SHARP STABILITY OF BRUNN-MINKOWSKI FOR HOMOTHETIC REGIONS

PETER VAN HINTUM, HUNTER SPINK, AND MARIUS TIBA

Abstract. The Brunn-Minkowski inequality applied to homothetic regions states that $|A| \leq \frac{t}{n} + (1-t)A$ for $A \subset \mathbb{R}^n$ and $t \in [0,1]$. We show there is a constant $C_n > 0$ and constants $d_n(\tau) > 0$ for each $\tau \in (0,\frac{1}{2}]$ such that if $t \in [\tau, 1-\tau]$ and $(tA + (1-t)A \setminus A| \leq d_n(\tau)|A|$, then $|\text{co}(A) \setminus A| \leq C_n \tau^{-1}|(tA + (1-t)A \setminus A|$, which is sharp up to the multiplicative constant $C_n$. For $t = \frac{1}{2}$ this resolves a conjecture of Figalli and Jerison.

1. Introduction

Inverse problems in additive combinatorics seek to ascertain the structure of a set $X \subset \mathbb{Z}^n$ given structural properties of its sumset $X + X$. In this paper we consider measurable analogues of one of the most basic inverse problems: if $|X + X| \sim 2^n|X|$, then is $X$ close to a convex set? For $n = 1$, a result of this form is due to Freiman [5].

Recall that the Brunn-Minkowski inequality states that for $A, B \subset \mathbb{R}^n$, then with $|\cdot|$ the outer Lebesgue measure on $\mathbb{R}^n$ we have

$$|A + B|^{\frac{1}{n}} \geq |A|^{\frac{1}{n}} + |B|^{\frac{1}{n}}.$$ 

Equality is known to hold if and only if $A$ and $B$ are, up to a measure 0 set, homothetic copies of the same convex body. It is therefore natural to ask whether the inequality is stable: if we are close to equality in the Brunn-Minkowski inequality, then are $A, B$ close to homothetic copies of the same convex body? More precisely, we want to know if there are homothetic convex sets $K_A \supset A$ and $K_B \supset B$ such that

$$\frac{|K_A \setminus A|}{|A|} \quad \text{and} \quad \frac{|K_B \setminus B|}{|B|}$$

are small in terms of the quantities

$$\delta' = \frac{|A + B|^{\frac{1}{n}}}{|A|^{\frac{1}{n}} + |B|^{\frac{1}{n}}} - 1, \quad \text{and} \quad t = \frac{|A|^{\frac{1}{n}}}{|A|^{\frac{1}{n}} + |B|^{\frac{1}{n}}}.$$ 

The bound should be stronger when $\delta'$ is smaller and weaker when the volumes of $A, B$ are disproportionate, so the bound should be positively correlated with $\delta'$ and negatively correlated with $\tau = \min(t, 1-t)$.

We note that such a bound can’t exist without further stipulations which rule out variants of the following construction. Take $A = B = ([0,1] \cup \{R\}) \times [0,1]^{n-1}$ with $R \geq 2$. Then we seek to upper bound $R - 1$ by a function of the constants $\delta' = (1.5)^{\frac{1}{n}} - 1$ and $t = \frac{1}{2}$, which will not hold if we take $R$ to be sufficiently big. We can avoid this example by stipulating an upper bound (depending on $\tau$) on $\delta'$, and surprisingly in many cases imposing such a constraint is sufficient for the desired stability result.

The first and second author would like to thank their respective institutions Clare College, University of Cambridge and Harvard University. The third author is grateful for the Trinity Hall research studentship for providing research funding.

1
There has been recent dramatic progress in this direction (see [1,2]), culminating in a general stability result [3], bounding the quantities $\frac{|K_A \setminus A|}{|A|}$ and $\frac{|K_B \setminus B|}{|B|}$ by a product of some positive power of $|\delta'|$ and a negative power of $\tau = \min(t, 1-t)$ assuming an upper bound (depending on $\tau$) of $|\delta'|$.

We note that we can equivalently consider $A, B \subset \mathbb{R}^n$ with $|A| = |B| = 1$, and bound the quantities $|K_A \setminus A|$ and $|K_B \setminus B|$ by a function of
\[
\delta' = |tA + (1 - t)B|^{\frac{1}{n}} - 1 \quad \text{and} \quad \tau = \min(t, 1 - t)
\]
for some parameter $t$, assuming an upper bound (depending on $\tau$) of $\delta'$. Formulated in this fashion, it will be more convenient to use
\[
\delta = |tA + (1 - t)B| - 1
\]
instead of $\delta'$, but these are equivalent up to a multiplicative constant under the upper bound assumption. For the rest of the paper, we consider the problem reformulated in this way.

