ATIYAH CLASS AND CHERN CHARACTER FOR GLOBAL MATRIX FACTORIZATIONS

BUMSIG KIM AND ALEXANDER POLISHCHUK

Abstract. We define the Atiyah class for global matrix factorizations and use it to give a formula for the categorical Chern character and the boundary-bulk map for matrix factorizations, generalizing the formula in the local case obtained in [11]. Our approach is based on developing the Lie algebra analogies observed by Kapranov [6] and Markarian [8].

Introduction
Recall that for a vector bundle $E$ over a smooth algebraic variety $X$, one has a natural class $\text{at}(E) \in \text{Ext}^1(E, \Omega^1_X \otimes E)$, called Atiyah class of $E$, such that the Chern character of $E$ is obtained as $\text{tr} (\exp (\text{at}(E)))$ when $X$ is a projective smooth variety over $\mathbb{C}$ (see [1]). This construction also generalizes to bounded complexes of vector bundles (see [5]). Furthermore, it shows up in the formula for the categorical Chern character and more generally, the boundary-bulk map (see [3], [13]).

The goal of this paper is to generalize the construction of the Atiyah class to the case of (global) matrix factorizations and to give a formula for the categorical boundary-bulk map for matrix factorizations.

Thus, we start with a smooth scheme $X$ equipped with a function $w$. We refer to [4], [7], [12] for the background on categories of matrix factorizations.

We want to construct an analog of Atiyah class for a matrix factorization $(E, \delta)$ of $w$. In the case when $X$ is affine the construction of such Atiyah class is due to Xuan Yu [16].

It turns out that in the case when $w \neq 0$ one cannot distill $\text{at}(E)$ on its own, however, one still has an analog of $1 + \text{at}(E)$, which we will call $\hat{\text{at}}(E)$.

Below we denote by $\text{Hom}^*_{\text{MF}(w)}(\cdot, \cdot)$ the cohomology of the $(\mathbb{Z}/2\text{-graded})$ morphisms spaces in the category of matrix factorizations of $w$. When considering the Hochschild homology/cohomology of $\text{MF}(w)$, we work over $k[u, u^{-1}]$, where $\deg(u) = 2$ (using the $\mathbb{Z}/2\text{-grading}$ on the category $\text{MF}(w)$).

Main construction. For every matrix factorization of $w$, $(E, \delta)$ we construct a natural class

$$\hat{\text{at}}(E) \in \text{Hom}^0_{\text{MF}(w)}(E, [\mathcal{O}_X \xrightarrow{dw} \Omega^1_X] \otimes E),$$

such that the image of $\hat{\text{at}}(E)$ under the natural projection $\text{Hom}^0_{\text{MF}(w)}(E, [\mathcal{O}_X \xrightarrow{dw} \Omega^1_X] \otimes E) \to \text{Hom}^0_{\text{MF}(w)}(E, E)$ is the identity element $\text{id}_E$. The formation of $\hat{\text{at}}(E)$ is functorial and compatible with pull-backs.

Next, we define the class

$$\exp (\text{at}(E)) \in \text{Hom}^0_{\text{MF}(w)}(E, (\Omega^*_X, \wedge dw) \otimes E)$$

as the composition of the iterated map

$$\hat{\text{at}}(E)^{(n)} : E \to [\mathcal{O}_X \xrightarrow{dw} \Omega^1_X] \otimes^n E \to S^n[\mathcal{O}_X \xrightarrow{dw} \Omega^1_X] \otimes E$$

with the isomorphism

$$S^n[\mathcal{O}_X \xrightarrow{dw} \Omega^1_X] \otimes E \sim (\Omega^*_X, \wedge dw) \otimes E.$$
induced by the isomorphism
\[
S^n[\mathcal{O}_X \xrightarrow{dw} \Omega_X^\bullet] = \mathcal{O}_X \xrightarrow{ndw} \Omega_X^{\bullet(n-1)\cdot dw} \to \ldots \to (\Omega_X^\bullet, \wedge dw)
\] (0.1)
given by \(\alpha_0 \mapsto \alpha_0, \alpha_i \mapsto \frac{\alpha_i}{n(n-1)\cdots(n-i+1)}\), where \(\alpha_i \in \Omega_X^i\).

The above definition may look a bit strange, however, it is easily explained by the fact that when one tries to recover \(\exp(x)\) from \((1 + x)^n\) in the ring \(\mathbb{Q}[x]/(x^{n+1})\), one has to rescale \(x^i\) by the factor \(\frac{1}{n(n-1)\cdots(n-i+1)}\).

Here is our main result.

**Theorem A.** Assume now that \(w = 0\) on the critical locus of \(w\) (set-theoretically). Under the natural identification
\[
HH_\bullet(MF(w)) \simeq H^\bullet(X, (\Omega_X^\bullet, \wedge dw)),
\] (0.2)
the categorical boundary-bulk map,
\[
\text{Hom}^\bullet_{MF(w)}(E, E) \to HH_\bullet(MF(w)),
\]
for a matrix factorization \(E\) of \(w\), is equal to the map induced on hypercohomology by the map
\[
\text{Hom}(E, E) \to (\Omega_X^\bullet, \wedge dw) : x \mapsto \text{str}(\exp(at(E)) \cdot x)
\]
in the \(\mathbb{Z}/2\)-graded derived category of \(X\).

Note that we give two constructions of isomorphism (0.2): an abstract one coming from the Lie analogies (see below), and the one given by an explicit chain map (this construction is due to [7]).

In the case of matrix factorizations over a regular local ring there is a simpler formula for the categorical Chern character obtained in [11]. It can be derived from the above theorem using a connection on the underlying vector bundle of \(E\) (see Remark 1.2). In the case of global matrix factorizations a formula similar to the one in Theorem A was obtained by Platt [9]. However, his definition of \(\exp(at(E))\) is much more complicated (based on some explicit resolutions of the relevant objects in the derived category).

Note that for \(w = 0\), i.e., in the classical case of vector bundles, we get a new proof of the compatibility of the categorical Chern character with the classical one, originally proved by Caldararu [3]. Our proof is more conceptual than that in [3]: we check the key technical statement (see Lemma 3.1 below) without using Čech representatives. 1

The proof of Theorem A uses analogs of some constructions of Markarian [8] for matrix factorizations. Recall that he used the Atiyah classes to equip the shifted tangent bundle \(T_X[-1]\) with a structure of a Lie algebra in the derived category of \(X\) (this construction goes back to Kapranov [6]), and showed that in appropriate sense the universal enveloping of this algebra can be identified with the sheafified Hochschild cohomology \(HH_\bullet(X)\). Furthermore, the Hochschild-Kostant-Rosenberg isomorphism can be viewed as an analog of the PBW theorem in this case.

It turns out that there is a similar Lie context for the sheafified Hochschild cohomology of the category of matrix factorizations, \(HH_\bullet MF(X,w)\).

Given a function \(w\), we equip the \(\mathbb{Z}/2\)-graded complex
\[
L_w := [T_X \xrightarrow{idw} \mathcal{O}_X]
\]
(where \(\mathcal{O}_X\) is placed in degree 0) with a structure of a Lie algebra, so that the exact triangle
\[
\mathcal{O}_X \to [T_X \xrightarrow{idw} \mathcal{O}_X] \to T_X[1]
\]
can be viewed as a central extension of Lie algebras in \(D(X)\), the \(\mathbb{Z}/2\)-graded derived category of \(X\) (note that it is essential to pass to the \(\mathbb{Z}/2\)-grading here, otherwise we get wrong shifts).

1We were not able to understand Markarian’s proof of a similar statement, [8, Prop. 5].
Recall that for a central extension of Lie algebras
\[ 0 \to k \cdot 1 \to \tilde{g} \to g \to 0 \quad (0.3) \]
it is natural to consider the quotient \( U(\tilde{g})/(1 - 1) \) of the universal enveloping algebra of \( \tilde{g} \). Extending the picture of Markarian [8], we will show that \( HH \), \( MF(X, w) \) can be viewed as the corresponding quotient of the universal enveloping algebra, \( U(L_w)/(1 - 1) \).

