THE $p$-ADIC GROSS–ZAGIER FORMULA ON SHIMURA CURVES, II:
NONSPLIT PRIMES

by

Daniel Disegni

Abstract. — The formula of the title relates $p$-adic heights of Heegner points and derivatives of $p$-adic $L$-functions. It was originally proved by Perrin-Riou for $p$-ordinary elliptic curves over the rationals, under the assumption that $p$ splits in the relevant quadratic extension. We remove the assumption, in the more general setting of Hilbert-modular abelian varieties.

1. Introduction and statement of the main result

The purpose of this work is to extend the general $p$-adic Gross–Zagier formula of [I], to the case of arbitrary splitting behaviour of primes above $p$ in the complex multiplication field. Since the result is new even in the context of elliptic curves over $\mathbb{Q}$, we start by informally discussing this case.
1.1. The main ideas in a classical context. — Classically, Heegner points on the elliptic curve $A_{/Q}$ are images of CM points (or divisors) on a modular curve $X$, under a parametrisation $f: X \to A$. More precisely, choosing an imaginary quadratic field $E$, for each ring class character $\chi: \text{Gal}(\overline{E}/E) \to \overline{\mathbb{Q}}^\times$, one can construct a point $P(f, \chi) \in A_E(\chi)$, the $\chi$-isotypic part of $A(\overline{E}/\mathbb{Q})$. The landmark formula of Gross–Zagier [GZ86] relates the height of $P(f, \chi)$ to the derivative $L'(A_E \otimes \chi, 1)$ of the $L$-function of a twisted base-change of $A$. The analogous formula in $p$-adic coefficients\(^{(1)}\)

\begin{equation}
(P(f, \chi), P(f, \chi^{-1})) \doteq \frac{d}{ds|_{s=0}} L_p(A_E, \chi \cdot \chi^s_{\text{cycl}})
\end{equation}

relates cyclotomic derivatives of $p$-adic $L$-functions to $p$-adic height pairings $\langle \phantom{\|}, \phantom{\|} \rangle$. It was proved by Perrin-Riou [PR87] under two main assumptions: first, $A$ should have (good) ordinary reduction at $p$; secondly, $p$ should split in $E$. (The formula has applications to both the $p$-adic and the classical Birch and Swinnerton-Dyer conjectures for $A_E(\chi)$.)

The first assumption was relaxed to allow for good supersingular reduction by Kobayashi [Kob13]\(^{(2)}\). The removal of the second assumption is the object of this work. We explain the main new idea in the proof; it will be clear that, at least in principle, it may be applied to the supersingular case as well.

Review of Perrin-Riou’s proof. — Our basic strategy is still Perrin-Riou’s variant of the one of Gross–Zagier; we briefly and informally review it, ignoring for simplicity of exposition the role of the character $\chi$. Letting $\varphi$ be the ordinary eigenform attached to $A$, each side of (1.1.1) is expressed as the image under a functional “$p$-adic Petersson product with $\varphi$” (denoted $\ell_{\varphi}$) of a certain kernel function (a $p$-adic modular form). For the left-hand side, the form in question is the generating series

\begin{equation}
Z = \sum_{m \geq 0} (P^0, T_m P^0)^X q^m = \sum_v Z_v,
\end{equation}

Here $P^0 \in \text{Div}^0(X)$ is a degree-zero modification of the CM point $P \in X$, $\langle \phantom{\|}, \phantom{\|} \rangle_X$ is a $p$-adic height pairing on $X$ compatible with the one on $A$, and the decomposition (1.1.2) into a sum running over all finite places of $\mathbb{Q}$ follows a general decomposition of the global height pairing into a sum of local ones. More precisely, global height pairings are valued in the completed tensor product $H^1 \times H^1_{\text{cyc}} \hat{\otimes} L$ of the finite ideles of the Hilbert class field $H$ of $E$, and of a suitable finite extension $L$ of $\mathbb{Q}_p$. The series $Z_v$ collects the local pairings at $w|v$, each valued in $H^1_{v, \text{cyc}} \hat{\otimes} L$.

The analytic kernel $\mathcal{F}$ is the derivative of a $p$-adic family of mixed theta-Eisenstein series. It also enjoys a decomposition

\[ \mathcal{F}' = \sum_{v \neq p} \mathcal{F}'_v \]

where, unlike (1.1.2), the sum runs over the finite places of $\mathbb{Q}$ different from $p$. Once established that $Z_v = \mathcal{F}'_v$ for $v \neq p$ by computations similar to those of Gross–Zagier, it remains to show that the $p$-adic modular form $Z_p$ is annihilated by $\ell_{\varphi}$.

In order to achieve this, one aims at showing that, after acting on $Z_p$ by a Hecke operator to replace $P^0$ by $P^{[\varphi]}$ (a lift of the component of its image in the $\varphi$-part of $\text{Jac}(X)$), the resulting form $Z_p^{[\varphi]}$ is $p$-critical. That is, its coefficients

\[ a_{mp^r} := \langle P^{[\varphi]}, T_{mp^r} P^0 \rangle_X, p \]

\(^{(1)}\) We denote by ‘$\doteq$’ equality up to a less important nonzero factor.

\(^{(2)}\) Strictly speaking, Kobayashi restricts to the case $\chi = 1$; under this assumption he is able to deduce a posteriori the nonsplit case from the split case, since by the decomposability of the motive $\text{Res}_{E/\mathbb{Q}} h_1(A_E)$ both are essentially equivalent to a result over $\mathbb{Q}$.
decay $p$-adically no slower than a constant multiple of $p^s$. The $p$-shift of Fourier coefficients extends the action on modular forms of the operator $U_p$ – which in contrast acts invertibly on the ordinary form $\varphi$ – this implies that $p$-critical forms are annihilated by $\ell_q$.

To study the terms $a_{mp^s}$, one constructs a sequence of points $P_s \in X_H$ whose fields of definitions are the layers $H_s$ of the anticyclotomic $p^\infty$-extension of $E$. The relations they satisfy allow to express

$$a_{mp^s} = \langle p^{[\varphi]}, D_{m,s} \rangle_{X,H},$$

where $D_{m,s}$ is a degree-zero divisor supported at Hecke-translates of $P_s$, which are all essentially CM points of conductor $p^s$ defined over $H_s$. By a projection formula for $X_H \to X_H$, the height $a_{mp^s}$ is then a sum, over primes $w$ of $H$ above $p$, of the images

$$N_{s,w}(h_{m,s,w})$$

of heights $h_{m,s,w}$ computed on $X_{H_s,w}$, under the norm map $N_{s,w} : H^*_{s,w} \otimes L \to H^*_{w} \otimes L$. Moreover it can be shown that the $L$-denominators of $h_{m,s,w} \in H^*_{s,w} \otimes L$ are uniformly bounded, so that here we may ignore them and think of $h_{m,s,w} \in H^*_{s,w} \otimes \mathcal{O}_L$.

A simple observation from [1] is that the valuation $w(h_{m,s,w})$ equals

$$(1.1.3) \quad m_{X_{H_s,w}}(p^{[\varphi]}, D_{m,s}),$$

the intersection multiplicity of the flat extensions (§4.2) of those divisors to some regular integral model $\mathcal{X}$ of $X_{H_s,w}$. In the split case, it is almost immediate to see that this intersection multiplicity vanishes. This implies that

$$(1.1.4) \quad N_{s,w}(h_{m,s,w}) \in N_{s,w}(\mathcal{O}^*_{H_{s,w}}) \otimes \mathcal{O}_L \subset H^*_{w} \otimes \mathcal{O}_L.$$ 

Since the extension $H_{s,w}/H_w$ is totally ramified of degree $p^s$, the subset in $(1.1.4)$ is $p^s(\mathcal{O}^*_{H_{w}}) \otimes \mathcal{O}_L \supset p^s(H^*_{w} \otimes \mathcal{O}_L)$, as desired.

The nonsplit case. — In the nonsplit case, the $p$-adic intersection multiplicity has no reason to vanish. However, the above argument will still go through if we more modestly show that $(1.1.3)$ itself decays at least like a multiple of $p^s$. The idea to prove this is very simple: we show that if $s$ is large then, for the purposes of computing intersection multiplicities with other divisors $\mathcal{D}$ on $\mathcal{X}$, the Zariski closure of a CM point of conductor at least $p^s$ can almost be approximated by some irreducible component $V$ of the special fibre of $\mathcal{X}$; hence the multiplicity will be zero if $\mathcal{D}$ arises as a flat extension of its generic fibre. The qualifier ‘almost’ means that the above holds except if $|\mathcal{D}|$ contains $V$ itself, which will be responsible for a multiplicity error term equal to a constant multiple of $p^s$.

The approximation result is precisely formulated in an (ultra)metric space of irreducible divisors on the local ring of a regular arithmetic surface, which we introduce following a recent work of García Barroso, González Pérez and Popescu-Pampu [GBGPPP18]. The proof of the result is also rather simple (albeit not effective), relying on Gross’s theory of quasicanonical liftings [Gro86]. The problem of effectively identifying the approximating divisor $V$ is treated in [Dis/b].

Subtleties. — The above description ignores several difficulties of a relatively more technical nature, most of which we deal with by the representation-theoretic approach of [I] (in turn adapted from Yuan–Zhang–Zhang [YZZ12]). Namely, we allow for arbitrary modular parametrisations $\varphi$, resulting into an extra parameter $\phi$ in the kernels $Z$ and $\mathcal{X}$. By representation-theoretic results, one is free to some extent to choose the parameter $\phi$ to work with without losing generality. A fine choice (or rather a pair of choices) for its $p$-adic component is dictated by the goal of interpolation,
while imposing suitable conditions on its other components allows to circumvent many obstacles in the proof.

1.2. Statement. — We now describe our result in the general context in which we prove it — which is the same as that of [I] (and [YZZ12]), to which we refer for a less terse discussion of the background. (At some points, we find some slightly different formulations or normalisations from those of [I] to be more natural; see §2.2 for the equivalence.)

Abelian varieties parametrised by Shimura curves. — Let $F$ be a totally real field and let $A/F$ be a simple abelian variety of GL2-type. Assume that $L(A, s)$ is modular (this is known in many cases if $A$ is an elliptic curve). Let $B$ be a quaternion algebra over the adeles $A = A_F$, whose ramification set $\Sigma_B$ has odd cardinality and contains all the infinite places. To $B$ is attached a tower of Shimura curves $(X_{U/F})_{U \subset B = \infty}$, with respective Albanese varieties $J_U$. It carries a canonical system of divisor classes $\xi_U \in \text{Cl}(X_U)_{Q}$ of degree 1, providing a system $\xi_\ell$ of maps $\xi: H^1(U/F) \to \text{Hom}(X_U, J_U)_Q$ defined by $D \mapsto D - \deg(D)\xi_U$. The space

$$\pi = \pi_{A,B} = \lim_{U \uparrow} \text{Hom}^0(J_U, A)$$

is either zero or a smooth irreducible representation of $B^\times$ (trivial at the infinite places), with coefficients in the number field $M := \text{End}^0(A)$. We assume we are in the case $\pi = \pi_{A,B} \neq 0$, which under the modularity assumption and the condition (1.2.2) below can be arranged by suitably choosing $B$. Then for all places $v \nmid \infty$, $L_v(A, s) = L_v(s - 1/2, \pi)$ in $M \otimes \mathbb{C}$. We denote by $\omega: F^\times \backslash A^\times \to M^\times$ the central character of $\pi$. We have a canonical isomorphism $\pi_{A^\times} \cong \pi_{A^\times}$, see [YZZ12, §1.2.2], and we denote by $\chi_\ell(\cdot) = \pi_{A,B} \otimes \pi_{A^\times,B} \to M$ the duality pairing.

