 1], \\ 2\rho \log \rho, & \text{for } \rho \in (1, +\infty). \end{cases}$$

Let us notice that $S$ defines a continuous superlinear function on $\mathbb{R}^+$ with $S'(1-) = 1$ and $S'(1+) = 2$.

Our main theorem from this section can be formulated as follows.

**Theorem 3.1.** For $\rho_0 \in \mathcal{P}(\Omega)$ such that $\mathcal{J}(\rho_0) < +\infty$ and $S$ given in (3.1), there exists $\rho \in L^1(Q) \cap AC^2([0, T]; \mathcal{P}(\Omega))$ and $p \in L^2([0, T]; H^1(\Omega)) \cap L^\infty(Q)$ with $\sqrt{p} \in L^2([0, T]; H^1(\Omega))$ such that $(\rho, p)$ is a weak solution of

$$\begin{cases}
\partial_t \rho - \Delta (\sqrt{p}) - \nabla \cdot (\nabla \Phi \rho) = 0, & \text{in } (0, T) \times \Omega, \\
\rho(0, \cdot) = \rho_0, & \text{in } \Omega, \\
(\nabla (\sqrt{p}) + \nabla \Phi) \cdot n = 0, & \text{in } [0, T] \times \partial \Omega,
\end{cases}$$

in the sense of distribution. Furthermore, $(\rho, p)$ satisfies

$$\begin{cases}
p(t, x) = 1 & \text{a.e. in } \{0 < \rho(t, x) < 1\}, \\
p(t, x) \in [1, 2] & \text{a.e. in } \{\rho(t, x) = 1\}, \\
p(t, x) = 2 & \text{a.e. in } \{\rho(t, x) > 1\}.
\end{cases}$$

If in addition $\rho_0 \in L^\infty(\Omega)$ and $\Phi$ satisfies (2.4), then $\rho \in L^2([0, T]; H^1(\Omega)) \cap L^\infty(Q)$.

In the proof of the previous theorem we rely on the minimizing movements scheme associated to the gradient flow of $\mathcal{J}$, defined in (2.3). As technical tools, we define different interpolations between the discrete in time densities $(\rho_k)_{k=0}^N$ and obtain a weak solution of (3.2) by sending $\tau \downarrow 0$. The new pressure term $p$ arises from the Wasserstein subdifferential of $\mathcal{J}$ and its ‘nontrivial’ value on the set $\{\rho = 1\}$ is due to the non-differentiability of $S$ at $s_0 = 1$.

**Definition 3.1.** Let $(\rho_k)_{k=1}^N$ be given by the minimizing movement scheme (2.3) and let $\sigma_k \in \mathcal{K}(\rho_k, \rho_{k-1})$. For $k \in \{1, \ldots, N\}$, let us define $p_k : \Omega \to \mathbb{R}$ and $p^\tau : Q \to \mathbb{R}$ by

$$p_k = p_k(\cdot; \tau) := \begin{cases} \max[C - \frac{C}{\sigma_k} - \Phi, S'(1-)] & \text{in } \rho_k^{-1}((0, 1]), \\
C - \frac{C}{\sigma_k} - \Phi & \text{in } \rho_k^{-1}(\{1\}), \\
\min[C - \frac{C}{\sigma_k} - \Phi, S'(1+)] & \text{in } \rho_k^{-1}(1, +\infty). \end{cases}$$

for $(t, x) \in ((k-1)\tau, k\tau] \times \Omega$, where the constant $C \in \mathbb{R}$ might be different at each step.
Remark 3.2. Let us notice that Lemma A.4 yields $\rho^1_k > 0$ a.e., therefore $(\rho_k^N)_{k=1}^N$ is well-defined also on the sets $\rho_k^{-1}(0,1))$. From the above definition, the optimality condition in Theorem 2.2 can be simplified as follows.

**Lemma 3.2.** For all $k \in \{1, \ldots, N\}$, there exists $C \in \mathbb{R}$ such that

\[
(3.5) \quad p_k(1 + \log \rho_k) + \frac{\Phi_k}{\tau} + \Phi = C \text{ a.e.}
\]

**Proof.** Note that a subdifferential $\partial S(\rho)$ of $S : [0, +\infty) \to \mathbb{R}$ is given by

\[
(3.6) \quad \partial S(\rho) = \begin{cases} 
1 + \log \rho & \text{for } 0 < \rho < 1, \\
[1, 2] & \text{for } \rho = 1, \\
(2 + \log \rho) & \text{for } \rho > 1.
\end{cases}
\]

Thus, Theorem 2.2 and (3.4) imply

\[
(3.7) \quad p_k = \begin{cases} 
1 & \text{in } \rho_k^{-1}(0,1)), \\
C - \frac{\Phi_k}{\tau} - \Phi \in [1, 2] & \text{in } \rho_k^{-1}(\{1\}), \\
2 & \text{in } \rho_k^{-1}((1, +\infty)).
\end{cases}
\]

Thus, we simplify (2.5) into (3.5). \hfill \Box

An easy consequence of the above constructions is the following result.

**Lemma 3.3.** For $k \in \{1, \ldots, N\}$, $p_k, p_k$ and $\Phi_k \in K(p_k, p_k - 1)$ are Lipschitz continuous in $\Omega$. Here, $\rho_k$ and $p_k$ are given in (2.3) and (3.4), respectively.

**Proof.**

Step 1. Let us show that $\Phi_k$ is Lipschitz continuous in $\Omega$. From [San15, Theorem 1.17] we have that $\Phi_k$ shares the modulus of continuity of the cost $(x, y) \mapsto |x - y|^2$. On the one hand, as $\Omega$ is compact, we conclude that $\Phi_k$ is Lipschitz continuous. On the other hand, (3.7) together with (2.5) imply that $p_k$ is Lipschitz continuous.

Step 2. From (3.5) in Lemma 3.2, we have that

\[
(3.8) \quad \rho_k(x) = \exp \left\{ \frac{1}{p_k(x)} \left( C - \frac{\Phi_k(x)}{\tau} - \Phi \right) - 1 \right\} \text{ a.e.}
\]

As $p_k$, $\Phi_k$ and $\Phi$ are Lipschitz continuous and $p_k$ has a lower bound $+1$ from (3.7), (3.8) implies that $\rho_k$ is Lipschitz continuous. \hfill \Box

### 3.1. Interpolations between the discrete in time densities, velocities, momenta and pressures.

As technical tools, similarly as it is done in the framework of models developed for instance in [MRCS10, MS16, San15], we introduce two different kinds of interpolations between the objects in the title of the subsection.

**Piecewise constant interpolations.** Let us define $\rho^\tau, p^\tau : Q \to \mathbb{R}$ and $v^\tau, E^\tau : Q \to \mathbb{R}^d$ as follows

\[
(3.9) \quad \begin{aligned}
\rho^\tau(t, x) &:= \rho_k(x; \tau), \\
v^\tau(t, x) &:= \frac{1}{\tau} \nabla \Phi_k(x), \\
E^\tau(t, x) &:= \rho^\tau(t, x) v^\tau(t, x)
\end{aligned}
\]

for $(\rho_k)_{k=1}^N$ obtained in (2.3) and $\Phi_k \in K(p_k, p_k - 1)$ given in Theorem 2.2 and let $p^\tau$ defined as in (3.4).

By standard arguments on gradient flows (see for instance [San15, Proposition 8.8], [MS16, Lemma 3.5]), we have the following.

**Lemma 3.4.** It holds that

\[
\frac{1}{2\tau} \sum_{k=1}^N W_2^2(\rho_k, p_k - 1) = \frac{1}{2\tau} \sum_{k=1}^N \int_{\Omega} |\nabla \Phi_k|^2 d\rho_k(x) \leq J(\rho_0) - \inf J.
\]

Furthermore, there exists a constant $C > 0$ such that for any $0 \leq s < t \leq T$

\[
(3.10) \quad W_2(\rho^\tau(t), \rho^\tau(s)) \leq C(t - s + \tau)^{\frac{1}{2}}.
\]

**Proposition 3.5.** Let $(\rho^\tau)_{\tau>0}$ and $(p^\tau)_{\tau>0}$ given (3.9) and (3.4), respectively. We have the followings.
(1) \( (p^*)_{	au > 0} \) is uniformly bounded in \( L^2([0, T]; H^1(\Omega)) \cap L^\infty(\Omega) \); 
(2) \( (\sqrt{p^*})_{	au > 0} \) is uniformly bounded in \( L^2([0, T]; H^1(\Omega)) \); 
(3) if in addition \( \rho_0 \in L^\infty(\Omega) \) and \( \Phi \) satisfies (2.4), then \( (p^*)_{	au > 0} \) is uniformly bounded in \( L^2([0, T]; H^1(\Omega)) \cap L^\infty(\Omega) \).

**Proof.** **Step 1.** Clearly, by construction, \( (p^*)_{	au > 0} \) is uniformly bounded. Furthermore, if \( \rho_0 \in L^\infty(\Omega) \), then Lemma 2.1 implies that \( (p^*)_{	au > 0} \) is uniformly bounded by a constant depending only on the data for all \( t \in [0, T] \).

**Step 2.** Now, let us show that \( (\nabla \sqrt{p^*})_{	au > 0} \) and \( (\nabla p^*)_{\tau > 0} \) are uniformly bounded in \( L^2(\Omega) \). Let \( \phi_k \in \mathcal{K}(\rho_k, \rho_{k-1}) \). Lemma 3.3 implies that \( \phi_k, \rho_k \) and \( p_k \) are Lipschitz continuous functions, and therefore by Rademacher’s theorem one can differentiate these function a.e. in \( \Omega \). Note that \( \{\rho_k \neq 1\} \) is an open by the continuity of \( \rho_k \) in Lemma 3.3 and thus (3.7) implies (3.11)
\[
\nabla p_k = 0 \text{ a.e. in } \{\rho_k \neq 1\}.
\]
Therefore, we get
\[
\log \rho_k \nabla p_k = 0 \text{ and } (\rho_k - 1) \nabla p_k = 0 \quad \text{a.e.}
\]

Next, we claim that
\[
\nabla p_k \cdot \nabla \rho_k = 0 \quad \text{a.e. in } \Omega.
\]

From (3.7), the above holds in the open set \( \{\rho_k \neq 1\} \) and in the interior of \( \{\rho_k = 1\} \), but we point out that \( \partial \{\rho_k = 1\} \) may have positive measure even though \( \rho_k \) is Lipschitz continuous. In order to show (3.13) in \( \Omega \), we apply the coarea formula and (3.11). As \( p_k \) is Lipschitz and \( \nabla p_k \) is in \( L^1(\Omega) \), we could use the coarea formula in [KP08, Corollary 5.2.6] and conclude that
\[
\int_\Omega |\nabla p_k| |\nabla \rho_k| \, dx = \int_\mathbb{R} \int_{(\rho_k)^{-1}(s)} |\nabla p_k| d\mathcal{H}^{d-1} \, ds,
\]
where \( \mathcal{H}^{d-1} \) stands for the \( (d - 1) \)-dimensional Hausdorff measure. From (3.11), we conclude (3.13).

Differentiating (3.5) and applying (3.12) and (3.13), we have
\[
-\frac{\nabla \phi_k}{\tau} - \nabla \Phi = \nabla (p_k (1 + \log \rho_k)) + \nabla \Phi = \nabla p_k + \frac{p_k}{\rho_k} \nabla \rho_k \quad \text{a.e.}
\]

From (3.14) and (3.13) again, we have
\[
2 \rho_k \left( \frac{|\nabla \phi_k|^2}{\tau^2} + |\nabla \Phi|^2 \right) \geq |\nabla p_k|^2 + \frac{p_k^2}{\rho_k} |\nabla \rho_k|^2 \quad \text{a.e.},
\]

from where we can write
\[
2 \rho_k \left( \frac{|\nabla \phi_k|^2}{\tau^2} + |\nabla \Phi|^2 \right) \geq |\nabla p_k|^2 + p_k^2 |\nabla \sqrt{p_k}|^2 \quad \text{a.e.}
\]

As \( p_k \in [1, 2] \) (from (3.7)), we have
\[
\int_{\Omega} \left( |\nabla p_k|^2 + |\nabla \sqrt{p_k}|^2 \right) \leq 2 \int_{\Omega} \frac{|\nabla \phi_k|^2}{\tau^2} \rho_k \, dx + 2 \mathcal{L}^d(\Omega) \|\nabla \Phi\|_{L^\infty}^2.
\]

From Lemma 3.4, we conclude that \( (\sqrt{p^*})_{	au > 0} \) and \( (p^*)_{	au > 0} \) are uniformly bounded in \( L^2([0, T]; H^1(\Omega)) \) for all \( \tau > 0 \).

Moreover, if \( \rho_0 \in L^\infty(\Omega) \), we have \( \|\rho_k\| \leq \|\rho_0\|_{L^\infty(\Omega)} e^{\int T^\Delta \Phi} \) (from Lemma 2.1), and therefore from (3.15) we get
\[
\int_{\Omega} |\nabla p_k|^2 \, dx + \int_{\Omega} \frac{1}{\|\rho_0\|_{L^\infty(\Omega)} e^{\int T^\Delta \Phi} \|\nabla \Phi\|_{L^\infty}} |\nabla p_k|^2 \, dx \leq C,
\]
from where we have \( (\rho^*)_{\tau > 0} \) is uniformly bounded in \( L^2([0, T]; H^1(\Omega)) \).

\(\square\)

**Corollary 3.6.** Let \( (p^*)_{\tau > 0} \) and \( (p^*)_{\tau > 0} \) be as in the previous proposition. There exists \( p \in L^2([0, T]; H^1(\Omega)) \) and \( \rho \in L^3(\Omega) \) such that
\[
\rho^* \rightarrow \rho \text{ in } L^1(\Omega), \text{ as } \tau \downarrow 0,
\]

17
and
\[ p^\tau \to p \text{ in } L^2([0, T]; H^1(\Omega)), \text{ as } \tau \downarrow 0. \]
along a subsequence. If in addition \( \rho_0 \in L^\infty(\Omega) \) and \( \Phi \) satisfies (2.4), then we also have \( \rho \in L^2([0, T]; H^1(\Omega)) \) and \( \rho^\tau \to \rho \text{ in } L^2(\Omega), \) as \( \tau \downarrow 0. \)

Proof. The weak sequential compactness of \( (\rho^\tau)_{\tau>0} \) follows from the uniform boundedness in \( L^2([0, T]; H^1(\Omega)) \) in the previous proposition. Also, as \( (\rho^\tau)_{\tau>0} \) has the ‘quasi-Hölder’ type estimates in Lemma 3.4 and \( (\sqrt{\rho^\tau})_{\tau>0} \) is uniformly bounded in \( L^2([0, T]; H^1(\Omega)) \), we conclude the strong compactness of \( (\rho^\tau)_{\tau>0} \) in \( L^1(\Omega) \) by a consequence of a modified version of the classical Aubin-Lions lemma in Lemma C.2, often used in similar context (see for instance [DFM14, Proposition 4.8] and [Lab17, Proposition 5.2]). If \( \rho_0 \in L^\infty(\Omega), \) the last statement simply follows from the similar arguments.

As a consequence of the above results, we have the following.

**Lemma 3.7.** \((\rho, p)\) given in Proposition 3.5 satisfies (3.3).

**Proof.** Step 1. Let \((\rho^*, p^*)\) be defined in (3.9) and (3.4). First, from (3.7), we have
\[ (p^\tau - 2)(\rho^\tau - 1)_+ = (p^\tau - 1)(\rho^\tau - 1)_- = 0 \text{ in } Q. \]
As it holds that
\[ |(\rho^\tau - 1)_+ - (\rho - 1)_+| \leq |p^\tau - \rho| \text{ and } |(\rho^\tau - 1)_- - (\rho - 1)_-| \leq |p^\tau - \rho|, \]
Proposition 3.5 implies that both \((\rho^\tau - 1)_+ \to (\rho - 1)_+ \) and \((\rho^\tau - 1)_- \to (\rho - 1)_- \) in \( L^1(\Omega) \) as \( \tau \downarrow 0 \) (up to passing to a subsequence).

Step 2. Let us show that for a.e. \( t \in [0, T] \)
\[ \int_Q (p(t,x) - 2)(p(t,x) - 1)_+ \, dx = 0 \text{ and } \int_{\Omega} (p(t,x) - 1)(\rho(t,x) - 1)_- \, dx = 0. \]
We only show the first one as the parallel arguments work for the second one. From (3.17), we have
\[ 0 = \int_Q (p^\tau(t,x) - 2)(\rho^\tau(t,x) - 1)_+ \, dx \, dt. \]
Recall that up to passing to a subsequence, \((p^\tau)_{\tau>0}\) converges weakly-\(\ast\) in \( L^\infty(\Omega) \) (see Proposition 3.5) and \((p^\tau(t,x) - 1)_+\) converges strongly (from Step 1) in \( L^1([0, T \times \Omega]) \) as \( \tau \downarrow 0 \). Combining these with (3.20), we conclude the first equation of (3.19).

As \( p^\tau \in [1, 2] \) for \( p^\tau \) given in (3.4), we have \( p \in [1, 2] \) a.e. in \( Q \). Thus, (3.19) implies that
\[ (p - 2)(\rho - 1)_+ = (p - 1)(\rho - 1)_- = 0 \text{ a.e.} \]
and we conclude (3.3). \( \square \)

**Proposition 3.8.** Let \( E^\tau \) be given in (3.9). Then up to passing to a subsequence, \((E^\tau)_{\tau>0}\) weakly-\(\ast\) converges to
\[ E := -\nabla(p\rho) − \nabla\Phi \rho, \text{ in } \mathcal{D}'(Q; \mathbb{R}^d), \]
as \( \tau \downarrow 0 \) where and \((\rho, p)\) is given in Proposition 3.5.

**Proof.** For any test function \( \zeta \in C_{c}^\infty(\Omega; \mathbb{R}^d) \), we claim that up to passing to a subsequence,
\[ \mathcal{I} := \int_Q \zeta \cdot d(E^\tau - E) \to 0, \text{ as } \tau \downarrow 0 \]
From (3.12), we have \( \log \rho^\tau \nabla p^\tau = 0 \) in a.e. in \( Q \) and thus it holds that
\[ -E^\tau = p\nabla \rho^\tau + \rho^\tau(1 + \log \rho^\tau) \nabla p^\tau + \nabla \Phi \rho^\tau = \nabla(\rho^\tau p^\tau) + \nabla \Phi \rho^\tau. \]
By the weak convergence of \((\rho^\tau)_{\tau>0}\) to \( \rho \), we already have that
\[ \int_Q \zeta \cdot \nabla \Phi \rho^\tau \, dt \to \int_Q \zeta \cdot \nabla \Phi \rho \, dt, \text{ as } \tau \downarrow 0, \]

18
we only focus on the other term. By integration by parts and from the fact that \(\zeta \in C_c^\infty(Q;\mathbb{R}^d)\), we study thus
\[
I_1 = \int_Q (\rho^\tau p^\tau - pp) \nabla \cdot \zeta \, dx \, dt
\]

By subtracting and adding the same term in the above equation, we get
\[
I_1 = I_2 + I_3 \quad \text{where} \quad I_2 = \int_Q (\rho^\tau - \rho) p^\tau \nabla \cdot \zeta \, dx \, dt \quad \text{and} \quad I_3 = \int_Q \rho (p^\tau - p) \nabla \cdot \zeta \, dx \, dt
\]

From the Hölder inequality, we have
\[
\|I_2\| \leq \|\rho^\tau - \rho\|_{L^1(Q)} \|p^\tau\|_{L^\infty(Q)} \|\nabla \cdot \zeta\|_{L^\infty(Q)}.
\]

As \(\rho^\tau \to \rho\) in \(L^1(Q)\) as \(\tau \downarrow 0\) and \(\|p^\tau\|_{L^\infty(Q)}\) is uniformly bounded (Proposition 3.5), we conclude \(I_2 \to 0\) as \(\tau \downarrow 0\). On the other hand, as \(p^\tau \rightharpoonup p\) in \(L^\infty(Q)\) as \(\tau \downarrow 0\) (Proposition 3.5), and \(\rho \in L^1(Q)\) we have \(I_3 \to 0\) as \(\tau \downarrow 0\) as well, and thus we conclude \((3.21)\).