**Conventions and notation.** We work with matrix factorizations of a regular function \( w \) on a smooth scheme \( X \) over a field of characteristic 0. Whenever we need to use the HKR-isomorphism for sheafified Hochschild homology of the category of matrix factorizations of \( w \), we assume that 0 is the only critical value of \( w \). We denote by \( D(X) \) the \( \mathbb{Z}/2 \)-graded derived category of \( X \).

He also would like to thank the Korea Institute for Advanced Study and Institut des Hautes Etudes Scientifiques, where parts of this work were done, for hospitality and excellent work conditions.

1. **Definition of the Atiyah class**

1.1. **Global definition.** Recall that the Atiyah class for vector bundles (or bounded complexes thereof) is defined using the canonical exact sequence
\[ 0 \to \Delta_* \Omega^1_X \to \mathcal{O}_{\Delta^{(2)}} \to \mathcal{O}_\Delta \to 0. \quad (1.1) \]
Here \( \mathcal{O}_{\Delta^{(2)}} := \mathcal{O}_{X^2}/I^2_{\Delta} \), where \( I_{\Delta} \subset \mathcal{O}_{X^2} \) is the ideal sheaf of the diagonal \( \Delta \subset X^2 \). For a vector bundle \( E \) (or any object in \( D(X) \)), we tensor the above sequence with \( p_1^*E \) and apply \( p_1 \) to get the extension sequence
\[ 0 \to \Omega^1_X \otimes E \to J(E) \to E \to 0 \]
representing \( at(E) \).

Equivalently, we can view \( [\Delta, \Omega^1_X] \to \mathcal{O}_{\Delta^{(2)}} \) (in degrees \(-1\) and \(0\)) as a complex quasi-isomorphic to \( \mathcal{O}_\Delta \). Then the natural projection to \( (\Omega^1_X)_\Delta[1] := \Delta_* \Omega^1_X[1] \) gives a morphism in \( D(X^2) \),
\[ at^{\text{univ}} : \mathcal{O}_\Delta \to (\Omega^1_X)_\Delta[1], \quad (1.2) \]
called the universal Atiyah class. From this morphism of kernels we get a morphism of functors, whose value on \( E \) is \( at(E) \).

**Lemma 1.1.** The universal Atiyah class, \( at^{\text{univ}} \), is equal to the composition
\[ \mathcal{O}_\Delta \xrightarrow{at(\mathcal{O}_\Delta)} \Omega^1_X \otimes \mathcal{O}_{\Delta}[1] \simeq \Delta_* \Delta^* \Omega^1_{X^2}[1] \to \Delta_* \Omega^1_X[1], \]
where the last arrow is induced by the canonical map \( \Delta^* \Omega^1_{X^2} \to \Omega^1_X \). Equivalently, if we use the decomposition \( \Omega^1_{X^2} = p_1^* \Omega^1_X \oplus p_2^* \Omega^1_X \), then \( at^{\text{univ}} \) is equal to the component
\[ at^1(\mathcal{O}_\Delta) \in \text{Hom}(\mathcal{O}_\Delta, p_1^* \Omega^1_X \oplus \mathcal{O}_{\Delta}[1]) \simeq \text{Hom}(\mathcal{O}_\Delta, \Delta_* \Omega^1_X[1]) \]
of \( at(\mathcal{O}_\Delta) \).

**Proof.** See [14, Sec. 5.5]. The main point is to use the natural map \( J(\mathcal{O}_\Delta) \to \mathcal{O}_{\Delta^{(2)}} \), where \( J(?) \) denotes the sheaf of 1st order jets.

We observe that the sequence (1.1) has the following analog in the category of (coherent) matrix factorizations \( MF(\bar{w}) \), where \( \bar{w} = w \otimes 1 - 1 \otimes w \in H^0(X^2, \mathcal{O}) \). Note that we have a natural functor
\[ \Delta_* : MF(X, 0) \to MF(X^2, \bar{w}), \]
3
since $\bar{w}|_{\Delta} = 0$. We denote by $\mathcal{O}_{\Delta, \bar{w}}^{(2)} \in \text{MF}(X^2, \bar{w})$ the image of $\mathcal{O}_X$ under this functor. Let us define the matrix factorization $\mathcal{O}_{\Delta, \bar{w}}^{(2)}$ of $\bar{w}$ as follows:

$$\mathcal{O}_{\Delta, \bar{w}}^{(2)} = \mathcal{O}_{X^2}/I_{\Delta}^2 \oplus \mathcal{O}_{\Delta}[1]$$

$$\delta_0 = -\bar{w} \mod I_{\Delta}^2 = -d\bar{w} : \mathcal{O}_X \rightarrow I_{\Delta}/I_{\Delta}^2 \subset \mathcal{O}_{\Delta}^{(2)}, \quad \delta_1 = -1 : \mathcal{O}_{\Delta}^{(2)} \rightarrow \mathcal{O}_{\Delta}.$$  

Then we have an exact sequence of matrix factorizations

$$0 \rightarrow \Delta_*[\mathcal{O}_X \xrightarrow{d\bar{w}} \Omega^1_X][1] \rightarrow \mathcal{O}_{\Delta, \bar{w}}^{(2)} \rightarrow \mathcal{O}_{\Delta}^{\bar{w}} \rightarrow 0$$

which can be viewed as a morphism in the derived category of MF$(X^2, \bar{w})$.

Now given a matrix factorization $E \in \text{MF}(X, w)$, we can tensor this sequence with $p_2^*E$ and then apply $R\pi_*$. This will produce a class

$$\hat{a}(E) \in \text{Hom}^0(E, [\mathcal{O}_X \xrightarrow{d\bar{w}} \Omega^1_X] \otimes E).$$

Equivalently, we can consider the curved analog of the resolution $[(\Omega^1_X)_{\Delta} \rightarrow \mathcal{O}_{\Delta}^{(2)}]$ of $\mathcal{O}_\Delta$. Namely, let us equip $\mathcal{O}_{\Delta}^{(2)} \oplus (\Omega^1_X)_{\Delta}[1]$ with the structure of a matrix factorization of $\bar{w}$ using the maps

$$\delta_0 : (\Omega^1_X)_{\Delta} \simeq I_{\Delta}/I_{\Delta}^2 \rightarrow \mathcal{O}_{\Delta}^{(2)}, \quad \delta_1 : \mathcal{O}_{\Delta}^{(2)} \xrightarrow{1} \mathcal{O}_{\Delta} \xrightarrow{d\bar{w}} (\Omega^1_X)_{\Delta}.$$  

**Lemma 1.2.** (i) The natural map in MF$(\bar{w})$,

$$q : [\mathcal{O}_{\Delta} \oplus \Delta_*\Omega^1_X][1], \delta] \rightarrow \mathcal{O}_{\Delta}^{\bar{w}},$$

induced by the projection $\mathcal{O}_{\Delta} \rightarrow \mathcal{O}_{\Delta}$, is an isomorphism in the derived category and $\hat{a}^{\text{univ}}$ is equal to the composition of $q^{-1}$ with the natural morphism in MF$(\bar{w})$,

$$[\mathcal{O}_{\Delta} \oplus \Delta_*\Omega^1_X][1], \delta] \rightarrow \Delta_*[\mathcal{O}_X \xrightarrow{d\bar{w}} \Omega^1_X],$$

which is identity on $\Delta_*\Omega^1_X[1]$ and the natural projection to $\mathcal{O}_{\Delta}$ on $\mathcal{O}_{\Delta}^{(2)}$.