Heegner points. — Let $E/F$ be a CM quadratic extension with associated quadratic character $\eta$, and assume that $E$ admits an $A$-embedding $E_A \hookrightarrow B$, which we fix. Then $E^\times$ acts on the right on $X = \lim_{U \uparrow} X_U$. The fixed-points subscheme $X_{E^\times} \subset X$ is $F$-isomorphic to $\text{Spec} E^{ab}$, and we fix a point $P \in X_{E^\times} (E^{ab})$. Let

$$\chi: E^\times \backslash A^\times \cong \text{Gal}(E^{ab}/E) \to L(\chi)^\times$$

be a character valued in a field extension of $M$, satisfying

$$\omega: \chi|_{A^\times} \chi = 1,$$

and let

$$A_E(\chi) := (A(E^{ab}) \otimes_M L(\chi)_{\mathbb{C}})^{\text{Gal}(E^{ab}/E)},$$

where $L(\chi)_\chi$ is an $L(\chi)$-line with Galois action by $\chi$.

Then we have a Heegner point functional

$$(1.2.1) \quad \int \quad P(f, \chi) := \int_{\text{Gal}(E^{ab}/E)} f(\xi_\ell(P)^{-1}) \otimes \chi(\tau) d\tau \in A_E(\chi)$$

(integration for the Haar measure of volume 1) in the space of invariant linear functionals $H(\pi_{A,B}, \chi) \otimes L(\chi) A_E(\chi)$, $H(\pi, \chi) := \text{Hom}_{E_A}(\pi \otimes \chi, L(\chi))$ where $E_A^\times$ acts diagonally. There is a product decomposition $H(\pi, \chi) = \otimes_v H(\pi_v, \chi_v)$, where similarly $H(\pi_v, \chi_v) := \text{Hom}_{E_v^\times}(\pi_v \otimes \chi_v, L(\chi))$.

A local unit of measure for invariant functionals. — By foundational local results, the dimension of $H(\pi, \chi)$ (for any representation $\pi$ of $B^\times$) is either 0 or 1. If $A$ is modular and the global root
\( \epsilon(A_E \otimes \chi) = -1 \)

then the set of local root numbers determines a unique quaternion algebra \( \mathcal{B} \) over \( \mathcal{A} \), satisfying the conditions required above and containing \( E_\mathcal{A} \); such that \( \pi_{\mathcal{A}, \mathcal{B}} \neq 0 \) and \( \dim_{\lambda(\chi)} H(\pi_{\mathcal{A}, \mathcal{B}}, \chi) = 1 \).

We place ourselves in this case; then there is a canonical factorisable generator

\[
Q(\_ , dt) = \prod_v Q(\_ , dt_v) \in H(\pi, \chi) \otimes H(\pi^\vee, \chi^{-1})
\]

depending on the choice of a pairing \( (\_ , ) = \prod_v (\_ , ) : \pi \times \pi^\vee \to \lambda(\chi) \) and a measure \( dt = \prod_v dt_v \) on \( E^\times_\mathcal{A}/\mathcal{A}^\times \). It is defined locally as follows. Let us use symbols \( V(\mathcal{A}, \chi) \) and \( V(\mathcal{A}, \chi)_v \) which we informally think of as denoting (up to abelian factors) the `virtual motive over \( F \)` with coefficients in \( L(\chi)'\)

\[
\text{“} V(\mathcal{A}, \chi) = \text{Res}_{E/F}(h_1(A_E) \otimes \chi) \otimes \text{ad}(h_1(A))(1)\text{”}
\]

and its local components (the associated local Galois representation or, if \( v \) is archimedean, Hodge structure). Then we let, for each place \( v \) of \( F \) and any auxiliary \( v : L(\chi) \to \mathcal{C} \).

\[
(1.2.3) \quad \mathcal{L}(iV(\mathcal{A}, \chi)_v, s) := \frac{\zeta_F(2) L(1/2 + s, \eta_v \otimes \chi_v)}{L(1, \eta_v) L(1, \pi_v, \text{ad})} \begin{cases} 1 & \text{if } v \text{ is finite} \\ \pi^{-|F:Q|} & \text{if } v|\infty \end{cases} \in iL(\chi),
\]

\[
(1.2.4) \quad Q(\_ , dt_v(f_1, v, f_2, v, \chi_v)) := \epsilon^{-1} \mathcal{L}(iV(\mathcal{A}, \chi)_v, 0)^{-1} \int_{E^\times_v / \mathcal{F}^\times_v} \chi(t_v)(\pi_v(t_v)f_1, v, f_2, v), dt_v.
\]

We make the situation more canonical by choosing \( dt = \prod_v dt_v \) to satisfy

\[
\text{vol}(E^\times \backslash E^\times_\mathcal{A} / \mathcal{A}^\times, dt) = 1
\]

and by defining for any \( f_3, f_4 \in \pi^\vee \) such that \( (f_3, f_4) \neq 0 \):

\[
(1.2.5) \quad Q \left( \frac{f_1 \otimes f_2}{f_3 \otimes f_4} \chi \right) := Q(\_ , dt(f_1, f_2, \chi)) / (f_3, f_4).
\]

\( p \)-adic heights. — Let us fix a prime \( p \) of \( \mathcal{M} \) and denote by \( p \) the underlying rational prime. Suppose from now on that for each \( v|p \), \( A_{F_v} \) has potentially \( p \)-ordinary (good or semistable) reduction. That is, the rational \( p \)-Tate module \( W := V_{F_v}A \otimes_{\mathcal{M}} \mathcal{M}_p \), once viewed as a 2-dimensional representation \( W_v \) of \( \text{Gal}(\overline{F}/F_v) \) over a sufficiently large finite extension \( L \supset \mathcal{M}_p \), becomes reducible:

\[
(1.2.6) \quad 0 \to W_v^+ \to W_v \to W_v^- \to 0.
\]

Fix such a coefficient \( L \)-field, and for each \( v|p \) let \( \alpha_v : F_v^\times \cong \text{Gal}(F_v^{ab}/F_v) \to L^\times \) be the character giving the action on the twist \( W_v^+(\cdot) \). The field \( L(\chi) \) considered above will from now on be assumed to be an extension of \( L \). Under those conditions there is a canonical \( p \)-adic height pairing

\[
\langle \_ , \_ \rangle : A_E(\chi) \otimes A_E^\vee(\chi^{-1}) \to \Gamma_F \hat{\otimes} L(\chi),
\]

where \( \Gamma_F := \mathcal{A}^\times / F^\times \hat{\otimes} \mathcal{F}^\times \) (the bar denotes Zariski closure). It is normalised `over \( F \)` as in [I, §4.1].

For \( f_1, f_3 \in \pi, f_2, f_4 \in \pi^\vee, \) and \( \pi^\vee \otimes \chi \to A_E^\vee(\chi^{-1}) \) the Heegner point functional of the dual, our result will measure the ratio \( \langle P(f_1, \chi), P^\vee(f_2, \chi^{-1}) \rangle/(f_3, f_4) \pi, \) against the value at the \( f_1 \) of the `unit` \( Q \). The size will be given by the derivative of the \( p \)-adic \( L \)-function that we now define.

\( ^{(3)} \) If \( \epsilon(A_E \otimes \chi) = +1 \) there is no such quaternion algebra and all Heegner points automatically vanish.

\( ^{(4)} \) Explicitly, if \( v \) is archimedean we have \( \mathcal{L}(V(\mathcal{A}, \chi)_v, 0) = 2 \) and \( Q(\_ , dt_v(f_1, v, f_2, v)) = 2^{-1} \text{vol}(C^\times / R^\times, dt_v(f_1, v, f_2, v)). \)
The \( p \)-adic \( L \)-function. — We continue to assume that \( A \) is potentially \( p \)-ordinary, and review the definition of the \( p \)-adic \( L \)-function from [l, Theorem A] (in an equivalent form). We start by defining the space on which it lives. Write \( \Gamma_F = \varprojlim_n \Gamma_{F,n} \) as the limit of an inverse system of finite groups, and let

\[
\mathcal{Y}^{1,c}_F := \bigcup_n \text{Spec } L[\Gamma_{F,n}] \subset \mathcal{Y}_F := \text{Spec } \mathcal{O}_L[\Gamma_F] \otimes_{\mathcal{O}_L} L.
\]

Then \( \mathcal{Y}_F \) is a space of continuous characters on \( \Gamma_F \), and the 0-dimensional ind-scheme \( \mathcal{Y}^{1,c}_F \) is its subspace of locally constant (finite-order) characters. We denote by \( \chi_{F,\text{univ}} : \Gamma_F \to \mathcal{O}(\mathcal{Y}_F)^{\times} \) the tautological character.

Let

\[
\Psi_p := \bigcup_{n \geq 0} \lim \text{Spec } \mathbb{Q}[p^{-n}\mathcal{O}_{F,p}/p^m\mathcal{O}_{F,p}] = \{1\}
\]

be the ind-scheme of nontrivial characters of \( F_p = F \otimes \mathbb{Q}_p \). It is a principal homogeneous space for the locally profinite group scheme \( F_p^\times \), which acts by \( a.\psi_p(x) = \psi_p(ax) \). For any \( \mathbb{Q} \)-scheme \( Y \) and character \( \chi_{F,Y} : F_p^\times \to \mathcal{O}(Y)^{\times} \), denote by \( \mathcal{O}(Y \times \Psi, \chi_{F,Y}) \subset \mathcal{O}(Y \times \Psi_p) \) the space of functions \( G \) satisfying \( G(y,a.\psi_p) = \chi_{F,Y}(a)G(y,\psi_p) \) for all \( a \in F_p^\times \). We identify \( \mathcal{O}(Y \times \Psi_p, 1) = \mathcal{O}(Y) \) via the pullback.

For a character \( \chi' : \text{Gal}(\bar{E}^{ab}/E) \to L^{\times} \) together with an embedding \( \iota : L' \to \mathbb{C} \), consider the ratio of complete \( L \)-functions

\[
\mathcal{L}(\iota V_{(A,\chi')}, s) := \prod_v \mathcal{L}(\iota V_{(A,\chi')}, v, s), \quad \mathcal{L}(\iota V_{(A,\chi')}, v, s) = (1.2.3), \quad \Re(s) \gg 0.
\]

Finally, recall that the (inverse) Deligne–Langlands gamma factor of a continuous representation \( \rho \) of \( \text{Gal}(\bar{F}/F) \) over a \( p \)-adic field \( L' \), with respect to a nontrivial character \( \psi_v : F_v \to \mathbb{C}^{\times} \) and an embedding \( \iota : L' \to \mathbb{C} \), is defined as

\[
\gamma(\iota \rho, \psi) := \frac{L(\iota \mathcal{W}(\rho))}{\varepsilon(\iota \mathcal{W}(\rho), \psi_v)L(\iota \mathcal{W}(\rho^*(1)))},
\]

where \( \mathcal{W} \) is the functor to complex Weil–Deligne representations. The function \( \gamma \) extends additively to a function on the Grothendieck group of representations. For \( v \mid p \) and \( \chi' : \text{Gal}(\bar{E}/E) \to L(\chi')^{\times} \), define the virtual representation over \( L(\chi') \)

\[
V^{+}_{(A,\chi'), v} := (W^+_v \otimes (\text{Ind}_{E}^F \chi')_v) \otimes \text{ad}(W_v)(1)^{+++},
\]

where \( \text{ad}(W_v)(1)^{+++} := \text{Hom}(W_v^+, W_v^+)(1) = \omega_v^{-1} \alpha_v^2 | v |^2 \).

**Theorem A.** — There is a function

\[
\mathcal{L}_p(V_{(A,\chi)}), s) \in \mathcal{O}(\mathcal{Y}_F \times \Psi_p, \eta_p \chi_{F,\text{univ}, p})
\]

characterised by the following property. For each complex geometric point \( s = (\chi_F, \psi_p) \in \mathcal{Y}^{1,c}_F \times \Psi_p(\mathbb{C}) \), with underlying embedding \( \iota : L(\chi_F) \hookrightarrow \mathbb{C} \),

\[
\mathcal{L}_p(V_{(A,\chi)}, s) = \iota e_p(V_{(A,\chi)}), \mathcal{L}(\iota V_{(A,\chi)}), 0), \quad \chi' := \chi \cdot \chi_{F,\text{Gal}(\bar{E}/E)}.
\]

Here the \( p \)-correction factor is

\[
e_p(V_{(A,\chi)}) := \iota^{-1} \prod_{v \mid p} \gamma(\iota V^{+}_{(A,\chi), v}, \psi_v)^{-1},
\]

where \( \psi_p = \prod_v \psi_v \) is any decomposition.