To arrive to the continuous in time in the time continuous PDE satisfied by \((\rho, p)\) from Proposition 3.5, as technical tools (inspired from [MRCS10, MS16, San15]), we introduce a geodesic interpolation between \((\rho_n)_{n=1}^N\) and we consider the corresponding velocities and momenta as well.

More precisely, we define \(\tilde{\rho}^\tau : [0, T] \to \mathcal{P}(\Omega)\), \(\tilde{\nu}^\tau, \tilde{\mathbf{E}}^\tau \in \mathcal{M}(Q; \mathbb{R}^d)\) as follows: for \(t \in ((k-1)\tau, k\tau]\) and \(k \in \{1, \ldots, N\}\)
\[
\begin{aligned}
\tilde{\rho}^\tau(t, x) &:= \left(\frac{k\tau-t}{\tau-t} \rho^\tau(t, x) + \text{id}\right)_{\#} \rho^\tau(t, x), \\
\tilde{\nu}^\tau(t, x) &:= \nu^\tau(t, x) + \left(\frac{k\tau-t}{\tau-t} \nu^\tau(t, x) + \text{id}\right)^{-1}, \\
\tilde{\mathbf{E}}^\tau(t, x) &:= \tilde{\rho}^\tau(t, x) \tilde{\nu}^\tau(t, x),
\end{aligned}
\]

where \(\rho^\tau\) and \(\nu^\tau\) are given in \((3.9)\).

Following the very same steps as in From [San15, Lemma 8.9] and [MS16, Step 2 in Theorem 3.1], we have the following.

**Lemma 3.9.** We have that
(i) \((\tilde{\rho}^\tau)_{\tau > 0}\) is uniformly bounded in \(AC([0, T]; \mathcal{P}(\Omega))\):
(ii) there exists \(C > 0\) such that \(\int_0^T \int_\Omega |\tilde{\nu}^\tau|^2 \, dx \, dt \leq C\):
(iii) \((\tilde{\mathbf{E}}^\tau)_{\tau > 0}\) is uniformly bounded in \(\mathcal{M}(Q; \mathbb{R}^d)\).

As a consequence, we have that along a subsequence
(iv) \(\sup_{\tau \in [0, T]} W_2(\tilde{\rho}^\tau_t, \rho_t) \to 0\), as \(\tau \downarrow 0\),
(v) \(\tilde{\mathbf{E}}^\tau \rightharpoonup \mathbf{E}\), in \(\mathcal{M}(Q; \mathbb{R}^d)\), as \(\tau \downarrow 0\),

where \(\rho\) is given in Proposition 3.5 and \(\mathbf{E}\) is given in Propositon 3.8.

Now, we are ready to prove Theorem 3.1.

**Proof of Theorem 3.1.** Let us underline that the main reason for introducing the interpolations \((\tilde{\rho}^\tau, \tilde{\mathbf{E}}^\tau)\) is that by construction, they satisfy the PDE
\[
\begin{aligned}
\partial_t \tilde{\rho}^\tau + \nabla \cdot \tilde{\mathbf{E}}^\tau &= 0, \quad \text{in } (0, T) \times \Omega, \\
\tilde{\rho}^\tau(0, \cdot) &= \rho_0, \quad \text{in } \Omega, \\
\tilde{\mathbf{E}}^\tau(0, \cdot) &= \mathbf{E}_0, \quad \text{on } [0, T] \times \partial \Omega,
\end{aligned}
\]
in the distributional sense. Then, Lemma 3.9 and Proposition 3.8 allow us to conclude that \((\rho, p)\) satisfies \((3.2)\) in the distributional sense. Last, from Lemma 3.7, we conclude that \((\rho, p)\) satisfies \((3.3)\). The thesis of the theorem follows. \(\square\)
4. Linear diffusion on \{\rho < 1\} and porous medium type diffusion on \{\rho > 1\}

As we will see below, in this section the diffusion coefficients and the diffusion rates are not necessarily supposed to be the same in the regions \{\rho < 1\} and \{\rho > 1\}. Therefore, a technical difficulty arises, because of the lack of a simple way (as in (3.3)) to derive the first order necessary optimality conditions for the minimizing movement scheme. To overcome this issue, instead, we use a particular decomposition for \(S\), which allows us to use the construction from Section 3.

In this section too, we impose Assumption 1.1. If \(\rho_0 \notin L^\infty(\Omega)\), we impose additionally (1.9). Furthermore, throughout this section we suppose also the following: \(S : [0, +\infty) \rightarrow \mathbb{R}\) satisfies

\[
\frac{\rho^{-1}}{\sigma_2} \leq S''(\rho) \text{ in } (0,1)
\]

for some constant \(\sigma_2 > \sigma_1\) for \(\sigma_1\) given in (1.9a). This corresponds to (1.8) with \(m = 1\).

A direct consequence of the above assumption is the following result.

**Lemma 4.1.** \(S : [0, +\infty) \rightarrow \mathbb{R}\) satisfies

\[
S'(0+) = -\infty
\]

**Proof.** Integrating (4.1) from \(\frac{1}{2}\) to \(\rho\), it holds that

\[
S'\left(\frac{1}{2}\right) - S'(\rho) \geq \frac{1}{\sigma_2} \left(\log \frac{1}{2} - \log \rho\right)
\]

As \(\sigma_2 > 0\), we conclude that

\[
S'(\rho) \leq S'\left(\frac{1}{2}\right) - \frac{1}{\sigma_2} \log \frac{1}{2} + \frac{1}{\sigma_2} \log \rho \rightarrow -\infty \text{ as } \rho \rightarrow 0^+.
\]

\[\square\]

**Example 4.1.** For \(m > 1\), \(S : [0, +\infty) \rightarrow \mathbb{R}\) given by

\[
(4.2) \quad S(\rho) := \begin{cases} 
\rho \log \rho, & \text{for } \rho \in [0, 1], \\
\frac{1}{m-1}(\rho^m - 1), & \text{for } \rho \in (1, +\infty).
\end{cases}
\]

Note that Assumption 1.1 follows from the smoothness and strict convexity of \(S\) in \(\mathbb{R}^+ \setminus \{1\}\) and

\[
S'(1-) = 1 < S'(1+) = \frac{m}{m-1}.
\]

(4.1) is obtained by

\[
\rho S''(\rho) = \begin{cases} 
1, & \text{for } \rho \in (0, 1), \\
m\rho^{m-1} \geq m, & \text{for } \rho \in (1, +\infty).
\end{cases}
\]

(1.9) is also fulfilled with \(r = m\).

In this case, \(L_S(\rho, p)(x)\) is given by

\[
L_S(\rho, p)(x) = \begin{cases} 
\rho(x), & \text{if } 0 < \rho(x) < 1, \\
p(x) \in \left[1, \frac{m}{m-1}\right], & \text{if } \rho(x) = 1, \\
(p(x))^m + \frac{1}{m-1}, & \text{if } \rho(x) > 1.
\end{cases}
\]

Our main theorem from this section reads as:

**Theorem 4.2.** Suppose that (1.9) and (4.1) hold true. For \(\rho_0 \in \mathcal{P}(\Omega)\) such that \(J(\rho_0) < +\infty\), there exists \(\rho \in L^2(\{0, T\}; \mathcal{P}(\Omega))\) for \(\beta\) given in (2.22) and \(p \in L^2([0, T]; H^1(\Omega)) \cap L^\infty(\Omega)\) with \(\sqrt{p} \in L^2([0, T]; H^1(\Omega))\) such that \((\rho, p)\) is a weak solution of

\[
(4.3) \quad \begin{cases} 
\partial_t \rho - \Delta (L_S(\rho, p)) - \nabla \cdot (\nabla \Phi \rho) = 0, & \text{in } (0, T) \times \Omega, \\
\rho(0, \cdot) = \rho_0, & \text{in } \Omega, \\
(\nabla (L_S(\rho, p)) + \nabla \Phi \rho \cdot \mathbf{n}) = 0, & \text{in } [0, T] \times \partial \Omega.
\end{cases}
\]
in the sense of distribution. Furthermore, \((\rho,p)\) satisfies for a.e. \((t,x) \in Q\)

\[
\begin{cases}
p(t,x) = S'(1-) & \text{if } 0 < \rho(t,x) < 1, \\
p(t,x) \in [S'(1-), S'(1+)] & \text{if } \rho(t,x) = 1, \\
p(t,x) = S'(1+) & \text{if } \rho(t,x) > 1.
\end{cases}
\]

(4.4)

If in addition \(\rho_0 \in L^\infty(\Omega)\) and \(\Phi\) satisfies (2.4), we can drop (1.9) from the statement and we obtain that \(\rho \in L^2([0,T]; H^1(\Omega)) \cap L^\infty(Q)\).

Let us briefly explain the outline of the proof. First, we define \(S_a\) and \(S_b : [0, +\infty) \to \mathbb{R}\) by

\[
S_a(\rho) := \begin{cases}
S'(1-)\rho \log \rho, & \text{for } \rho \in [0, 1], \\
S'(1+)\rho \log \rho, & \text{for } \rho \in (1, +\infty),
\end{cases}
\]

and

\[
S_b(\rho) := S(\rho) - S_a(\rho).
\]

(4.5)

(4.6)

We show the convexity of \(S_a\) and twice differentiability of \(S_b\) in Lemma 4.4. This particular decomposition will be useful when deriving optimality conditions in our minimizing movement scheme. Under (4.1), we are able to apply similar arguments as the ones in Section 3.

We point out that Lemma 4.1 implies the positivity of \(\rho_k\) a.e. (See Lemma A.4). From Theorem 2.2 and (4.1), \(\rho_k\) satisfies the following lemma.

**Lemma 4.3.** Let \((\rho_k)_{k=1}^N\) be obtained via the minimizing movement scheme (2.3). For \(k \in \{1, \ldots, N\}\) and \(\hat{\phi}_k \in K(\rho_k, \rho_{k-1})\) given in Theorem 2.2, we have that

\[
\rho_k = \begin{cases}
1, & \text{in } f_k^{-1}([S'(1-), S'(1+)]), \\
(S')^{-1} \circ f_k, & \text{otherwise},
\end{cases}
\]

where \(f_k := C - \frac{\tau}{\tau_0} - \Phi, \text{ and } S'(0+) \text{ and } S'(1\pm) \text{ are given in (2.1). In particular, } \rho_k \text{ is Lipschitz continuous in } \Omega \text{ and its Lipschitz constant might degenerate when } \tau \downarrow 0.\)

**Proof.**

**Step 1.** As \(S'\) is strictly increasing function in \(\mathbb{R}^+ \setminus \{1\}\) from Assumption 1.1, (2.5) implies that \(\rho_k(x) = 1\) for \(x \in f_k^{-1}([S'(1-), S'(1+)])\). Also, as \(S'\) is invertible in \(\mathbb{R}^+ \setminus \{1\}\), therefore (2.5) implies

\[
\rho_k(x) = (S')^{-1} \circ f_k(x) \text{ for } x \in f_k^{-1}((-\infty, S'(1-)) \cup (S'(1+), +\infty))
\]

and we conclude (4.7).

**Step 2.** Let us show that \(\rho_k\) is continuous in \(\Omega\). Define \((S')^{-1} : \mathbb{R} \to \mathbb{R}\) by

\[
(S')^{-1} = \begin{cases}
1, & \text{in } [S'(1-), S'(1+)], \\
(S')^{-1}, & \text{otherwise}.
\end{cases}
\]

(4.8)

Note that from (4.7), we have

\[
\rho_k = (S')^{-1} \circ f_k.
\]

(4.9)

From the continuity and invertibility of \(S'\) in \(\mathbb{R}^+ \setminus \{1\}\), we conclude that \((S')^{-1}\) is continuous in \(\mathbb{R}\). Furthermore, from Lemma 3.3 we know that \(\tilde{\sigma}_k\) is Lipschitz continuous (and \(\Phi\) is Lipschitz continuous by assumption), therefore \(f_k\) is Lipschitz continuous. From (4.9), we conclude that \(\rho_k\) is continuous.

Lastly, as \(S'\) is strictly convex and twice differentiable in \(\mathbb{R}^+ \setminus \{1\}\) from Assumption 1.1, \((S')^{-1}\) is differentiable in \((-\infty, S'(1-)) \cup (S'(1+), +\infty)\) and on this set we have

\[
((S')^{-1})' = \frac{1}{S' \circ (S')^{-1}}.
\]

(4.10)

Thus, from (4.1) and (4.10), we conclude that a.e. in \(\rho_k^{-1}(\mathbb{R}^+ \setminus \{1\})\) we can compute

\[
|\nabla \rho_k| = \frac{|\nabla f_k|}{S'(\rho_k)} \leq \sigma_2 \|\rho_k\|_{L^\infty(\Omega)} |\nabla f_k|
\]

(4.11)

As \(f_k\) is Lipschitz continuous and \(\rho_k\) is continuous, we conclude that \(\rho_k\) is Lipschitz continuous in \(\Omega\). □

The following properties hold for \(S_a\) and \(S_b\).
Lemma 4.4. \( S_a \) is convex and continuous in \( \mathbb{R}^+ \). Also, \( S_b \) is continuously differentiable and \( S_b' \) is locally Lipschitz continuous in \( \mathbb{R}^+ \). In particular, we have

\begin{equation}
S_b(1) = S(1) \quad \text{and} \quad S_b'(1) = 0.
\end{equation}

Proof. From convexity of \( S \), it holds that \( S'(1^-) < S'(1^+) \) and thus \( S_a \) is convex. It is obviously also continuous by construction.

On the other hand, by the construction in (4.5), \( S_b(\rho) \) is differentiable on \( \mathbb{R}^+ \setminus \{1\} \). Let us show that \( S_b(\rho) \) is differentiable at \( \rho = 1 \). By differentiating (4.5) on \( \mathbb{R}^+ \setminus \{1\} \), we have that

\begin{equation}
S_b'(\rho) = \begin{cases} 
S'(1^-)(1 + \log \rho), & \text{for } \rho \in (0, 1), \\
S'(1^+)(1 + \log \rho), & \text{for } \rho \in (1, +\infty), 
\end{cases}
\end{equation}

Therefore, we conclude that

\begin{equation}
S_b'(1^-) = S'(1^-) - S_a'(1^-) = 0 \quad \text{and} \quad S_b'(1^+) = S'(1^+) - S_a'(1^+) = 0
\end{equation}

and \( S_b \) is continuously differentiable in \( \mathbb{R}^+ \). As both \( S' \) and \( S_a' \) are locally Lipschitz in \( \mathbb{R}^+ \setminus \{1\} \), \( S_b' \) is also locally Lipschitz continuous in \( \mathbb{R}^+ \setminus \{1\} \). As \( S_b' \) is continuous, we conclude that \( S_b' \) is locally Lipschitz continuous in \( \mathbb{R}^+ \). Lastly, \( S_b(1) = S(1) \) follows from \( S_b(1) = 0 \).

\[ \Box \]

Lemma 4.5. Let \( (p_k)_{k=1}^N \) be obtained via the minimizing movement scheme (2.3) and let \( (p_k)_{k=1}^N \) be constructed in (3.4). For \( k \in \{1, \ldots, N\} \), we have that

\begin{equation}
p_k(1 + \log \rho_k) + S_b'(\rho_k) + \frac{\partial |\rho_k|}{\tau} + \Phi = C, \quad \text{a.e. in } \Omega.
\end{equation}

Proof. We first note that Lemma 4.1 implies that \( \rho_k > 0 \) a.e. in \( \Omega \) (see also Lemma A.4). From Theorem 2.2, we have

\begin{equation}
p_k = \begin{cases} 
S'(1^-), & \text{in } \rho_k^{-1}(0, 1), \\
C - \frac{\partial |\rho_k|}{\tau} - \Phi, & \text{in } \rho_k^{-1}(\{1\}), \\
S'(1^+), & \text{in } \rho_k^{-1}(1, +\infty).
\end{cases}
\end{equation}

As \( S_b'(1) = 0 \), (4.13) holds in \( \rho_k^{-1}(\{1\}) \) by (4.14).

Lastly, from (4.14), in \( \rho_k^{-1}(\mathbb{R}^+ \setminus \{1\}) \) we have that

\begin{equation}
S_b'(\rho_k) = p_k(1 + \log \rho_k).
\end{equation}

As \( S' = S_a' + S_b' \) in \( \rho_k^{-1}(\mathbb{R}^+ \setminus \{1\}) \), we conclude (4.13) from Proposition 2.8.

\[ \Box \]

Remark 4.2. As \( S_b \) is differentiable, in the previous proof we also used the fact

\[ \partial S = \partial S_a + S_b', \]

the proof of which can be found for instance in [Kru03, Corollary 1.12.2].

Similarly as in Section 3, we construct piecewise constant and continuous in time interpolations \( (\rho^\tau, \nu^\tau, E^\tau) \) and \( (\tilde{\rho}^\tau, \tilde{\nu}^\tau, \tilde{E}^\tau) \). Similarly to Proposition 3.5, we can formulate the following result.

Proposition 4.6. \( (\rho^\tau)_{\tau > 0} \) and \( (p^\tau)_{\tau > 0} \) satisfy the exact same bounds as in Proposition 3.5.

Proof. Let us notice first that the uniform boundedness of \( (p^\tau)_{\tau > 0} \) in \( L^\infty(Q) \) follows from the construction in (4.14).

Let us show the other estimates from Proposition 3.5. Note that both \( S_b' \) and \( p_k \) are locally Lipschitz continuous (as we have shown in Lemma 4.4 and Lemma 4.3). Thus, Lemma 4.5 implies that

\begin{equation}
-\nabla \frac{\partial |\rho_k|}{\tau} - \nabla \Phi = \nabla p_k + \left( \frac{p_k}{\rho_k} + S_b''(\rho_k) \right) \nabla \rho_k, \quad \text{a.e. in } \Omega.
\end{equation}

By the parallel computation as in (3.15), we conclude that

\[ 2p_k \frac{\nabla |\rho_k|^2}{\tau^2} + 2p_k |\nabla \Phi|^2 \geq |\nabla p_k|^2 + p_k \left( \frac{p_k}{\rho_k} + S_b''(\rho_k) \right)^2 |\nabla \rho_k|^2 \]
From Lemma 4.8 below, we have
\[ \rho_k \left( \frac{p_k}{\rho_k} + S_b''(\rho_k) \right)^2 |\nabla \rho_k|^2 \geq \frac{1}{\sigma_2^2} |\nabla \rho_k|^2 \text{ a.e. in } \Omega. \]

The rest of arguments is parallel to Step 3 in Proposition 3.5, thus we conclude the thesis of the proposition. \( \square \)

**Corollary 4.7.** Up to passing to subsequences, the sequences \((\rho^r)_{r>0}\) and \((p^r)_{r>0}\) converge in the same sense as in Corollary 3.6.

**Remark 4.3.** From (4.16), we have
\[ 2\rho_k \frac{[\nabla \rho_k]^2}{\tau^2} + 2\rho_k |\nabla \Phi|^2 \geq \frac{|\nabla (F(\rho_k, p_k))|^2}{\rho_k}, \text{ where } F(\rho, p) := pp + \rho S_b'(\rho) - S_b(\rho). \]

Then, if \(\rho_0 \in L^\infty(\Omega)\), this observation together with the uniform \(L^\infty\) bounds on \(\rho^r\) imply uniform \(L^2([0,T]; H^1(\Omega))\) bounds on \(F(\rho^r, p^r)\).

As the proof of Proposition 3.5, we rely on the coarea formula when proving the following result.

**Lemma 4.8.** For \((\rho_k)_{k=1}^N\) and \((p_k)_{k=1}^N\) given in (2.3) and (3.4), it holds that
\[ |p_k + \rho_k S_b''(\rho_k)||\nabla \rho_k| \geq \frac{1}{\sigma_2} |\nabla \rho_k| \text{ a.e. in } \Omega. \]

**Proof.** If \(x \in \{\rho_k \neq 1\}\), then (4.15) implies that
\[ \frac{p_k(x)}{\rho_k(x)} + S_b''(\rho_k(x)) = S_a''(\rho_k(x)) + S_b''(\rho_k(x)) = S''(\rho_k(x)). \]

From (4.1), we conclude
\[ |p_k + \rho_k S_b''(\rho_k)| \geq \frac{1}{\sigma_2} \text{ a.e. in } \{\rho_k \neq 1\}. \]

Recall that as \(\rho_k\) is Lipschitz continuous from Lemma 5.7 and thus
\[ \nabla \rho_k = 0 \text{ a.e. in } \{\rho_k = 1\} \]
(see for instance [EG92, Theorem 4.(iv), Section 4.2.2]). Therefore, we conclude (4.17). \( \square \)

**Proof of Theorem 4.2.** As an initial observation, let us remark that by similar arguments as in Lemma 3.9, one obtains the same estimates for the continuous in time interpolations \((\tilde{\rho}^r, \tilde{\nabla}^r, \tilde{E}^r)\), and by passing to the limit as \(\tau \downarrow 0\), we obtain a continuity equation of the form
\[ \partial_t \rho + \nabla \cdot E = 0. \]
Since the limits of \((\tilde{\rho}^r, \tilde{E}^r)\) and \((\rho^r, E^r)\) are the same, it remains to identify the limit of the latter one to get the precise form of our limit equation.