(ii) The composition

$$\mathcal{O}_{\Delta}^{\bar{w}} \rightarrow \Delta_*[\mathcal{O}_X \xrightarrow{d\bar{w}} \Omega^1_X] \rightarrow \Delta_*\mathcal{O}_X = \mathcal{O}_{\Delta}$$

is the identity map. Hence, the image of $\hat{a}(E)$ under the natural projection $\text{Hom}^0(E, E \otimes [\mathcal{O}_X \xrightarrow{d\bar{w}} \Omega^1_X]) \rightarrow \text{Hom}^0(E, E)$ is the identity element $\text{id}_E$.

(iii) The universal Atiyah class $\hat{a}^{\text{univ}}$ is obtained as the composition of the Atiyah class

$$\hat{a}(\mathcal{O}_{\Delta}^{\bar{w}}) : \mathcal{O}_{\Delta}^{\bar{w}} \rightarrow [\mathcal{O}_{X^2} \xrightarrow{d\bar{w}} \Omega^1_{X^2}] \otimes \mathcal{O}_{\Delta}^{\bar{w}}$$

with the projection

$$[\mathcal{O}_{X^2} \xrightarrow{d\bar{w}} \Omega^1_{X^2}] \otimes \mathcal{O}_{\Delta}^{\bar{w}} \rightarrow [\mathcal{O}_{X^2} \xrightarrow{d(w \otimes 1)} p_1^*\Omega^1_X] \otimes \mathcal{O}_{\Delta}^{\bar{w}} \simeq \Delta_*[\mathcal{O}_X \xrightarrow{d\bar{w}} \Omega^1_X].$$

**Proof.** (i) Let $f : \Delta_*[\mathcal{O}_X \xrightarrow{d\bar{w}} \Omega^1_X][1] \rightarrow \mathcal{O}_{\Delta}^{(2), \bar{w}}$ be the map from the sequence (1.3) ($f$ is the identity on $\mathcal{O}_\Delta$ and is the natural embedding into $\mathcal{O}_{\Delta}^{(2)}$ on $\Delta_*\Omega^1_X$). We have a natural quasi-isomorphism

$$Cone(f) \rightarrow [\mathcal{O}_{\Delta} \oplus (\Omega^1_X)_{\Delta}[1], \delta]$$

which is identical on $\Delta_*\Omega^1_X[1]$ and $\mathcal{O}_{\Delta}^{(2)}$, zero on $\mathcal{O}_{\Delta}[1]$ and equal to $-d\bar{w} : \mathcal{O}_\Delta \rightarrow \Delta_*\Omega^1_X$ on $\mathcal{O}_\Delta$. One can check that its composition with (1.4) is homotopic to the canonical projection $Cone(f) \rightarrow \Delta_*[\mathcal{O}_X \xrightarrow{d\bar{w}} \Omega^1_X]$ (one uses $\text{id} : \mathcal{O}_{\Delta}[1] \rightarrow \mathcal{O}_{\Delta}[1]$ as a homotopy). This implies our assertion.
This follows easily from (i): the composition of (1.4) with the natural projection \( \Delta_{\ast}[O_X \overset{dw}{\longrightarrow} \Omega_X^1] \to \Delta_{\ast}O_X = \widetilde{O}_X \) is exactly the map \( q \).

(iii) This is proved similarly to Lemma 1.1. \( \square \)

1.2. Čech representative. Let \((U_i)\) be an affine open covering of \(X\). Over every \(U_i\) we can choose an algebraic connection

\[
\nabla_i : \mathcal{E}|_{U_i} \to \Omega^{1}_{U_i} \otimes \mathcal{E}|_{U_i}
\]

which is even, i.e., compatible with the \(\mathbb{Z}/2\)-grading on \(\mathcal{E}|_{U_i}\). Over each intersection \(U_{ij} = U_i \cap U_j\) we have a 1-form with values in \(\text{End}^{0}(\mathcal{E})\), \(\alpha_{ij} \in \Omega^1 U_{ij}, \) such that

\[
\nabla_j - \nabla_i = \alpha_{ij}.
\]

Assume for simplicity that \(X\) is separated, so all intersections \(U_{i_1 \ldots i_k}\) are still affine. Then for any matrix factorizations of \(w, E\) and \(F\), we can calculate the space \(\text{Hom}^1(E, F)\) as the 0th cohomology of the \(\mathbb{Z}/2\)-graded complex

\[
(C^\ast(\text{Hom}(E, F)), [\delta, ?] + d_C)
\]

where \(C^\ast(?)\) denotes the Čech complex and \(d_C\) is the Čech differential. More precisely, the differential on \(\alpha \in C^0(\text{Hom}(E, F))\) is \((-1)^{\delta}[\delta, \alpha] + d_C(\alpha).

**Proposition 1.3.** For a matrix factorization \(E \in \text{MF}(X, w)\), the Atiyah class \(\hat{a}(E)\) is represented by the cocycle

\[
(id_E, -[\nabla_i, \delta], \alpha_{ij}) \in C^\ast([O_X \overset{dw}{\longrightarrow} \Omega_X^1] \otimes \text{End}(E)).
\]

**Proof.** We use the following general fact: if

\[
0 \to E_1 \overset{f}{\longrightarrow} E_2 \overset{g}{\longrightarrow} E_3 \to 0
\]

is an exact sequence of matrix factorizations then the corresponding class in \(\text{Hom}^1(E_3, E_1)\) is represented by the following Čech cocycle. First, we find local retractions \(r_i : E_2 \to E_1\) of the embedding \(E_1 \to E_2\), which are morphisms of \(\mathbb{Z}/2\)-graded \(\mathcal{O}\)-modules over \(U_i\). Then we consider \(\alpha_{ij} : E_3 \to E_1\) over \(U_{ij}\) such that \(\alpha_{ij}g = r_j|_{U_{ij}} - r_i|_{U_{ij}}\). On the other hand, we consider \(\beta_i : E_3 \to E_1[1]\) over \(U_i\) such that \(\beta_i \cdot g = [\delta, t_i] = \delta_{E_1} t_i - t_i \delta_{E_1}\). Now we claim that the Čech cocycle \(c = (\beta_i, \alpha_{ij})\) represents the class corresponding to our extension. Indeed, by definition, this class corresponds to the obvious projection \(\text{Cone}(f) \to E_1[1]\) under the isomorphism

\[
\text{Hom}^1(E_3, E_1) \xrightarrow{\sim} \text{Hom}^1(\text{Cone}(f), E_1)
\]

induced by \(g\). Now the image of \(c\) under the morphism

\[
C^1(\text{Hom}(E_3, E_1)) \to C^1(\text{Hom}(\text{Cone}(f), E_1))
\]

is given by the cocycle

\[
(\beta_i g, \alpha_{ij} g) = ([\delta, t_i], t_j - t_i).
\]

Subtracting the coboundary of the element \((t_i) \in C^0(\text{Hom}(\text{Cone}(f), E_1))\), we get the cocycle given by \((t_i f)\), i.e., by \(\text{id}_{E_1}\), as claimed.

We apply the above general fact to the sequence

\[
0 \to [O_X \overset{dw}{\longrightarrow} \Omega_X^1] \otimes E[1] \to J(E) \to E \to 0
\]

obtained from (1.3) by tensoring with \(p_2^*E\) and taking the push-forward \(p_{1*}\). Note that

\[
J(E) = J(E) \oplus E[1]
\]

as a \(\mathbb{Z}/2\)-graded vector bundle. A connection \(\nabla_i\) on \(E|_{U_i}\) can be viewed as a retraction

\[
\nabla_i : J(E) \to \Omega_X^1 \otimes E : 1 \otimes s \mapsto \nabla_i(s).
\]
Namely, one should consider resolution. First, one checks that for an exact sequence of matrix factorizations (1.5), a choice of 

$$\text{Proof}$$

on $E$ (the proof uses the Dolbeault complex of Cone($f$), where the differential on the latter complex is given by

$$\hat{\text{at}}(E)$$

Then

$$C$$

give a $C\infty$-connection on $E$, compatible with the holomorphic structure.