We now focus on the case where $A, B$ are homothetic copies of each other in the original formulation, corresponding to $A = B$ in this equal volume reformulation. Given a subset $A \subset \mathbb{R}^n$, we denote the convex hull by $co(A)$. The interpolated semisum of $A$ is
\[
d(A; t) := tA + (1 - t)A = \{ta_1 + (1 - t)a_2 \mid a_1, a_2 \in A\}.
\]
Note that we always have $A \subset d(A; t)$, and as a special case $d(A; \frac{1}{2}) = \frac{1}{2}(A + A)$. To quantify how small $d(A; t)$ is, we introduce the interpolated doubling constant
\[
\delta(A; t) := |d(A; t) \setminus A|.
\]
Note that under the normalization assumption $|A| = 1$, we have $\delta(A; t) = |tA + (1 - t)A| - 1$.

Figalli and Jerison proved in [2] the following quantitative stability result corresponding to the cases where $A, B$ are translates of each other in the original formulation.

**Theorem 1.1.** (Figalli and Jerison [2]) For $n \geq 2$ there are (computable) constants $\alpha_n, C_n, d_n > 0$ such that if $A \subset \mathbb{R}^n$ is a measurable set, then
\[
|co(A) \setminus A| \leq C_n |A| \left(\frac{\delta(A; \frac{1}{2})}{|A|}\right)^{\alpha_n}
\]
whenever $\delta(A; \frac{1}{2}) \leq d_n |A|$.

Note that we must have $\alpha_n \leq 1$ by considering the discussion below Theorem 1.2. Subsequently, as a corollary of the main result in Figalli and Jerison’s later paper [3], we have the following strengthening from $\frac{1}{2}$ to arbitrary $t$, corresponding to the cases where $A, B$ are homothetic copies of each other in the original formulation.

**Theorem 1.2.** (Figalli and Jerison [3] main result when $A = B$) For $n \geq 2$ there are (computable) constants $\alpha_n, \beta_n, C_n > 0$, and (computable) constants $d_n(\tau) > 0$ for each $\tau \in (0, \frac{1}{2}]$, such that the following is true. If $A \subset \mathbb{R}^n$ is a measurable set, $\tau \in (0, \frac{1}{2}]$ and $t \in [\tau, 1 - \tau]$, then
\[
|co(A) \setminus A| \leq C_n |A| \tau^{-\beta_n} \left(\frac{\delta(A; t)}{|A|}\right)^{\alpha_n}
\]
whenever $\delta(A; t) \leq d_n(\tau)|A|$.

In a followup paper to [2], Figalli and Jerison [4] attempted to compute the optimal constant $\alpha_n$ for $n \geq 2$ in Theorem 1.1.
**Conjecture 1.3.** (Figalli and Jerison [4]) We can take $\alpha_n = 1$ for all $n \geq 2$.

In [4] this conjecture was proved in the special case $n \leq 3$ using an intricate analysis which unfortunately does not extend beyond this case.

In this paper, we resolve this conjecture, optimizing $\alpha_n = 1$ in Theorem 1.1 using, after an initial reduction, very different methods to those used by Figalli and Jerison in [4]. In fact, we are able to optimize the exponents $\alpha_n = 1$ and $\beta_n = 1$ in Theorem 1.2 which are best possible. This leaves the only room for improvement in the multiplicative constant $C_n$.

**Theorem 1.4.** For all $n \geq 2$, there is a (computable) constant $C_n > 0$, and (computable) constants $\Delta_n(\tau) > 0$ for each $\tau \in (0, \frac{1}{2}]$ such that the following is true. If $A \subset \mathbb{R}^n$ is a measurable set, $\tau \in (0, \frac{1}{2}]$ and $t \in [\tau, 1-\tau]$, then

$$|\text{co}(A) \setminus A| \leq C_n \frac{1}{\tau} \delta(A; t)$$

whenever $\delta(A; t) \leq \Delta_n(\tau)|A|$.

To see that the exponents on $\tau$ and $\delta$ are sharp, suppose we have some inequality of the form

$$|\text{co}(A) \setminus A| \leq C_n \tau^{-\rho_1}(\delta(A; t)|A|^{-1})^{\rho_2}|A|$$

provided $\delta(A; t) \leq \Delta_n(\tau)|A|$. Take $A = \{(0, 0) \cup [\lambda, 1 + \lambda] \times [0, 1]\} \times [0, 1]^{n-2}$, with $\lambda < \frac{\Delta_n(\tau)}{2}$, and $t = \tau$. The inequality then becomes $\frac{1}{2} \leq C_n \tau^{-\rho_1}(\tau \lambda(2 - 3\tau))^{\rho_2}$. Because we can take $\lambda$ arbitrarily small, it follows that $\rho_2 \leq 1$, so $\rho_2 = 1$ would be the optimal exponent. Given $\rho_2 = 1$, we then have $\rho_1 \geq 1$, so $\rho_1 = 1$ would be the optimal exponent.