**Step 1.** From direct computation as in (3.22), we obtain that
\[ -E^r = \rho^r \nabla (S_b'(\rho^r) + p^r (1 + \log \rho^r)) + \rho^r \nabla \Phi = \nabla (\rho^r S_b'(\rho^r) - S_b(\rho^r) + S_b(1) + p^r \rho^r) + \rho^r \nabla \Phi \]
From Proposition 4.6 and Corollary 4.7 we can claim that
\[ \nabla (\rho^r S_b'(\rho^r) - S_b(\rho^r) + S_b(1) + p^r \rho^r) \rightarrow \nabla (p S_b'(\rho) - S_b(\rho) + S_b(1) + pp), \]
as \(\tau \downarrow 0\) in the sense of distribution. Indeed, using the strong \(L^1(Q)\) compactness of \((\rho^r)_{r>0}\) and the weak-* compactness of \((p^r)_{r>0}\) in \(L^\infty(Q)\), we can pass to the limit \(\rho^r \rightarrow \rho^r\). Recall that \((\rho^r)_{r>0}\) is uniformly bounded in \(L^2(Q)\) for \(\beta\) given in (2.22). As \(r < \beta\), Corollary 4.7 yields the convergence of \((\rho^r)_{r>0}\) in \(L^r(Q)\). As the growth rate of \(p S_b'(\rho)\) and \(S_b(\rho)\) is \(r\), we conclude that \(\rho^r S_b'(\rho^r) - S_b(\rho^r) \rightarrow p S_b'(\rho) - S_b(\rho)\) in \(L^1(Q)\) as \(\tau \downarrow 0\).

**Step 2.** Let us show that
\[ p S_b'(\rho) - S_b(\rho) + S_b(1) + pp = L_S(\rho, p), \]
By parallel arguments as in Lemma 3.7, we conclude that \((\rho, p)\) satisfies (4.4). Thus, it holds that
\[(4.24) \quad \rho S_b'(\rho) - S_b(\rho) = pp, \text{ a.e. in } \rho^{-1}(\mathbb{R}^+ \setminus \{1\})\]
and we conclude (4.23) a.e. in \(\rho^{-1}(\mathbb{R}^+ \setminus \{1\})\). From (4.22) and (4.23), we conclude (4.3).

Furthermore, from Lemma 4.4, we obtain that
\[(4.25) \quad \rho S_b'(\rho) - S_b(\rho) + S_b(1) + pp = p in \rho^{-1}(\{1\}),\]
and we conclude (4.23) a.e. in \(\rho^{-1}(\{1\})\). \(\square\)

In particular, (4.3) can be also represented in the form of a continuity equation, as we show below.

**Theorem 4.9.** Suppose that (1.9) and (4.1) hold true. Let \(\rho_0\) and \((\rho, p)\) be given in Theorem 4.2. If
\[(4.26) \quad r \geq \frac{3d - 4}{2d},\]
then \((\rho, p)\) also satisfies
\[
\begin{cases}
\partial_t \rho - \nabla \cdot \left( \rho \nabla \left( S'(\rho) \mathbb{1}_{\{\rho \neq 1\}} + p \mathbb{1}_{\{\rho = 1\}} \right) \right) - \nabla \cdot (\rho \nabla \Phi) = 0, & \text{in } (0, T) \times \Omega, \\
\rho(0, \cdot) = \rho_0, & \text{in } \Omega, \\
\rho \left[ \nabla \left( S'(\rho) \mathbb{1}_{\{\rho \neq 1\}} + p \mathbb{1}_{\{\rho = 1\}} \right) + \nabla \Phi \right] \cdot n = 0, & \text{in } [0, T] \times \partial \Omega,
\end{cases}
\]
in the sense of distribution. If in addition \(\rho_0 \in L^\infty(\Omega)\) and \(\Phi\) satisfies (2.4), we can drop (1.9) and (4.25) from the statement.

**Remark 4.4.** Note that (4.25) is equivalent to \(\beta \geq 2\) for \(\beta\) given in (2.22) and the inequality holds for any \(r \geq 1\) if \(d = 1\) or \(d = 2\).

**Proof.** Note that (4.4) and (4.5) imply that \(S_b'(\rho) = p(1 + \log \rho)\) in \(\rho^{-1}(\mathbb{R}^+ \setminus \{1\})\). Furthermore, from (4.6) and (4.12), it holds that
\[(4.27) I_1 := S'(\rho) \mathbb{1}_{\{\rho \neq 1\}} + p \mathbb{1}_{\{\rho = 1\}} = p(1 + \log \rho) + S_b'(\rho)\]
From \(p \in L^2([0, T]; H^1(\Omega))\) and (4.4), we obtain
\[(4.28) \quad \rho \log \rho \nabla p = 0 \text{ a.e.} \]
From (4.27) and (4.28), we have
\[
\rho \nabla I_1 = \rho \nabla p + p \nabla \rho + \rho \nabla (S_b'(\rho)) = 0.
\]
Next, we claim that
\[
\rho \nabla p + p \nabla \rho + \rho \nabla (S_b'(\rho)) \in L^1(\Omega).
\]
Consider the first term \(\rho \nabla p\). Recall from Theorem 4.2 that \(\nabla p \in L^2(\Omega)\). If \(\rho_0 \in L^\infty(\Omega)\), then \(\rho \in L^\infty(\Omega)\) from Lemma 2.1 and thus \(\rho \nabla p \in L^1(\Omega)\). On the other hand, if (4.25) is fulfilled, then \(\beta\) given in (2.22) is greater than or equal to 2. As \(\rho \in L^2(\Omega)\) from Lemma 2.11, we obtain \(\rho \in L^2(\Omega)\) and thus \(\rho \nabla p \in L^1(\Omega)\).

Furthermore, as \(\nabla \sqrt{p} \in L^2(\Omega)\), \(\nabla p = 2\rho \nabla \sqrt{p} \in L^1(\Omega)\) and the second term is in \(L^1(\Omega)\). Lastly,
\[
\rho \nabla (S_b'(\rho)) = 2\rho \nabla \nabla \sqrt{p}
\]
As the growth rate of \(\rho \nabla S_b''(\rho)\) is \(r - \frac{1}{2}\) and \(r - \frac{1}{2} \leq \beta\), \(\rho \in L^\beta(\Omega)\) implies \(\rho \nabla S_b''(\rho) \in L^2(\Omega)\) and the last term is in \(L^1(\Omega)\).

Lastly, we have
\[
\rho \nabla I_1 = \nabla (pp + S_b'(\rho) - S_b(\rho) + S_b(1)) = \nabla L_S(\rho, p)
\]
for \(L_S\) given in (1.5). By Theorem 4.2, we conclude that \((\rho, p)\) is a weak solution of (4.26). \(\square\)

5. Porous medium type diffusion on \(\{\rho < 1\}\) and general diffusion on \(\{\rho > 1\}\)

Similarly to the classical porous medium equation, in this section we do not expect solutions to be fully supported. As in Section 3, let us first study an example with a particular nonlinearity.
5.1. Same diffusion exponent. In this subsection, we suppose that \( S : [0, +\infty) \rightarrow \mathbb{R} \) is defined by

\[
S(\rho) := \begin{cases} 
\frac{\rho^n}{m-1}, & \text{for } \rho \in [0, 1], \\
\frac{2\rho^m}{m-1} - \frac{1}{m-1}, & \text{for } \rho \in (1, +\infty).
\end{cases}
\]

where \( m > 1 \).

Our main theorem in this section can be formulated as follows.

**Theorem 5.1.** For \( \rho_0 \in \mathcal{P}(\Omega) \) such that \( J(\rho_0) < +\infty \) and \( S \) given in (5.1), there exists \( \rho \in L^2(Q) \cap \mathcal{AC}^2([0,T]; \mathcal{P}(\Omega)) \) and \( p \in L^2([0,T]; H^1(\Omega)) \cap L^\infty(Q) \) with \( \rho^{m-\frac{1}{2}} \in L^2([0,T]; H^1(\Omega)) \) such that \((\rho, p)\) is a weak solution of

\[
\begin{aligned}
\frac{\partial \rho}{\partial t} - \Delta \left( (m-1)\rho^m + 1 \right) \frac{\Delta \rho}{m} - \nabla \cdot (\nabla \Phi \rho) &= 0, & & \text{in } (0, T) \times \Omega, \\
\nabla \left( (m-1)\rho^m + 1 \right) \frac{\Delta \rho}{m} + \nabla \Phi \rho \cdot n &= 0, & & \text{in } [0, T] \times \partial \Omega,
\end{aligned}
\]

in the sense of distribution. Furthermore, \((\rho, p)\) satisfies

\[
\begin{aligned}
p(t, x) &= \frac{\rho(t, x)}{m}, & & \text{a.e. in } \{0 < \rho(t, x) < 1\}, \\
p(t, x) &= \frac{m}{m-1}, & & \text{a.e. in } \{\rho(t, x) = 1\}, \\
p(t, x) &= \frac{2m}{m-1}, & & \text{a.e. in } \{\rho(t, x) > 1\}.
\end{aligned}
\]

In addition, if \( \rho_0 \in L^\infty(\Omega) \) and \( \Phi \) satisfies (2.4), then \( \rho \in L^\infty(\Omega) \) and \( \rho^m \in L^2([0,T]; H^1(\Omega)) \).

Let us recall the definition of \((p_k)^N_{k=1}\) and \((\rho_k)^N_{k=1}\) from (2.3) and (3.4), respectively. Let us underline that in the setting of this section due to the structure of the nonlinearity we typically expect \( \text{spt}(p_k) \) to be a proper subset of \( \Omega \), unlike in the case of Lemma A.4 which was used in Section 3 and Section 4. For this reason, we expect the Lipschitz continuity of \( \rho^{-1}_k \) instead of \( p_k \).

**Lemma 5.2.** For all \( k \in \{1, \ldots, N\} \), there exists \( C \in \mathbb{R} \) such that

\[
\rho^{-1}_k p_k = C - \frac{\phi_k}{\tau} - \Phi \quad \text{a.e.}
\]

In particular, \( p_k \) and \( \rho^{-1}_k \) are Lipschitz continuous. Here, \( \phi_k \) is given in Theorem 2.2.

**Proof.** Note that

\[
\begin{aligned}
\partial S(\rho) = \begin{cases} 
\frac{m}{m-1} \rho^{m-1}, & \text{for } \rho < 1, \\
\frac{m}{m-1} \cdot \frac{2m}{m-1}, & \text{for } \rho = 1, \\
\frac{2m}{m-1} \rho^{m-1}, & \text{for } \rho > 1.
\end{cases}
\end{aligned}
\]

for \( p_k \) given in (3.4). Then, Theorem 2.12 implies that

\[
\rho^{-1}_k p_k + \frac{\phi_k}{\tau} + \Phi = C \quad \text{a.e. on } \text{spt}(p_k)
\]

for some constant \( C \in \mathbb{R} \).

Moreover, if \( \rho_k = 0 \) a.e. on some set \( A \subset \Omega \), then Theorem 2.12 and \( S'(0^+) = 0 \) from (5.5) imply that

\[ C - \frac{\phi_k}{\tau} - \Phi \leq 0 \quad \text{a.e. in } A, \]

and we conclude (5.4).

Next, recall that \( \phi_k \) is Lipschitz continuous (as shown in Lemma 3.3). From this and (5.5), we conclude that \( p_k \) and \( C - \frac{\phi_k}{\tau} - \Phi \) are Lipschitz continuous as well. As \( p_k \) is Lipschitz continuous and has a positive lower bound \( \frac{m}{m-1} \) (from (5.5) and (2.5)), we conclude that \( \rho^{-1}_k \) is also Lipschitz continuous.

\[ \square \]

**Lemma 5.3.** Let \((\rho^\tau)^{\tau>0}\) and \((p^\tau)^{\tau>0}\) stand for the piecewise constant interpolations given in (3.9) and (3.4), respectively. Then \((\rho^\tau)^{\tau>0}\) and \((p^\tau)^{\tau>0}\) are uniformly bounded in \( L^2([0,T]; H^1(\Omega)) \).
Proof. From Lemma 5.2, it holds that
\begin{equation}
(5.7) \quad I_1 := -\rho_k \frac{\partial}{\partial t} \nabla \Phi - \rho_k \frac{\partial}{\partial t} \nabla \Phi + \rho_k \nabla (\rho_k^{m-1} p_k) \ a.e.
\end{equation}
As \( p_k \) and \( \rho_k^{m-1} \) are Lipschitz continuous from Lemma 5.2, we have
\begin{equation}
(5.8) \quad I_1 = \rho_k \frac{\partial}{\partial t} p_k \nabla (\rho_k^{m-1}) + \rho_k \frac{m-1}{m} \nabla p_k \ a.e. \ on \ spt(\rho_k).
\end{equation}
Furthermore, since we have the Lipschitz continuity of \( \rho_k^{m-1} \) and (5.5), we apply the parallel argument in the proof of Proposition 3.5 and conclude that
\begin{equation}
(5.9) \quad (\rho_k^{m-\frac{1}{m}} - 1) \nabla p_k = 0 \ and \ \nabla (\rho_k^{m-1}) \cdot \nabla p_k = 0 \ a.e. \ on \ \Omega.
\end{equation}
From (5.8) and (5.9), we have that
\begin{equation}
(5.10) \quad I_1^2 = \rho_k^2 |\rho_k^{\frac{1}{m}} \nabla (\rho_k^{m-1})|^2 + |\nabla p_k|^2 \ a.e. \ on \ spt(\rho_k).
\end{equation}
As \( p_k \geq \frac{m}{m-1} \) a.e. in \( \Omega \) as in (5.5), we conclude that
\begin{equation}
(5.11) \quad I_1^2 \geq \left( \frac{m}{m-1} \right)^2 |\rho_k^{\frac{1}{m}} \nabla (\rho_k^{m-1})|^2 + |\nabla p_k|^2 \ a.e. \ on \ spt(\rho_k).
\end{equation}
From (5.9) it holds also that \( \nabla p_k = 0 \ a.e. \ on \ spt(\rho_k) = \{\rho_k = 0\} \). Furthermore, as \( \rho_k^{m-1} \) is Lipschitz continuous (see Lemma 5.2), we have
\begin{equation}
\rho_k^{\frac{1}{m}} \nabla (\rho_k^{m-1}) = 0 \ a.e. \ on \ spt(\rho_k) \cap \Omega.
\end{equation}
Therefore, (5.11) holds a.e. on \( \Omega \).

On the other hand, applying Lemma 3.4, it holds that
\begin{equation}
\int_0^T \int_\Omega I_1^2 \ dx \ dt \leq 2 (J(p_0) - \inf J) + T \mathcal{L}^d(\Omega) \|\nabla \Phi\|_{L^\infty}
\end{equation}
As \( \rho_k \frac{\partial}{\partial t} (\rho_k^{m-1}) = \frac{m-1}{m} \nabla (\rho_k^{m-\frac{1}{m}}) \) and since \( (\rho^\tau)_{\tau>0} \) is uniformly bounded in \( L^2(\Omega) \) (with \( \beta > m - 1/2 \), see Lemma 2.10) we conclude that \( ((\rho^\tau)^{m-\frac{1}{m}})_{\tau>0} \) and \( (p^\tau)_{\tau>0} \) are uniformly bounded in \( L^2([0,T];H^1(\Omega)) \) (since \( (p^\tau)_{\tau>0} \) is also uniformly bounded) and therefore we conclude.

As a consequence of Lemma 5.3 and Lemma C.2, we have the following convergence.

**Corollary 5.4.** Let \( (\rho^\tau)_{\tau>0} \) and \( (p^\tau)_{\tau>0} \) be as in the previous lemma. Then, there exists \( \rho \in L^m(\Omega) \) and \( p \in L^2([0,T];H^1(\Omega)) \) with \( \rho^{m-\frac{1}{m}} \in L^2([0,T];H^1(\Omega)) \), such that
\[ \rho^\tau \to \rho \ in \ L^m(\Omega), \ a.s. \ \tau \downarrow 0, \]
and
\[ p^\tau \to p \ in \ L^2([0,T];H^1(\Omega)), \ a.s. \ \tau \downarrow 0. \]
along a subsequence.

*Proof of Theorem 5.1.* Note that (5.5) implies (5.3) for \( (\rho^\tau, p^\tau) \). Then, a similar argument as the one in Lemma 3.7 together with the convergence results from Corollary 5.4 reveals that \( (\rho, p) \) satisfies (5.3).

Furthermore, from Lemma 5.2, we can write that
\[ \mathbf{E}^\tau = \rho^\tau \nabla \tau^\tau - \rho^\tau \nabla ((\rho^\tau)^{m-1} p^\tau) - \nabla \Phi \rho^\tau = - (m-1)p^\tau (\rho^\tau)^{m-1} \nabla \rho^\tau + (\rho^\tau)^m \nabla p^\tau - \nabla \Phi \rho^\tau. \]
Note that (5.5) implies
\[ ((\rho^\tau)^m - 1) \nabla p^\tau = 0 \ a.e. \]
From (5.12), we conclude that
\begin{equation}
(5.12) \quad (m-1)p^\tau (\rho^\tau)^{m-1} \nabla p^\tau + (\rho^\tau)^m \nabla p^\tau = (m-1)p^\tau (\rho^\tau)^{m-1} \nabla \rho^\tau + \frac{1}{m} ((m-1)(\rho^\tau)^m + 1) \nabla p^\tau.
\end{equation}
\begin{equation}
(5.13) \quad = \frac{1}{m} \nabla ((m-1)(\rho^\tau)^m + 1) p^\tau.
\end{equation}
As described in Proposition 3.8, up to passing to a subsequence and using the weak-∗ convergence of \((p^\tau)_{\tau>0}\) in \(L^\infty(Q)\) and strong convergence of \(((\rho^\tau)^m)_{\tau>0}\) in \(L^1(Q)\) from Corollary 5.4, we conclude that \((E')_{\tau>0}\) converges to

\[
E := -\frac{1}{m} \nabla \left( ([m-1] \rho^m + 1)p \right) = \nabla \Phi \rho
\]

in \(\mathcal{D}'(Q;\mathbb{R}^d)\), as \(\tau \downarrow 0\) where \((\rho, p)\) is given in Corollary 5.4. The rest of argument is parallel to the proof of Theorem 3.1.

A last remark is that if \(\rho_0 \in L^\infty(\Omega)\), then clearly \(\rho \in L^\infty(Q)\) and thus \(\rho^m \in L^2([0, T]; H^1(\Omega))\).

In particular, (5.2) can be also represented in the form of a continuity equation, as we show below. Note that the condition (5.14) below is equivalent to \(\beta \geq 2m\).

**Theorem 5.5.** For \(S\) given in (5.1), let \(\rho_0\) and \((\rho, p)\) be given in Theorem 5.1. If

\[
d \leq 4m,
\]

then \((\rho, p)\) also satisfies

\[
\begin{cases}
\partial_t \rho - \nabla \cdot \left( \rho \left( \nabla (\rho^{m-1}p) + \nabla \Phi \right) \right) = 0, & \text{in } (0, T) \times \Omega, \\
\rho(0, \cdot) = \rho_0, & \text{in } \Omega, \\
\rho \left( \nabla (\rho^{m-1}p) + \nabla \Phi \right) \cdot \mathbf{n} = 0, & \text{in } [0, T] \times \partial \Omega,
\end{cases}
\]

in the sense of distribution. If in addition \(\rho_0 \in L^\infty(\Omega)\) and \(\Phi\) satisfies (2.4), we can drop (5.14) from the statement.