---

\(^{(5)}\)The terms \( \varepsilon \) and \( \varepsilon \) are normalised as in [Tat79].
The factor $e_p(\Lambda_{(A,\chi)})$ coincides with the one predicted by Coates and Perrin-Riou (see [Coa91]) for $V_{(A,\lambda)}$, up to constants depending only on $\mathcal{E}$ and the removal of a trivial zero from their interpolation factor for $\text{ad}(W_p)(1)$.

**The $p$-adic Gross–Zagier formula.** — We are ready to state our main result. We say that $\chi_p$ is not exceptional for $A$ if $e_p(V_{(A,\lambda)}) \neq 0$. We say that $\chi_p$ is sufficiently ramified if it is nontrivial on a certain open subgroup of $\Theta^\times_{E,p}$ depending only on $\omega_p$ (see Assumption 3.4.1 below).

Denote by $0 \in \mathcal{Y}_p$ the point corresponding to $\chi = 1$, and let

$$\mathcal{L}^\prime_p(V_{(A,\chi)}, 0) := d \mathcal{L}_p(V_{(A,\chi)}, 0) \in T_0 \mathcal{Y}_p \cong \Gamma_p \otimes L(\chi).$$

**Theorem B.** — Suppose that the abelian variety $A/\mathcal{F}$ is modular and potentially $p$-ordinary. Let $\chi: \text{Gal}(\mathcal{E}^{ab}/\mathcal{E}) \to L(\chi)$ be a finite-order character satisfying $\varepsilon(A_\mathcal{E} \otimes \chi) = -1$, and suppose that $\chi_p$ is not exceptional for $A$ and sufficiently ramified.

Then for any $f_1, f_2, f_3, f_4 \in \pi^\times$ such that $(f_3, f_4) \pi \neq 0$, we have

$$\frac{(P(f_1, \chi), P(\chi, f_2, \chi^{-1}))}{(f_3, f_4) \pi} = e_p(V_{(A,\chi)})^{-1} \cdot \mathcal{L}^\prime_p(V_{(A,\chi)}, 0) \cdot Q \left( \frac{f_1 \otimes f_2}{f_3 \otimes f_4}; \chi \right)$$

in $\Gamma_p \otimes L(\chi)$.

**Remark 1.2.1.** — The technical assumption that $\chi_p$ is sufficiently ramified can be removed by $p$-adic analytic continuation as in [I], after deducing from Theorem B a version in anticyclotomic families. We do not do this here since in the forthcoming [Dis/c] we will deploy a substantial generalisation of this strategy – first proving a version of the formula in the universal ordinary deformation of $V_{(A,\chi)}$, then deducing analogues of Theorem B for automorphic motives of higher weight.

The theorem has familiar applications extending to the non-split case those from [I] (when the other ingredients are available); we leave their formulation to the interested reader, and highlight instead an application specific to this case pointed out in [Dis/a], and a new application to the nonvanishing of $p$-adic heights.

A new proof of a result of Greenberg–Stevens. — Note first that concrete versions of the formula of Theorem B may be obtained by choosing explicit parametrisations $f_i$ and evaluating the term $Q$. This is a local problem, solved in [CST14]. In particular, by starting from Theorem B and applying the same steps of the proofs of [Dis/a, Theorems 4.3.1, 4.3.3], we obtain the simple $p$-adic Gross–Zagier formula in anticyclotomic families for elliptic curves $A/\mathcal{Q}$ proposed in [Dis/a, Conjecture 4.3.2].

Now as noted in Remark 5.2.3 *ibid.*, such formula, combined with a result of Bertolini–Darmon, gives yet another proof (quite likely the most complicated so far, but amenable to generalisations) of the following famous result of Greenberg and Stevens [GS93]. If $A/\mathcal{Q}$ is an elliptic curve of split multiplicative reduction at $p$, with Néron period $\Omega_A$ and $p$-adic $L$-function $L_p(A, -)$ on $\mathcal{Y}_\mathcal{Q}$, then $L_p(A, 1) = 0$ and

$$L_p(A, 1) = \lambda_p(A) \cdot \frac{L(A, 1)}{\Omega_A},$$

where $\lambda_p(A)$ is the $\mathcal{L}$-invariant of Mazur–Tate–Teitelbaum [MTT86].

We recall a sketch of the argument, referring to [Dis/a] for more details. One chooses an imaginary quadratic field $\mathcal{E}$ such that $p$ is inert in $\mathcal{E}$ and that the twist $A(\mathcal{E})$ satisfies $L(A(\mathcal{E}), 1) \neq 0$. By the anticyclotomic $p$-adic Gross–Zagier formula, $L_p'(A, 1)$ is the value at $\chi = 1$ of the height of an anticyclotomic family $\mathcal{P}$ of Heegner points. It is shown in [BD01, §5.2] that the value $\mathcal{P}(1)$ equals, in an extended Selmer group, the Tate parameter $q_{A,p}$ of $A_{\mathcal{Q}_p}$ multiplied by a square root
of $L(A_E, 1)/\Omega_{A_E}$. The height of $q_{A,p}$, in the ‘extended’ sense of [MTT86, Nek06], essentially equals $\lambda_p(A)$. This shows that, after harmlessly multiplying by $L(A^{(E)}, 1)/\Omega_{A^{(E)}}$, the two sides of (1.2.8) are equal.

**Exceptional cases and non-vanishing results.** — Suppose that $A/Q$ has multiplicative reduction at a prime $p$ inert in $E$, and that $L(A_E, 1) \neq 0$. Then for all but finitely many anticyclotomic characters $\chi$ of $p$-power conductor, a Heegner point in $A_E(\chi)$ is nonzero and the $p$-adic height pairing on $A_E(\chi)$ is nondegenerate. This follows from noting, similarly to the above, that in the $p$-adic Gross–Zagier formula in anticyclotomic families for $A_E$, both sides are nonzero since the heights side specialises, at the character $\chi = 1$, to a nonzero multiple of $\lambda_p(A)$, which is in turn nonzero by [BSDGP96].

A similar argument, applied to the formula in Hida families of [DIs/c], will yield the following result: if $A/Q$ is an elliptic curve with multiplicative reduction and $L(A, 1) \neq 0$, then the Selmer group of the selfdual Hida family $f$ through $A$ has generic rank one, and both the height regulator and the cyclotomic derivative of the $p$-adic $L$-function of $f$ do not vanish. The details will appear in a separate work.

1.3. Organisation of the paper. — In §2, we restate our theorems in an equivalent form, direct generalisation of the statements from [I] (up to a correction involving a factor of 2, discussed in Appendix B). In §3 we recall the proof strategy from [I], with suitable modification and corrections. The new argument to treat $p$-adic local heights in the nonsplit case is developed in §4.

We conclude with two appendices, one dedicated to some local results, the other containing a list of errata to [I].

2. Comparison with [I]

We compare Theorems A and B with the corresponding results from [I]. We continue with the setup and notation of §1.2.

2.1. The $p$-adic $L$-function. — We deduce our Theorem A from [I, Theorem A]. Let $\sigma^\infty$ be the nearly $p$-ordinary, $M$-rational ([I, Definition 1.2.1]) representation of $\text{GL}_2(A)$ attached to $A$ as in [I]. In Theorem A ibid. we have constructed a $p$-adic $L$-function

$$L_{p,\alpha}(\sigma_E),$$

which is a bounded function on the product of a rigid space $\mathcal{B}^{\rig}_{/\mathcal{L}}$ (denoted by $\mathcal{B}'$ in [I]) and a scheme $\Psi_p^\circ$ (denoted by $\Psi_p$ in [I]). The space $\mathcal{B}^{\rig}_{/\mathcal{L}}$ parametrises certain continuous $p$-adic characters of $E^\times \setminus E^\times_{\mathcal{A}}$ invariant under an arbitrarily fixed compact open subgroup $V_p \subset E^\times_{\mathcal{A}^{\rig}}$; and the scheme $\Psi_p^\circ$ parametrises characters of $F_v$ of a fixed level. The boundedness means precisely that we may (and do) identify $L_{p,\alpha}(\sigma_E)$ with a function on a corresponding scheme

$$(2.1.1) \quad \mathcal{B}' \subset \text{Spec} \mathcal{O}_{\mathcal{L}}[E^\times \setminus E^\times_{\mathcal{A}}/V_p] \otimes \mathcal{L},$$

which, when also viewed as a space of characters $\chi'$, is the subscheme cut out by the closed condition $\omega \cdot \chi'_{\mathcal{O}_{\mathcal{L}}} = 1$. Similarly yo $\mathcal{B}_F$, the scheme $\mathcal{B}'$ contains a 0-dimensional subscheme $\mathcal{B}'^{\rig}$ parametrising the locally constant characters in $\mathcal{B}'$. The function $L_{p,\alpha}(\sigma_E)$ is characterised by the following property. Denote by $D_K$ the discriminant of a number field $K$. Then at all $(\chi', \psi) \in \mathcal{B}' \times \Psi_p^\circ$ with underlying embedding $i: L \hookrightarrow \mathbb{C}$, we have

$$(2.1.2) \quad L_{p,\alpha}(\sigma_E)(\chi', \psi_p) = \prod_{v|p} P_{i_v}(\chi'_v, \psi_v) \cdot \frac{\pi^{2|F|Q(Q)|D_F|^{1/2}}}{2\zeta_p(2)} \cdot \mathcal{L}(\mathcal{V}(\chi'_v, \psi_v)).$$
for certain local factors \( Z_v^\circ \).

Fix a finite-order character

\[ \chi : E_\infty^\times \to \text{Gal}(E_{\text{ab}}/E) \to L(\chi)^\times \]

satisfying \( \omega \cdot \chi_{|A^\infty} = 1 \), and consider the map

\[ j_\chi : \mathcal{X} \to \mathcal{Y} \]

\[ \chi_F \mapsto \chi \cdot \chi_F \cdot N_{E_\infty^\times/A^\infty^\times} \cdot \]

Proof of Theorem A. — For \( \psi_p = \prod_v \psi_v \in \Psi_p \), let

\[ C(\chi_F, \psi_p) := \frac{c_p(V(X, \chi_v), \psi_v)^{-1}}{\prod_{v|p} Z_v^\circ(\chi_v, \psi_v)} \]

We show in Proposition A.1.4 that this is independent of \( \chi'_F \) and defines an element \( C \in O(\Psi_p, \omega_p^{-2} \cdot | -2 \cdot ) \).

Define

\[ L_p(V(X, \chi)) := \frac{\zeta_F(2)}{\pi [\mathcal{Q} : D_F]^{1/2}} \cdot C \cdot L(1, \sigma_v, \text{ad}) \cdot j^*_p L_{p,\alpha}(\sigma_E) \]

a function in \( O(\mathcal{Y}_F \times \Psi_p^\circ) \). By the equivariance properties on \( \Psi_p^\circ(\cdot) \) from above, and of \( L_{p,\alpha}(\sigma_E) \) from [I, Theorem A] as corrected in Appendix B, the function \( L_p(V(X, \chi)) \) is a section of \( O(\mathcal{Y}_F \times \Psi_p^\circ, \chi_F^\circ, \chi_F^\circ, \chi_F^\circ) \). Hence we can uniquely extend it to a function on \( \mathcal{Y}_F \times \Psi_p \) with the same equivariance property. It is clear from the definition and (2.1.2) that it satisfies the required interpolation property.

2.2. Equivalence of statements. — We now restate Theorem B in a form which directly generalises [I, Theorem B]. It is the form in which we will prove it, for convenience of reference.