**Remark 1.5.** When $n = 1$, Theorem 1.1 from [2] with $A$ replaced with $tA$ and $B$ replaced with $(1-t)A$ shows that the optimal exponents are actually $\tau^0 \delta(A; t)^1$ in contrast to the case $n \geq 2$.

### 2. Proof of Theorem 1.4

We will first reduce our main result to Theorem 2.1 similar to the initial reduction in [4] to [4, Lemma 2.2]. After this initial reduction, we prove Theorem 2.1 using very different methods to [4].

**Theorem 2.1.** For all $n \geq 2$ there are (computable) constants $\Gamma_n > 0$ and constants $0 < \delta_n(\tau) < 1$ for each $\tau \in (0, \frac{1}{2}]$ such that the following is true. Let $\tau \in (0, \frac{1}{2}]$, $t \in [\tau, 1-\tau]$, and suppose $T \subset \mathbb{R}^n$ is a simplex with $|T| = 1$, $A \subset T$ a measurable subset containing all vertices of $T$, and $|A| = 1 - \delta$ with $0 < \delta \leq \delta_n(\tau)$. Then

$$|T \setminus d(A; t)| \leq (1 - \Gamma_n \tau)|T \setminus A|.$$ 

We first need the following geometric lemma.

**Lemma 2.2.** For every polytope $T$, there exists a point $o \in T$ (which we set to be the origin) such that the following is true. For any constant $b_n(\tau) \in (0, 1)$, there exists a constant $\epsilon_n(\tau)$ such that for any $A \subset T$ with $\text{co}(A) = T$, if $t \in [\tau, 1-\tau]$ and $|T \setminus A| \leq \epsilon_n(\tau)|T|$, then $(1-b_n(\tau))T$ is contained in $d(A; t)$.

**Proof.** Without loss of generality we may assume that $|\text{co}(A)| = 1$. By a lemma of F. John [6], after a volume-preserving affine transformation, there exists a ball $B \subset \text{co}(A)$ of radius $n^{-1}$. Denote $o$ for the center of $B$, and set $o$ to be the origin.

We will show that $(1-b_n(\tau))\text{co}(A) \subset d(A; t)$. Take $x \in (1-b_n(\tau))\text{co}(A)$, and let $y$ be the intersection of the ray $ox$ with $\partial\text{co}(A)$. Note that the ratio $r = |xy|/|oy| \geq b_n(\tau)$.

Take the homothety $H$ with center $y$ and ratio $r$. This homothety sends $o$ to $x$ and $\text{co}(A)$ to $H(\text{co}(A))$. 

Note that \( H(\co(A)) \subset \co(A) \) because \( \co(A) \) is convex. Denoting \( A' = A \cap H(\co(A)) \), we have
\[
|A'| \geq r^n - \epsilon_n(\tau).
\]
The statement \( x \in d(A'; t) \) is implied by the statement that \( o \in d(C; t) \) for \( C = H^{-1}(A') \), which we will now show. Note that \( |C| \geq 1 - r^{-n} \epsilon_n(\tau) \), which is the only property of \( C \) that will be used.

Then \([B \cap C] \leq r^{-n} \epsilon_n(\tau)\). We will now show that \( o \in d(C \cap B; t) \). Now, consider the homothety \( H' \) scaling by a factor of \(-\frac{1}{1-t}\) about \( o \). If \( o \not\in (C \cap B; t) \), then at least one of \( y \) and \( H'(y) \) is not in \( C \cap B \) for every \( y \in B \). Therefore, a simple volume argument shows that if this were the case, then (as \( B \) contains a cube of side length \( 2/\sqrt{n} \)):
\[
\epsilon_n(\tau) \leq (1 - \epsilon_n(\tau)) \epsilon_n(\tau) = \epsilon_n(\tau - \epsilon_n(\tau)).
\]

Therefore as \( b_n(\tau)^{-n} \geq r^{-n} \), taking
\[
\epsilon_n(\tau) < b_n(\tau)^{n}(\frac{\tau}{1 - \tau})^n (2/\sqrt{n})^n,
\]
we deduce that \( o \in d(C \cap B; t) \) and therefore in particular \( x \in d(A'; t) \).

\[\square\]

**Proof that Theorem 2.4 implies Theorem 1.4 using Theorem 1.2.** By approximation, we can assume that \( A \) has polyhedral convex hull \( \co(A) \) with the vertices of \( \co(A) \) lying in \( A \) (see e.g. [4, p.3 footnote 2]). Also, we may assume that \( t \leq \frac{1}{2} \) since Theorem 1.4 is invariant under replacing \( t \) with \( 1 - t \).