**Proof.** As \(p \in L^2([0, T]; H^1(\Omega))\) and \((\rho, p)\) satisfies (5.3) from Theorem 5.1, we have

\[
\nabla p = 0 \quad \text{a.e. in } \{\rho \neq 1\}
\]

and thus

\[
(\rho^m - 1) \nabla p = 0 \quad \text{a.e.}
\]

From the direct computation using (5.17), it holds that

\[
\mathcal{I}_1 := \rho \nabla \left( \rho^{m-1}p \right) = (\rho^{m})^{\frac{m-1}{m}} \nabla \left( \rho^{\frac{m}{m-1}}p \right) = \rho^m \nabla p + \frac{m-1}{m} p \nabla (\rho^m)
\]

We claim that \(\mathcal{I}_1 \in L^1(Q)\), which is enough for the representation (5.15). Recall from Theorem 5.1 and Lemma 2.11, \(\nabla p \in L^2(Q)\), \(p \in L^\infty(Q)\) and \(\rho \in L^\beta(Q)\) for \(\beta\) given in (2.22). Consider the first term \(\rho^m \nabla p\). If \(\rho_0 \in L^\infty(\Omega)\), then \(\rho \in L^\infty(Q)\) and thus \(\rho^m \in L^2(Q)\). If (5.14) holds (which is automatically the case if \(d = 1, 2\)), then \(\beta \geq 2m\) for \(\beta\) given in (2.22) \((r = m\) in this case) and thus \(\rho^m \in L^2(Q)\). Furthermore, as \(\nabla \rho^{m-\frac{1}{2}} \in L^2(Q)\) and

\[
\nabla (\rho^m) = \frac{m}{m-\frac{1}{2}} \rho^{\frac{m}{2}} \nabla (\rho^{m-\frac{1}{2}}),
\]

so the last term is also in \(L^1(Q)\).

Lastly, it is easy to see that

\[
\mathcal{I}_1 = \frac{(m-1)\rho^m + 1}{m} \nabla p + \frac{m-1}{m} p \nabla (\rho^m),
\]

\[
= \nabla \left( ([m-1] \rho^m + 1)p \right).
\]

\[
\square
\]

5.2. **Porous medium type diffusion on** \(\{\rho < 1\}\) **and general diffusion on** \(\{\rho > 1\}\.** In this subsection, we suppose that Assumption 1.1 and (1.8) hold for some \(r \geq 1\) and \(S : [0, +\infty) \rightarrow \mathbb{R}\) satisfies (1.9) for some \(m > 1\) and a constant \(\sigma_2 > 0,\)

\[
\frac{\rho^{m-2}}{\sigma_2} < S''(\rho) \quad \text{for all } \rho \in (0, 1).
\]

Note that \(S\) can be any function satisfying the assumptions, and in particular in the case of \(r = 1\), \(S\) behaves as the logarithmic entropy when \(\rho > 1\).

Our main theorem from this section reads as:
Theorem 5.6. Suppose that (1.9), (5.18) and

\begin{equation}
 m < r + \frac{\beta}{2}
\end{equation}

hold true for \( \beta \) given in (2.22). For \( \rho_0 \in \mathcal{P}(\Omega) \) such that \( J(\rho_0) < +\infty \), there exists \( \rho \in L^\beta(Q) \) and \( p \in L^2([0,T]; H^1(\Omega)) \cap L^\infty(Q) \) such that \((\rho,p)\) is a weak solution of

\begin{equation}
 \begin{cases}
 \partial_t \rho - \Delta(\rho \cdot (\nabla \rho p)) - \nabla \cdot (\nabla \Phi \rho) = 0, & \text{in } (0,T) \times \Omega, \\
 \rho(0,\cdot) = \rho_0, & \text{in } \Omega, \\
 (\nabla (\rho \cdot (\nabla \Phi \rho)) + \nabla \Phi \rho) \cdot n = 0, & \text{in } [0,T] \times \partial \Omega,
\end{cases}
\end{equation}

in the sense of distribution. Furthermore, \((\rho,p)\) satisfies

\begin{equation}
 \begin{cases}
 p(t,x) = S'(1-) & \text{if } 0 \leq \rho(t,x) < 1, \\
 p(t,x) \in [S'(1-),S'(1+)] & \text{if } \rho(t,x) = 1, \\
 p(t,x) = S'(1+) & \text{if } \rho(t,x) > 1.
\end{cases}
\end{equation}

Here, \( L_S \) is given in (1.5). In particular,

\begin{equation}
 \rho^{n-\frac{1}{2}} \in L^2([0,T]; H^1(\Omega)) \text{ if } m \leq r \text{ and } \rho^{m-\frac{1}{2}} \in L^q([0,T]; W^{1,q}(\Omega)) \text{ if } r < m < r + \frac{\beta}{2}
\end{equation}

for \( q \in (1,2) \) given in (5.40). If in addition \( \rho_0 \in L^\infty(\Omega) \) and \( \Phi \) satisfies (2.4), we can drop (1.9) and (5.19) from the statement and we obtain \( \rho \in L^\infty(Q) \) and \( \rho^0 \in L^2([0,T]; H^1(\Omega)) \).

Example 5.1. As a nonlinearity, one can consider for instance the following one. For \( \rho \)

\begin{equation}
 S(\rho) := \begin{cases}
 \rho^m - \frac{1}{m-1} & \text{for } \rho \in [0,1], \\
 \frac{1}{m-1} - \frac{1}{r-1} & \text{for } \rho \in (1,\infty).
\end{cases}
\end{equation}

This clearly satisfies Assumption 1.1 and (5.18), since

\[ S'(1-) = \frac{m}{m-1} < \frac{r}{r-1} = S'(1+). \]

In this case, the operator \( L_S(\rho,p) \) becomes

\[ L_S(\rho,p)(x) = \begin{cases}
 \rho(x)^m + \frac{1}{m-1} & \text{if } 0 < \rho(x) < 1, \\
 \rho(x) \in \left[ \frac{m}{m-1}, \frac{1}{r-1} \right] & \text{if } \rho(x) = 1, \\
 \rho(x)^r + \frac{1}{r-1} & \text{if } \rho(x) > 1.
\end{cases} \]

First, using similar ideas as in Section 4, we choose a constant \( l \) such that

\begin{equation}
 1 < l < \beta
\end{equation}

for \( \beta \) given in (2.22) and split the function \( S \) into \( S_a \) and \( S_b : [0,\infty) \rightarrow \mathbb{R} \) defined by

\begin{equation}
 S_a(\rho) := \begin{cases}
 S'(1-)(\rho-1), & \text{for } \rho \leq 1, \\
 S'(1+)(\rho-1), & \text{for } \rho > 1,
\end{cases}
\end{equation}

and

\begin{equation}
 S_b(\rho) := S(\rho) - S_a(\rho).
\end{equation}

Note that \( S'(1+) > S'(1-) \). Then, as shown in Lemma 4.4, we conclude that \( S_a \) is convex and continuous in \([0,\infty)\). Also, \( S_b \) is continuously differentiable and \( S_b' \) is locally Lipschitz continuous in \([0,\infty)\).

Let us recall the definition of \((\rho_k)_{k=1}^N \) and \((p_k)_{k=1}^N\) from (2.3) and (3.4). Also, recall the definition of \( \Phi_k \) given in Theorem 2.2.

Lemma 5.7. For all \( k \in \{1,\ldots,N\} \), there exists \( C \in \mathbb{R} \) such that

\begin{equation}
 \rho_k^{l-1} p_k + S_b'(\rho_k) = \left( C - \frac{\Phi_k}{\tau} - \Phi \right) \quad \text{a.e.}
\end{equation}

In particular, \( p_k \) and \( \rho_k^{m-1} \) are Lipschitz continuous in \( \Omega \). Also, \( \rho_k \) is locally Lipschitz continuous in \( \text{spt}(p_k) \).
Proof. First we notice that $\overline{\phi_k}$ is Lipschitz continuous (cf. Lemma 3.3), $p_k$ and $f_k := C - \overline{\phi_k} - \Phi$ are Lipschitz continuous. Furthermore, (5.26) follows from the parallel argument in the proof of Lemma 5.2.

Next, let us show that $\rho^m_k$ is Lipschitz continuous. From (5.26), it holds that for
\begin{equation}
(5.27) \quad \rho_k = \begin{cases} 
1_{(S')^{-1}(f_k)} & \text{in } f^{-1}_k[S'(1-), S'(1+)], \\
(S')^{-1}(f_k) & \text{otherwise,}
\end{cases} \quad \text{a.e.}
\end{equation}
As $f_k$ are continuous, $\rho_k$ is continuous on each regions,
\begin{equation}
(5.28) \quad f^{-1}_k[S'(1-), S'(1+)], f^{-1}_k(-\infty, S'(1-)) \text{ and } f^{-1}_k(S'(1+), +\infty).
\end{equation}
Let us show that $\rho_k$ is continuous on the boundary between two regions. By the continuity of $f_k$, it holds that
\begin{equation}
(5.29) \quad f_k = \begin{cases} 
S'(1-) & \text{in } \partial f^{-1}_k(-\infty, S'(1-)) \cap \partial f^{-1}_k[S'(1-), S'(1+)], \\
S'(1+) & \text{in } \partial f^{-1}_k(S'(1+), +\infty) \cap \partial f^{-1}_k[S'(1-), S'(1+)].
\end{cases}
\end{equation}
As $(S')^{-1}(S'(1-)) = (S')^{-1}(S'(1+)) = 1$, (5.27) and (5.29) show the continuity of $\rho_k$ on the boundary between two regions in (5.28). Thus, we conclude that $\rho_k$ is continuous in $\Omega$.

Furthermore, as $S$ is strictly convex, $S'$ is invertible in $(1, +\infty)$. From (4.11), it holds that
\begin{equation}
|\nabla(\rho_k)^{m-1}| = (m-1)\rho_k^{m-2}|\nabla \rho_k| = (m-1)\rho_k^{m-2} \frac{\nabla f_k}{\text{S}(\rho_k)} \text{ a.e. in } \text{spt}(\rho_k).
\end{equation}
From (5.18), we have
\begin{equation}
|\nabla(\rho_k)^{m-1}| \leq \sigma_2(m-1)|\nabla f_k| \text{ a.e. in } \{x \in \Omega : 0 < \rho_k < 1\}
\end{equation}
and from the assumption (1.9a)
\begin{equation}
|\nabla(\rho_k)^{m-1}| \leq \sigma_1(m-1)|\nabla f_k|\rho_k^{m-1} \leq \sigma_1(m-1)|\nabla f_k| \max\{\|\rho_k\|_{L^{\infty}(\Omega)}^{m-1}, 1\} \text{ a.e. in } \{x \in \Omega : \rho_k > 1\}
\end{equation}
Therefore, we conclude that $\rho_k^{m-1}$ is Lipschitz continuous in $\Omega$.

Lastly, the following identity
\begin{equation}
|\nabla \rho_k| = \frac{1}{(m-1)\rho_k^{m-2}}|\nabla(\rho_k)^{m-1}| \text{ a.e. in } \text{spt}(\rho_k)
\end{equation}
displays that $\rho_k$ is locally Lipschitz continuous in $\text{spt}(\rho_k)$. \hfill \Box

Proposition 5.8. Let $(\rho^r_{\tau > 0}), (\rho^r_{\tau > 0})$ stand for the piecewise constant interpolations given in (3.9) and (3.4), respectively. Then, $(\rho^r_{\tau > 0})$ is uniformly bounded in $L^2([0, T]; H^1(\Omega))$.

(1) If $r \geq m$, then $(\rho^r)^{m-\frac{1}{2}}_{\tau > 0}$ is uniformly bounded in $L^2([0, T]; H^1(\Omega))$.

(2) If $r < m < r + \frac{2}{3}$, then $(\rho^r)^{m-\frac{3}{2}}_{\tau > 0}$ is uniformly bounded in $L^2([0, T]; W^{1,q}(\Omega))$ for some $q \in (1, 2)$.

(3) If in addition $\rho_0 \in L^\infty(\Omega)$ and $\Phi$ satisfies (2.4), then $(\rho^r)^{m}_{\tau > 0}$ is also uniformly bounded in $L^2([0, T]; H^1(\Omega))$ for any $m > 1$ and $r \geq 1$.

Proof. From Lemma 5.7, it holds that
\begin{equation}
I_1 := -\rho_k^\frac{1}{m} \nabla \overline{\phi_k} - \rho_k^\frac{1}{m} \nabla \Phi = \rho_k^\frac{1}{m} \nabla(\rho_k^{m-1} + S_b(\rho_k)) \text{ a.e. in } \text{spt}(\rho_k).
\end{equation}
We follow the very same steps and in the proof of Lemma 5.2 (where we also use (5.8) and (5.9)). Therefore, we have
\begin{equation}
I_1 = \frac{l-1}{m-1} \rho_k^{l-m+\frac{3}{2}} \nabla(\rho_k^{m-1}) + \rho_k^{l-\frac{3}{2}} \nabla \rho_k + \rho_k^\frac{3}{2} \nabla(S_b''(\rho_k)) \text{ a.e. on } \text{spt}(\rho_k).
\end{equation}
Note that
\begin{equation}
\rho_k^\frac{3}{2} \nabla(S_b''(\rho_k)) = \frac{1}{m-1} \rho_k^{\frac{1}{2}m} S_b''(\rho_k) \nabla(\rho_k^{m-1}) \text{ a.e. on } \text{spt}(\rho_k)
\end{equation}
From (5.30) and (5.31), it holds that
\begin{equation}
I_1 = \frac{1}{(m-1)\rho_k^{m-2}} ((l-1) \rho_k^{l-2} + S_b''(\rho_k)) \rho_k^\frac{3}{2} \nabla(\rho_k^{m-1}) + \rho_k^\frac{3}{2} \nabla \rho_k \text{ a.e. on } \text{spt}(\rho_k).
\end{equation}
We can apply (5.9) and conclude (since $\nabla p_k = 0$ a.e. in \{\(\rho_k \neq 1\)\}) that

$$I_1^k = \frac{1}{(m-1)^2\rho_k^{2m-4}} (l-1)^{\frac{1}{2}} p_k + S_k''(\rho_k)) \rho_k' |\nabla(p_k^{m-1})|^2 + |\nabla p_k|^2 \text{ a.e. on } \text{spt}(\rho_k).$$

(1) If $r \geq m$, then Lemma 5.9 below implies

$$I_1^k \geq \frac{\sigma_3^2}{(m-1)^2} |\nabla(p_k^{m-\frac{1}{2}})|^2 + |\nabla p_k|^2 \text{ a.e. on } \text{spt}(\rho_k).$$

for $\sigma_3$ given in (5.47). By the parallel argument in Lemma 5.3, we conclude the uniform bound in $L^2([0, T]; H^1(\Omega))$.

(2) If $r < m < r + \frac{q}{2}$, then Lemma 5.10 below yields the uniform bound of $(\nabla(p^r)^{m-\frac{1}{2}})_{r > 0}$ in $L^q(\Omega)$ for $q$ given in (5.40). On the other hand, as $2r - 1 \leq \beta$, it holds that

$$\left(\frac{m-1}{2}\right)^q = \frac{m-1}{m} \left(1 + \frac{1}{q} \right) = \frac{2m-1}{2m-2r+\beta} \leq \beta,$$

As $\rho^r$ is uniformly bounded in $L^2(\Omega)$ from Lemma 2.11, $(\rho^r)^{m-\frac{1}{2}}$ is uniformly bounded in $L^q(\Omega)$.

(3) From Lemma 5.11, we conclude that

$$I_1^k \geq \frac{\sigma_3^2}{(m-1)^2} |\nabla(p_k^{m-\frac{1}{2}})|^2 + |\nabla p_k|^2 \text{ a.e. on } \text{spt}(\rho_k).$$

The same argument as before yields that $(p^r)^{m-\frac{1}{2}}$ is uniformly bounded in $L^2([0, T]; H^1(\Omega))$.

\[\square\]

**Lemma 5.9.** Let us suppose that we are in the setting of Proposition 5.8. If $r \geq m$, it holds that

$$\left| \frac{1}{\rho_k^{m-2}} ((l-1)^{\frac{1}{2}} p_k + S_k''(\rho_k)) \rho_k' |\nabla(p_k^{m-1})| \right| \geq \sigma_3 |\nabla(p_k^{m-1/2})|,$$

where

$$\sigma_3 := \frac{m-1}{m-\frac{1}{2}} \min \left\{ \frac{1}{\sigma_1}, \frac{1}{\sigma_2} \right\}.$$

**Proof.** We claim that

$$\left| \frac{1}{\rho_k^{m-2}} ((l-1)^{\frac{1}{2}} p_k + S_k''(\rho_k)) \right| \geq \min \left\{ \frac{1}{\sigma_1}, \frac{1}{\sigma_2} \right\} \text{ in } \{\rho_k \neq 1\}$$

Recall that

$$S_k''(\rho_k) = \begin{cases} (l-1)S'(l-1)^{\frac{1}{2}} & \text{if } \rho_k < 1, \\ (l-1)S'(l+1)^{\frac{1}{2}} & \text{if } \rho_k > 1, \end{cases}$$

and thus by the definition of $p_k$ (see (3.4)) we have

$$(l-1)^{\frac{1}{2}} p_k + S_k''(\rho_k) = S_k''(\rho_k) + S_k''(\rho_k) = S''(\rho_k) \text{ a.e. in } \{\rho_k \neq 1\}$$

Thus, (5.18) implies that

$$\frac{S''(\rho_k)}{\rho_k^{m-2}} \geq \frac{1}{\sigma_2} \text{ a.e. in } \{0 < \rho_k < 1\}.$$

Furthermore, as $r \geq m$, (1.9a) implies

$$\frac{S''(\rho_k)}{\rho_k^{r-m}} \geq \frac{\rho_k^{r-m}}{\sigma_1} \geq \frac{1}{\sigma_1} \text{ a.e. in } \{\rho_k > 1\}.$$ 

and we conclude (5.34).

Recall that $\rho_k^{m-1}$ is Lipschitz continuous from Lemma 5.7. Thus, we have

$$\nabla(p_k^{m-1}) = 0 \text{ a.e. in } \{\rho_k = 1\}$$

(see for instance [EG92, Theorem 4(iv), Section 4.2.2]). As $\rho_k^{\frac{1}{m-\frac{1}{2}}} \nabla(p_k^{m-1}) = \frac{m-1}{m-\frac{1}{2}} \nabla(p_k^{m-1})$, (5.32) follows from (5.34) and (5.38).

\[\square\]
Lemma 5.10. Let us suppose that we are in the setting of Proposition 5.8. If \( r < m < r + \frac{\beta}{2} \), then

\[
\left\| \frac{1}{\rho_k^{m-2}} ((l-1)\rho_k^{l-2} p_k + S_b''(\rho_k)) \left| \nabla (\rho_k^{m-\frac{1}{2}}) \right| \right\|_{L^1(\Omega)} \geq C \left\| \nabla (\rho_k^{m-\frac{1}{2}}) \right\|_{L^1(\Omega)}
\]

for some \( q \in (1, 2) \) and a constant \( C > 0 \).

Proof. From the relation between \( r \) and \( m \), the constant \( q \) defined by

\[
q := \frac{1 - \frac{r}{m}}{1 - \frac{r}{\beta} + \frac{1}{2}}
\]

is in the interval \((1, 2)\). As shown in (5.35), it holds that

\[
\mathcal{I}_2 := \frac{1}{\rho_k^{m-2}} ((l-1)\rho_k^{l-2} p_k + S_b''(\rho_k)) \left| \nabla (\rho_k^{m-\frac{1}{2}}) \right| = \frac{S''(\rho_k)}{\rho_k^{m-2}} \left| \nabla (\rho_k^{m-\frac{1}{2}}) \right| \text{ a.e. in } \{\rho_k \neq 1\}
\]

In \( \{0 < \rho_k < 1\} \), (5.36) implies that

\[
\left\| \mathcal{I}_2 \right\|_{L^q(0 < \rho_k < 1)} \geq \frac{1}{\sigma_2} \left\| \nabla (\rho_k^{m-\frac{1}{2}}) \right\|_{L^2(0 < \rho_k < 1)}
\]

for \( \sigma_2 \) given in (5.18). As \( q \in (1, 2) \) and the domain is compact, the Hölder inequality yields that

\[
\left\| \mathcal{I}_2 \right\|_{L^q(0 < \rho_k < 1)} \geq \frac{\Omega^{\frac{1}{2} - \frac{1}{q}}}{\sigma_2} \left\| \nabla (\rho_k^{m-\frac{1}{2}}) \right\|_{L^2(0 < \rho_k < 1)}
\]

Next, we claim that

\[
\left\| \mathcal{I}_2 \right\|_{L^2(\rho_k > 1)} \geq C \left\| \nabla (\rho_k^{m-\frac{1}{2}}) \right\|_{L^2(\rho_k > 1)}
\]

for some constant \( C > 0 \).