We retain the setup of §1.2. Let \( \omega_F \) be the \( \Gamma_F \)-differential defined before [I, Theorem B]. For all \( v | \infty \) let \( dt_v \) be the measure on \( E_v^\times / F_v^\times \) specified in [I, paragraph after (1.1.2)] if \( v | \infty \) and the measure giving \( C^\times / R^\times \) volume 2 if \( v | \infty \).

Theorem 2.2.1. — Suppose that \( \chi_p \) is not exceptional and sufficiently ramified. Fix a decomposition \( (\chi)_v = \prod_v (\chi_v)_v \), with \( (1, 1)_v = 1 \) if \( v | \infty \). Then for all \( f_1 \in \pi, f_2 \in \pi^\vee \),

\[ \langle P(f_1, \chi), P^\vee(f_2, \chi^{-1}) \rangle = c_E \cdot \prod_{v | \infty} Z_v^\circ(\chi_v)^{-1} \cdot \omega_F L_{p,\alpha}(\sigma_{A, E})(\chi) \cdot \prod_{v | \infty} Q_{\psi_v}(f_1, f_2, \chi) \]

in \( \Gamma_F \otimes L(\chi) \), where

\[ c_E := \frac{\zeta_F(2)}{(\pi/2) [\mathcal{Q} : D_F]^{1/2} L(1, \eta)} \in \mathbb{Q}^\times. \]

Lemma 2.2.2. — Theorem 2.2.1 is equivalent to Theorem B. When every prime \( v | p \) splits in \( E \), it specialises to [I, Theorem B] with the correction given in Appendix B.

Proof. — The second assertion is immediate; we prove the first one. First, we note that (2.2.1) is equivalent to

\[ \langle P(f_1, \chi), P^\vee(f_2, \chi^{-1}) \rangle = c_E \cdot \prod_{v | \infty} Z_v^\circ(\chi_v)^{-1} \cdot \omega_F L_{p,\alpha}(\sigma_{A, E})(\chi) \cdot \prod_{v | \infty} Q_{\psi_v}(f_1, f_2, \chi) \]

for any \( f_1 \in \pi, f_4 \in \pi \) with \( f_3, f_4 = 1 \) and \( (f_3, f_4)_\pi \neq 0 \) (the extra power of 2 comes from the archimedean places). The left-hand side of (2.2.2) is the same as that of the formula of Theorem
B, and the product of the terms after the $L$-derivative in its right-hand side equals

$$2^{-[F:Q]} \prod_v \frac{dt_v}{dt} \cdot Q \left( \frac{f_1 \otimes f_2}{f_3 \otimes f_4} \chi \right) = 2^{-[F:Q]} |D_{E/F}|^{1/2} |D_F|^{1/2} \pi^{-[F:Q]} L(1, \eta) \cdot Q \left( \frac{f_1 \otimes f_2}{f_3 \otimes f_4} \chi \right),$$

because the measure $\prod_v dt_v$ (respectively $dt$) gives $E^\infty \backslash A^\infty_E / A^\infty$ volume $2 |D_{E/F}|^{1/2} |D_F|^{1/2} \pi^{-[F:Q]} L(1, \eta)$ (respectively 1).

Next, we have $d_P L_{p,\alpha}(\sigma_E)(\chi) = \frac{1}{2} d(j_{p,\alpha}(\sigma_E))(1)$, and it is clear from comparing the interpolation properties that

$$\prod_{v \mid p} Z_v(\chi_v)^{-1} \cdot \frac{1}{2} d(j_{p,\alpha}(\sigma_E))(1) = \frac{2^{[F:Q]} |D_{E/F}|^{1/2}}{2\zeta_F(2)} \cdot e_p(V_{A,\chi})^{-1} \cdot \mathcal{L}_p(V_{A,\chi}, 0).$$

It follows that the right hand side of (2.2.1) equals $c \cdot e_p(V_{A,\chi})^{-1} \cdot \mathcal{L}_p(V_{A,\chi}, 0) \cdot Q \left( \frac{\mu \otimes L\chi}{\zeta_F(2)} \chi \right)$, where

$$c = c_E \cdot \frac{2^{[F:Q]} |D_{E/F}|^{1/2}}{2\zeta_F(2)} \cdot 2^{1-[F:Q]} |D_{E/F}|^{1/2} |D_F|^{1/2} \pi^{-[F:Q]} L(1, \eta) = 1.$$

\[\blacksquare\]

3. Structure of the proof

We review the formal structure of the proof in [I], dwelling only on those points where the arguments need to be modified or corrected. For an introductory description with some more details than given in §1.1, see [I, §1.7]. Readers interested in a more detailed understanding of the present section are advised to keep a copy of [I] handy.

3.1. Notation and setup. — We very briefly review some notation and definitions from [I], which will be used throughout the paper.

Local fields. — For $v$ finite a place of $F$, we denote by $w_v$ a fixed uniformiser and by $q_{F,v}$ the cardinality of the residue field of $F_v$. We denote by $d_v$ a generator of the absolute different of $F_v$, by $D_v$ a generator of the relative discriminant of $E_v/F_v$ (equal to 1 unless $v$ ramifies in $E$), and by $e_v$ the ramification degree of $E_v/F_v$.

Groups, measures, integration. — We adopt the same notation and choices of measures as in [I, §1.9], including a regularised integration $\int^*$. In particular $T := \text{Res}_{E/F} G_{m,E}, Z = G_{m,F}$, and on the adelic points of $T/Z$ we use two measures $dt$ (the same as introduced above Theorem 2.2.1) and $d^*t$. The measure denoted by $dt$ in the introduction will not be used.

Operators at $p$. — Let $v|p$ be a place of $F$. We denote by $w_v$ a fixed uniformiser at $v$. For $r \geq 1$ we let $K_1^r(w_v) \subset \text{GL}_2(E_{F,v})$ be the subgroup of matrices which become upper unipotent upon reduction modulo $w_v^{-r}$. We denote by

$$U_{v,*} = K_1^1(w_v) \left( \begin{array}{cc} 1 & \omega_v^{-1} \\ \omega_v & 1 \end{array} \right) K_1^1(w_v), \quad U_v^* = K_1^1(w_v) \left( \begin{array}{cc} \omega^r & 0 \\ 0 & 1 \end{array} \right) K_1^1(w_v),$$

the usual double coset operators, and by

$$w_{r,v} := \left( \begin{array}{cc} 1 & 0 \\ \omega_v^{-r} & 1 \end{array} \right) \in \text{GL}_2(F_v).$$

We also denote by $w_r = \prod_{v|p} w_{r,v} \in \text{GL}_2(F_p)$ and, if $(\beta_v)_{v|p}$ are characters of $F_v^\times$, we denote $\beta_p(w) := \prod_{v|p} \beta_v(w_v)$.

Spaces of characters. — We denote by $\mathcal{Y}_F, \mathcal{Y}_1, \mathcal{Y}$ respectively the schemes over $L$ defined in (1.2.7), (2.1.1) and the subscheme of $\mathcal{Y}$ cut out by the condition $\chi|_{A^\infty} = \omega^{-1}$. We add to this
notation a superscript ‘l.c.’ to denote the ind-subschemes of locally constant characters (which has a model over a finite extension of \( M \) in \( L \)).

Let \( \mathcal{I}_Y \), be the ideal sheaf of \( Y \subset Y' \). If \( \mathcal{M} \) is a coherent \( \mathcal{O}_Y \)-module, we denote

\[
\mathcal{d}_r: \mathcal{M} \otimes_{\mathcal{O}_Y} \mathcal{I}_Y \to \mathcal{M} \otimes_{\mathcal{O}_Y} \mathcal{I}_Y^2 \overset{\epsilon}{=} \mathcal{M} \cdot \mathcal{I} \Gamma_F
\]

the normal derivative (cf. the definition before [I, Theorems B]).

**Kirillov models.** — Let \( \sigma^\infty = \bigotimes_{v \mid \infty} \sigma_v \) be the \( M \)-rational automorphic representation of \( \text{GL}_2(\mathbb{A}) \) attached to \( \mathcal{A} \), and denote abusively still by \( \sigma^\infty \) its base-change to \( L \). For every place \( v \) the representations \( \sigma_v \) of \( \mathbb{B}_v^\infty \) and \( \pi_v \) of \( \text{GL}_2(F_v) \) are Jacquet–Langlands correspondents.

For \( v \mid p \), we denote by

\[
\mathcal{K}_{\psi_v}: \sigma_v \to C^\infty(F_v^\times, L)
\]

a fixed rational Kirillov model. It depends on a choice of character \( \psi_v \), after choosing an extension of the base to a universal space \( \Psi_v \) analogous to \( \Psi_p \). (We do not dwell on this subtlety discussed in [I, §2.3].)

**Orthogonal spaces.** — We let \( \mathbf{V} := \mathbb{B} \) equipped with the reduced norm \( q \), a quadratic form valued in \( \mathbf{A} \). The image of \( E_A \) is a subspace \( \mathbf{V}_1 \) of the orthogonal space \( \mathbf{V} \), and we let \( \mathbf{V}_2 \) be its orthogonal complement. The restriction \( q_{\mathbf{V}} \) is the adelisation of the norm of \( E/F \).

**Schwartz spaces and Weil representation.** — If \( \mathbf{V}' \) is any one of the above spaces, we denote by \( \mathcal{F}(\mathbf{V}' \times \mathbb{A}^\times) = \bigotimes_v \mathcal{F}(\mathbf{V}_v' \times F_v^\times) \) the Fock space of Schwartz functions considered in [I]. (This differs from the usual Schwartz space only at infinity.) There is a Weil representation

\[
r = r_\psi: \text{GL}_2(\mathbb{A}) \times O(V, q) \to \text{End} \mathcal{F}(\mathbf{V} \times \mathbb{A}^\times),
\]

defined as in [I, §3.1]. The orthogonal group of \( \mathbf{V} \) naturally contains the product \( T(\mathbb{A}) \times T(\mathbb{A}) \) acting by left and right multiplication on \( \mathbf{V} \). The Weil representation also depends on a choice of additive characters \( \psi \). The restriction \( r_{T(\mathbb{A}) \times T(\mathbb{A})} \) preserves the decomposition \( \mathbf{V}_1 \oplus \mathbf{V}_2 \), hence it accordingly decomposes as \( r_1 \oplus r_2 \).

**Special data at \( p \).** — We list the functions at the places \( v \mid p \) that we use. The additive character \( \psi_v \) will be assumed to be of level \( d_v^{-1} \).

Define

\[
W_v(y) := 1_{\mathcal{E}_{F_v} \varepsilon}(y)\left|\begin{array}{c} y \\ \alpha_v(y) \end{array}\right|, \quad \text{(3.1.1)}
\]

the ordinary vector in the fixed Kirillov model \( \mathcal{K}_{\psi_v} \) of \( \sigma_{A,v} \). We consider

\[
\varphi_v = \varphi_{v,r} := \mathcal{K}_{\psi_v}^{-1}(\alpha_v(\varpi_v)^{-1} w_v W_v) \in \sigma_v. \quad \text{(3.1.2)}
\]

Now we consider Schwartz functions. We let

\[
\mathbb{B}_v \cong M_2(F_v)
\]

be the indefinite quaternion algebra over \( F_v \); this choice is justified *a posteriori* by Corollary A.2.3. The following choices of functions correct and modify the ones fixed in [I] (cf. the Errata in Appendix B); note in particular that we will use two different functions on \( \mathbf{V}_{2,v} \).