We have the following analog for matrix factorizations.

**Proposition 1.5.** Let $(E, \delta)$ be a holomorphic matrix factorization of $w$. Let $\nabla$ be an even $C\infty$-connection on $E$, compatible with the holomorphic structure, and let $F^{1,1}$ be the $(1,1)$-part of the curvature of $\nabla$. Then $\hat{\text{at}}(E)$ is represented by the cocycle

$$\left(\text{id}_E, -[\nabla, \delta], F^{1,1}\right) \in \Omega^{1,1}(\End(E, E)),$$

where the differential on the latter complex is given by $[\delta,?] + \partial w + \partial r$.

**Proof.** The proof is similar to that of Proposition 1.3, with the Čech resolution replaced by the Dolbeault resolution. First, one checks that for an exact sequence of matrix factorizations (1.5), a choice of $C\infty$-retractions $r : E_2 \to E_1$ gives a Dolbeault representative for the corresponding class in $\text{Hom}^1(E_3, E_1)$. Namely, one should consider

$$\left(\beta, \alpha\right) \in \Omega^{0,0}(\text{Hom}(E_3, E_1)) \oplus \Omega^{(0,1)}(\text{Hom}(E_3, E_1)_0),$$

where

$$\alpha g = \partial r, \; \beta g = [\delta, r]$$

(the proof uses the Dolbeault complex of $\text{Cone}(f)$, similarly to Proposition 1.3).

Now we apply this for the exact sequence (1.6). We use $\nabla^{1,0}$, the $(1,0)$-part of the connection $\nabla$, to get a $C\infty$-retraction of the embedding $\Omega^{1,0} \otimes E \to J(E)$. This leads to the claimed formula, where the $(1,1)$-curvature $F^{1,1}$ appears as $[\partial, \nabla^{1,0}]$. 

\section{Lie algebra analogies}

**2.1. Lie bracket in the case $w = 0$.** Recall that the Atiyah class $\text{at}(\Omega^1) : \Omega^1_X \to \Omega^1_X \otimes \Omega^1_X[1]$ factors through a map $\Omega^1_X \to S^2(\Omega^1_X)[1]$ whose dual can be viewed as a Lie bracket on $T_X[-1]$ (see [6], [8]).

In addition, there is a morphism

$$\iota : T_X[-1] \to H^0(X) = Rp_1_* \text{End}(\mathcal{O}_\Delta)$$

obtained by adjunction from the component

$$\text{at}^1(\mathcal{O}_\Delta) \in \text{Hom}(\mathcal{O}_\Delta, p_1^* \Omega^1_X \otimes \mathcal{O}_\Delta[1]) \simeq \text{Hom}(p_1^* T_X[-1], \text{End}(\mathcal{O}_\Delta))$$

dues to the Atiyah class $\text{at}(\mathcal{O}_\Delta) \in \text{Hom}(\mathcal{O}_\Delta, \Omega^1_{X_2} \otimes \mathcal{O}_\Delta[1])$. 

\[\text{This leads to the claimed formula. \hfill \square}\]
2.2. HKR-isomorphisms in the case \( w = 0 \). The fact that \( HH^*(X) \) can be identified with the universal enveloping algebra \( U(T_X[-1]) \) means that the above map \( \iota \) satisfies the identity \( \iota([x, y]) = \iota(x)\iota(y) - \iota(y)\iota(x) \) (appropriately formulated), and the morphism
\[
I^{ab}_0: S^*(T_X[-1]) \to T^*(T_X[-1]) \to HH^*(X),
\]
induced by \( \iota \) and by the multiplication on \( HH^*(X) \), is an isomorphism (see [8, Def. 4]).

One of the key tools in the arguments of [8] is the natural duality between \( HH^*(X) \) and \( HH^*(X) \) induced by the canonical functional
\[
\varepsilon: HH^*(X) = \Delta^*(\mathcal{O}_X) \to \mathcal{O}_X,
\]
and by the canonical action
\[
D_0: HH^*(X) \otimes HH^*(X) \to HH^*(X).
\]
More precisely, dualizing the composition
\[
S^*(T_X[-1]) \otimes HH^*(X) \xrightarrow{I^{ab}_0 \otimes 1} HH^*(X) \otimes HH^*(X) \xrightarrow{D_0} HH^*(X) \xrightarrow{\varepsilon} \mathcal{O}_X
\]
we get a map
\[
I^{ab}_0: HH^*(X) \to S^*(T_X[-1])^\vee \simeq S^*(\mathcal{O}_X[1]),
\]
which is an isomorphism (see [8, Prop. 3]).

**Lemma 2.1.** The composition
\[
\varepsilon \circ D_0: HH^*(X) \otimes HH^*(X) \to \mathcal{O}_X
\]
is a perfect pairing, which corresponds to the natural isomorphism
\[
\text{Hom}(\mathcal{H}, \mathcal{F}, \mathcal{G}) = \text{Hom}(\Delta^* \mathcal{O}_X, \mathcal{O}_X) \simeq R\pi_1 \Delta^* \text{Hom}(\Delta^* \mathcal{O}_X, \mathcal{O}_X)
\]
\[
\simeq R\pi_1 \text{Hom}(\Delta^* \mathcal{O}_X, \mathcal{O}_X).
\]

**Proof.** Note that for any morphism \( f: X \to Y \) and sheaves \( F \) on \( Y \) and \( G \) on \( X \), the composition of the natural maps
\[
\text{Hom}(\mathcal{F}, \mathcal{G}) \xrightarrow{f^*} \text{Rf}_* \text{Hom}(\mathcal{F}, \mathcal{G}) \xrightarrow{\text{can}_G} \text{Rf}_* \text{Hom}(\mathcal{G}, \mathcal{F})
\]
is precisely the (sheafified) adjunction isomorphism. Applying this to \( f = \Delta, F = \mathcal{G}, G = \mathcal{O} \), we obtain that the composition
\[
\text{Hom}(\mathcal{F}, \mathcal{G}) \xrightarrow{\Delta^*} \text{Hom}(\Delta^* \mathcal{F}, \mathcal{G}) \xrightarrow{\varepsilon} \text{Hom}(\Delta^* \mathcal{O}_X, \mathcal{O}_X)
\]
is the adjunction isomorphism. Now the assertion follows from the fact that applying \( R\pi_1 \) to the first arrow we get the map \( HH^*(X) \to \text{Hom}(\Delta^* \mathcal{O}_X, \mathcal{O}_X) \) defining \( D_0 \).

**Theorem 2.2.** The isomorphisms \( I^{ab}_0 \) and \( I^{ab}_0 \) in \( D(X) \) coincide with the Hochschild-Kostant-Rosenberg isomorphisms \( I^\text{HKR} \) and \( I^\text{HKR} \), given by the explicit chain maps in [3].

**Proof.** Recall that the action of \( T_X[-1] \) on \( HH^*(X) \) is obtained by applying \( \Delta^* \) to the map \( p_i T_X[-1] \otimes \mathcal{O}_X \to \mathcal{O}_X \) given by \( \text{at}^\text{univ} = \text{at}^1(\mathcal{O}_X) \). We are going to realize the latter map by an explicit chain map of complexes on \( X^2 \), replacing \( \mathcal{O}_X \) by its completed bar-resolution \( \mathcal{B}_* \) (see [15], [3, Sec. 4]). Recall that \( \mathcal{B}_i \) is the push-forward to \( X^2 \) of the formal completion of \( X^{i+2} \) along the small diagonal. We denote local sections of \( \mathcal{B}_i \) as \( [a_0 \otimes a_1 \ldots \otimes a_{i+1}] \), where \( a_j \) are local functions on \( X \).