From (1.9) (and 5.41), it holds that

\[
\left\| \mathcal{I}_2 \right\|_{L^2(\rho_k > 1)} = \left\| \rho_k^{2-m} S''(\rho_k) \nabla (\rho_k^{m-\frac{1}{2}}) \right\|_{L^2(\rho_k > 1)} \geq \frac{1}{\sigma_1} \left\| \rho_k^{r-m} \nabla (\rho_k^{m-\frac{1}{2}}) \right\|_{L^2(\rho_k > 1)}
\]

On the other hand, as

\[
\frac{1}{2} + \frac{m - r}{\beta} = \frac{1}{q},
\]

the Hölder inequality yields that

\[
\left\| \rho_k^{r-m} \nabla (\rho_k^{m-\frac{1}{2}}) \right\|_{L^2(\rho_k > 1)} \left\| \rho_k^{m-r} \right\|_{L^2(\rho_k > 1)} \geq \left\| \nabla (\rho_k^{m-\frac{1}{2}}) \right\|_{L^2(\rho_k > 1)}
\]

As \( \rho_k \) is uniformly bounded in \( L^2(\Omega) \) from Lemma 2.10, \( \rho_k^{m-r} \) is uniformly bounded in \( L^{\frac{2}{m-r}}(\Omega) \). From (5.44) and (5.45), we conclude (5.43).

Lastly, as (5.38) holds true, (5.39) follows from (5.42) and (5.43).

\[\square\]

Lemma 5.11. Let us suppose that we are in the setting of Proposition 5.8. If \( \rho_0 \in L^\infty(\Omega) \) and \( \Phi \) satisfies (2.4), then it holds that

\[
\left| \frac{1}{\rho_k^{m-2}} ((l-1)\rho_k^{l-2} p_k + S_b''(\rho_k)) \rho_k^{\frac{1}{2}} \left| \nabla (\rho_k^{m-1}) \right| \right| \geq \sigma_4 \left| \nabla (\rho_k^{m}) \right|,
\]

where

\[
\sigma_4 := \frac{m - \min \{ 1, \sigma_1, \frac{1}{\sigma_2} \}}{m - \min \{ 1, \frac{1}{\sigma_1}, \frac{1}{\sigma_2} \}} \min \left\{ \left( \left\| \rho_0 \right\|_{L^\infty} e^{dt\|\Delta \Phi\|_{L^\infty}} \right)^{-\frac{m - \frac{1}{2}}{2}}, \left( \left\| \rho_0 \right\|_{L^\infty} e^{dt\|\Delta \Phi\|_{L^\infty}} \right)^{-\frac{m - \frac{1}{2}}{2}} \right\}
\]

Proof. Recall from Lemma 2.1 that if \( \rho_0 \in L^\infty(\Omega) \), then we have

\[
\left\| \rho_k \right\|_{L^\infty} \leq \left\| \rho_0 \right\|_{L^\infty} e^{dt\|\Delta \Phi\|_{L^\infty}} := C.
\]

On the other hand, from (5.35) and \( \nabla (\rho_k^{m-1}) = \frac{m - \frac{1}{2}}{m} \nabla (\rho_k^{m}) \), it holds that

\[
\mathcal{I}_3 := \frac{1}{\rho_k^{m-2}} ((l-1)\rho_k^{l-2} p_k + S_b''(\rho_k)) \rho_k^{\frac{1}{2}} \left| \nabla (\rho_k^{m-1}) \right| = \frac{m - 1}{m} \frac{S''(\rho_k)}{\rho_k^{m-2}} \nabla (\rho_k^{m}) \text{ a.e. in } \{\rho_k \neq 1\}.
\]
Then, \((5.36)\) and \((5.48)\) yield that
\[
|I_3| \geq \frac{m-1}{m \sigma_2} \rho_k^{-\frac{r}{2}} |\nabla (\rho_k^m)| \geq \frac{m-1}{m \sigma_2} C^{-\frac{r}{2}} |\nabla (\rho_k^m)| \quad \text{a.e. in } \{0 < \rho_k < 1\}.
\]
Furthermore, \((1.9b)\) and \((5.48)\) imply that
\[
|I_3| \geq \frac{m-1}{m \sigma_1} \rho_k^{r-m-\frac{r}{2}} |\nabla (\rho_k^m)| \geq \frac{m-1}{m \sigma_1} C^{-\frac{r}{2}} \min \{C^{r-m}, 1\} |\nabla (\rho_k^m)| \quad \text{a.e. in } \{\rho_k > 1\}.
\]
Lastly, as \((5.38)\) holds, \((5.46)\) follows from \((5.50)\) and \((5.51)\).

**Corollary 5.12.** Let \((\rho^r)_{r>0}\) and \((p^r)_{r>0}\) be as in the previous proposition and \((5.19)\) hold. There exists \(\rho \in L^\beta(Q)\) and \(p \in L^2([0,T]; H^1(\Omega))\) such that
\[
\rho^r \to \rho \text{ in } L^*(Q), \quad \tau \downarrow 0,
\]
and
\[
p^r \to p \text{ in } L^2([0,T]; H^1(\Omega)), \quad \tau \downarrow 0.
\]
along a subsequence for any \(s \in (0, \beta)\) and \(\beta\) given in \((2.22)\).

**Proof.** Recall that Lemma 2.11 yields that \((\rho^r)_{r>0}\) is uniformly bounded in \(L^\beta(Q)\). In both cases \(r \geq m\) and \(r < m < r + \frac{d}{2}\), Lemma C.2 and Proposition 5.8 yield \((\rho^r)_{r>0}\) is precompact in \(L^*(Q)\) for any \(s \in (0, \beta)\).

Indeed, we consider the case \(r < m < r + \frac{d}{2}\). We apply Proposition 5.8(2) and Lemma C.2(1) to conclude that \((\rho^r)_{r>0}\) converges to \(\rho\) in \(L^\beta(L^{\frac{d-1+q}{2}}(Q))\) along a subsequence, where \(q^* := \frac{\beta - q}{d - q}\) and \(q \in (1, 2)\) is given in Proposition 5.8(2). Note that a direct computation shows that
\[
q^* = \frac{2r - 1}{2m - 1} \frac{2d}{d - 2} = \frac{\beta}{m - 1/2}.
\]
By a similar argument, we conclude the strong convergence of \((\rho^r)_{r>0}\) in \(L^*(Q)\) along a subsequence, also in the case when \(r \geq m\).

**Proof of Theorem 5.6.** Note that by the direct computation as in \((5.13)\) and \((4.21)\), we have
\[
-\mathbf{E}^\tau = -\rho^r \mathbf{V}^\tau = \rho^r \nabla ((\rho^r)^{l-1} p^r + S_b^l(\rho^r)) + p^r \nabla \Phi,
\]
\[
= \nabla \left( \frac{1}{l} ((l-1)(\rho^r)^l + 1)p^r + \rho^r S_b^l(\rho^r) - S_b(l) + S_b(1) \right) + p^r \nabla \Phi.
\]
Then, we have \(-\mathbf{E}^\tau = \nabla L_S(\rho^r, p^r) + \rho^r \nabla \Phi\) for \(L_S\) given in \((1.5)\). Since \(l, r < \beta\) from \((5.19)\), Corollary 5.12 yields that \((\rho^r)^l, \rho^r S_b^l(\rho^r)\) and \(S_b(\rho^r)\) converge in \(L^1(Q)\) as \(\tau \downarrow 0\). As \(p^r\) is uniformly bounded, we conclude that
\[
-\mathbf{E}^\tau \to \nabla \left( \frac{1}{l} ((l-1)(\rho^r)^l + 1)p^r + \rho S_b^l(\rho) - S_b(\rho) + S_b(1) \right) + \rho \nabla \Phi, \quad \tau \to 0
\]
along a subsequence in \(\mathcal{D}'(Q; \mathbb{R}^d)\). Note that we have \(\rho \in L^\beta\) from the uniform boundedness in Lemma 2.11 and \(p \in L^2([0,T]; H^1(\Omega)) \cap L^\infty(Q)\) from Proposition 5.8. As
\[
L_S(\rho, p) = \frac{1}{l} ((l-1)(\rho^l + 1)p^r + \rho S_b^l(\rho) - S_b(\rho) + S_b(1))
\]
for \(L_S\) given in \((1.5)\), we conclude that \((\rho, p)\) satisfies \((5.20)\). The rest of argument is parallel to Theorem 4.2.

In particular, \((5.2)\) can be also represented in the form of a continuity equation, as we show below.

**Theorem 5.13.** Suppose that \((1.9)\) and \((4.1)\) hold true. Let \(\rho_0\) and \((\rho, p)\) be given in Theorem 5.6. If
\[
m < r + \frac{1}{2}
\]
and
\[
\beta > 2 \text{ and } m < \frac{\beta}{2} + \frac{1}{2}
\]
(5.53) and (5.54) hold true. Let \(\rho_0\) and \((\rho, p)\) be given in Theorem 5.6. If
\[
m < r + \frac{1}{2}
\]
and
\[
\beta > 2 \text{ and } m < \frac{\beta}{2} + \frac{1}{2}
\]
hold, then \((\rho, p)\) is a weak solution of

\[
\begin{aligned}
\rho(0, \cdot) &= \rho_0, \\
\rho \left[ \nabla \left( S'(\rho) \mathbb{1}_{(\rho \neq 1)} + p \mathbb{1}_{(\rho = 1)} \right) \right] + \nabla \Phi &= 0, \quad \text{in } (0, T) \times \Omega, \\
\rho \left( \frac{\nabla \Phi}{\rho} \right) \cdot n &= 0, \quad \text{in } [0, T] \times \partial \Omega,
\end{aligned}
\]

in the sense of distribution. If in addition \(\rho_0 \in L^\infty(\Omega)\) and \(\Phi\) satisfies (2.4), we can drop (5.54) from the statement.

Here, note that if \(d = 1\) or 2, (5.54) holds true for any \(m\).

**Proof.** (5.53) implies (5.19) and thus (5.22) follows from Proposition 5.8. From (5.54), we can choose \(l\) such that

\[
\max \left\{ 1, m - \frac{1}{2} \right\} < l \leq \frac{\beta}{2}.
\]

From (5.21) and the construction in (5.24), we have

\[
S'(\rho) \mathbb{1}_{(\rho \neq 1)} + p \mathbb{1}_{(\rho = 1)} = pp^{l-1} + S'_b(\rho).
\]

We claim that

\[
\rho \nabla (pp^{l-1} + S'_b(\rho)) \in L^1(\Omega). \tag{5.57}
\]

By the direct computation, we obtain

\[
\rho \nabla (pp^{l-1} + S'_b(\rho)) = \nabla pp^l + \rho \nabla (\rho^{l-1}) + \rho \nabla (S'_b(\rho)),
\]

\[
= \nabla pp^l + \frac{l-1}{m-\frac{1}{2}} pp^{l-m+\frac{1}{2}}(\rho^{m-\frac{1}{2}}) + \frac{1}{m-\frac{1}{2}} S''_b(\rho) \rho^{2-m} \nabla (\rho^{m-\frac{1}{2}})
\]

As \(\rho \in L^2(\Omega)\) and \(\beta \geq 2l\), \(\rho^l \in L^2(\Omega)\) and thus \(\nabla pp^l \in L^1(\Omega)\). Now, let us consider the second term. From (5.22), \(\nabla (\rho^{m-\frac{1}{2}}) \in L^2(\Omega)\) for \(q\) given in (5.40) and \(m, r\) satisfying (19). Recall that \(p \in L^\infty(\Omega)\) and \(\rho \in L^\beta(\Omega)\). As \(l \leq \frac{\beta}{2}\) from (5.56), we have

\[
\frac{1}{q} + \frac{m-r+\frac{1}{2}}{\beta} = m - r + \frac{1}{2} + \frac{l-m+\frac{1}{2}}{\beta} = 1
\]

Thus, from the Hölder inequality, we conclude that the second term in (5.58) is in \(L^1(\Omega)\). Similarly, as \(r-m+\frac{1}{2} > 0\) from (5.53), \(S''_b(\rho) \rho^{2-m} \in L^{\frac{\alpha}{r-m+\frac{1}{2}}}(\Omega)\) and

\[
\frac{1}{q} + \frac{r-m+\frac{1}{2}}{\beta} = 1 + \frac{1}{2\beta} \leq 1,
\]

we conclude that the third term is in \(L^1(\Omega)\) and (5.57).

Next, we claim that

\[
\rho \nabla (pp^{l-1} + S'_b(\rho)) = \nabla L_S(\rho, p) \tag{5.59}
\]

for \(L_S\) given in (1.5). As \(p \in L^2([0, T]; H^1(\Omega))\) and \((\rho, p)\) satisfies (5.3) from Theorem 5.1, we have

\[
\nabla p = 0 \quad \text{a.e. in } \{\rho \neq 1\}. \tag{5.60}
\]

As \(\rho^l \in L^2(\Omega)\) from Theorem 5.6 and (5.56), we have

\[
(\rho^l - 1) \nabla p = 0 \quad \text{a.e.} \tag{5.61}
\]

From the direct computation using (5.61), it holds that

\[
\rho \nabla (\rho^{-1} p) = \rho^{\frac{l}{l-1}} \nabla \left( (\rho^{\frac{l}{l-1}}) \rho^l \right) = \rho \nabla p + \frac{l-1}{l} p \nabla (\rho^l),
\]

\[
= \left( \frac{l-1}{l} \rho^l + 1 \right) \nabla p + \frac{l-1}{l} p \nabla (\rho^l),
\]

\[
= \nabla \left( (l-1) \rho^l + 1 \right) \frac{p}{l}.
\]

Therefore, we have

\[
\nabla (pp^{l-1} + S'_b(\rho)) = \nabla \left( ((l-1) \rho^l + 1) \frac{p}{l} + \rho S'_b(\rho) - S_b(\rho) + S_b(1) \right). \tag{5.62}
\]

From (5.52) and (5.62), we conclude (5.59).
Lastly, note that if $\rho_0 \in L^\infty(\Omega)$ and and $\Phi$ satisfies (2.4), then $\rho \in L^\infty(Q)$ and thus $\rho' \in L^2(Q)$ for any $l > 0$. Furthermore, we choose $l = m+1$, then from Proposition 5.8.(3), we conclude that $p\rho \nabla(\rho^m) \in L^1(Q)$. Therefore, we show (5.57) without (5.54).

\[ \square \]

6. Uniqueness via an $L^1$-contraction

We construct an $L^1$ contraction result, inspired by [DMM16, Section 3] and [Váz07, Theorem 6.5]. In particular, this will imply the uniqueness of the solution of (4.3)-(4.4) and (5.20)-(5.21). Let us underline the fact that because of the generality of the previous two problems, on the one hand, the techniques from [DMM16, Section 3] do not apply directly. On the other hand, because of the presence of the critical regimes $\{\rho' = 1\}$, $i = 1, 2$, the construction from [Váz07, Theorem 6.5] does not apply directly either. Therefore, we develop a careful combination of these two approaches to be able to provide an $L^1$-contraction for all the systems considered previously, with general initial data.

**Theorem 6.1.** Let $(\rho^1, p^1), (\rho^2, p^2)$ be solutions to (1.4)-(1.6) with initial conditions $\rho^0_i, \rho^2_i \in \mathcal{P}(\Omega)$ such that $\mathcal{J}(\rho^0) < +\infty, i = 1, 2$. Suppose that $L_S(\rho^i, p^i) \in L^2(Q), i = 1, 2$. Then we have

\[ \|\rho^1_t - \rho^2_t\|_{L^1(\Omega)} \leq \|\rho^1_0 - \rho^2_0\|_{L^1(\Omega)}, \quad \mathcal{L}^1 \text{-a.e. } t \in [0, T]. \]

**Remark 6.1.** It worth noticing that the assumption $L_S(\rho^i, p^i) \in L^2(Q), i = 1, 2$ in the statement of the previous theorem seems quite natural in the setting of $L^1$-type contractions for porous medium equations (see [Váz07]). In our setting, because of the $L^2(Q)$ estimates on $\rho'$ (where $\beta$ is defined in (2.22)) and because of the $L^1$-type growth condition on $L_S$ at $+\infty$, this assumption is fulfilled already if $\beta \geq 2r$. In the same time, no assumption is needed if the initial data is in $L^\infty(\Omega)$, since in that case $L^\infty$ estimates hold true for $\rho_t$ for a.e. $t \in [0, T]$ (see Lemma 2.1).

**Proof.** Let $(\rho^1, p^1)$ and $(\rho^2, p^2)$ be two solutions to (1.4)-(1.6) with initial data $\rho^0_1$ and $\rho^0_2$ respectively. Let $\varphi \in C_c^2((0, T] \times \Omega)$ and using the notation

\[ \mathcal{I}(\varphi, t) := \int_\Omega \varphi_t (\rho^1_t - \rho^2_t) \, dx \]

we compute

\[ \frac{d}{dt} \mathcal{I}(\varphi, t) = \int_\Omega \frac{\partial_t \varphi (\rho^1_t - \rho^2_t)}{\rho^1_t - \rho^2_t} + \varphi \frac{\partial_t (\rho^1_t - \rho^2_t)}{\rho^1_t - \rho^2_t} \, dx \]

Now, using the equation (4.3) and by integrating the above expression on $(0, t)$, we get

\begin{equation}
\mathcal{I}(\varphi, t) = \mathcal{I}(\varphi, 0) + \int_0^t \int_\Omega \partial_t \varphi (\rho^1 - \rho^2) + \Delta \varphi (L_S(\rho^1, p^1) - L_S(\rho^2, p^2)) - \nabla \varphi \cdot \nabla \Phi (\rho^1 - \rho^2) \, dx \, ds
\end{equation}

\[ = \mathcal{I}(\varphi, 0) + \int_0^t \int_\Omega \left( L_S(\rho^1, p^1) - L_S(\rho^2, p^2) \right) [A \partial_t \varphi + \Delta \varphi - A \nabla \Phi \cdot \nabla \varphi] \, dx \, ds, \]

where we use the notation

\[ A := \frac{\rho^1 - \rho^2}{L_S(\rho^1, p^1) - L_S(\rho^2, p^2)}, \]

with the convention $A = 0$, when $L_S(\rho^1, p^1) = L_S(\rho^2, p^2)$. Note that Lemma 6.2 below implies that if $L_S(\rho^1, p^1) = L_S(\rho^2, p^2)$ a.e., then $\rho^1 = \rho^2$ and $p^1 = p^2$ a.e. Furthermore, on this very particular set actually there is no contribution in the integral on the right hand side of (6.1), so it is meaningful to set $A = 0$ there. Also, because of the monotonicity property of the operator $L_S$ (see Lemma 6.2), we have that $A \geq 0$ a.e. in $Q$.