Decompose orthogonally \( \mathbf{V}_v = \mathbf{V}_{1,v} \oplus \mathbf{V}_{2,v} \), where \( \mathbf{V}_{1,v} = E_v \) under the fixed embedding \( E_A \hookrightarrow \mathbb{B} \). We define the following Schwartz functions on, respectively, \( F_v^\times \) and its product
3.1.2 In those spaces is annihilated by $p$

and

(3.1.4)

$$
\phi_{r}(x_{1}, u) := \delta_{1,U_{F,r}}(x_{1})\delta_{1,U_{F,r}}(u), \quad \text{where } \delta_{1,U_{F,r}}(x_{1}) = \frac{\text{vol}(\mathcal{O}_{E,v}^{\times})}{\text{vol}(1 + \omega^{1}\mathcal{O}_{E,v})}1_{1 + \omega^{r}\mathcal{O}_{E,v}}(x_{1});
$$

$p$-adic modular forms and $q$-expansions. — In [1, §2], we have defined the notion of Hilbert automorphic forms and twisted Hilbert automorphic forms (the latter depend on an extra variable $u \in \mathbf{A}^{\infty}$). We have also defined the associated space of $q$-expansions, and a less redundant space of reduced $q$-expansions. When the coefficient field is a finite extension $L'$ of $\mathbf{Q}_{p}$, these spaces are endowed with a topology. We have an (injective) reduced-$q$-expansion map on modular forms, denoted by

$$\varphi' \mapsto q\varphi'.
$$

The image of modular forms (respectively cuspsforms) of level $K^{p}K_{1}^{1}(p^{\infty}) \subset \text{GL}_{2}(\mathbf{A}^{p\infty})$ and central character $\omega^{-1}$ is denoted by $\mathbf{M} = \mathbf{M}(K^{p}, \omega^{-1})$ (respectively $\mathbf{S}$). The closure of $\mathbf{M}$ (respectively $\mathbf{S}$) in the space of $q$-expansions with coefficients in $L'$ is denoted $\mathbf{M}'$, respectively $\mathbf{S}'$, and its elements are called $p$-adic modular forms (respectively cuspsforms).

If $\mathcal{Y} = \mathcal{Y}_{F}$, we define the notion of a $\mathcal{Y}$-family of modular forms by copying word for word [1, Definition 2.1.3]; the resulting notion coincides with that of bounded families on the analogous rigid spaces considered in loc. cit.

For a finite set of places $S$ disjoint from those above $p$, we have also defined a certain quotient space $\overline{\mathcal{S}}_{S}$ of cuspidal reduced $q$-expansions modulo those all of whose coefficients of index $a \in F^{\times}\mathbf{A}^{\infty\times}$ vanish. According to [1, Lemma 2.1.2], for any $S$ the reduced-$q$-expansion map induces an injection

(3.1.5)

$$\mathcal{S} \hookrightarrow \overline{\mathcal{S}}_{S}.
$$

$p$-adic Petersson product and $p$-critical forms. — For $\varphi^{p} \in \sigma$, we defined in [1, Proposition 2.4.4] a functional

$$
\ell_{\varphi^{p},\alpha} : \mathbf{M}(K^{p}, \omega^{-1}, L) \to L,
$$

whose restriction to classical modular forms equals, up to an adjoint $L$-value, the limit as $r \to \infty$ of Petersson products with antiholomorphic forms $\varphi^{p}\varphi_{p,r} \in \sigma$ with component $\varphi_{p,r} = \prod_{v\mid p} \varphi_{v,r}$ as in (3.1.2).

Let $v|p$. We say that a form or $q$-expansion over a finite-dimensional $\mathbf{Q}_{p}$-vector space $L'$ is $v$-critical if its coefficients $a_{s}$ (where $s \in \mathbf{A}^{\infty\times}$)

(3.1.6)

$$a_{m\omega_{v}^{t}} = O(q_{v}^{r_{v}})
$$

in $L'$, uniformly in $m \in \mathbf{A}^{\infty\times}$. Here for two functions $f, g : \mathbf{N} \to L$, we write

$f = O(g) \iff$ there is a constant $c > 0$ such that $|f(s)| \leq cg(s)$ for all sufficiently large $s$.

The space of $p$-critical forms is the sum of the spaces of $v$-critical forms for $v|p$. Any element in those spaces is annihilated by $\ell_{\varphi^{p},\alpha}$. 

3.2. Analytic kernel. — The analytic kernel is a $p$-adic family of theta-Eisenstein series, related to the $p$-adic $L$-function. We review its main properties.

**Proposition 3.2.1.** — There exist $p$-adic families of $q$-expansions of modular forms $\mathcal{E}$ over $\mathcal{F}$ and $\mathcal{I}$ over $\mathcal{F}'$, satisfying:

1. For any $\chi_F \in \mathcal{F}_F^\times(C)$ and any $r = (r_v)_{v \mid p}$ satisfying $c(\chi_F)|p^r$, we have the identity of $q$-expansions of twisted modular forms of weight 1:

$$\mathcal{E}(u, \phi_2^\infty; \chi_F) = |D_F|^{L(p)(1, \eta \chi_F)} \frac{L(p)(1, \eta)}{L(p, \eta)} a_E(u, \phi_2, \chi_F),$$

where

$$E_r(g, u, \phi_2, \chi_F) := \sum_{\gamma \in P^1(F) \setminus SL_2(F)} \delta_{\chi_F, r}((\gamma gw_r)t) \phi_2(0, u)$$

is the Eisenstein series defined in [I, §3.2], with respect to $\phi_2 = \phi_2^\infty(\chi_F) \phi_2^p \in \phi_2^\infty$ with $\phi_2^1$ as in (3.1.4) for $v\not|p$, and $\phi_2^\infty$ equal the standard Schwartz function ([I, §3.1]) for $v|\infty$.

2. For $\phi_1 \in \mathcal{F}(V_1 \times A^\times)$ and $\chi' \in \mathcal{F}_F^{\times}$, consider the twisted modular form of weight 1 with parameter $t \in E_\mathcal{A}$:

$$\theta(g, (t, 1)u, \phi_1) := \sum_{x_1 \in E} r_1(g, (t, 1)) \phi_1(x, u).$$

For any $\chi' \in \mathcal{F}_F^{\times}$, let $\chi_F := \omega^{-1} \chi'_{|A^\times} \in \mathcal{F}_F^{\times}$. Then for any $r = (r_v)_{v \mid p}$ satisfying $r_v \geq 1$ and $c(\chi_F)|p^r$ we have

$$\mathcal{F}(\phi^\infty; \chi') = \frac{c_{U_F} |D_E|^{1/2}}{|D_F|^{1/2}} \int_{|T|^*} \chi'(t) \sum_{u \in \mu_{U_F}^{\times}} q \theta((t, 1), u, \phi_1; \chi') \phi(q(t)u, \phi_2^\infty; \chi_F) dt,$$

where for $v|p$, $\phi_1, v = \phi_1, v$. is as in (3.1.3).

3. We have

$$\ell_{\sigma, p, \alpha}(\mathcal{F}(\phi^\infty)) = L_p(\alpha(\sigma_E) \cdot \prod_{v \mid p} |d_v^2| |D_v| \prod_{v \mid \infty} \mathcal{F}_p(W_v, \phi_v, \chi_v'),$$

where the local terms $\mathcal{F}_p$ are as in [I, Propositions 3.5.1, 3.6.1].

**Proof.** — Part 1 is [I, Proposition 3.3.2]. Part 2 summarises [I, §3.4]. Part 3 is [I, (3.7.1)] with the correction of Appendix B below. \qed

**Derivative of the analytic kernel.** — We denote

$$\mathcal{F}'(\phi^\infty; \chi) := d_{\mathcal{F}} \mathcal{F}(\phi^\infty; \chi),$$

a $p$-adic modular form with coefficients in $\Gamma_F \hat{\otimes} L(\chi)$.

3.3. Geometric kernel. — The geometric kernel function, see [I, §§5.2-5.3], is related to heights of Heegner points. We recall its construction and modularity.

For any $x \in B^\infty$, we have a Hecke correspondence $Z(x) \subset X_U \times X_U$. For $a \in A^\infty$, $\phi^\infty \in \mathcal{F}(V \times A^\times)$, consider the correspondences

$$\tilde{Z}_a(\phi^\infty) := c_{U_F} w_U |a| \sum_{x \in K \backslash B^\infty} \phi^\infty(x, aq(x)^{-1}) Z(x) \cup$$

where $w_U = \{|\pm 1\} \cap U|$ and $c_{U_F}$ is defined in [I, (3.4.3)]. By [I, Theorem 5.2.1] (due to Yuan–Zhang–Zhang), their images in $\text{Pic}(X_U \times X_U)_\mathbb{Q}$ are the reduced $q$-expansion coefficients different from the constant term of an automorphic form.
Fix any \( P \in X F^r(E^\text{ab}) \), and for \( t \in E_\infty^r \) let \([t]\) be the Hecke-translate of \( P \) by \( t \). Denote by 
\[ (\cdot)^*: \text{Cl}(X_U,\overline{\mathbb{T}})_{\mathbb{Q}} \to \text{Cl}^0(X_U,\overline{\mathbb{T}})_{\mathbb{Q}} \]
the linear section whose kernel is spanned by the pushforwards to \( X_U,\overline{\mathbb{T}} \) of the classes of the canonical bundles of the connected components of \( X_U,\overline{\mathbb{T}} \), for any sufficiently small \( U' \).

Let 
\[ \theta_{a}\colon (\sigma^\infty \otimes \overline{\mathbb{T}}(\mathbb{V}^\infty \times A^\infty,\mathbb{X})) \otimes_M L \to (\pi \otimes \pi^\vee) \otimes_{M,s} L \]
be Shimizu’s theta lifting defined in [I, §5.1]. Let 
\[ T_{\text{alg}}: \pi \otimes_M \pi^\vee \to \text{Hom}(J_U, J''_U) \otimes_M \]
be defined by 
\[ T_{\text{alg}}(f_1, f_2) := f_2^* \circ f_1. \]
Finally, let 
\[ (\cdot, \cdot)_X: J''(\mathbb{F}) \times J(\mathbb{F}) \to \Gamma_F \otimes L \]
be the \( p \)-adic height pairing defined as in [I, Lemma 5.3.1]. (We abusively omit the subscript \( X \) as we will no longer need to use the pairing on \( A_E(\chi) \otimes A^\text{alg}_E(\chi) \).

**Proposition 3.3.1.** — The series 
\[ \tilde{Z}(\phi^\infty, \chi) := \int_{[1]}^\infty \chi(t) \left( \sum_{a \in E^r} (\tilde{Z}_a(\phi^\infty)|1^0, [t^{-1}]^0) a^0 \right) dt \]
is (the \( q \)-expansion of) a weight-two cuspidal Hilbert modular form of with coefficients in \( \Gamma_F \otimes L(\chi) \).

For any sufficiently large \( r' \), it is invariant under \( \prod_{v|p} K_1^r(\varpi_v^{c_r}) \) and it satisfies 
\[ \ell_{v', c}(\tilde{Z}(\phi^\infty, \chi)) = 2|D_F|^{1/2}|D_E|^{1/2} L(1, \eta)(\text{T}_{\text{alg}, \mathbf{a}}(\theta_{a}(\varphi, \alpha|\cdot|_p(\varpi^{-r'} w_v^{-1} \phi)))P_X, P_\chi^{-1}) J. \]
for all sufficiently large integers \( r' \).

**Proof.** — We have already recalled the modularity. The invariance under \( \prod_{v|p} K_1^r(\varpi_v^{c_r}) \) follows from the invariance of \( \phi_v \) under the action of \( \{1, \sigma^p\} \) and the continuity of the Weil representation. Finally, the proof of (3.3.3) is indicated in [I, proof of Proposition 5.4.3] (with the correction of Appendix B).