We take \( C_n = \Gamma_n^{-1} \), take \( b_n(\tau) \) to be the minimum of \( \tau \) and the constant such that
\[
\delta_n(\tau)^{-1}(1 - (1 - b_n(\tau))^{n}) = 1 - \Gamma_n \tau,
\]
and take \( \epsilon_n(\tau) \) as in Lemma 2.2.

From Theorem 1.2, we see that we can choose \( \Delta_n(\tau) \) sufficiently small so that
\[
|\co(A) \setminus A| \leq (1 - \epsilon_n(\tau))|A| \leq (1 - \epsilon_n(\tau))|\co(A)|,
\]
and therefore by Lemma 2.2 there is a translate of \((1 - b_n(\tau))\co(A) \subset d(A; t)\). Let \( o \) be the center of homothety relating this translate of \((1 - b_n(\tau))\co(A) \) and \( \co(A) \). Because \( b_n(\tau) \leq \tau \), the region \( tO + (1 - t)\co(A) \) is contained in \( d(A; t) \), so from this we deduce that \( d(A \cup \{o\}; t) = d(A; t) \). Therefore we may assume without loss of generality that \( o \in A \).

Note that the inequality in Theorem 1.4 that we want to deduce is equivalent to
\[
|\co(A) \setminus d(A; t)| \leq (1 - C_n^{-1} \tau)|\co(A) \setminus A|.
\]

Triangulate \( \co(A) \) into simplices \( T_i \) by triangulating \( \partial \co(A) \) and coning off each facet at \( o \). Then in each simplex \( T_i \), we claim that
\[
|T_i \setminus d(A; t)| \leq (1 - \Gamma_n \tau)|T_i \setminus A| = (1 - C_n^{-1} \tau)|T_i \setminus A|.
\]

Provided \( |T_i \setminus A| \leq \delta_n(\tau)|T_i| \), we have by Theorem 2.1 the stronger inequality
\[
|T_i \setminus d(A \cap T_i; t)| \leq (1 - \Gamma_n \tau)|T_i \setminus A|.
\]

On the other hand, if \( |T_i \setminus A| \geq \delta_n(\tau)|T_i| \), then as \( b_n(\tau) o + (1 - b_n(\tau)) T_i \subset d(A; t) \cap T_i \), we have
\[
|T_i \setminus d(A; t)| \leq |T_i|(1 - (1 - b_n(\tau))^{n}) \leq \delta_n(\tau)^{-1}(1 - (1 - b_n(\tau))^{n})|T_i \setminus A| \leq (1 - \Gamma_n \tau)|T_i \setminus A|.
\]
We conclude by noting
\[
|\text{co}(A) \setminus d(A; t)| \leq \sum (1 - \Gamma_n t)|T_i \setminus A| = (1 - C_n^{-1} t)|\text{co}(A) \setminus A|.
\]
\[\square\]

We will now prove Theorem 2.1. We may assume that \( t \leq \frac{1}{2} \) since Theorem 2.1 is invariant under replacing \( t \) with \( 1 - t \).

It suffices to prove the statement for a particular choice of \( T \) since all simplices of volume 1 in \( \mathbb{R}^n \) are equivalent under volume-preserving affine transformations. Hence we work in a fixed simplex \( T \subset \mathbb{R}^n \) from now on. Let \( x_0, \ldots, x_n \) denote the vertices of \( T \), and define the corner \( \lambda \)-scaled simplices to be
\[
S^j_i(\lambda) = (1 - \lambda^i)x_j + \lambda^i T \quad \text{for } 0 \leq j \leq n
\]
and set
\[
S_i(\lambda) := \{S^0_i(\lambda), \ldots, S^n_i(\lambda)\}.
\]
In the picture below, we’ve shaded one of the \( S^1_2(\frac{1}{2}) \)’s inside \( T \) when \( n = 2 \).