Similarly to the arguments from [DMM16, Section 3], for $\zeta : \Omega \rightarrow \mathbb{R}$ smooth with $|\zeta| \leq 1$, we consider the dual backward equation as

\begin{equation}
\left\{ \begin{array}{ll}
A \partial_t \varphi + \Delta \varphi - A \nabla \Phi \cdot \nabla \varphi = 0, & \text{in } (0, T) \times \Omega, \\
\nabla \varphi \cdot n = 0, & \text{on } (0, T) \times \partial \Omega, \\
\varphi(T, \cdot) = \zeta, & \text{in } \Omega.
\end{array} \right.
\end{equation}

Let us notice that if we are able to construct a suitable (weak) solution $\varphi$ to (6.3), for which the computations in (6.1) remain valid, we can deduce the $L^1$-contraction result, after optimizing w.r.t. $\zeta$. In general one cannot hope for smoothness of $A$, and so (6.3) is degenerate. Therefore, we introduce suitable approximations which will allow to construct smooth test function.
Let us define two Borel sets

\[ E_1 := \{ \rho^1 \geq 1/2 \} \cup \{ \rho^2 \geq 1/2 \} \]

and \( E_2 := Q \setminus E_1 \). We suppose that both sets \( E_1 \) and \( E_2 \) have positive measures w.r.t. \( \mathcal{L}^{d+1} \), otherwise we simply do not consider the negligible one in the consideration below. First, by Lemma 6.3, we have that \( A \mathbb{1} E_1 \) is bounded. Second we have the following

**Claim.** \( A^{-1} \mathbb{1} E_2 \in L^2(E_2) \).

**Proof of the claim.** Let us notice that we can write

\[ E_2 = \left( \{ \rho^1 < 1/2 \} \cap \{ \rho^2 \geq 1/2 \} \right) \cup \left( \{ \rho^1 \geq 1/2 \} \cap \{ \rho^2 < 1/2 \} \right) \cup \left( \{ \rho^1 < 1/2 \} \cap \{ \rho^2 < 1/2 \} \right) \]

\[ := E_2^1 \cup E_2^2 \cup E_2^3. \]

We further decompose \( E_2^1 := \left( \{ \rho^1 < 1/2 \} \cap \{ 1/2 \leq \rho^2 < 1 \} \right) \cup \left( \{ \rho^1 < 1/2 \} \cap \{ \rho^2 \geq 1 \} \right) =: E_1^{11} \cup E_1^{12}. \)

For a.e. \( q \in E_1^{12} \), we have

\[ \tilde{A}^{-1}(q) = \frac{L_S(\rho^1(q), \rho^1(q)) - L_S(\rho^2(q), \rho^2(q))}{\rho^1(q) - \rho^2(q)} = \tilde{\rho}(q)\tilde{S}'(\tilde{\rho}(q)), \]

where \( \tilde{\rho}(q) \) is a point between \( \rho^1(q) \) and \( \rho^2(q) \). Since restricted to \( E_1^{11} \) both \( \rho^1 \) and \( \rho^2 \) are bounded by 1, we have that \( \tilde{A}^{-1} \mathbb{1} E_1^{11} \in L^\infty(E_1^{11}) \). For a.e. \( q \in E_2^1 \) we have

\[ A^{-1}(q) = \frac{L_S(\rho^1(q), \rho^1(q)) - L_S(\rho^2(q), \rho^2(q))}{\rho^1(q) - \rho^2(q)} \leq 2|L_S(\rho^1(q), \rho^1(q)) - L_S(\rho^2(q), \rho^2(q))|, \]

since restricted to this set \( |\rho^1(q) - \rho^2(q)| \geq 1/2 \) a.e. Therefore, by our assumption on \( L_S(\rho^1, \rho^1) \) we have that \( \tilde{A}^{-1} \mathbb{1} E_2^1 \in L^2(E_2^1) \).

Similarly, we can draw the same conclusion in the case of \( E_2^2 \), and so \( \tilde{A}^{-1} \mathbb{1} E_2^2 \in L^2(E_2^2) \).

For a.e. \( q \in E_2^2 \), we conclude similarly as in the case of \( E_2^{11} \), i.e. we have that

\[ A^{-1}(q) = \frac{L_S(\rho^1(q), \rho^1(q)) - L_S(\rho^2(q), \rho^2(q))}{\rho^1(q) - \rho^2(q)} = \tilde{\rho}(q)\tilde{S}'(\tilde{\rho}(q)), \]

where \( \tilde{\rho}(q) \) is a point between \( \rho^1(q) \) and \( \rho^2(q) \). Since restricted to \( E_2^2 \) both \( \rho^1 \) and \( \rho^2 \) are bounded by 1/2, we have that \( \tilde{A}^{-1} \mathbb{1} E_2^2 \in L^\infty(E_2^2) \).

Therefore, combining all the previous arguments, one obtains that \( \tilde{A}^{-1} \mathbb{1} E_2 \in L^2(E_2) \), and the claim follows.

Let \( \varepsilon > 0 \) and let \( K_1 := \|A \mathbb{1} E_1\|_{L^\infty(Q)} \). Let \( A_1^\varepsilon := \max\{\varepsilon, A \mathbb{1} E_1\} \). Then, we have \( \varepsilon \leq A_1^\varepsilon \leq K_1 \) and \( \|A_1^\varepsilon - A \mathbb{1} E_1\|_{L^\infty(Q)} \leq \varepsilon \). In the same time, for \( 0 < \delta \leq K \) given, let \( A_2^\delta := A_2^\delta(\delta, K) \) be smooth such that \( 0 \leq (A_2^\delta)^{-1} \leq K \) and

\[ (A_2^\delta)^{-1} \to [(A \mathbb{1} E_2)^{-1}]_{\delta,K} \text{ strongly in } L^3(E_2), \quad \varepsilon \downarrow 0, \]

for any \( q \in [1, +\infty) \) and in particular, \( A_1^\varepsilon^{-1} \to [(A \mathbb{1} E_1)^{-1}]_{\delta,K} \text{ weakly-}^* \text{ in } L^\infty(E_2) \) as \( \varepsilon \downarrow 0 \). Here, for a nonnegative function \( f : Q \to [0, +\infty) \) we use the notation \( f|_{\delta,K} := \min\{\max\{f, \delta\}, K\} \).

Now, let us define \( A_\varepsilon : Q \to [0, +\infty) \) as

\[ A_\varepsilon := \begin{cases} A_1^\varepsilon, & \text{a.e. in } E_1, \\ A_2^\delta, & \text{a.e. in } E_2. \end{cases} \]

By construction \( \min\{\varepsilon; 1/K\} \leq A_\varepsilon \leq \max\{K_1, 1/\delta\} \), for \( \theta > 0 \) let \( A_\theta \) (which depends also on \( \varepsilon, \delta \) and \( K \)) be a smooth approximation of \( A_\varepsilon \) such that

\[ \min\{\varepsilon; 1/K\} \leq A_\theta \leq \max\{K_1, 1/\delta\}, \text{ in } Q; \]

\[ \varepsilon \leq A_\theta \leq K_1, \text{ a.e. in } E_1; \]

\[ 1/K \leq A_\theta \leq 1/\delta, \text{ a.e. in } E_2; \]

and \( A_\theta \to A_\varepsilon \) strongly in \( L^3(Q) \) for any \( q \in [1, +\infty) \) and in particular

\[ A_\theta \rightharpoonup A_\varepsilon \text{ weakly-}^* \text{ in } L^\infty(Q), \quad \varepsilon \downarrow 0. \]
Moreover, we have
\begin{equation}
A_0^{-1} \rightarrow [(A_1 E_2)^{-1}]_{\delta,K} \text{ in } L^q(E_2), \quad \forall \, q \in [1, +\infty) \text{ and } A_0^{-1} \Delta [(A_1 E_2)^{-1}]_{\delta,K} \text{ in } L^\infty(E_2), \quad \text{as } \max\{\theta, \varepsilon\} \downarrow 0.
\end{equation}

To check this last claim, we argue as follows:
\begin{align*}
\|A_0^{-1} - [(A_1 E_2)^{-1}]_{\delta,K}\|_{L^q(E_2)} &\leq \|A_0^{-1} - (A_2)^{-1}\|_{L^q(E_2)} + \|(A_2)^{-1} - [(A_1 E_2)^{-1}]_{\delta,K}\|_{L^q(E_2)} \\
&= \|A_0 - A_2^{-1}\|_{L^q(E_2)} + \|[A_1 E_2]^{-1}_{\delta,K}\|_{L^q(E_2)} \\
&\leq K^2 \|A_0 - A_2^{-1}\|_{L^q(E_2)} + \|(A_2)^{-1} - [(A_1 E_2)^{-1}]_{\delta,K}\|_{L^q(E_2)} \rightarrow 0,
\end{align*}
as \max\{\theta, \varepsilon\} \downarrow 0, by the construction of \(A_0\) and \(A_2\). We conclude similarly about the weak-\* convergence as well.

Let us consider the regularized dual equation which reads as
\begin{equation}
\begin{cases}
\partial_t \varphi_\theta + (1/A_0) \Delta \varphi_\theta - \nabla \Phi \cdot \nabla \varphi_\theta = 0, & \text{in } (0, T) \times \Omega, \\
\nabla \varphi_\theta \cdot \mathbf{n} = 0, & \text{on } (0, T) \times \partial \Omega, \\
\varphi_\theta(T, \cdot) = \zeta, & \text{in } \Omega.
\end{cases}
\end{equation}

Let \(\varphi_\theta\) be the smooth solution of (6.8), when the coefficient function is \(A_0\) and we use this in (6.1) as
\begin{align*}
\mathcal{I}(\varphi_\theta, T) - \mathcal{I}(\varphi_0, 0) &= \int_0^T \int_{\Omega} \partial_s \varphi_\theta (\rho^1 - \rho^2) + \Delta \varphi_\theta (L_S(\rho^1, p^1) - L_S(\rho^2, p^2)) - \nabla \varphi_\theta \cdot \nabla \Phi (\rho^1 - \rho^2) \, dx \, ds \\
&= \int_{E_1} \partial_s \varphi_\theta (\rho^1 - \rho^2) + \Delta \varphi_\theta (L_S(\rho^1, p^1) - L_S(\rho^2, p^2)) - \nabla \varphi_\theta \cdot \nabla \Phi (\rho^1 - \rho^2) \, dx \, ds \\
&\quad + \int_{E_2} \partial_s \varphi_\theta (\rho^1 - \rho^2) + \Delta \varphi_\theta (L_S(\rho^1, p^1) - L_S(\rho^2, p^2)) - \nabla \varphi_\theta \cdot \nabla \Phi (\rho^1 - \rho^2) \, dx \, ds \\
&= \int_{E_1} (L_S(\rho^1, p^1) - L_S(\rho^2, p^2)) [A \partial_s \varphi_\theta + \varphi_\theta \varphi_\theta - A \nabla \Phi \cdot \nabla \varphi_\theta] \, dx \, ds \\
&\quad + \int_{E_2} (\rho^1 - \rho^2) [A \partial_s \varphi_\theta + \varphi_\theta \varphi_\theta - A \nabla \Phi \cdot \nabla \varphi_\theta] \, dx \, ds =: I_1 + I_2.
\end{align*}

It remains to show that both \(|I_1|\) and \(|I_2|\) can be made arbitrary small. Because \(\phi_\theta\) solves (6.8) with the coefficient function \(A_0\), we have
\begin{align*}
I_1 &= \int_{E_1} (L_S(\rho^1, p^1) - L_S(\rho^2, p^2)) [A \partial_s \varphi_\theta + \varphi_\theta \varphi_\theta - A \nabla \Phi \cdot \nabla \varphi_\theta] \, dx \, ds \\
&\quad - \int_{E_1} (L_S(\rho^1, p^1) - L_S(\rho^2, p^2)) A [\partial_s \varphi_\theta + \varphi_\theta \varphi_\theta - A \nabla \Phi \cdot \nabla \varphi_\theta] \, dx \, ds \\
&= \int_{E_1} (L_S(\rho^1, p^1) - L_S(\rho^2, p^2)) (A_0 - A) A_0^{-1} \varphi_\theta \varphi_\theta \, dx \, ds
\end{align*}
From here, by (6.5) we have
\begin{align*}
|I_1| &\leq \varepsilon^{-\frac{1}{2}} \|A_0^{-\frac{1}{2}} \varphi_\theta \varphi_\theta\|_{L^2(\mathcal{Q})} \left( \int_{E_1} |L_S(\rho^1, p^1) - L_S(\rho^2, p^2)|^2 |A_0 - A|^2 \, dx \right)^{\frac{1}{2}}.
\end{align*}

By Lemma 6.4(2), we have that \(\|A_0^{-\frac{1}{2}} \varphi_\theta \varphi_\theta\|_{L^2(\mathcal{Q})} \leq C\) for some constant independent of \(\theta\) and \(\varepsilon\). Furthermore, by (6.6), by the summability assumption on \(L_S(\rho^1, p^1)\) and by the construction of \(A_1\), for \(\theta\) small enough we have
\begin{align*}
\int_{E_1} |L_S(\rho^1, p^1) - L_S(\rho^2, p^2)|^2 |A_0 - A|^2 \, dx \, ds &\leq 2 \int_{E_1} |L_S(\rho^1, p^1) - L_S(\rho^2, p^2)|^2 |A_0 - A|^2 \, dx \, ds + 2 \int_{E_1} |L_S(\rho^1, p^1) - L_S(\rho^2, p^2)|^2 |A_1 - A|^2 \, dx \, ds \\
&\leq \varepsilon^2 + C\varepsilon^2,
\end{align*}
for some constant independent of \(\varepsilon, \theta, K\) and therefore by the arbitrariness of \(\varepsilon\), we conclude that \(I_1 = 0\).
In the case of $\mathcal{I}_2$ we argue as follows.

\[
\mathcal{I}_2 = \int_{E_2} (\rho^1 - \rho^2)^2 [\partial_\theta \varphi_\theta + A^{-1} \Delta \varphi_\theta - \nabla \Phi \cdot \nabla \varphi_\theta] \, d\mathcal{L}^{d+1}
- \int_{E_2} (\rho^1 - \rho^2)^2 [\partial_\theta \varphi_\theta + A^{-1} \Delta \varphi_\theta - \nabla \Phi \cdot \nabla \varphi_\theta] \, d\mathcal{L}^{d+1}
= \int_{E_2} (\rho^1 - \rho^2)^2 (A^{-1} - A^{-1}) A_\theta^{\frac{1}{2}} A_\theta^{-\frac{1}{2}} \Delta \varphi_\theta \, d\mathcal{L}^{d+1}
= \int_{E_2} (\rho^1 - \rho^2)^2 (A^{-1} - A^{-1}) A_\theta^{\frac{1}{2}} A_\theta^{-\frac{1}{2}} \Delta \varphi_\theta \, d\mathcal{L}^{d+1}
+ \int_{E_2} (\rho^1 - \rho^2)^2 (A^{-1} - A^{-1}) A_\theta^{\frac{1}{2}} A_\theta^{-\frac{1}{2}} \Delta \varphi_\theta \, d\mathcal{L}^{d+1}
=: \mathcal{I}_{21} + \mathcal{I}_{22}
\]

Let us notice that by the definition of $A^{-1}_{\theta,K}$ (on $E_2$), we have that

\[
\left| A^{-1} - A^{-1}_{\theta,K} \right| = \begin{cases} 
\delta & \text{a.e. in } \{0 \leq A^{-1} < \delta\} \cap E_2, \\
0 & \text{a.e. in } \{\delta \leq A^{-1} \leq K\} \cap E_2, \\
A^{-1} - K & \text{a.e. in } \{K \leq A^{-1}\} \cap E_2,
\end{cases}
\]

and thus

\[
(6.9) \quad \left| A^{-1} - A^{-1}_{\theta,K} \right| \leq \delta + (A^{-1} - K)_+, \text{ a.e. in } E_2.
\]

Therefore, since $A_\theta^{\frac{1}{2}} \leq \delta^{-\frac{1}{4}}$, we obtain

\[
|\mathcal{I}_{21}| \leq \|A_\theta^{\frac{1}{2}} \Delta \varphi_\theta\|_{L^2(Q)} \delta^{-\frac{1}{4}} \left(\|\rho^1 - \rho^2\|_{L^2(E_2)} + \|\rho^1 - \rho^2\|_{L^2((K \leq A^{-1}) \cap E_2)}\right) \to 0,
\]

as $K \to +\infty$ and $\delta \downarrow 0$ (in this order). This is true indeed, by Lemma 6.4(2) and by the fact that

\[
\int_{(K \leq A^{-1}) \cap E_2} (\rho^1 - \rho^2)^2 (A^{-1} - K)^2 \, d\mathcal{L}^{d+1} \leq \int_{(K \leq A^{-1}) \cap E_2} (\rho^1 - \rho^2)^2 (A^{-1})^2 \, d\mathcal{L}^{d+1}
\leq \int_{(K \leq A^{-1}) \cap E_2} \left( L_S(\rho^1, p^1) - L_S(\rho^2, p^2) \right)^2 \, d\mathcal{L}^{d+1}
\]

Since $A^{-1} \in L^2(E_2)$, by Chebyshev’s inequality $\mathcal{L}^{d+1}(\{K \leq A^{-1}\} \cap E_2) \to 0$, as $K \to +\infty$, so by the summability of $L^2_S(\rho^1, p^1)$ we deduce that for $K$ large enough last term in the last inequality is smaller than $\delta^2$. Therefore, by the arbitrariness of $\delta$, we conclude that $\mathcal{I}_{21}$ has to be zero.

To show that $|\mathcal{I}_{22}|$ can be made arbitrary small, using again $A_\theta^{\frac{1}{2}} \leq \delta^{-\frac{1}{4}}$ a.e. on $E_2$ and Lemma 6.4(2), we have

\[
|\mathcal{I}_{22}| \leq \delta^{-1} C \int_{E_2} (\rho^1 - \rho^2)^2 (A^{-1}_{\theta,K} - A^{-1})^2 \, d\mathcal{L}^{d+1}.
\]

By the fact that $A^{-1}_{\theta,K}, A^{-1}_\theta \in L^\infty(E_2), \rho^1, \rho^2 \in L^2(E_2)$ and by the weak-* convergence of $A^{-1}_\theta$ to $A^{-1}_{\theta,K}$ in $L^\infty(E_2)$, we conclude that for $\theta$ small enough, the r.h.s. of the previous inequality is smaller than $\delta$, therefore by the arbitrariness of $\delta$ we conclude that $\mathcal{I}_{22} = 0$. \hfill \Box

**Lemma 6.2.** Let $(\rho^1, p^1), (\rho^2, p^2)$ satisfy (4.4). Then $L_S$ (defined in (1.5)) defines a monotone operator in the sense that

\[
(6.10) \quad \text{if } \rho^1(x) < \rho^2(x), \text{ then } L_S(\rho^1, p^1)(x) < L_S(\rho^2, p^2)(x).
\]

In particular, for $x \in \Omega$, if

\[
(6.11) \quad L_S(\rho^1, p^1)(x) = L_S(\rho^2, p^2)(x),
\]

then $\rho^1(x) = \rho^2(x)$ and $p^1(x) = p^2(x)$.

**Proof.** First of all, if we have (6.11) and $\rho^1(x) = \rho^2(x)$, then (1.5) and (4.4) imply $p^1(x) = p^2(x)$. Thus, it is enough to show that $\rho^1(x) = \rho^2(x)$. We claim that $L_S$ is a monotone operator in the sense of (6.10). Note that $\rho \mapsto \rho S'(\rho) - S(\rho)$ is strictly increasing in $\R^+ \setminus \{1\}$ because it holds that

\[
(6.12) \quad \partial_\rho (\rho S'(\rho) - S(\rho)) = \rho S''(\rho) > 0 \text{ in } \R^+ \setminus \{1\}
\]

from the strict convexity of $S$ in Assumption 1.1. Therefore, (6.10) holds if $\rho^1(x), \rho^2(x) \in (0, 1)$ or $\rho^1(x), \rho^2(x) \in (1, +\infty)$. 

37
Consider the case that $\rho^1(x) = 1 < \rho^2(x)$. Recall from Assumption 1.1 that $S$ and $S'$ are continuous in $\mathbb{R}^+$ and $\mathbb{R}^+ \setminus \{1\}$, respectively. As $\rho \mapsto \rho S'(\rho) - S(\rho)$ is strictly increasing in $(1, +\infty)$, it holds that

\begin{equation}
L_S(\rho^2, \rho^2) = \rho^2(x) S'(\rho^2(x)) - S(\rho^2(x)) + S(1) > \lim_{\rho \to 1^+} \rho S'(\rho) - S(\rho) + S(1) = S'(1+)
\end{equation}

\[\geq p^1(x) = L_S(p^1, p^1)(x).\]

From (6.13) and (4.4), we conclude (6.10) if $\rho^1(x) = 1 < \rho^2(x)$. Similar arguments hold for $\rho^1(x) < \rho^2(x) = 1$. Lastly, by combining the inequalities in (6.10) for two cases, $\rho^1(x) = 1 < \rho^2(x)$ or $\rho^1(x) < 1 = \rho^2(x)$, we conclude (6.10) for $\rho^1(x) < 1 < \rho^2(x)$. \hfill \Box

**Lemma 6.3.** We differentiate two cases.

1. Assume $m = 1$ for $m$ given in (1.8). Let $(\rho^1, p^1)$ and $(\rho^2, p^2)$ satisfy (4.4), then we have

\begin{equation}
0 \leq A \leq \max \left\{ \sigma_1, \sigma_2 \right\}, \text{ a.e. in } Q
\end{equation}

for $A = A(\rho, p^1, \rho^1, p^2)$ given in (6.2) and $\sigma_1, \sigma_2$ are from Assumption (1.8)-(1.9).