**3.4. Kernel identity.** — We state our kernel identity and recall how it implies the main theorem.

**Assumptions on the data.** Consider the following local assumptions on the data at primes above \( p \).

**Assumption 3.4.1.** — Let \( U^\circ_{F,v} := 1 + \varpi_v^n \mathcal{O}_{F,v} \) with \( n \geq 1 \) be such that \( \omega_v \) is invariant under \( U^\circ_{F,v} \). The character \( \chi_p \) is sufficiently ramified in the sense that it is nontrivial on 
\[ V^\circ_p := \prod_{v|p} q^{-1}_{v}(U^\circ_{F,v}) \subset \mathcal{O}^\times_E. \]

**Assumption 3.4.2.** — For each \( v\nmid p \), the open compact \( U_v \subset \mathcal{B}^\times_E \) satisfies:
- \( U_v = U_{v,r} = 1 + \varpi^r M_{2}(\mathcal{O}_{F,v}) \) for some \( r \geq 1 \);
- the integer \( r \geq n \) is sufficiently large so that the ordinary vector \( W_v \in \sigma_v \) of (3.1.1) is invariant under \( U_{v,r} \) and \( \chi_v \) is invariant under \( U_{v,r} \cap \mathcal{O}^\times_{E,\sigma} \).

**Convention on citations from [I].** — In [I], we have denoted by \( S_{\text{non-split}} \) the set of places of \( F \) non-split in \( E \), and by \( S_p \) the set of places of \( F \) above \( p \). When referring to results from [I], we henceforth convene that one should read any assumption such as \( \text{let } v \in S_{\text{non-split}} \) or ‘let \( v \) be a place in \( F \) non-split in \( E' \) as ‘let \( v \in S_{\text{non-split}} - S_p \). Similarly, the set \( S_I \) fixed in [I, §6.1] should be understood to consist only of places not above \( p \).
**Theorem 3.4.3 (Kernel identity).** — Suppose that $U$, $\varphi$, $\phi^{p\infty}$, $\chi$, $r$ satisfy the assumptions of [I, §6.1] as well as Assumptions 3.4.1, 3.4.2. Let $\phi_p := \otimes_{\nu|p} \phi_{\nu, r}$ with $\phi_{\nu, r} = (3.1.4)$. Then

$$
\ell_{\varphi, \alpha}(d_F F(\phi^{p\infty}; \chi)) = 2|D_F|L_p(1, \eta) \cdot \ell_{\varphi, \alpha}(\bar{Z}(\phi^{\infty}, \chi)).
$$

The elements of the proof will be gathered in §3.6.

**Corollary 3.4.4.** — Suppose that $\chi$ satisfies Assumption 3.4.1. Then Theorem 2.2.1 holds.

**Proof.** — As in [I, Proposition 5.4.3] corrected in Appendix B, we consider the following equivalent (by [I, Lemma 5.3.1]) form of the identity of Theorem 2.2.1:

$$
(3.4.1)
$$

$$
\langle T_{\text{alg, ir}}(f_1 \otimes f_2)P_{\chi, r}, P_{\chi^{-1}} \rangle = \frac{\zeta_F^\circ(2)}{(\pi^2/2)^r} |D_F|^{1/2} L(1, \eta) \prod_{\nu|p} Z_v^\circ(\alpha_v, \chi_\nu)^{-1} \cdot d_F L_p, \sigma(A, E)(\chi) \cdot Q(f_1, f_2, \chi)
$$

where $t_p : M \hookrightarrow L(\chi)$, and $P_{\chi} = \int_{[I]} T_t(P - \xi_p) \chi(t) dt \in J(\overline{F})_L(\chi)$. By linearity, (3.4.1) extends to an identity which makes sense for any element $f \in \pi \otimes \pi^\vee$. By the multiplicity-one result for $E_X^{\infty}$-invariant linear functionals on each of $\pi, \pi^\vee$, it suffices to prove (3.4.1) for one element $f \in \pi \otimes \pi^\vee$ such that $Q(f, \chi) \neq 0$ (cf. [YZZ12, Lemma 3.23]).

We claim that Theorem 3.4.3 gives (3.4.1) for $f = \theta(\varphi, \phi)$, where:

- $\varphi^\infty$ is standard antiholomorphic in the sense of [I], $\phi^\infty$ is standard in the sense of [I];
- for all $v|p$, $\varphi_v = (3.1.2)$ and $\phi_v = \phi_{\nu, r} = (3.1.4)$ for any sufficiently large $r$.

The claim follows from (3.2.4), (3.3.3), the local comparison between $\mathcal{H}_g$ and $Q_v \circ \theta_v$ for $v \nmid p$ of [I, Lemma 5.1.1], and the local calculation at $v|p$ of Proposition A.2.2.

Finally, the existence of $\varphi, \phi$ satisfying both the required assumptions and $Q(\theta(\varphi, \phi)) \neq 0$ follows from [I, Lemma 6.1.6] away from $p$, and the explicit formula of Proposition A.2.2 at $p$. \qed

### 3.5. Derivative of the analytic kernel.

We start by studying the incoherent Eisenstein series $\delta(\phi^{p\infty}_r)$. For $a \in F_v^\times$, denote by

$$
W_{a, v}^o
$$

the normalised local Whittaker function of $E_r(\phi^{p\infty}_r(\chi_F)\phi^{p\infty}_{2, r}, \chi_F) = (3.2.1)$, defined as in [I, Proposition 3.2.1 and paragraph following its proof].

The following reviews and corrects [I, Proposition 7.1.1].

**Proposition 3.5.1.** — For each $v|p$, let $\phi_{2, v} = \phi_{2, r, v}$ be as in (3.1.4).

1. Let $v$ be a place of $F$ and $a \in F_v^\times$.
   
   (a) If $a$ is not represented by $(V_{2, v}, uq)$ then $W_{a, v}^o(g, u, 1) = 0$.
   
   (b) (Local Siegel–Weil formula.) If $v \nmid p$ and there exists $x_a \in V_{2, v}$ such that $uq(x_a) = a$, then
     
     $$
     W_{a, v}^o \left( \begin{pmatrix} 1 & \Sigma \\ 0 & 1 \end{pmatrix} \right), u, 1 = \int E_v^\times r \left( \begin{pmatrix} 1 & \Sigma \\ 0 & 1 \end{pmatrix} \right) \phi_{2, v}(x_a, u) \, dh
     $$
     
   (c) (Local Siegel–Weil formula at $p$.) If $v|p$, $a \in -1 + \varpi^r \mathcal{O}_{F_v}$, $u \in 1 + \varpi^r \mathcal{O}_{F_v}$, let $x_a \in V_{2, v}$ be such that $uq(x_a) = a$. Then
     
     $$
     W_{a, v}^o \left( \begin{pmatrix} 1 & \Sigma \\ 0 & 1 \end{pmatrix} \right), u, 1 = |d_v| \int E_v^\times r \left( \begin{pmatrix} 1 & \Sigma \\ 0 & 1 \end{pmatrix} \right) \phi_{2, v}(x_a, u) \, dh.
     $$
     
   (3.5.1)

2. For any $a \in F_v^\times \cap \prod_{v|p} (-1 + \varpi^r \mathcal{O}_{F_v})$, $u \in F_v^\times \cap \prod_{v|p} (1 + \varpi^r \mathcal{O}_{F_v})$, there is a place $v|p$ of $F$ such that $a$ is not represented by $(V_{2, v}, uq)$.

**Proof.** — Parts 1(a)-(b) are as in [I, Proposition 7.1.1]. Before continuing, observe that, under our assumptions, $a$ is always represented by $(V_{2, v}, uq_v)$ for all $v|p$: this is clear if $v$ splits in $E$ and,
up to possibly enlarging the integer $r$, it may be seen by the local constancy of $q_v$ and the explicit identity $q_v(i_v) = -1$, where $i_v = (4.1.2)$ below if $v$ is nonsplit. Then part 1(c) follows by explicit computation of both sides (starting e.g. as in [YZZ12, proof of Proposition 6.8] for the left-hand side). Explicitly, we have

$$\begin{align*}
(3.5.1) = \begin{cases} 
\frac{1}{c_v} |d_v| \text{vol}(E_v, T_v^* \cap \mathcal{O}_{E_v}^*, dh) |y|^{1/2} \sigma_{\mathcal{O}_{E_v}}(ay) \eta_{\mathcal{O}_{E_v}}(y^{-1}u) & \text{if } v(a) \geq 0 \text{ and } v(u) = 0 \\
0 & \text{otherwise.}
\end{cases}
\end{align*}$$

Finally, part 2 follows from the observation of the previous paragraph and [YZZ12, Lemma 6.3].

Lemma 3.5.2. — Suppose that, for all $v|p$, $\phi_{1,v} = \phi_{1,r,v}$ is as in (3.1.3). Then, for any $t \in T(A)$, the $a^\text{th}$ $q$-expansion coefficient of the the theta series of $\phi_{1,r,v}$ vanishes unless

$$a \in \bigcap_{v|p} 1 + \omega^r \mathcal{O}_{E_v}.$$  

Proof. — Straightforward.

Denote

$$U_{p,*}^r := \left( \prod_{v|p} U_{v,*} \right)^r,$$

an operator on modular forms which extends to an operator on all the spaces of $p$-adic $q$-expansions defined so far.

Corollary 3.5.3. — Suppose that $\phi^{\infty} \in \mathcal{F}(\mathcal{V}^{\infty}_2 \times \mathcal{A}^{\infty,\chi})$ satisfies the assumptions of [I, §6.1]. Let $\chi \in \mathcal{A}^{1,c}$. For any sufficiently large $r$, we have

$$U_{p,*}^r \mathcal{F}(\phi^{\infty}; \chi) = 0.$$

Proof. — For the first assertion, we need to show that the $a^\text{th}$ reduced $q$-expansion coefficient of $\mathcal{F}$ vanishes for all $a$ satisfying $v(a) \geq r$ for all $v|p$. By the defining property 3.2.3 of $\mathcal{F}(\chi')$ and the choice of $\phi_p$, the group $T(F_p) \subset T(A)$ acts trivially on the $q$-expansion coefficients of $\mathcal{F}(\chi')$. The remaining integration on $T(F)Z(A)V^p \setminus T(A)/T(F_p)$ is a finite sum, so the coefficients $a$ is a sum of products of the coefficients of index $a_1$ of $\theta$ and index $a_2$ of $\mathcal{E}(1)$, for pairs $(a_1, a_2)$ with $a_1 + a_2 = a$. When $a = 0$, the vanishing follows from the vanishing of the constant term of $\mathcal{E}$, which is proved in [YZZ12, Proposition 6.7]. For $a \neq 0$, by Lemma 3.5.2 only the pairs $(a_1, a_2)$ with $a_1 \in \bigcap_{v|p} 1 + \omega^r \mathcal{O}_{E_v}$ contribute. If $v(a) \geq r$ for $v|p$, this forces $a_2 \in -1 + \omega^r \mathcal{O}_{E_v}$.

3.6. Decomposition of the geometric kernel and comparison. — Suppose that Assumptions 3.4.1, 3.4.2 as well as the assumptions of [I, §6.1] are satisfied. Then we may decompose (see [I, §8.2]) the generating series of Proposition 3.3.1

$$\mathcal{Z}(\phi^{\infty}, \chi) = \sum_v \mathcal{Z}(\phi^{\infty}, \chi)(v).$$
accoring to the decomposition \( (\ , \ J) = \sum_v (\ , \ J)_v \) of the height pairing. Here the sum runs over all finite places of \( F \).

The following is the main result of [I] on the local comparison away from \( p \). Let \( \mathfrak{S} = \mathfrak{S}_{S_1} \) be the quotient of the space of \( p \)-adic \( q \)-expansions recalled above (3.1.5).

**Theorem 3.6.1** ([I, Theorem 8.3.2]). — Let \( \phi_\infty = \phi_\infty \phi_p = \prod_{v \mid p} \phi_v \) as in (3.1.4). Suppose that Assumptions 3.4.1, 3.4.2 as well as the assumptions of [I, §6.1] are satisfied. Then we have the following identities of reduced \( q \)-expansions in \( \mathfrak{S}' \):

1. If \( v \in S_{\text{split}} - S_p \), then
   \[ \tilde{Z}(\phi_\infty, \chi)(v) = 0. \]
2. If \( v \in S_{\text{non-split}} - S_1 - S_p \), then
   \[ U_{p,*} \mathcal{S}'(\phi_\infty; \chi)(v) = 2|D_F|L(p)(1, \eta)U_{p,*} \tilde{Z}(\phi_\infty, \chi)(v). \]
3. If \( v \in S_1 \), then
   \[ U_{p,*} \mathcal{S}'(\phi_\infty; \chi)(v), \quad U_{p,*} \tilde{Z}(\phi_\infty, \chi)(v) \]
   are theta series attached to a quaternion algebra over \( F \).
4. The sum
   \[ U_{p,*} \tilde{Z}(\phi_\infty, \chi)(p) := \sum_{v \in S_p} U_{p,*} \tilde{Z}(\phi_\infty, \chi)(v) \]
   belongs to the isomorphic image \( \mathfrak{S} \subset \mathfrak{S}' \) of the space of \( p \)-adic modular forms \( \mathfrak{S} \).