Define the \( \lambda \)-scaled \( k \)-averaged simplices \( T_{i,k}(\lambda) \) iteratively by
\[
T_{i,0}(\lambda) = S_i(\lambda)
\]
\[
T_{i,k+1}(\lambda) = \{\lambda B_1 + (1 - \lambda)B_2 \mid B_1, B_2 \in T_{i,k}(\lambda)\}.
\]
Note that all simplices in \( T_{i,k}(\lambda) \) are translates of \( \lambda^i T \), and we have the inclusions
\[
T_{i,0}(\lambda) \subset T_{i,1}(\lambda) \subset T_{i,2}(\lambda) \subset \ldots
\]
For fixed \( i, \lambda \), the simplices in the family \( T_{i,k}(\lambda) \) eventually cover all of \( T \) and heavily overlap each other as \( k \to \infty \) (in fact the translates become dense among all possible translates of \( \lambda^i T \) which lie inside \( T \)). Shaded below are the simplices in \( T_{2,1}(\frac{1}{2}) \) when \( n = 2 \).
Remark 2.3. Lemma 2.3 is the crux of our argument. The proof of Lemma 2.3 shows that for all $T' \in \mathcal{T}_{i,k}(1-t)$, the set $|A \cap T'|$ contains a translated copy of $(1-t)\lambda A$ (up to a bounded error). This fractal structure allows us to conclude that $|A \cap T'|$ is bounded below by $|T'|(1-\delta)$ (up to a bounded error).

Lemma 2.4. The constants $c_{i,k,n} = i + 2k$ are such that for every $T' \in \mathcal{T}_{i,k}(1-t)$ we have

$$|A \cap T'| \geq |T'|(1-\delta) - c_{i,k,n}|d(A; t) \setminus A|.$$  

Proof. For the remainder of this proof, we will denote

$$\lambda = 1-t,$$

and write for notational convenience $S_j^i$ instead of $S_j^i(\lambda)$. The following notation will be useful for us: consider the translation that brings $\lambda T$ to $T'$ and denote by $(\lambda^t A)_T$ the shift of the set $\lambda^t A$ under this translation.

We shall actually show the stronger inequalities

$$|(\lambda^t A)_T \setminus A| \leq c_{i,k,n}|d(A; t) \setminus A|$$

(this is stronger as $|(\lambda^t A)_T| = |T'|(1-\delta)$).

First, we show the inequality when $k = 0$. Recall that if $T' \in \mathcal{T}_{i,0}(\lambda)$ then $T' = S_j^i$ for some $j$. The inequality is trivial for $(i, k) = (0,0)$ by definition of $\delta$.

We now show the inequality for $(i, k) = (1,0)$. Note $(\lambda A)_{S_j^i} = \lambda x_j + (1-\lambda)A \subset d(A; t)$, so

$$|(\lambda A)_{S_j^i} \setminus A| \leq |d(A; t) \setminus A|.$$ 

Suppose we know the result for $(i,0)$, we now prove the result for $(i+1,0)$. Then $(\lambda^{i+1} A)_{S_j^i} = (1-\lambda^{i+1})x_j + \lambda^{i+1}A$, and we have

$$|(\lambda^{i+1} A)_{S_j^i} \setminus A| \leq |(\lambda^{i+1} A)_{S_j^i} \setminus (\lambda A)_{S_j^i}| + |(\lambda A)_{S_j^i} \setminus A|$$

$$= \lambda^n|(\lambda^t A)_{S_j^i} \setminus A| + |(\lambda A)_{S_j^i} \setminus A|$$

$$\leq (\lambda^n c_{i+1,0,n} + c_{1,0,n})|d(A; t) \setminus A|$$

$$\leq c_{i+1,0,n}|d(A) \setminus A|.$$ 

Finally, we induct on $k$. We have proved the base case $k = 0$, so assume the inequality for $(i,k)$. We will now prove the inequality for $(i,k+1)$.

Thus we suppose that $T' \in \mathcal{T}_{i,k+1}$, which by definition means that there exists $T'_1, T'_2 \in \mathcal{T}_{i,k}$ such that

$$T' = \lambda T'_1 + (1-\lambda)T'_2.$$ 

We now prove an easy claim before returning to the proof of the lemma.

Claim 2.5. If $X, X'$ are translates of each other in $\mathbb{R}^n$ with common volume $V = |X| = |X'|$, and $Y \subset X, Y' \subset X'$ are subregions. Then if $V'$ is a constant such that $|X \setminus Y|, |X' \setminus Y'| \leq V'$, we have

$$|\lambda Y + (1-\lambda)Y'| \geq V - V'.$$

Proof. We have $|Y|, |Y'| \geq V - V'$, so the result follows from the Brunn-Minkowski inequality. 