2. Let $m > 1$. If there exist $c_0 > 0$ and a Borel set $E \subseteq Q$ such that $\rho^1, \rho^2 \geq c_0$ a.e. on $E$, then

\[A \leq \max \left\{ \sigma_1, \frac{\sigma_2}{\rho^1} \right\} \text{ a.e. in } E.\]

**Proof.** We recall that $L_S(\rho, \rho)(t, x) := [\rho(t, x) S'(\rho(t, x)) - S(\rho(t, x)) + S(1)] I_{\{\rho \neq 1\}}(t, x) + p(t, x) I_{\{\rho = 1\}}(t, x)$ from (1.5). The non-negativity of $A$ follows from the monotonicity of $L_S$ shown in Lemma 6.2. We fix $q = (t, x) \in Q$ a Lebesgue for $\rho^1, \rho^2, \rho^1, \rho^2$ and assume that $\rho^1(t, x) \geq \rho^2(t, x)$. If $q \in \{\rho^1 = 1\} \cap \{\rho^2 = 1\}$ there is nothing to check, since $A(q) = 0$ in both cases. We fix $q \in (\{\rho^1 > 1\} \cap \{\rho^2 > 1\}) \cup (\{\rho^1 < 1\} \cap \{\rho^2 < 1\})$ have that

\[\rho^1(q) S'(\rho^1(q)) - S(\rho^1(q)) - p^1(q) S'(\rho^2(q)) + S(\rho^2(q)) = \hat{\rho} S''(\hat{\rho})(\rho^1(q) - \rho^2(q)) \geq \min\left\{ \frac{1}{\sigma_1}, \frac{1}{\sigma_2} \right\} (\rho^1(q) - \rho^2(q)),\]

where $\hat{\rho}$ is a constant between $\rho^1(q)$ and $\rho^2(q)$. Therefore, we get that $A(q) \leq \max \{\sigma_1, \sigma_2\}$.

Case 1. If $q \in \{\rho^1 > 1\} \cap \{\rho^2 > 1\}$ we have from (4.4) that

\[\rho^1(q) S'(\rho^1(q)) - S(\rho^1(q)) + S(1) - p^2(q) \geq \rho^1(q) S'(\rho^1(q)) - S(\rho^1(q)) - (S'(1) - S(1)).\]

As $\rho \mapsto \rho S'(\rho) - S(\rho)$ is continuous in $[1, \rho^1(q)]$ and differentiable in $(1, \rho^1(q))$, the mean value theorem yields that

\[\rho^1(q) S'(\rho^1(q)) - S(\rho^1(q)) - p^2(q) \geq \hat{\rho} S''(\hat{\rho})(\rho^1(q) - 1) \geq \frac{1}{\sigma_1}(\rho^1(q) - 1),\]

where $\hat{\rho}$ is between 1 and $\rho^1(q)$. Parallel arguments show (6.14) on the region $\{\rho^1 = 1\} \cap \{\rho^2 < 1\}$.

Case 2. If $q \in (\{\rho^1 > 1\} \cap \{\rho^2 < 1\})$ from similar arguments as in Case 2, we have that

\[\rho^1(q) S'(\rho^1(q)) - S(\rho^1(q)) - (S'(1+) - S(1)) \geq \frac{1}{\sigma_1}(\rho^1(q) - 1)\]

and

\[(S'(1-) - S(1)) - [\rho^2(q) S'(\rho^2(q)) - S(\rho^2(q))] \geq \frac{1}{\sigma_2}(1 - \rho^2(q)).\]

As $S'(1+) \geq S'(1-)$, we conclude that

\[L_S(\rho^1, p^1)(q) - L_S(\rho^2, p^2)(q) \geq \sigma_1(\rho^1(q) - 1) + \sigma_2(1 - \rho^2(q)) = \min\left\{ \frac{1}{\sigma_1}, \frac{1}{\sigma_2} \right\} (\rho^1(q) - \rho^2(q)).\]

The proof of (2) follows the very same steps as the one of (1). By the lower bound $c_0 > 0$ on the densities in $E$, we conclude that $A \leq \max \left\{ \sigma_1, \frac{\sigma_2}{c_0} \right\}$.

\hfill \Box

**Lemma 6.4.** Let $\varepsilon > 0$ and let $\varphi_\varepsilon$ be a smooth solution to (6.8). Then there exists a constant $C = C(T, \|\nabla \varphi\|_{L^2}) > 0$ such that

1. $\sup_{t \in [0, T]} \|\nabla \varphi_\varepsilon\|_{L^2(\Omega)} \leq C$;

2. $\|A_{\varepsilon}^{-\frac{1}{2}} \Delta \varphi_\varepsilon\|_{L^2(\Omega)} \leq C$.

38
Proof. The proof of this results follows the same lines as the one of [DMM16, Lemma 3.1], therefore we omit it.

**Corollary 6.5.** Let \( \rho_0 \in \mathcal{P}(\Omega) \) satisfy \( \mathcal{J}(\rho_0) < +\infty \). A solution pair to (1.3)-(1.6) such that \( L_S(\rho, p) \in L^2(Q) \) is uniquely determined by \( \rho_0 \).

**Proof.** From the contraction result in Theorem 6.1 we deduce the uniqueness of \( \rho \). Now suppose that there exists to pressure fields \( p^1, p^2 \) solving (4.3) with the same \( \rho \). Taking the difference of these two equations we get

\[
\Delta(L_S(\rho, p^1) - L_S(\rho, p^2)) = 0, \text{ in } \mathcal{D}'((0, T) \times \Omega).
\]

For a.e. \( t \in [0, T] \) and for any \( \varphi \in C^2_c(\Omega) \) we have that

\[
0 = \int_{\Omega} (L_S(\rho_t, p^1_t) - L_S(\rho_t, p^2_t)) \Delta \varphi \, dx = \int_{\{\rho_t = 1\}} (p^1_t - p^2_t) \Delta \varphi \, dx,
\]

where in the last equality we used the fact that \( p^1_t = p^2_t \) a.e. in \( \{\rho_t < 1\} \cup \{\rho_t > 1\} \). By the arbitrariness of \( \varphi \) we conclude that \( p^1_t = p^2_t \) a.e. on \( \{\rho_t = 1\} \) and therefore the uniqueness of \( p \) follows.

\[ \square \]

7. Discussions

**7.1. The emergence of the ‘critical region’ \( \rho = 1 \) - an example.** We consider \( d = 1 \) and we show that the critical region \( \{\rho = 1\} \) is of positive measure, whenever the two regions \( \{\rho > 1\} \) and \( \{\rho < 1\} \) are also of positive measure. We will see that this also implies that the critical region is expected to emerge for positive times, even if \( \mathcal{L}^1(\{\rho_0 = 1\}) = 0 \) (and if \( \mathcal{L}^1(\{\rho_0 < 1\}) > 0 \) and \( \mathcal{L}^1(\{\rho_0 > 1\}) > 0 \)). This phenomenon corresponds to the growth of the critical region for self-organized criticality in [BJ92].

**Proposition 7.1.** Let \( \Omega \subset \mathbb{R} \) and \( (\rho, p) \) be given in Theorem 3.1. If \( t \in (0, T) \) is a Lebesgue point both for \( t \mapsto \rho_t \) and \( t \mapsto p_t \) with

\[
\mathcal{L}^1(\{\rho_t < 1\}) > 0 \quad \text{and} \quad \mathcal{L}^1(\{\rho_t > 1\}) > 0
\]

then \( \mathcal{L}^1(\{\rho_t = 1\}) > 0 \).

**Proof.** Let us show that \( p(t, \cdot) \in C^{0, \frac{1}{2}}(\Omega) \) for a.e. \( t \in [0, T] \). From Theorem 3.1 we know that \( \partial_x p \in L^2(Q) \). As a consequence, we have that

\[
\int_0^T \text{osc}_{x \in [a, b]} p(t, x) \, dt \leq \int_0^T \int_a^b |\partial_x p(t, x)| \, dt \leq \|\partial_x p\|_{L^2(Q)} T^{\frac{1}{2}} |b - a|^{\frac{1}{2}}.
\]

Thus, \( p \in L^1(0, T; C^{0, \frac{1}{2}}(\Omega)) \) and we conclude.

Let \( t \in (0, T) \) be a Lebesgue point for both \( t \mapsto \rho_t \) and \( t \mapsto p_t \) such that \( \mathcal{L}^1(\{\rho_t < 1\}) > 0 \) and \( \mathcal{L}^1(\{\rho_t > 1\}) > 0 \). Then (7.1) and (3.3) imply that there exists \( \{U_i\}_{i \in \{1, 2\}} \) subsets of \( \Omega \) such that \( \mathcal{L}^1(U_i) > 0 \) and \( p_t = i \) a.e. in \( U_i \) for \( i \in \{1, 2\} \). As \( p_t \) is continuous in \( \Omega \) for a.e. \( t \in [0, T] \), there exists a point \( x_0 \in \Omega \) such that \( p_t(x_0) \neq 3/2 \). Since \( N := \rho_t^{-1}(15/4, 7/4) \) is a nonempty open set, \( N \) has a positive measure. From (3.3), we have that \( N \subset \{\rho_t = 1\} \) and thus we conclude.

**Remark 7.1.** A similar result can be stated in higher dimensions as well, based on the fact that Sobolev functions cannot take finitely many values, except if they are constants.

7.2. Formal derivation of a free boundary problem - an example. Next, we formally derive the free boundary motion corresponding to the particular problem in (3.2)-(3.3). For the analysis, we assume that \( \rho \) and \( p \) are continuous in \( Q \) and smooth in \( \{pp < 1\}, \{1 < pp < 2\} \) and \( \{pp > 2\} \), which also have smooth boundaries. Under this assumption, we deduce the following free boundary problem,

\[
\begin{align*}
\partial_t \rho - \Delta \rho - \nabla \cdot (\nabla \Phi p) &= 0, & \text{in } \{pp < 1\}, \\
\rho &= 1, & \text{in } \{1 < pp < 2\}, \quad \text{and } -\Delta p = \Delta \Phi, & \text{in } \{1 < pp < 2\}, \\
\partial_t \rho - 2\Delta \rho - \nabla \cdot (\nabla \Phi p) &= 0, & \text{in } \{pp > 2\}, \\
\end{align*}
\]

with boundary conditions

\[
\begin{align*}
|D(pp)|^{1+} - |D(pp)|^{1-} &= 0, & \text{on } \{pp = 1\}, \\
|D(pp)|^{2+} - |D(pp)|^{2-} &= 0, & \text{on } \{pp = 2\},
\end{align*}
\]

39
where for any \( f : Q \rightarrow \mathbb{R} \) and \( c \in \mathbb{R} \), denotes
\[
DF^c(t, x) := \lim_{(s, y) \to (t, x), (s, y) \in \{ f - c > 0 \}} DF(s, y).
\]

As the condition (3.3) implies
\[
\begin{align*}
\rho < 1, & \quad p = 1 \quad \text{in } \{ pp < 1 \}, \\
\rho = 1, & \quad 1 < p < 2, \quad \text{in } \{ 1 < pp < 2 \}, \\
\rho > 1, & \quad p = 2, \quad \text{in } \{ pp > 2 \},
\end{align*}
\]
the first system of equations in (7.2) is a direct consequence of Theorem 3.1. Next, we consider the second system of equations in (7.2). For a test function \( \xi \in C_c^\infty(Q) \) such that \( \xi \) is compactly supported in \( \{ 1 < pp < 2 \} \), (7.4) implies
\[
\begin{align*}
0 = & \int_Q \rho \partial_t \xi + D(pp) \cdot D\xi + D\Phi \cdot D\xi \, dx \, dt = \int_Q (\rho Dp + pD\rho + D\Phi) \cdot D\xi \, dx \, dt \\
& = \int_Q (Dp + D\Phi) \cdot D\xi \, dx \, dt.
\end{align*}
\]
Thus, we conclude that \(-\Delta \rho = \Delta \Phi \) in \( \{ 1 < pp < 2 \} \). The other cases follow from (7.4).

Lastly, let us find the boundary condition (7.3) on \( \{ pp = 1 \} \) and \( \{ pp = 2 \} \). As [EP04, Theorem 3.1], we deduce the condition based on integration by parts. Note that the boundary condition (7.3) can be regarded as Rankine-Hugoniot conditions. For a test function \( \xi \in C_c^\infty(Q) \), (3.2) implies that
\[
\begin{align*}
0 = & \int_Q \rho \partial_t \xi + [D(pp) + pD\Phi] \cdot D\xi \, dx \, dt = \int_{\{ pp < 1 \}} \rho \partial_t \xi + [D(pp) + pD\Phi] \cdot D\xi \, dx \, dt \\
& + \int_{\{ pp < 2 \}} \rho \partial_t \xi + [D(pp) + pD\Phi] \cdot D\xi \, dx \, dt + \int_{\{ pp > 2 \}} \rho \partial_t \xi + [D(pp) + pD\Phi] \cdot D\xi \, dx \, dt.
\end{align*}
\]
For a set \( N = \{ pp < 1 \} \), \( \{ 1 < pp < 2 \} \) or \( \{ pp > 2 \} \), the smoothness of \( p \) and \( \rho \) in \( N \) and (7.2) imply that
\[
\int_N \rho \partial_t \xi + [D(pp) + pD\Phi] \cdot D\xi \, dx \, dt = \int_{\partial N} \rho [n_t + [D(pp) + pD\Phi] \cdot n_x] \xi \, dS^d.
\]
where \( n_t \) and \( n_x \) are the outward normal vectors on \( \partial N \) in \( x \) and \( t \) directions, respectively. From (7.6) and (7.7), we conclude that
\[
\begin{align*}
0 = & \int_{\{ pp < 1 \}} [D(pp)^{1-} - D(pp)^{1+}] \cdot n_x \xi \, dS^d + \int_{\{ pp > 2 \}} [D(pp)^{2+} - D(pp)^{2-}] \cdot n_x \xi \, dS^d.
\end{align*}
\]
By the arbitrariness of \( \xi \), (7.8) implies that
\[
\begin{align*}
[D(pp)^{1-} - D(pp)^{1+}] \cdot n_x = 0 \quad & \text{on } \{ pp = 1 \}, \\
[D(pp)^{2+} - D(pp)^{2-}] \cdot n_x = 0 \quad & \text{on } \{ pp = 2 \}.
\end{align*}
\]
As \( n_x \) is parallel to \( D(pp) \) on the level set of \( pp \), we conclude (7.3).

7.3. A nontrivial stationary solution - an example. In this subsection, in one spacial dimension, we study stationary solutions to our problems. For simplicity, let us consider \( \Omega := (0, l) \subset \mathbb{R} \) for \( l > 0 \). Let \((\rho, p)\) be a solution to (3.2)-(3.3) with potential \( \Psi(x) = 2x \), where we have associated energy functional,
\[
\mathcal{J}(\rho(x)) = \int_0^l S(\rho(x)) \, dx + \int_0^l \Psi(x) \rho(x) \, dx,
\]
where \( S \) is given in (3.1). From Theorem 3.1, there exists a solution \((\rho, p)\) of
\[
\begin{align*}
\partial_t \rho - \partial_x^2(p) - 2\partial_x \rho &= 0, \quad \text{in } (0, T) \times (0, l), \\
\rho(0, \cdot) &= \rho_0, \quad \text{in } (0, l), \\
\partial_x (\rho(p)) + 2p &= 0, \quad \text{in } [0, T] \times \partial(0, l),
\end{align*}
\]
and \((\rho, p)\) satisfies (3.3). A stationary problem associated to (7.9) is as follows: find \( \rho, p : [0, l] \rightarrow \mathbb{R} \) satisfying (3.3) and
\[
\begin{align*}
\partial_x^2(p) + 2\partial_x \rho &= 0, \quad \text{at } x = 0 \text{ and } x = l.
\end{align*}
\]
The solution \((\rho, p)\) can be also characterized as minimizers of the the free energy \(J\). Writing down the optimality conditions (using Lemma 3.2) we have

\[
\rho = \begin{cases} 
\exp(A - x) & \text{in } [0, A) \cap [0, l], \\
1 & \text{in } [A, A + \frac{1}{2}] \cap [0, l], \\
\exp(2A + 1 - 2x) & \text{in } (A + \frac{1}{2}, l] \cap [0, l],
\end{cases}
\]

(7.11)

where \(A\) is chosen to satisfy

\[
\int_0^l \rho \, dx = 1.
\]

(7.12)

Depending on the value \(l\), some cases in (7.11) may not be present (see Figure 2).

![Figure 2. Stationary solutions](image)

**Figure 2. Stationary solutions**

**Lemma 7.2.** If \(l > \ln \left(\frac{3}{2}\right) + \frac{1}{2}\), then all three sets \(\{\rho < 1\}, \{\rho = 1\} \text{ and } \{\rho > 1\}\) have positive measure.

**Proof.** We consider the continuous function \(f : \mathbb{R} \to \mathbb{R}\) defined by

\[
f(x) := \exp(x) - \frac{1}{2}\exp(2x + 1 - 2l) - 1.
\]

We claim that there exists a solution of \(f(x) = 0\) in \((0, l - \frac{1}{2})\). First, \(f(0) = -\frac{1}{2}\exp(1 - 2l) < 0\). Also, as \(l > \ln \left(\frac{3}{2}\right) + \frac{1}{2}\), it holds that

\[
f \left( l - \frac{1}{2} \right) = \exp \left( l - \frac{1}{2} \right) - \frac{3}{2} > 0.
\]

Therefore, by the continuity of \(f\) and by the intermediate value theorem, we can find \(A \in (0, l - \frac{1}{2})\) such that \(f(A) = 0\). For given \(A\), we recall \(\rho\) from (7.11). Since we have

\[
A, \ A + \frac{1}{2} \in (0, l),
\]

all three sets \(\{\rho < 1\}, \{\rho = 1\} \text{ and } \{\rho > 1\}\) have positive measure.

It remains to show that with this choice of \(A, \rho\) given in (7.11) satisfies (7.12). From (7.11) and (7.13), it holds that

\[
\int_0^l \rho(x) \, dx = \int_0^A \exp(A - x) \, dx + \int_A^{A + \frac{1}{2}} 1 \, dx + \int_{A + \frac{1}{2}}^l \exp(2A + 1 - 2x) \, dx,
\]

\[
= (\exp(A) - 1) + \frac{1}{2} + \left( \frac{1}{2} - \frac{1}{2}\exp(2A + 1 - 2l) \right) = f(A) + 1 = 1.
\]

and we conclude. \(\square\)

**Remark 7.2.** By a parallel argument as above, one can check that a set \(\{\rho > 1\}\) will have zero measure if \(l \in (0, \ln \left(\frac{3}{2}\right) + \frac{1}{2})\). To see this, let us differentiate two cases.

**Case 1.** If \(l \in (0, \ln 2]\), then we have

\[
\rho(x) = \frac{\exp(-x)}{1 - \exp(-l)} \text{ in } [0, l].
\]
Case 2. If \( l \in (\ln 2, \ln \left( \frac{3}{2} \right) + \frac{1}{2}] \), then it holds that

\[
\rho(x) = \begin{cases} 
\exp(A - x) & \text{in } [0, A), \\
1 & \text{in } [A, l].
\end{cases}
\]

where \( A \in [l - \frac{1}{2}, l) \) is a solution of \( \exp(A) - A = 2 - l \).

Appendix A. Optimal transport toolbox

Let us recall now some basic definitions and results from the theory of optimal transport. Let \( \Pi(\mu, \nu) \) be the set of all Borel probability measure \( \pi \) on \( \Omega \times \Omega \) such that

\[
\pi(A \times \Omega) = \mu(A), \quad \pi(\Omega \times B) = \nu(B)
\]

for all measurable subsets \( A, B \subset \Omega \). For \( \mu, \nu \in \mathcal{P}_2(\Omega) \) we define the 2-Wasserstein or Monge-Kantorovich distance as

\[
W_2(\mu, \nu) := \min \left\{ \int_{\Omega \times \Omega} |x - y|^2 \, d\gamma : \gamma \in \Pi(\mu, \nu) \right\}^{\frac{1}{2}}
\]

For \( \phi : \Omega \to \mathbb{R} \) measurable, we use the notations

\[
\phi^+(x) := \max\{\phi(x), 0\}, \quad \phi^-(x) := \max\{-\phi(x), 0\} \quad \text{and} \quad \phi^0(x) := \essinf_{y \in \Omega} \left\{ \frac{1}{2} |x - y|^2 - \phi(y) \right\}
\]

where \( x \in \Omega \).