By this theorem and the decompositions of \( \mathcal{S}' \) and \( \tilde{Z} \), the proof of the kernel identity of Theorem 3.4.3 (hence of the main theorem) is now reduced to showing the following proposition. (See [I, §8.3, last paragraph] for the details of the deduction.)

**Proposition 3.6.2.** — Under the assumptions of Theorem 3.6.1, the \( p \)-adic modular form

\[ U_{p,*} \tilde{Z}(\phi_\infty, \chi)(p) \in \mathfrak{S} \]

is annihilated by \( \ell_{\varphi, \alpha} \).

Let \( S \) be a finite set of non-archimedean places of \( F \) such that, for all \( v \notin S \), all the data are unramified, \( U_v \) is maximal, and \( \phi_v \) is standard. Let \( K = K_F K_p \) be the level of the modular form \( \tilde{Z}(\phi_\infty) \), and let \( T_{\varphi}(\sigma^\vee) \in \mathcal{H}_{\bar{S}}(L) = \mathcal{H}_{\bar{S}}(M) \otimes_{M_{\varphi}} L \)

be any \( \sigma^\vee \)-idemponent in the Hecke algebra as in [I, Proposition 2.4.4] By that result, in order to establish Proposition 3.6.2 suffices to prove that

\[ (3.6.1) \quad \ell_{\varphi, \alpha}(U_{p,*} T_{\varphi}(\sigma^\vee) \tilde{Z}(\phi_\infty, \chi)(p)) = 0. \]

As in [I], we will in fact prove the following, which implies (3.6.1).

**Proposition 3.6.3.** — Let \( v \mid p \). Under the assumptions of Theorem 3.6.1, for all \( v \mid p \), the element

\[ T_{\varphi}(\sigma^\vee) \tilde{Z}(\phi_\infty, \chi)(v) \in \mathfrak{S} \]

is \( v \)-critical in the sense of (3.1.6).

Its proof will occupy the following section.
4. Local heights at $p$

The goal of this section is to prove Proposition 3.6.3, whose assumptions we retain throughout except for an innocuous modification to the data at the places $v|p$. Namely, let $\tilde{\phi}_v = \phi'_{v,v}$ be the Schwartz function denoted by $\phi_v$ in (3.1.4), and let $U_v \subset B_v^\infty$ be the open compact subgroup denoted by $U_{v,v}$ in Assumption 3.4.2. Then we let

$$U_v := \tilde{U}_v U_{F,v}, \quad \phi_v := \int_{U_{F,v}} r(z,1)\tilde{\phi}_v \, dz.$$ 

The function $\phi_v$ is invariant under $U_v$ and, since $\chi_{v|F_v} = \omega_v^{-1}$ is by construction invariant under $U_{F,v}$, the generating series $\tilde{Z}(\phi^\infty \tilde{\phi}_p, \chi)$ and $\tilde{Z}(\phi^\infty \phi_p)$ are equal. Therefore we may work on the curve $X_U$.

We fix a place $v|p$. If $v$ splits in $E$ then the desired result is proven in [I, §9]. Therefore we may and do assume that $v$ is nonsplit.

4.1. Norm relation for the generating series. — We consider the $U_{v,v}$-action on the generating series $\tilde{Z}(\phi^\infty)$.

**Lemma 4.1.1.** — If $v(a) \geq -v(d)$, the $a^\text{th}$ reduced $q$-expansion coefficient of $U_{v,v} \tilde{Z}(\phi^\infty)$ equals

$$\tilde{Z}_{a\pi_v}(\phi^\infty),$$

where $\tilde{Z}_{a\pi_v}(\phi^\infty)$ is defined in (3.3.1).

**Proof.** — After computing the Weil action of $U_{v,v}$ on $\phi$, this is a simple change of variables. □

We have

$$\tilde{Z}_a(\phi^\infty) = \tilde{Z}_{a\pi_v}(\phi^\infty)Z_{a\pi_v}(\phi_v)$$

where

$$\tilde{Z}_a(\phi^\infty) := e_{U^v} \sum_{x^v \in U^\vee \backslash B^\infty / U^v} \phi^\infty(x^v, ax(x^v)^{-1})Z(x^v)_U,$$

$$Z_{a\pi_v}(\phi_v) := \sum_{x_v \in U_v \backslash B_v^\infty / U_v} \phi_v(x_v, ax_v(x_v)^{-1})Z(x_v)_U. \tag{4.1.1}$$

From here until after the proof of Lemma 4.1.3, we work in a local situation and drop $v$ from the notation. Let $\theta_v \in \mathcal{O}_{E,v}$ be such that $\mathcal{O}_{E,v} = \mathcal{O}_{F,v} + \theta_v \mathcal{O}_{F,v}$, and write $T = \text{Tr}_{E/F}(\theta)$, $N = N_{E/F}(\theta)$. Fix the embedding $E \to B = M_2(F)$ to be

$$t = a + \theta b \mapsto \begin{pmatrix} a + bT & bN \\ -b & a \end{pmatrix}.$$

Let

$$j := \begin{pmatrix} 1 & T \\ -1 & \end{pmatrix}. \tag{4.1.2}$$

Then $j^2 = 1$ and for all $t \in E$, $jt = t'j$; and in the orthogonal decomposition $V = V_1 \oplus V_2$, we have

$$\mathcal{O}_{V_2} = V_2 \cap M_2(\mathcal{O}_E) = j \mathcal{O}_E.$$

Let $\Xi(\omega^\tau) = 1 + \omega^\tau \mathcal{O}_E + j(\mathcal{O}_E \cap q^{-1}(1 + \omega^\tau \mathcal{O}_E));$ then $\phi$ is a fixed multiple of the characteristic function of $\Xi(\omega^\tau) \times (1 + \omega^\tau \mathcal{O}_E) \subset B \times F^\infty$. For $a \in F^\times$, let

$$\Xi(\omega^\tau)_a = \{ x \in \Xi(\omega^\tau) \mid q(x) \in a(1 + \omega^\tau \mathcal{O}_E) \}.$$
Then the local component (4.1.1) of the generating series equals

\[ Z_a(\hat{\phi}) = \sum_{x \in U \setminus \Xi(x^r), U^r/U} Z(x)_U, \]

up to a constant which is independent of \( a \).

**Lemma 4.1.2.** — Let \( a \in F^\times \) satisfy \( v(a) = s \geq r \). The natural map \( \Xi(x^r)_a U^r_F/U \to U \setminus \Xi(x^r)_a U^r_F/U \) is a bijection. For either quotient set, a complete set of representatives is given by the elements

\[ x(b) \equiv 1 + jb \]

as \( b \) ranges through a complete set of representatives for

\[ q^{-1}(1 - a(1 + \varpi^r \mathcal{O}_F))/\varpi^{r+s} \mathcal{O}_E) \subset \mathcal{O}_E/\varpi^{r+s} \mathcal{O}_E). \]

**Proof.** — It is equivalent to prove the same statement for the quotients of \( \Xi(x^r)_a \) by the group \( \tilde{U} = 1 + \varpi^r M_2(\mathcal{O}_F) \). By acting on the right with elements of \( \mathcal{O}_E \cap U \), we can bring any element of \( \Xi \) to one of the form \( x(b) \). Write any \( \gamma \in \tilde{U} \) as \( \gamma = 1 + \varpi^r u_1 + j \varpi^r u_2 \) with \( u_1, u_2 \in \mathcal{O}_E \). Then

\[ x(b)\gamma = (1 + jb)(1 + \varpi^r u_1 + j \varpi^r u_2) = 1 + \varpi^r (u_1 + b \cdot u_2) + j(b + \varpi^r (bu_1 + u_2)) \]

is another element of the form \( x(b') \) if and only if \( u_1 = -b \cdot u_2 \). In this case

\[ b' = b + \varpi^r (1 - q(b))u_2 \in b(1 + \varpi^{r+s} \mathcal{O}_E). \]

Thus the class of \( b \) modulo \( \varpi^{r+s} \) is the only invariant of the quotient \( \Xi/\tilde{U} \). The \( \tilde{U} \)-action on the left similarly preserves this invariant.

Denote by \( \text{rec}_E \) the reciprocity map of class field theory.

**Lemma 4.1.3.** — Fix \( a \in \mathcal{O}_F \) with \( v(a) = s \geq r \).

1. Let \( b \in (\mathcal{O}_E/\varpi^{r+s} \mathcal{O}_E)^\times, t \in 1 + \varpi^r \mathcal{O}_E \). Then

\[ \text{rec}_E(t)[x(b)]_U = [x(bt^r/t)]_U. \]

2. We have

\[ \Xi(x^r)_a U^r_F/U = \bigsqcup \text{rec}_E((1 + \varpi^r \mathcal{O}_E)/(1 + \varpi^r \mathcal{O}_F)(1 + \varpi^{r+s} \mathcal{O}_E))[x(b)]_U, \]

where the Galois action is faithful, and \( b \) ranges through a set of representatives for

\[ q^{-1}(1 - a(1 + \varpi^r \mathcal{O}_F))/\varpi^{r+s} \mathcal{O}_E \cdot (1 + \varpi^{r+s} \mathcal{O}_E). \]

The size of the set (4.1.3) is bounded uniformly in \( a \).

**Proof.** — For part 1, we have

\[ \text{rec}_E(t)[x(b)]_U = [t + jb]_U = [t + j t^r b]_U = [1 + j b t^r/t]_U. \]

Part 2 follows Lemma 4.1.2 and part 1, noting that the group \( (1 + \varpi^{r+s} \mathcal{O}_E)/(1 + \varpi^{r+s} \mathcal{O}_E) \) is the image of the map \( t \mapsto t^r/t \) on \( 1 + \varpi^r \mathcal{O}_E \). Finally, the map (projection, \( q \)) gives an injection from

\[ q^{-1}(1 - a(1 + \varpi^r \mathcal{O}_F))/\varpi^{r+s} \mathcal{O}_E \cdot (1 + \varpi^{r+s} \mathcal{O}_E) \]

and

\[ (\mathcal{O}_E/\varpi^{r+s} \mathcal{O}_E)^\times \times (1 - a(1 + \varpi^r \mathcal{O}_F)/q(1 + \varpi^{r+s} \mathcal{O}_E), \]

whose size is bounded uniformly in \( a \) (more precisely, the second factor is isomorphic to \( \mathcal{O}_F/\text{Tr}(\mathcal{O}_E) \) via the map \( 1 - a(1 + \varpi^r x) \mapsto x \).
We go back to a global setting and notation, restoring the subscripts \( v \), and we denote by \( \overline{\mathfrak{m}} \) an extension of the place \( v \) to \( E^{ab} \). For \( s \geq 0 \), let

\[
H_s \subset E^{ab}
\]

be the finite abelian extension of \( E \) with norm group \( U_s^0U_T^v(1 + \varpi^{r} + \Theta_E) \), where \( U_s^0 = U^v \cap E_\mathfrak{A}^{\infty} \).