We claim that the map \( \text{at}^\text{univ} \) is represented by the chain map
\[
p_i T_X \otimes \mathcal{B}_* \to \mathcal{B}_*[1]: v \otimes [a_0 \otimes a_1 \ldots \otimes a_{i+1}] \mapsto (-1)^{i+1}[a_0 v(a_1) \otimes a_2 \otimes \ldots \otimes a_{i+1}].
\]
Indeed, it is enough to look at the induced map of complexes $p_{i}^* T_X \otimes B_* \to \mathcal{O}_\Delta[1]$, or equivalently, $B_* \to \Delta_* \Omega^1_X[1]$ induced by the map $f_1 : B_* \to \Delta_* \Omega^1 : [a_0 \otimes a_1 \otimes a_2] \mapsto a_2 a_0 da_1$. Now we observe that there is a quasi-isomorphism of complexes,

$$
\begin{array}{ccc}
B_2 & \to & B_1 \\
\downarrow f_1 & & \downarrow 1 \\
\Delta_* \Omega^1_X & \to & \mathcal{O}_\Delta[2]
\end{array}
$$

Since $at^{univ}$ is induced by the exact sequence (1.1), this implies our claim.

It follows that the map

$$(at^{univ})_{(i)} : p_i^* \bigwedge^i T_X \otimes \mathcal{O}_\Delta \to \mathcal{O}_\Delta[i]$$

obtained by iterating $at^{univ}$ and restricting to skew-symmetric tensors, is represented by the chain map $p_i^* \bigwedge^i T_X \otimes B_* \to B_\bullet[i] : (v_1 \wedge \ldots \wedge v_i) \otimes [a_0 \otimes a_1 \otimes \ldots \otimes a_m] \mapsto (-1)^{im} [a_0 (v_1 \wedge \ldots \wedge v_i, da_1 \wedge \ldots da_i) \otimes a_{i+1} \otimes \ldots \otimes a_m]$.

Composing with the projection $B_\bullet[i] \to \mathcal{O}_\Delta[i]$, we see that $(at^{univ})_{(i)}$ is represented by the chain map $p_i^* \bigwedge^i T_X \otimes B_* \to \mathcal{O}_\Delta[i]$ which corresponds by duality to the map

$$B^i \to p_i^* \Omega^1_X \otimes \mathcal{O}_\Delta \simeq \Delta_* \Omega^1_X[1] : [a_0 \otimes a_1 \otimes \ldots \otimes a_{i+1}] \mapsto a_{i+1} a_0 da_1 \wedge \ldots \wedge da_i$$

which is exactly the $i$th component of $I_{HKR}$. This proves the equality $I_{abs} = I_{HKR}$.

Recall (see [3, Sec. 4]) that the other HKR-map

$$I_{HKR}^*: \bigoplus \bigwedge^i T_X[-i] \to Rp_1 \mathbf{End}(\mathcal{O}_\Delta)$$

is essentially the dual of $I_{HKR}$: it is given by the composition

$$\bigoplus \bigwedge^i T_X[-i] = \text{Hom}(\bigoplus \Omega^i_X[i], \mathcal{O}_X) \to \text{Hom}(\Delta^* \mathcal{O}_\Delta, \mathcal{O}_X) \simeq Rp_1 \mathbf{End}(\mathcal{O}_\Delta, \mathcal{O}_\Delta),$$

where the last isomorphism follows from the adjunction of $(\Delta^*, \Delta_*)$.

On the other hand, it is easy to see that the composition

$$\mathbf{HH}^* \otimes \mathbf{HH} \to \mathbf{HH} \xrightarrow{Du} \mathbf{HH} \xrightarrow{\varepsilon} \mathcal{O}_X$$

corresponds to the same duality, so the equality $I_{abs} = I_{HKR}^*$ follows from the equality $I_{abs} = I_{HKR}$. \hfill \Box

**Remark.** The above theorem can be easily deduced from the arguments in the proof of [3, Prop. 4.4]. Note that $I_{HKR}^*$ (and hence $I_{abs}$) is not an algebra homomorphism with respect to the natural algebra structures on $S^*(T_X[-1])$ and $\mathbf{HH}^*(X)$; to become one it has to be twisted by the square root of the Todd class (see [3], [2]).

### 2.3. The general case.

The (usual) Atiyah class of the complex $L_w^\vee = [\mathcal{O}_X \xrightarrow{dw} \Omega^1_X]$ is an element

$$at(L_w^\vee) : L_w^\vee \to \Omega^1_X[1] \otimes L_w^\vee.$$ 

In the $\mathbb{Z}/2$-graded derived category we have a natural morphism $\Omega^1_X[1] \to L_w^\vee$. Thus, composing the map $at(L_w^\vee)$ with this morphism, we get a map

$$L_w^\vee \to L_w^\vee \otimes L_w^\vee,$$

or dualizing, a map

$$[\cdot, \cdot] : L_w \otimes L_w \to L_w,$$

which factors through $T_X[1] \otimes L_w$. 

8
The following lemma will show that our bracket is skew-symmetric and that $O_X \subset L_w$ is central with respect to it.

**Lemma 2.3.** *The dual of the bracket $[,]$ factors in the $\mathbb{Z}/2$-graded derived category as a composition* $L_w^\vee \to S^2\Omega_X^1 \to \Omega_X^1 \otimes \Omega_X^1 \to L_w^\vee \otimes L_w^\vee$.

**Proof.** The proof is a slight variation of the proof of [8, Prop. 1.1]. By definition, the map $\hat{a}(L_w^\vee)$ corresponds to an exact sequence of complexes

$$0 \to p_1([I_\Delta/I_\Delta^3 \otimes p_2^*L_w^\vee]) \to p_1([O_{X^2}/I_\Delta^3 \otimes p_2^*L_w^\vee]) \to p_1([O_\Delta \otimes p_2^*L_w^\vee]) \to 0.$$  

Now we use the natural morphism induced by the canonical differential $d_{X^2}$ of $\Omega_{X^2}$:

$$[O_X \to p_1([I_\Delta/I_\Delta^3]) \to p_1([O_{X^2}/I_\Delta^3 \otimes p_2^*L_w^\vee]).$$

where $\delta(f) = f \cdot (1 \otimes w - w \otimes 1)$, and the map $O_X \to p_1([O_{X^2}/I_\Delta^3])$ is given by $f \mapsto f \otimes 1 \mod I_\Delta^3$.

Furthermore, this chain map extends naturally to a chain map of complexes

$$[O_X \to p_1([I_\Delta/I_\Delta^3]) \to [O_X \to p_1([I_\Delta/I_\Delta^3])] \to 0.$$  

in which the leftmost vertical arrow can be identified with the natural map $S^2\Omega_X^1[-1] \to \Omega_X^1 \otimes L_w^\vee$. This implies our assertion. \qed

By analogy with morphism (2.1) we want to define a morphism

$$\iota_w : L_w \to HH^*(MF(X, w)) = Rp_{1\ast}(\Omega_\Delta^\vee)$$

in $D(X)$. For this we consider the universal Atiyah class

$$\hat{a}(\O_\Delta^\vee) \in \text{Hom}(\O_\Delta^\vee \otimes \O_\Delta^\vee)$$

(see Lemma 1.2(iii)).

As in the proof of [8, Thm. 1], the universal enveloping algebra identity follows from the commutative diagram

$$\xymatrix{ O_\Delta^\vee \ar[r]^{\hat{a}(O_\Delta)} \ar[d]_{\hat{a}(O_\Delta^\vee)} & p_1^*(L_w^\vee \otimes O_\Delta^\vee) \ar[d]_{\hat{a}(p_1^*L_w^\vee \otimes O_\Delta^\vee)} \ar[d]_{\text{id} \otimes \hat{a}(O_\Delta^\vee)} \ar[d]_{\hat{a}(p_1^*L_w^\vee \otimes O_\Delta^\vee)} \ar[r]_{\text{id} \otimes \hat{a}(O_\Delta^\vee)} & p_1^*(L_w^\vee \otimes O_\Delta^\vee) \ar[d]_{\hat{a}(p_1^*L_w^\vee \otimes O_\Delta^\vee)} \ar[d]_{\hat{a}(p_1^*L_w^\vee \otimes O_\Delta^\vee)} \ar[r]_{\text{id} \otimes \hat{a}(O_\Delta^\vee)} & p_1^*(L_w^\vee \otimes O_\Delta^\vee) \ar[d]_{\hat{a}(p_1^*L_w^\vee \otimes O_\Delta^\vee)} \ar[d]_{\hat{a}(p_1^*L_w^\vee \otimes O_\Delta^\vee)} \ar[r]_{\text{id} \otimes \hat{a}(O_\Delta^\vee)} & p_1^*(L_w^\vee \otimes O_\Delta^\vee) }$$

together with Lemma 1.4.