A1. Basic facts from optimal transport. Let us recall the definition and properties of Kantorovich potentials and optimal transport maps. There results are well-known in the literature, we refer for instance to [San15] for the proofs of the statements.

Definition A.1. Let \( \mu, \nu \in \mathcal{P}(\Omega) \) be given.

(1) We say that \( \phi : \Omega \to \mathbb{R} \) is a Kantorovich potential from \( \mu \) to \( \nu \) if \( (\phi, \tilde{\phi}) \) is a maximizer of the Kantorovich problem:

\[
\sup \left\{ \int_{\Omega} \phi \, d\mu + \int_{\Omega} \psi \, d\nu : (\phi, \psi) \in L^1_\mu(\Omega) \times L^\infty(\Omega), \phi(x) + \psi(y) \leq \frac{1}{2} |x - y|^2, \mu \otimes \nu - \text{a.e. } (x, y) \in \Omega \times \Omega \right\}.
\]

We denote the set of Kantorovich potential from \( \mu \) to \( \nu \) by \( K(\mu, \nu) \).

(2) We say that a Borel map \( T : \Omega \to \Omega \) is a optimal transport map from \( \mu \) to \( \nu \) if \( T \) is a minimizer of the following problem:

\[
\inf \left\{ \int_{\Omega} |x - T(x)|^2 \, d\mu : T_{\#}\mu = \nu \right\}.
\]

Here, \( (T^{-1}(A)) = T_{\#}\mu(A) \) for any Borel set \( A \subseteq \Omega \).

Lemma A.1 ([San15]). For \( \mu \in \mathcal{P}^{ac}(\Omega) \) and \( \nu \in \mathcal{P}(\Omega) \), there exists a Lipschitz continuous Kantorovich potential \( \phi \) and an optimal transport map \( T \) from \( \mu \) to \( \nu \). Also, it holds that

\[
x - T(x) = \nabla \phi(x) \quad \text{for a.e. } x \in \text{spt}(\mu) \quad \text{and} \quad W_2(\mu, \nu) = \|\nabla \phi\|_{L^1_\mu}.
\]

Lemma A.2. [Vil03, Theorem 1.3],[San15, Proposition 1.11] Let \( \mu, \nu \in \mathcal{P}(\Omega) \). Define \( \mathcal{L} : L^1_\mu(\Omega) \times L^\infty(\Omega) \to \mathbb{R} \) as

\[
\mathcal{L}(\phi, \psi) := \int_{\Omega} \phi \, d\mu + \int_{\Omega} \psi \, d\nu.
\]
Then, it holds that

$$\frac{1}{2}W_2^2(\mu, \nu) = \max \left\{ \mathcal{L}(\phi, \psi) : (\phi, \psi) \in C_b(\Omega) \times C_b(\Omega), \phi(x) + \psi(y) \leq \frac{1}{2}|x - y|^2 \text{ for all } x, y \in \Omega \right\},$$

$$= \sup \left\{ \mathcal{L}(\phi, \psi) : (\phi, \psi) \in L^1(\Omega) \times L^1(\Omega), \phi(x) + \psi(y) \leq \frac{1}{2}|x - y|^2 \text{ for } \mu \otimes \nu - \text{a.e. } (x, y) \in \Omega \times \Omega \right\}.$$  

**Proposition A.3.** For \( r \in [1, +\infty] \), let \( \mu \in L^r(\Omega) \cap \mathcal{P}(\Omega) \) and \( \nu \in \mathcal{P}(\Omega) \). Then, it holds that

$$\text{(A.4)} \quad \sup_{\phi \in L^r(\Omega)} \mathcal{L}(\phi, \phi^\varepsilon) = \frac{1}{2}W_2^2(\mu, \nu)$$

where \( r^\varepsilon := \frac{r}{r^\varepsilon} (r^\varepsilon = 1 \text{ if } r = +\infty \text{ and } r^\varepsilon = +\infty \text{ if } r = 1) \) and \( \mathcal{L} \) is given in (A.3).

**Proof.** Step 1. Let us show that

$$\text{(A.5)} \quad \frac{1}{2}W_2^2(\mu, \nu) = \mathcal{I}_1$$

where

$$\text{(A.6)} \quad \mathcal{I}_1 := \sup \left\{ \mathcal{L}(\phi, \psi) : (\phi, \psi) \in L^1(\Omega) \times L^1(\Omega), \phi(x) + \psi(y) \leq \frac{1}{2}|x - y|^2 \text{ for } \mu \otimes \nu - \text{a.e. } (x, y) \in \Omega \times \Omega \right\}.$$

By Hölder’s inequality, it holds that

$$\text{(A.7)} \quad \|\phi\|_{L^1(\Omega)} = \int_{\Omega} |\phi(x)| \mu(x) \, dx \leq \|\phi\|_{L^r(\Omega)} \|\mu\|_{L^{r^\varepsilon}(\Omega)}.$$  

As \( \mu \in L^r(\Omega) \cap \mathcal{P}(\Omega) \), we conclude that

$$L^r(\Omega) \subset L^1(\Omega) \quad \text{and thus } C_b(\Omega) \times C_b(\Omega) \subset L^{r^\varepsilon}(\Omega) \times L^1(\Omega) \subset L^1(\Omega) \times L^1(\Omega).$$

From Lemma A.2, we conclude (A.5).

**Step 2.** It remains to show that

$$\text{(A.8)} \quad \sup_{\phi \in L^{r^\varepsilon}(\Omega)} \mathcal{L}(\phi, \phi^\varepsilon) = \mathcal{I}_1$$

for \( \mathcal{I}_1 \) given in (A.6). Indeed, let us notice that by density we have

$$\sup_{\phi \in L^{r^\varepsilon}(\Omega)} \mathcal{L}(\phi, \phi^\varepsilon) = \sup_{\phi \in C_b(\Omega)} \mathcal{L}(\phi, \phi^\varepsilon) = \max_{\phi \in C_b(\Omega)} \mathcal{L}(\phi, \phi^\varepsilon),$$

and the latter two quantities are finite by [San15, Proposition 1.11]. Therefore the thesis of the proposition follows. \( \square \)

### A.2. Some properties of minimizers in the minimizing movements scheme and optimality conditions.

**Lemma A.4.** For \( \rho_k \) given in (2.3) and \( S \) satisfying (4.2), it holds that \( \rho_k > 0 \) a.e.

**Proof.** The proof is inspired by [San15, Lemma 8.6]. The difference is that we consider the sub-differential of \( S \) instead of its derivative.

**Step 1.** For simplicity, let us use the notation \( \mu := \rho_k \) and consider a competitor

$$\text{(A.9)} \quad \mu_1 := \frac{1}{|\mathcal{E}^a(\Omega)|}.$$  

Define \( \mu_\varepsilon := (1 - \varepsilon)\mu + \varepsilon \mu_1 \) for \( \varepsilon \in (0, 1) \). From convexity of Wasserstein distance, we have

$$\mathcal{I}_1 := \mathcal{J}(\mu) - \mathcal{J}(\mu_\varepsilon) \leq \frac{1}{2\varepsilon}W_2^2(\mu_\varepsilon, \rho_{k-1}) - \frac{1}{2\varepsilon}W_2^2(\mu, \rho_{k-1}) \leq \varepsilon \left\{ \frac{1}{2\varepsilon}W_2^2(\mu_1, \rho_{k-1}) - \frac{1}{2\varepsilon}W_2^2(\mu, \rho_{k-1}) \right\}.$$  

The compactness of \( \Omega \) implies

$$\text{(A.10)} \quad \mathcal{I}_1 \leq C_1 \varepsilon \text{ for some } C_1 > 0.$$
Step 2. Set $A := \{x \in \Omega : \mu > 0\}$ and $B := \{x \in \Omega : \mu = 0\}$. Let us show that $\mathcal{L}^d(B) = 0$. For sufficiently small $\varepsilon > 0$, it holds that $\varepsilon \mu_1 < 1$ and thus

$$I_1 = \int_A S(\mu(x)) - S(\mu_1(x)) + \Phi(\mu(x) - \mu_1(x))dx + (S(0) - S(\varepsilon \mu_1))\mathcal{L}^d(B) - \frac{1}{\mathcal{L}^d(\Omega)} \int_B \Phi dx$$

By convexity of $S$, it holds that

$$I_1 \geq \varepsilon \int_A [\xi_\varepsilon(x) + \Phi(\mu(x) - \mu_1)dx + (S(0) - S(\varepsilon \mu_1))\mathcal{L}^d(B) - \frac{1}{\mathcal{L}^d(\Omega)} \int_B \Phi dx,$$

where $\xi_\varepsilon(x) \in \partial S(\mu_1(x))$.

From (A.10), we conclude that for all $\xi_\varepsilon(x) \in \partial S(\mu_1(x))$

$$I_2 := \int_A [\xi_\varepsilon(x) + \Phi(\mu(x) - \mu_1)dx + \frac{1}{\varepsilon}(S(0) - S(\varepsilon \mu_1))\mathcal{L}^d(B) \leq C_1 + C.$$

Note that by the convexity of $S$, its subdifferential is monotone, therefore for all $\varepsilon \in [0, 1]$,

$$\langle \xi_\varepsilon(x) - \xi_1, \mu(x) - \mu_1 \rangle \geq 0,$$

and thus

$$I_2 \geq \int_A [\xi_1 + \Phi(\mu(x) - \mu_1)dx + \frac{1}{\varepsilon}(S(0) - S(\varepsilon \mu_1))\mathcal{L}^d(B)$$

Since $S'(0+) = -\infty$ from (4.2), the right hand side blows up as $\varepsilon$ goes to zero unless $\mathcal{L}^d(B) = 0$. As $I_2$ is bounded by $C_1 + C$ from (A.11), we conclude that $\mathcal{L}^d(B) = 0$, and thus $\mu > 0$ a.e. \qed

Appendix B. Some results from convex analysis

For a Banach space $X$ and $F : X \rightarrow \mathbb{R} \cup \{\pm \infty\}$, we say that $F^* : X^* \rightarrow \mathbb{R} \cup \{\pm \infty\}$ is a Legendre transform of $F$ if

$$F^*(y) := \sup_{x \in X} \{\langle x, y \rangle_{X, X^*} - F(x)\} \text{ for } y \in X^*.$$  

Here, $X^*$ stands for the topological dual space of $X$. We will denote by $C_b(\Omega)$ the space of bounded continuous functions in $\Omega$. In the derivation of optimality conditions associated to the minimizing movement schemes, in Section B, we use subdifferential calculus in $L^r(\Omega)$ ($r \in [1, +\infty]$) spaces. Let us recall some basic results on this.

Let us recall the definition of subdifferentials on $L^r(\Omega)^*$ for $r \in [1, +\infty]$.

Definition B.1. [Roc71, (1.9), (1.10) & (1.13)] For $\psi : \mathbb{R} \rightarrow \mathbb{R} \cup \{+\infty\}, r \in [1, +\infty]$ and $\Psi : L^r(\Omega) \rightarrow \mathbb{R} \cup \{+\infty\}$ defined by

$$\Psi(\mu) := \int_\Omega \psi(\mu(x))dx,$$

we say that $\xi \in L^r(\Omega)^*$ belongs to the subdifferential of $\Psi$ at $\mu \in L^r(\Omega)$ if

$$\Psi(\nu) \geq \Psi(\mu) + \langle \xi, \nu - \mu \rangle_{L^r(\Omega)^*, L^r(\Omega)}$$

for every $\nu \in L^r(\Omega)$. We denote by $\partial \Psi(\mu)$ the set of subdifferentials of $\Psi$ at the point $\mu \in L^r(\Omega)$.

Definition B.2. [ET76, Definition 1.3.1] Let $X$ be a Banach space. The set of functions $F : X \rightarrow \mathbb{R} \cup \{\pm \infty\}$ which are pointwise supremum of a family of continuous affine functions is denoted by $\Gamma(X)$.

Lemma B.1. [ET76, Proposition 1.3.1] The following properties are equivalent to each other:

1. $F \in \Gamma(X)$
2. $F$ is a convex lower semicontinuous function from $X$ into $\mathbb{R} \cup \{\pm \infty\}$ and if $F$ takes the value $-\infty$, then $F$ is identically equal to $-\infty$.

Lemma B.2. [ET76, Proposition 1.5.6] If $F_1, F_2 \in \Gamma(X)$ and if there exists $\hat{\mu} \in X$ such that $F_1(\hat{\mu}), F_2(\hat{\mu}) < +\infty$ and either $F_1$ or $F_2$ is continuous at $\hat{\mu}$, then it holds that

$$\partial F_1(\mu) + \partial F_2(\mu) = \partial(F_1 + F_2)(\mu) \text{ for all } \mu \in X.$$
Suppose that convention previous theorem to gain pre-compactness of interpolated curve $s$. In our setting we use the following Lemma C.2.

Theorem C.1. [RS03, Theorem 2] Let $B$ be a Banach space and $U$ be a family of measurable $B$-valued function. Let us suppose that there exist a normal coercive integrand $\mathfrak{F} : (0, T) \times B \to [0, +\infty]$, meaning that

1. $\mathfrak{F}$ is $\mathcal{B}(0, T) \otimes \mathcal{B}(B)$-measurable, where $\mathcal{B}(0, T)$ and $\mathcal{B}(B)$ denote the $\sigma$-algebras of the Lebesgue measurable subsets of $(0, T)$ and of the Borel subsets of $B$ respectively;

2. the maps $v \mapsto \mathfrak{F}(t, v) := \mathfrak{F}(t, v)$ are l.s.c. for a.e. $t \in (0, T)$;

3. $\{v \in B : \mathfrak{F}(t, v) \leq c\}$ are compact for any $c \geq 0$ and for a.e. $t \in (0, T)$, and a l.s.c. map $g : B \times B \to [0, +\infty]$ with the property

$$[u, v \in D(\mathfrak{F})_t, g(u, v) = 0] \Rightarrow u = w,$$ for a.e. $t \in (0, T)$.

If

$$\sup_{u \in D} \int_0^T \mathfrak{F}(t, u(t)) dt < +\infty$$ and

$$\lim_{h \downarrow 0} \sup_{u \in D} \int_0^{T-h} g(u(t+h), u(t)) dt = 0,$$

then $U$ is relatively compact in $\mathcal{M}(0, T; B)$.

Many recent papers (including [KM18, Lab17]) on gradient flows in the Wasserstein space used the previous theorem to gain pre-compactness of interpolated curves. In our setting we use the following result.

Lemma C.2. Let $T > 0$ and let $q \in [1, +\infty)$ and $n > 0$ be such that $nq^* > 1$, where $q^* := \frac{qd}{d-q}$ (with the convention $q^* \in (0, +\infty)$ is arbitrary if $d \geq 2$, and therefore, $n > 0$ and $nq^* > 1$ can also be arbitrary). Suppose that $(\rho^\tau)_{\tau > 0}$ is a sequence of curves on $[0, T]$ with values in $\mathcal{P}(\Omega)$ and suppose that there exists $C > 0$ such that

$$W_2^2(\rho^\tau_n, \rho^\tau_s) \leq C|t - s + \tau|, \forall 0 \leq s < t \leq T$$

and $((\rho^\tau)^n)_{\tau > 0}$ is uniformly bounded in $L^q([0, T]; W^{1,q}(\Omega))$ by $C$. We suppose moreover that there exists $\beta > 1$ such that $\|\rho^\tau_{t}\|_{L^q(\Omega)} \leq C$ for a.e. $t \in [0, T]$.

1. Then, $(\rho^\tau)^\tau_{\tau > 0}$ is pre-compact in $L^\gamma(Q)$, with $1 \leq \gamma \leq \beta$ if $\beta < nq^*$ and $1 \leq \gamma < nq^*$, if $\beta \geq nq^*$.

2. If in addition, $(\rho^\tau)^\tau_{\tau > 0}$ is uniformly bounded in $L^{\beta^2}(Q)$ for some $\beta > \gamma$ (where $\gamma$ is given in (1)), then $(\rho^\tau)^\tau_{\tau > 0}$ is pre-compact in $L^{\gamma^2}(Q)$, for any $1 \leq \gamma < \beta^2$.

Proof. Let us use the previously stated Aubin-Lions lemma, i.e. Theorem C.1. Let $1 \leq \alpha < q^*$ be fixed (that we set up later) and let us set $B := L^{\alpha}(\Omega)$, $\mathfrak{F} : L^{\alpha}(\Omega) \to [0, +\infty]$ defined as

$$\mathfrak{F}(\rho) := \left\{ \begin{array}{ll} \|\rho^\alpha\|_{W^{1,q}(\Omega)} & \text{if } \rho^\alpha \in W^{1,q}(\Omega), \\ +\infty & \text{otherwise.} \end{array} \right.$$ 

and $g : L^{\alpha}(\Omega) \times L^{\alpha}(\Omega) \to [0, +\infty]$ defined as

$$g(\mu, \nu) := \left\{ \begin{array}{ll} W_2(\mu, \nu) & \text{if } \mu, \nu \in \mathcal{P}(\Omega), \\ +\infty & \text{otherwise.} \end{array} \right.$$ 

In this setting, $(\rho^\tau)^\tau_{\tau > 0}$ and $\mathfrak{F}$ satisfy the assumptions of Theorem C.1. Indeed, from the assumption, one has in particular that

$$\int_0^T \|\rho^\tau_n\|_{W^{1,q}(\Omega)}^2 dt \leq C.$$ 

The injection $W^{1,q}(\Omega) \hookrightarrow L^{\alpha}(\Omega)$ is compact for any $1 \leq \alpha < q^*$, the injection $i : s \mapsto s_\tau$ is continuous from $L^{\alpha}(\Omega)$ to $L^{\alpha}(\Omega)$ and the sub-level sets of $\rho \mapsto \|\rho^\alpha\|_{W^{1,q}(\Omega)}$ are compact in $L^{\alpha}(\Omega)$.

Moreover, by the fact that $g$ defines a distance on $D(\mathfrak{F})$ and from (C.1), one has that $g$ also satisfies the assumptions from Theorem C.1, hence the implication of the theorem hold and one has that $(\rho^\tau)^\tau_{\tau > 0}$ is pre-compact in $\mathcal{M}(0, T; L^{\alpha}(\Omega))$. Let us notice that (C.1) implies that there exists $\rho \in C([0, T]; \mathcal{P}(\Omega))$ such that up to passing to a subsequence $(\rho^\tau)^\tau_{\tau > 0}$ converges uniformly (w.r.t. $W_2$) to $\rho$ as $\tau \to 0$. Up to passing to another subsequence, $\rho$ is the limit also in $\mathcal{M}(0, T; L^{\alpha}(\Omega))$.

From our assumption, we know that $\|\rho^\tau_n\|_{L^{\alpha}(\Omega)} \leq C$ for a.e. $t \in [0, T]$. Now, if $\beta < nq^*$, then setting $\alpha$ such that $n\alpha = \beta$, Lebesgue’s dominated convergence theorem implies the strong pre-compactness of $(\rho^\tau)^\tau_{\tau > 0}$ in $L^{\beta}(Q)$. Otherwise, Lebesgue’s dominated convergence implies the strong pre-compactness in $L^{\alpha}(Q)$ for any $1 \leq \gamma < nq^*$. This concludes the proof of (1).
To show (2), we notice that (1) already implies that $\rho^\gamma \to \rho$, strongly in $L^\gamma(Q)$ as $\tau \downarrow 0$ and in particular a.e. in $Q$. Furthermore, by the by the uniform bounds in $L^{2\gamma}(\Omega)$, with $\beta_2 > \gamma$, for any $1 \leq \gamma_2 < \beta_2$ we have that

$$\int (\rho^\gamma)^{\gamma_2} \, dx \, dt \leq (T^L(\Omega))^{1-\frac{\beta_2}{\gamma_2}} \|\rho^\gamma\|_{L^{\gamma_2}}^2,$$

which implies that $(\rho^\gamma)^{\gamma_2}$ is uniformly integrable on $Q$. Therefore, Vitali's convergence theorem yields the claim. \hfill \Box