Returning to the proof of the lemma, we have by the induction hypothesis that both

$$|(\lambda^t A)_{T'_1} \setminus A| \leq c_{i,k,n}|d(A; t) \setminus A|,$$

and

$$|(\lambda^t A)_{T'_2} \setminus A| \leq c_{i,k,n}|d(A; t) \setminus A|.$$
Because \((\lambda' A)_{T_1}\) and \((\lambda' A)_{T_2}\) are translates of each other with common volume \((1 - \delta)|T'|\), setting 
\[X = (\lambda' A)_{T_1}, X' = (\lambda' A)_{T_2}, Y = A \cap (\lambda' A)_{T_1}, Y' = A \cap (\lambda' A)_{T_2}\] we deduce from the claim that
\[|\lambda(A \cap (\lambda' A)_{T_1}) + (1 - \lambda)(A \cap (\lambda' A)_{T_2})| \geq |T'|(1 - \delta) - c_{i,k,n}|d(A; t) \setminus A|.
\]
Because 
\[d(A; t) = \lambda A + (1 - \lambda)A \text{ and } (\lambda' d(A; t))_{T'} = \lambda(\lambda' A)_{T_1} + (1 - \lambda)(\lambda' A)_{T_2},\]
we have
\[|d(A; t) \cap (\lambda' A)_{T'}| \geq |d(A; t) \cap (\lambda' d(A; t))_{T'}| - |\lambda' d(A; t) \setminus \lambda' A|\]
\[\geq |d(A; t) \cap (\lambda' d(A; t))_{T'}| - |d(A; t) \setminus A|\]
\[\geq |\lambda(A \cap (\lambda' A)_{T_1}) + (1 - \lambda)(A \cap (\lambda' A)_{T_2})| - |d(A; t) \setminus A|\]
\[\geq |T'|(1 - \delta) - (c_{i,k,n} + 1)|d(A; t) \setminus A|,
\]
which as \(|(\lambda' A)_{T'}| = (1 - \delta)|T'|\) is equivalent to
\[|(\lambda' A)_{T'} \setminus d(A; t)| \leq (c_{i,k,n} + 1)|d(A; t) \setminus A|.
\]
We conclude that
\[|(\lambda' A)_{T'} \setminus d(A; t)| \leq |(\lambda' A)_{T'} \setminus d(A; t)| + |d(A; t) \setminus A|\]
\[\leq (c_{i,k,n} + 2)|d(A; t) \setminus A|\]
\[\leq c_{i,k+1,n}|d(A; t) \setminus A|.
\]

**Lemma 2.6.** Let \(\lambda \in \left[\frac{1}{2}, 1\right]\). Then every translate \(T' \subset T\) of \(\frac{1}{2\lambda} \lambda' T\) is completely contained in some element of \(\mathcal{T}_{i,k}(\lambda)\) with
\[k = \sum_{j=1}^{n} \lceil \log\left(\frac{1}{2\lambda^j}\right) / \log(\lambda) \rceil.
\]

**Proof.** We will need the following notation. Let \(\mathcal{T}_{k}(\lambda; \lambda'; T)\) be recursively defined by setting
\[\mathcal{T}_{0}(\lambda; \lambda'; T) = \{\lambda' T + (1 - \lambda')x_j \mid j \in \{0, \ldots, n\}\}\]
\[\mathcal{T}_{k}(\lambda; \lambda'; T) = \{\lambda B_1 + (1 - \lambda)B_2 \mid B_1, B_2 \in \mathcal{T}_{k-1}(\lambda; \lambda'; T)\}.
\]
Note that by definition, \(\mathcal{T}_{i,k}(\lambda) = \mathcal{T}_{k}(\lambda; \lambda^i; T)\). We will actually prove the stronger statement that every translate of \(\frac{1}{2\lambda^i} \lambda' T\) is completely contained in some element of \(\mathcal{T}_{k'}(\lambda; \mu; T)\) for
\[k' = \sum_{j=1}^{n} \lceil \log\left(\frac{1}{2\lambda^j}\right) / \log(\lambda) \rceil.
\]
To prove this we need the following claim, which is essentially equivalent to the result for \(n = 1\).

**Claim 2.7.** Let \(\lambda \in \left[\frac{1}{2}, 1\right]\) and \(\mu \in (0, 1]\). Then every weighted average of two (corner) simplices in \(\mathcal{T}_{0}(\lambda; \mu/2; T)\) lies in some simplex of \(\mathcal{T}_{k}(\lambda; \mu; T)\) with \(k = \lceil \log(\frac{1}{2\lambda^{i}}) / \log(\lambda) \rceil\)

**Proof.** Because we are only taking weighted averages of two simplices, the claim is implied by the one-dimensional version of the claim. We may assume that \(T = [0, 1]\), so that \(\mathcal{T}_{0}(\lambda; \mu; T) = \{[0, \mu], [1 - \mu, 1]\}\), and we want to show that \(\mathcal{T}_{k}(\lambda; \mu; T)\) contains every sub-interval of \([0, 1]\) of length \(\mu/2\).