The fact that $\hat{a}(E)$ projects to the identity $\text{id}_E$ implies (by taking $E = O_\Delta^\vee$) that the composition

$$O_X \xrightarrow{1} L_w \xrightarrow{\iota_w} HH^*(MF(X, w))$$

is the natural embedding of a unit.
Lastly, we need to check the analog of the property that for a central extension (0.3) the natural map

$$S(\tilde{g})/(1-1) \to U(\tilde{g})/(1-1)$$

is an isomorphism. Note the source of this map can be identified with $\varprojlim i S^i(\tilde{g})$, which is a better expression for us since it makes sense also in non-abelian categories. Thus, we claim that the induced map

$$I_{abs,w} : \varprojlim i S^i(L_w) \to \mathbb{H}^* (MF(X, w))$$

(2.6)

is an isomorphism. Furthermore, it is easy to see that the limit here stabilizes and we have

$$\varprojlim i S^i(L_w) = S^n(L_w) \simeq (\bigwedge^\bullet \langle T_X \rangle, i dw),$$

where $n = \dim X$. Here the second isomorphism is dual to (0.1). The fact that the map (2.6) is an isomorphism can be checked formally locally using the Koszul resolution of the diagonal matrix factorization (it also follows from Theorem 2.5 below and from the results of [7]).

Similarly to the case of Lie algebras, where the PBW-theorem can be used to derive the Jacobi identity (see e.g., [10, Ch. 5]), one can show that the properties proved above imply that the bracket $[\cdot, \cdot]$ on $L_w$ satisfies the Jacobi identity (we will not use this fact).

Similarly to the case $w = 0$, we have a canonical functional

$$\varepsilon : \mathbb{H}_* (MF(X, w)) = \Delta^* (\mathcal{O}_X^w) \to \mathcal{O}_X,$$

coming from the adjoint pair of functors $(\Delta^*, \Delta_*)$ between $MF(X, 0)$ and $MF(X^2, \tilde{w})$. On the other hand, we have the natural action of $\mathbb{H}_* (MF(X, w)) = Rp_1 \text{End}(\mathcal{O}_X^w)$ on $\mathbb{H}_* (MF(X, w))$,

$$D : \mathbb{H}_* (MF(X, w)) \otimes \mathbb{H}_* (MF(X, w)) \to \mathbb{H}_* (MF(X, w)).$$

**Lemma 2.4.** The composition

$$\varepsilon \circ D : \mathbb{H}_* (MF(X, w)) \otimes \mathbb{H}_* (MF(X, w)) \to \mathcal{O}_X$$

is a perfect pairing, which corresponds to the natural isomorphism

$$\text{Hom}(\mathbb{H}_* (MF(X, w)), \mathcal{O}_X) = \text{Hom}(\Delta^* \mathcal{O}_X^w, \mathcal{O}_X) \simeq Rp_1 \Delta_* \text{Hom}(\Delta^* \mathcal{O}_X^\tilde{w}, \mathcal{O}_X) \simeq Rp_1 \text{Hom}(\mathcal{O}_X^w, \mathcal{O}_X),$$

induced by the adjoint pair of functors $(\Delta^*, \Delta_*)$ between $MF(X, 0)$ and $MF(X^2, \tilde{w})$.

**Proof.** The proof is very similar to that of Lemma 2.1 and is left to the reader. \(\square\)

Let us consider the composition

$$S^n(L_w) \otimes \mathbb{H}_* (MF(X, w)) \xrightarrow{I_{abs,w} \otimes \text{id}} \mathbb{H}_* (MF(X, w)) \otimes \mathbb{H}_* (MF(X, w)) \xrightarrow{\varepsilon \circ D} \mathcal{O}_X.$$  

Dually, we get a morphism

$$I_{abs,w} : \mathbb{H}_* (MF(X, w)) \to S^n(L_w)^\vee \simeq [\Omega_\bullet, \wedge dw],$$  

(2.7)

where the last isomorphism is (0.1).

**Theorem 2.5.** The maps $I_{abs,w}$ and $I_{abs,w}$ in $D(X)$ coincide with the maps $I_{HKR,w}$ and $I_{HKR,w}$ defined using the completed bar-resolution in [7] and [9].

**Proof.** As in the proof of Theorem 2.2, to check the equality $I_{abs,w} = I_{HKR,w}$, we first realize

$$\hat{\text{at}}^\text{univ} : p_1^* L_w \otimes \mathcal{O}_\Delta^w \to \mathcal{O}_\Delta^w$$

by a closed map of matrix factorizations.
Recall that the completed bar-resolution \((B_\bullet, b)\) is equipped with the second differential
\[
B_w[a_0 \otimes a_1 \otimes \ldots \otimes a_{m+1}] = \sum_{i=0}^{m} (-1)^i a_0 \otimes \ldots \otimes a_i \otimes w \otimes a_{i+1} \otimes \ldots \otimes a_{m+1},
\]
so that \(B^\sim := (B_\bullet, b + B_w)\) is a (quasicoherent) matrix factorization of \(\tilde{w} = w \otimes 1 - 1 \otimes w\).

Similarly to the case \(w = 0\), we define a closed morphism of matrix factorizations
\[
p_1^* L_w \otimes B^\sim \to B^\sim : (v + f) \otimes [a_0 \otimes a_1 \otimes \ldots \otimes a_m] = (-1)^m [a_0v(a_1) \otimes a_2 \otimes \ldots \otimes a_m] + [fa_0 \otimes a_1 \otimes \ldots \otimes a_m].
\]
We claim that it represents \(\hat{a}^{univ} \). Indeed, it is enough to consider the composed map
\[
p_1^* L_w \otimes B^\sim \to \mathcal{O}_\Delta^\sim
\]
and compare its dualization
\[
B^\sim \to p_1^* L_w^\sim \otimes \mathcal{O}_\Delta^\sim \simeq \Delta_* [\mathcal{O}_X \xrightarrow{dw} \Omega_X^1] \quad (2.8)
\]
with \(a^{univ} \). It remains to observe that (2.8) factors as the composition
\[
B^\sim \to [\mathcal{O}_\Delta] \otimes (\Omega_X^1)_\Delta [1], \delta \to [\mathcal{O}_\Delta \otimes (\Omega_X^1)_\Delta [1], dw]
\]
where the first map is an isomorphism of resolutions of \(\mathcal{O}_\Delta^\sim\), while the second map induces \(a^{univ} \) by Lemma 1.2(i).

Considering the induced map \(p_1^* S^n L_w \otimes B^\sim \to B^\sim \to \mathcal{O}_\Delta^\sim\), we deduce that \(I_{abs}\) coincides with the Hochschild-Kostant-Rosenberg isomorphism \(I_{HKR,w}\) given by the map
\[
\Delta^* B^\sim \to (\Omega_X^1, \wedge dw) : [a_0 \otimes \ldots \otimes a_{i+1}] \mapsto a_{i+1} a_0 da_1 \wedge \ldots \wedge da_i.
\]
The equality \(I_{abs,w} = I_{HKR,w}\) follows by duality as in the case \(w = 0\). \qed

3. Boundary-bulk map

3.1. Generalities. Recall that the diagonal matrix factorization \(\mathcal{O}_\Delta^\sim \in \text{MF}(X^2, \tilde{w})\) corresponds to the identity functor on \(\text{MF}(X, w)\). The categorical trace functor can be identified with the composition
\[
\text{Tr} : \text{MF}(X^2, \tilde{w}) \xrightarrow{\Delta^*} D(X) \xrightarrow{\text{HF}} D(k).
\]

Thus, the Hochschild homology of the category \(\text{MF}(X, w)\) can be computed as
\[
\text{HH}_*(\text{MF}(X, w)) = \text{R}\Gamma(X, \text{HH}_*(\text{MF}(X, w)));
\]
where
\[
\text{HH}_*(\text{MF}(X, w)) \simeq [\Omega^*, \wedge dw].
\]
Furthermore, we have an isomorphism
\[
\text{HH}_*(\text{MF}(X, w)) \simeq [\Omega^*, \wedge dw].
\]
The sheafified boundary-bulk map
\[
\text{End}(E) \to \text{HH}_*(\text{MF}(X, w)), \quad (3.1)
\]
which is a map in \(D(X)\), is obtained by applying \(\Delta^*\) to the evaluation morphism in \(\text{MF}(X^2, \tilde{w})\),
\[
ev_E : E \boxtimes E^\vee \to \mathcal{O}_\Delta^\sim.
\]
The latter morphism is obtained by dualization from the morphism
\[
\eta_E : p_1^* E \to E_\Delta \simeq p_1^* E \otimes \mathcal{O}_\Delta^\sim
\]
in \(\text{MF}(X^2, w \otimes 1)\), which corresponds by adjunction to the isomorphism \(E \to Rp_{1*}(p_1^* E \otimes \mathcal{O}_\Delta^\sim)\).

Since the boundary-bulk map is obtained from \(\ev_E\) by applying the categorical trace functor \(\text{Tr}\), it is obtained from the sheafified boundary-bulk map (3.1) by passing to derived global sections.
3.2. **Exponentials.** Our exponentials are analogs of the following Lie theoretic construction. Let \( g \) be a Lie algebra, \( M \) a \( g \)-module. Then for every \( n \geq 0 \), we have a morphism given by the iterated action,

\[
u_i : g^\otimes i \otimes M \to M : x_1 \otimes \ldots \otimes x_i \otimes m \mapsto x_1 \cdot (\ldots (x_{i-1} \cdot (x_i \cdot m)) \ldots).
\]

We denote by \( s_i : S^i(g) \otimes M \to M \) the restriction of \( u_n \) to symmetric tensors. We can think of \( s_i \) as an element of \( S^i(g)^* \otimes \text{End}(M) \). Combining these elements together we get the element

\[
\exp_M \in S^\bullet(g)^* \otimes \text{End}(M).
\]

Now given an object \( E \) in \( D(X) \), the Atiyah class of \( E \) defines a map

\[
T_X[-1] \otimes E \to E
\]

which is an action of \( T_X[-1] \) (viewed as a Lie algebra) on \( E \). Thus, we get the corresponding element

\[
\exp_E \in \text{Hom}(E, S^\bullet(\Omega_X[1]) \otimes E) = \text{Hom}(E, \bigoplus_i \Omega^i_X[i] \otimes E).
\]

Unraveling the definitions, we see that

\[
\exp_E = \exp(\text{at}(E)),
\]

where the right-hand side is defined in the standard way (see e.g., [3, Sec. 4]).

Similarly, we can consider \( O_\Delta \) as a module over \( p^*_t T_X [-1] \) using the universal Atiyah class, \( \text{at}^{\text{univ}} : p^*_t T_X [-1] \otimes O_\Delta \to O_\Delta \). This gives rise to the element

\[
\exp(\text{at}^{\text{univ}}) \in \text{Hom}(O_\Delta, \bigoplus_n p^*_t \Omega^i_X[i] \otimes O_\Delta) = \text{Hom}(O_\Delta, \Delta^* \bigoplus_i \Omega^i_X[i]).
\]

In the same way for a matrix factorization \( E \in MF(X, w) \) we define

\[
\exp(\text{at}(E)) \in \text{Hom}^0(E, (\Omega^*_X, \wedge dw) \otimes E)
\]

using the action of \( L_w \) on \( E \), passing to the induced map

\[
S^n(L_w) \otimes E \to E
\]

dualizing, and using the isomorphism of \( S^n(L_w^\vee) \) with \( (\Omega^*_X, \wedge dw) \) (see (0.1)). This is equivalent to the definition given in Theorem A.

Similarly, we have a version for the universal Atiyah class,

\[
\exp(\text{at}^{\text{univ}}) : O_\Delta \to p^*_t (\Omega^*_X, \wedge dw) \otimes O_\Delta^\vee,
\]

obtained from the action of \( p^*_t L_w \) on \( O_\Delta \).

3.3. **Key lemma.** First, let us formulate the assertion we need in the case \( w = 0 \). Recall that we have the morphism

\[
\exp(\text{at}^{\text{univ}}) : O_\Delta \to \Delta^* \bigoplus_i \Omega^i_X[i].
\]

We have the following key fact.

**Lemma 3.1.** One has a commutative triangle

\[
\begin{array}{ccc}
O_\Delta & \xrightarrow{\text{can}} & \Delta^* O_\Delta \\
\downarrow{\exp(\text{at}^{\text{univ}})} & & \downarrow{\Delta^* I_{abs}} \\
\Delta^* \bigoplus_i \Omega^i_X[i] & \xrightarrow{\Delta^*} & \Delta^* \bigoplus_i \Omega^i_X[i]
\end{array}
\]
Proof. Since the action of $T_X[-1]$ on $HH_*(X) = \Delta^*\mathcal{O}_\Delta$ is obtained by applying $\Delta^*$ to $at^{univ}$, by naturality of can, we get the following commutative diagram

\[
\begin{array}{ccc}
p_1^*T_X[-1] \otimes \mathcal{O}_\Delta & \xrightarrow{id \otimes can} & p_1^*T_X[-1] \otimes \Delta_*\Delta^*\mathcal{O}_\Delta \\
\text{at}^{univ} & & \\
\mathcal{O}_\Delta & \xrightarrow{can} & \Delta_*\Delta^*\mathcal{O}_\Delta
\end{array}
\]

where the right vertical arrow corresponds to the action of $T_X[-1]$ on $HH_*(X)$. In other words, the map $can : \mathcal{O}_\Delta \to \Delta_*\Delta^*\mathcal{O}_\Delta$ is compatible with the action of $p_1^*T_X[-1]$. Hence, it is also compatible with the iteration of this action and its restriction to (skew)-symmetric tensors:

\[
\begin{array}{ccc}
p_1^*S^*(T_X[-1]) \otimes \mathcal{O}_\Delta & \xrightarrow{id \otimes can} & p_1^*S^*(T_X[-1]) \otimes \Delta_*\Delta^*\mathcal{O}_\Delta \\
\text{exp(at}^{univ}) & & \\
\mathcal{O}_\Delta & \xrightarrow{can} & \Delta_*\Delta^*\mathcal{O}_\Delta
\end{array}
\]

where the left vertical arrow corresponds to $\text{exp(at}^{univ})$ by duality. Composing with the map $\Delta_*\varepsilon : \Delta_*\Delta^*\mathcal{O}_\Delta \to \mathcal{O}_\Delta$ (whose composition with can is the identity), we get the commutative triangle

\[
\begin{array}{ccc}
p_1^*S^*(T_X[-1]) \otimes \mathcal{O}_\Delta & \xrightarrow{id \otimes can} & p_1^*S^*(T_X[-1]) \otimes \Delta_*\Delta^*\mathcal{O}_\Delta \\
\text{exp(at}^{univ}) & & \\
\mathcal{O}_\Delta & \xrightarrow{can} & \Delta_*\Delta^*\mathcal{O}_\Delta
\end{array}
\]

where the vertical arrow is the push-forward by $\Delta$ of the composition

\[
\varepsilon \circ D_0 \circ (I_{abs} \otimes id) : S^*(T_X[-1]) \otimes \Delta^*\mathcal{O}_\Delta \to \mathcal{O}_X.
\]

Now the assertion follows from the fact that $I_{abs}$ is obtained from the latter map by dualization. \qed

Remark. Note that the assertion of Lemma 3.1, with $I_{abs}$ replaced by the standard HKR-isomorphism defined using completed bar-resolution, is exactly Prop. 4.4 in [3]. However, the only place where the computations using global resolutions are needed is Theorem 2.2.