We will now proceed by showing that the largest distance between consecutive midpoints of intervals in \(\mathcal{T}_{j+1}(\lambda; \mu; T)\) is at most \(\lambda\) times the largest such distance in \(\mathcal{T}_{j}(\lambda; \mu; T)\). Let \(I_1, I_2\) be two consecutive intervals in \(\mathcal{T}_{j}(\lambda; \mu; T)\) for some \(j\). Then in \(\mathcal{T}_{j+1}(\lambda; \mu; T)\) we also have the intervals
\[ J = \lambda I_1 + (1 - \lambda) I_2 \] and \[ K = (1 - \lambda) I_1 + \lambda I_2, \] and the intervals \( I_1, J, K, I_2 \) appear in this order from left to right as \( \lambda \geq \frac{1}{2} \). If \( d \) is the distance between the midpoints of \( I_1, I_2 \), then the distances between the consecutive midpoints of \( I_1, J, K, I_2 \) are \((1 - \lambda)d, (2\lambda - 1)d, (1 - \lambda)d\) respectively. Therefore, the largest distance between two midpoints in \( T_{j+1}(\lambda; \mu; T) \) is at most \( max(1 - \lambda, 2\lambda - 1, 1 - \lambda) \leq \lambda \) times the largest distance between two consecutive midpoints in \( T_j(\lambda; \mu; T) \).

Therefore, the distance between two consecutive midpoints in \( T_\ell(\lambda; \mu; T) \) is at most \( \lambda ^\ell \). If \( \lambda ^\ell \leq \mu / 2 \), then every interval of length \( \mu / 2 \) contains the midpoint of an interval of \( T_\ell(\lambda; \mu; T) \) (which consists of intervals of length \( \mu \)), and is hence contained in this interval.

We prove our desired statement by induction on the dimension \( n \). The claim above proves the base case \( n = 1 \), so now assuming the statement is true for dimensions up to \( n - 1 \), we will show it to be true for \( n \).

Let \( T' \subset T \) be a fixed translate of \( \frac{1}{2\lambda} \mu T \), with vertices \( x'_0, \ldots, x'_n \). Denote by \( F \) the facet of \( T \) opposite \( x_n \), and denote by \( F' \) the facet of \( T' \) opposite the corresponding vertex \( x'_n \). Denote by \( H \) the hyperplane spanned by \( F' \). Then \( S = H \cap T \) is an \( n - 1 \)-simplex, with vertices \( y_0, \ldots, y_{n-1} \) such that \( y_i \) is on the edge of \( T \) connecting \( x_i \) to \( x_n \).

If the common ratio \( r := |y_i x_n|/|x_j x_n| \leq \mu / 2 \), then \( T' \) is already contained inside \( T_0(\lambda; \mu; T) \) and we are done. Otherwise, denote by \( T_0, \ldots, T_{n-1} \subset T \) the translates of \( \frac{1}{2\lambda} \mu T \) that sit on \( H \) and have corners at \( y_0, \ldots, y_{n-1} \) respectively. Denote the facet \( T_1 \cap H \) of \( T_0 \) by \( F_1 \). We remark that each \( F_i \) is a translate of \( \mu' S \) for some fixed \( \mu' \geq \mu / 2 \).

By the claim, the simplices \( T_0, \ldots, T_{n-1} \) are completely contained in elements of \( T_\ell(\lambda; \mu; T) \) with \( \ell = \lceil \log(\frac{1}{2\lambda} \mu) / \log(\lambda) \rceil \).

By the induction hypothesis applied to the \( n - 1 \)-simplex \( S, F' \) is completely contained in a simplex from the family \( T_\ell(\lambda; \mu'; S) \) for \( \ell' := \sum_{j=1}^{n-1} \lceil \log(\mu'/2^j) / \log(\lambda) \rceil \).

Note that \( F' \) is contained in a certain iterated weighted average of the facets \( F_0, \ldots, F_{n-1} \) if and only if \( T' \) is contained in the analogously defined iterated weighted average of \( T_0, \ldots, T_{n-1} \). Therefore \( T' \in T_{\ell + \ell'}(\lambda; \mu) \).

Finally, note that as \( \mu' \geq \mu / 2 \), we have that \( \ell + \ell' \leq k' \), so \( T' \in T_k(\lambda; \mu) \) as desired.

**Proof of Theorem 2.1** First, note there exists a constant \( D_n \geq 1 \) such that the following is true. For any proper sub-simplex \( R \subset T \) with \( R \) homothetic to \( T \) and \( |R| \geq \frac{1}{2} \), there exists a \( \mu \in (0, 1) \) (depending on \( R \)) and a collection of sub-simplices \( T_1, \ldots, T_N \subset T \) which are translates of \( \frac{1}{2\lambda} \mu T \), covering \( T \setminus R \), and such that

\[
\sum_i |T_i| \leq 2^{-n(n+1)} D_n |T \setminus R|.
\]