Now let us consider the case of matrix factorizations. Recall that we have a universal Atiyah class,

\[
\hat{at}^{univ} \in \text{Hom}(\mathcal{O}_\Delta^\vee, p_1^*L^\vee_w \otimes \mathcal{O}_\Delta^\vee),
\]

which should be thought of as an analog of $1 + at^{univ}$. Next, we define an element

\[
\text{exp(at}^{univ}) \in \text{Hom}(\mathcal{O}_\Delta^\vee, p_1^*S^n(L^\vee_w) \otimes \mathcal{O}_\Delta^\vee),
\]

where $n = \dim X$. 

13
Lemma 3.2. One has a commutative triangle

\[ \begin{array}{c}
\mathcal{O}_\Delta^\wedge \xrightarrow{\text{can}} \Delta_\ast \Delta^\ast \mathcal{O}_\Delta^\wedge \\
\downarrow \exp(\hat{\text{at}}^\text{univ}) \quad \downarrow \Delta_\ast \mathcal{I}^\text{abs,w} \\
\Delta_\ast (\Omega_X^\bullet \wedge dw) 
\end{array} \]

Proof. The proof is similar to that of Lemma 3.1. We use the fact that the dualization of the universal Atiyah class induces an action of \( p_1^1L_w \) on \( \mathcal{O}_\Delta^\wedge \) so we get a commutative diagram

\[ \begin{array}{c}
p_1^1L_w \otimes \mathcal{O}_\Delta^\wedge \xrightarrow{\text{id} \otimes \text{can}} p_1^1L_w \otimes \Delta_\ast \Delta^\ast \mathcal{O}_\Delta^\wedge \\
\downarrow \hat{\text{at}}^\text{univ} \quad \downarrow \\
\mathcal{O}_\Delta^\wedge \xrightarrow{\text{can}} \Delta_\ast \Delta^\ast \mathcal{O}_\Delta^\wedge 
\end{array} \]

and then use the iteration of this action to get a commutative diagram

\[ \begin{array}{c}
p_1^1S^n(L_w) \otimes \mathcal{O}_\Delta^\wedge \xrightarrow{\text{id} \otimes \text{can}} p_1^1S^n(L_w) \otimes \Delta_\ast \Delta^\ast \mathcal{O}_\Delta^\wedge \\
\downarrow \exp(\hat{\text{at}}^\text{univ}) \quad \downarrow \\
\mathcal{O}_\Delta^\wedge \xrightarrow{\text{can}} \Delta_\ast \Delta^\ast \mathcal{O}_\Delta^\wedge 
\end{array} \]

Finally, composing with \( \Delta_\ast \varepsilon : \Delta_\ast \Delta^\ast \mathcal{O}_\Delta^\wedge \rightarrow \mathcal{O}_\Delta^\wedge \) and dualizing we get the result. \( \square \)

3.4. Proof of Theorem A. Let us first consider the case \( w = 0 \). We can view the commutative triangle of Lemma 3.1 as the triangle of Fourier-Mukai functors from \( D(X) \) to \( D(X) \) (where to a kernel \( K \) in \( D(X \times X) \) we associate the functor \( Rp_1(K \otimes p_1^1(\cdot)) \)). Applying these functors to an object \( E \in D(X) \), we get a commutative triangle of the form

\[ \begin{array}{c}
E \xrightarrow{\text{can}_E} \Delta^\ast \mathcal{O}_\Delta \otimes E \\
\downarrow \exp(\hat{\text{at}}(E)) \quad \downarrow \mathcal{I}^\text{abs} \otimes \text{id} \\
\Omega_X^\bullet \otimes E 
\end{array} \] (3.2)

We claim that the morphism \( \text{can}_E \) is obtained by applying \( \Delta^\ast \) to the canonical morphism

\[ \eta_E : p_1^1E \rightarrow \Delta_\ast E \simeq \mathcal{O}_\Delta \otimes p_2^1E. \]

Indeed, first let us observe that for any \( F, G \in D(X \times X) \) we have a commutative triangle

\[ \begin{array}{c}
F \otimes G \xrightarrow{a_F \otimes \text{id}_G} \Delta_\ast \Delta^\ast F \otimes G \\
\downarrow \quad \downarrow \\
\Delta_\ast \Delta^\ast (F \otimes G) 
\end{array} \]
where \( a_F : F \to \Delta_! \Delta^* F \) is the adjunction map, and the vertical arrow is the composition of the natural isomorphisms

\[
\Delta_! \Delta^* F \otimes G \simeq \Delta_! (\Delta^* F \otimes \Delta^* G) \simeq \Delta_! \Delta^*(F \otimes G).
\]

Applying this to \( F = \mathcal{O}_\Delta \) and \( G = p_2^* E \) we get the commutativity of the triangle in the diagram

\[
P_1^* E \xrightarrow{\eta_E} \mathcal{O}_\Delta \otimes p_2^* E \xrightarrow{\text{can} \otimes \text{id}} \Delta_! \Delta^* \mathcal{O}_\Delta \otimes p_2^* E
\]

\[
\Delta_! \Delta^* p_1^* E \xrightarrow{\Delta_! \Delta^* \eta_E} \Delta_! \Delta^* (\mathcal{O}_\Delta \otimes p_2^* E)
\]

Note that here the vertical arrows are the adjunction maps, so the square in the above diagram is also commutative. Using the adjointness of \((p_1^*, p_1^*)\), we get a commutative diagram

\[
E \xrightarrow{\sim} Rp_1^* (\mathcal{O}_\Delta \otimes p_2^* E) \xrightarrow{R \text{can} \otimes \text{id}} \Delta^* \mathcal{O}_\Delta \otimes p_2^* E
\]

By definition, the composition of arrows in the first row is \( \text{can}_E \), and our claim follows.

This implies that \( \text{can}_E \) corresponds by dualization to the sheafified boundary-bulk map

\[
E \otimes E^\vee \to \Delta^* \mathcal{O}_\Delta = \mathcal{H} \mathcal{H}_\ast (X)
\]

(obtained as \( \Delta^* \) of the evaluation map \( E \otimes E^\vee \to \mathcal{O}_\Delta \)). Composing with \( I_{\text{abs}} \) and using commutativity of (3.2) we get its expression in terms of \( \exp(\text{at}(E)) \).

Now we can repeat the same argument in the case of matrix factorizations. For \( E \in \text{MF}(X, w) \), using Lemma 3.2, we get a commutative triangle

\[
E \xrightarrow{\text{can}_E} \Delta^* \mathcal{O}_X^\vee \otimes E \xrightarrow{\exp(\text{at}(E))} (\Omega^\bullet_X \wedge dw) \otimes E
\]

where the morphism \( \text{can}_E \) is obtained by applying \( \Delta^* \) to \( \eta_E \). Since \( \text{ev}_E \) corresponds to \( \eta_E \) by dualization, this implies that the sheafified boundary-bulk map,

\[
\Delta^* (\text{ev}_E) : \text{End}(E) \to \Delta^*(\mathcal{O}_\Delta^\vee)
\]

is given by \( x \mapsto \text{str}(\exp(\text{at}(E)) \cdot x) \). \( \square \)