Take the point \( o \in T \) furnished by Lemma 2.2 and set \( o \) to be the origin. Then if we choose \( \delta_n (\tau) \) sufficiently small, we have by Lemma 2.2 that \( R_0 = (1 - \frac{1}{2D_n}) T \) is contained in \( d(A; t) \). Note that by construction \( |R_0| = 1 - \frac{1}{2D_n} \). The above yields fixed simplices \( T_1, \ldots, T_N \) which are translates of \( \frac{1}{2\lambda} \mu T \) for a fixed constant \( \mu \) satisfying the above properties with \( R = R_0 \).
Set \( i = \lfloor \log(\mu)/\log(1-t) \rfloor \). This \( i \) satisfies \((1-t)^{i+1} < \mu \leq (1-t)^i \). Note \( i \) depends on \( t \).

Then we have for every \( k \), every simplex in \( \mathcal{T}_{i,k}(1-t) \) is a translate of \( \alpha \mu T \) for some fixed \( \alpha \in [1, 2] \) (depending on \( t \)), as \([1, \frac{1}{1-t}] \subset [1, 2] \). Note that

\[
\sum_{j=1}^{n} \lfloor \log(\frac{1}{2^j}(1-t)^i)/\log(1-t) \rfloor \leq \sum_{j=1}^{n} \lfloor \log(\frac{1}{2^j}\mu)/\log(1-t) \rfloor \\
\leq n(\lfloor \log(\frac{1}{2^n}\mu)\rfloor + 1)
\]

Therefore taking \( k = n(\lfloor \log(\frac{1}{2^n}\mu)\rfloor + 1) \), which we note depends on \( t \), Lemma 2.6 implies that the simplices in \( \mathcal{T}_{i,k}(1-t) \) cover every translate of \( \frac{1}{2^n}\mu T \), and in particular there are simplices which cover each of \( T_1, \ldots, T_N \). Let \( \mathcal{A} = \{T'_1, \ldots, T'_N\} \) with \( T_j \subset T'_j \in \mathcal{T}_{i,k}(1-t) \) be such a family. Note that \(|\mathcal{A}| = N \) is a universal constant. As each \( T'_j \) is a translate of \( \alpha \mu T \) with \( \alpha \in [1, 2] \), we have

\[
|T'_j| \leq 2^{n(n+1)}|T_j|
\]

for all \( j \). Therefore,

\[
\sum_{T' \in \mathcal{A}} |T'| \leq D_n|T \setminus R|.
\]

Recalling that \( R_0 \subset d(A; t) \), we thus have

\[
|T \setminus d(A; t)| = |(T \setminus R_0) \setminus d(A; t)| \\
\leq \sum_{T' \in \mathcal{A}} |T' \setminus d(A; t)| \\
\leq \sum_{T' \in \mathcal{A}} |T'| - |T' \cap A| \\
\leq \sum_{T' \in \mathcal{A}} |T'| - \sum_{T' \in \mathcal{A}} (|T'|(1 - \delta) - c_{i,k,n}d(A; t) \setminus A) \\
= \delta \sum_{T' \in \mathcal{A}} |T'| + |\mathcal{A}| \cdot c_{i,k,n} \cdot |d(A; t) \setminus A| \\
\leq \delta D_n |T \setminus R_0| + |\mathcal{A}| \cdot c_{i,k,n} \cdot |d(A; t) \setminus A| \\
= \frac{1}{2} \delta + |\mathcal{A}| \cdot c_{i,k,n} \cdot |d(A; t) \setminus A| \\
= \frac{1}{2} |T \setminus A| + |\mathcal{A}| \cdot c_{i,k,n} \cdot (|T \setminus A| - |T \setminus d(A; t)|).
\]

Therefore

\[
|T \setminus d(A; t)| \leq \frac{1}{2} + \frac{|\mathcal{A}| \cdot c_{i,k,n}}{1 + |\mathcal{A}| \cdot c_{i,k,n}} |T \setminus A| \\
= (1 - \frac{1}{2(1 + |\mathcal{A}| \cdot c_{i,k,n})}) |T \setminus A|.
\]

Note that

\[
i = \lfloor \log(\mu)/\log(1-t) \rfloor \leq \lfloor \log(\mu) \rfloor \frac{1}{t} \leq \lfloor \log(\frac{1}{2^n}\mu) \rfloor \frac{1}{t}.
\]
As $|\mathcal{A}| = N$ is a constant and $c_{i,k,n} = i + 2k \leq (2n + 1)(\log(\frac{1}{2\pi\mu}))^{\frac{1}{2}} + 2n$, there is an absolute constant $\Gamma_n$ such that
\[
\frac{1}{2(1 + |\mathcal{A}| \cdot c_{i,k,n})} \leq -\Gamma_n \tau,
\]
and the result follows. \qed