Let \( H_s = \bigcup_{s \geq 0} H_s \). If \( r_v \) is sufficiently large, for all \( s \geq 0 \) the extension \( H_s/H_0 \) is totally ramified at \( \overline{\mathfrak{m}} \) of degree \( q_{F,v}^s \), and

\[
\text{Gal}(H_s/H_0) \cong \text{Gal}(H_s,\overline{\mathfrak{m}}/H_0,\overline{\mathfrak{m}}) \cong (1 + \varpi^{r} \Theta_E)/ (1 + \varpi^{r} \Theta_F, \varpi^{r} \Theta_{E,v}).
\]

In particular,

\[
[H_s : H_0] = [H_s,\overline{\mathfrak{m}} : H_0,\overline{\mathfrak{m}}] = q_{F,v}^s.
\]

We will say that a CM point \( z \in X_{H_0,\overline{\mathfrak{m}}} \) has pseudo-conductor \( s \geq 0 \) if \( H_0,\overline{\mathfrak{m}}(z) = H_s,\overline{\mathfrak{m}}. \)

**Proposition 4.1.4.** — There exists an integer \( d > 0 \) such that for all \( a \in \mathbb{A}^{\infty} \) with \( v(a) = s \geq r_v \), there exists a degree-zero divisor \( D_a \in \text{div}^0(X_{U,H_s}) \), supported on CM points, such that

\[
\tilde{Z}_a(\phi^\infty)[1]_U = \text{Tr}_{H_s/H_0}(D_a)
\]

in \( \text{div}^0(X_{U,H_s}). \) All prime divisor components of \( D_a \) are CM points of pseudo-conductor \( s \).

**Proof.** — This follows from Lemma 4.1.3.2, by taking \( D_a \) to be a fixed rational multiple (independent of \( a \)) of

\[
\tilde{Z}_a(\phi^\infty)Z(\omega_v) \sum_{\mathfrak{p} \in \mathfrak{p}(4.1.3)} |x(\overline{\mathfrak{p}})|_U.
\]

The divisor is of degree zero by [I, Proposition 8.1.1]. Its prime components are not defined over proper subfields \( H_s' \subset H_s \) because of the faithfulness statement of Lemma 4.1.3.2.

**4.2. Intersection multiplicities on arithmetic surfaces.** — Before continuing, we gather some definitions and a key result.

**Ultrametricity of intersections on surfaces.** — Let \( \mathcal{X} \) be a 2-dimensional regular Noetherian scheme, finite flat over a field \( k \) or a discrete valuation ring \( \mathcal{O} \) with residue field \( \kappa \). We denote by \( (\cdot, \cdot)_X \) the usual bilinear intersection multiplicity of divisors intersecting properly on \( \mathcal{X} \), defined for effective divisors \( D_j \) \( (j = 1, 2) \) with \( \mathcal{O}_{D_j} = \mathcal{O}_X/\mathcal{I}_j \)

\[
(D_1 \cdot D_2)_X = \text{length}_k \mathcal{O}_X/\mathcal{I}_1 + \mathcal{I}_2.
\]

The subscript \( \mathcal{X} \) will be omitted when clear from context.

We will need the following result of García Barroso, González Pérez and Popescu-Pampu.

**Proposition 4.2.1.** — Let \( R \) be a noetherian regular local ring of dimension 2, which is a flat module over a field or a discrete valuation ring. Let \( \Delta \) be any irreducible curve in \( \text{Spec} R \). Then the function

\[
d_{\Delta}(D_1, D_2) := \begin{cases} (D_1 \cdot \Delta)/(D_1 \cdot D_2) & \text{if } D_1 \neq D_2 \\ 0 & \text{if } D_1 = D_2 \end{cases}
\]

is an ultrametric distance on the space of irreducible curves in \( \text{Spec} R \) different from \( \Delta \).

**Proof.** — For those rings \( R \) which further satisfy the property of containing \( \mathbb{C} \), this is proved in [GBGPP18]. The proof only relies on (i) the existence of embedded resolutions of divisors in the spectra of such rings, and (ii) the negativity of the intersection matrix of the exceptional divisor of a projective birational morphism between spectra of such rings. Both results still hold under
our weaker assumptions: see [Liu02, Theorem 9.2.26] for (i) and [Liu02, Theorem 9.1.27, Remark 9.1.28] for (ii).

Arithmetic intersection multiplicities. — Suppose now that $\mathcal{X}$ is a 2-dimensional regular Noetherian scheme, proper flat over a discrete valuation ring $\mathcal{O}$. A divisor on $\mathcal{X}$ is called horizontal (respectively vertical) if each of the irreducible components of the support $|D|$ is flat over $\mathcal{O}$ (respectively contained in the special fibre $\mathcal{X}_0$). We extend $(\cdot)$ to a bilinear form $(\cdot, \cdot)$ on pairs of divisors sharing no common horizontal irreducible component of the support by

$$(\mathcal{X}_k \cdot V) := 0$$

if $V$ is any vertical divisor.

Denote by $X$ the generic fibre of $\mathcal{X}$. If $D \in \text{Div}^0(X)$ with Zariski closure $\overline{D}$ in $\mathcal{X}$, a flat extension of $D$ is a divisor $\widehat{D} \in \text{Div}(\mathcal{X})_{\mathbb{Q}}$ such that $\widehat{D} - \overline{D}$ is vertical and

$$(\widehat{D} \cdot V) = 0$$

for any vertical divisor $V$ on $\mathcal{X}$. A flat extension of $D$ exists and it is unique up to addition of rational linear combinations of the connected components of $\mathcal{X}_k$.

The arithmetic intersection multiplicity on divisors with disjoint supports in $\text{Div}^0(X)$ is then defined by

$$m_X(D_1, D_2) := (\overline{D}_1 \cdot \overline{D}_2) = (\widehat{D}_1 \cdot \overline{D}_2) \in \mathbb{Q}.$$  

4.3. Decay of intersection multiplicities. — We continue using the notation introduced in §4.1. Let $m_{\mathbb{F}} := m_{X_{H_0,\mathbb{F}}}$. We will show that for any degree-$0$ divisor $D$ on $X_{H_0}$, we have

$$m_{\mathbb{F}}([\mathcal{X}_{\mathbb{F}}, 1], D) = O(q_F^0)$$

in $L$, uniformly in $a$.

Let $U_{0, v} := \text{GL}_2(\mathcal{O}_{F, v}) \subseteq \mathbb{B}_v^\times$, let $X_0 := X_{\overline{\mathbb{Q}^\times} \cap \mathcal{U}_0}$, let $\mathcal{X}_0$ be the canonical model of $X_{0, \overline{\mathbb{Q}}}$ over $\mathcal{O}_{F, v}$, and let $\mathcal{X}_0'$ be its base-change to $\mathcal{O}_{H_0, \overline{\mathbb{F}}}$, which is smooth over $\mathcal{O}_{H_0, \overline{\mathbb{F}}}$ (see [Car86]). Let $\mathcal{X}$ be the integral closure of $\mathcal{X}_0'$ in $X_{H_0, \overline{\mathbb{F}}}$, which is a regular model of the latter over the ring of integers of $\mathcal{O}_{H_0, \overline{\mathbb{F}}}$, and let $p \colon \mathcal{X} \to X'_0$ be the projection. We denote by $\kappa$ the residue field of $H_0, \mathbb{F}$.

Lemma 4.3.1. — Let $z_0 \in X_{H_0}$ be a CM point with pseudo-conductor $s$, let $\overline{\mathbb{F}}$ be its closure in $X$, and let $y \in X(\kappa)$ be its reduction modulo $\overline{\mathbb{F}}$. Let $\mathcal{X}_y := \text{Spec} \mathcal{O}_{\mathcal{X}, y}$, let $\mathcal{X}_{y, \kappa}$ denote its special fibre. Then

$$(\overline{\mathbb{F}} \cdot [\mathcal{X}_{y, \kappa}])_{\mathbb{F}} = [\kappa(y) : \kappa]q_{F, v}.$$  

Proof. — We will deduce this from Gross’s theory of quasicanonical liftings [Gro86], which we recall. The situation is purely local and we drop all subscripts $v$ and $\overline{\mathbb{F}}$. For $E \subseteq K \subseteq F_{\mathbb{F}}$, let $K^{un}$ be the maximal unramified extension of $K$ contained in $E_{\mathbb{F}}$. Let $k$ be the residue field of $\mathcal{O}_{E^{un}}$. By [Car86, §7.4], for any supersingular point $y_0 \in \mathcal{X}_{0, \overline{\mathbb{Q}}}$, the local ring of $\mathcal{X}_{0, \overline{\mathbb{Q}}}$ at $y_0$ is isomorphic to $\mathcal{O}_{E^{un}, [u]}$ and it is the deformation ring of formal modules studied by Gross. The main result of [Gro86] is that for any CM point $z_0 \in \mathcal{X}_{0, \overline{\mathbb{Q}}}^{un}$, there exist a unique integer $t$ (the conductor of $z_0$) such that the following hold. The field $E^{un}(z_0)$ is the abelian extension $E^{(t)}$ of $E^{un}$ with norm group $(\mathcal{O}_{F} + \mathcal{O}_{E})^{t}/\mathcal{O}_{\mathbb{F}}$, which is totally ramified of some degree $d_t$. And the corresponding map

$$\mathcal{O}_{X_{0, \overline{\mathbb{Q}}}} \cong \mathcal{O}_{E^{un}}[u] \twoheadrightarrow \mathcal{O}_{E^{(t)}} = \text{Spec } z_0$$

sends $u$ to a uniformiser of $E^{(t)}$. It follows that if $\mu_t$ is the minimal polynomial of $\overline{\mathbb{F}}^{(t)}$, $$(z_0 \cdot [\mathcal{X}_{0, \kappa}) = \dim_k \mathcal{O}_{E^{un}}[u]/(\mathcal{O}_{E^{un}}[u]) = \dim_k \mathcal{O}_{E^{(t)}}/\mathcal{O}_{F} = d_t.$$
Consider now the situation of the lemma. By the projection formula,

\[(\tau_d \cdot [\mathcal{Z}_{y,r,s}]) = (\tau_d \cdot \mathcal{Z}_{y,r,s}) = [H_0(z) : H_0(z_0,s)] \cdot (\tau_d \cdot [\mathcal{Z}_{y,r,s}]) = [H_0(z) : H_0(z_0,s)] \cdot (\tau_d \cdot [\mathcal{Z}_{y,r,s}]),\]

where \(y' = p(y)\) and \(z_0,s = p(z_1) \in X_0, H_0\) is a CM point. The base change multiplicity is \([\kappa(y) : \kappa]\) times the multiplicities of the base-changed divisors to the ring of integers of \(H^{\text{un}}_0\), where \(z_0,s\) remains an irreducible divisor since \(H_0(z_0,s) \subset H_0(z)\) is totally ramified over \(H_0\). We perform such base-change without altering the notation. Let \(z\) be the image of \(z_0,s \in X_0 H^{\text{un}}_0\) in \(X^{\text{un}}\), and let \(t\) be the conductor of \(z\); so \(E^{(t)} \subset H^{\text{un}}_0(z_0,s)\). The base-change of \(z \cong \text{Spec} E^{(t)}\) to \(H^{\text{un}}_0\) is

\[\text{Spec} E^{(t)} \otimes E^{\text{un}} H^{\text{un}}_0 = \text{Spec} H^{\text{un}}_0(z_0,s)^{\text{un}}\]

for \(e = [E^{(t)} : E^{\text{un}}] \cdot [H_0^{\text{un}} : E^{\text{un}}]/[H_0(z_0,s) : H_0]\), and \(z_0,s\) is one of the factors in the right hand side. By the projection formula applied to \(\mathcal{Z} \times \text{Spec} \mathcal{O}^{\text{un}}_H \rightarrow \mathcal{X} \times \text{Spec} \mathcal{O}^{\text{un}}_E\), we have

\[\left[H_0(z) : H_0(z_0,s)\right] \cdot (\tau_d \cdot [\mathcal{Z}_{y,r,s}])_{y'} = [\kappa(y) : \kappa][E^{(t)} : E^{\text{un}}] \cdot d_t\]

\[= [\kappa(y) : \kappa][H_0(z) : H_0] \cdot d_t \cdot d_t = [\kappa(y) : \kappa]q_{E^{(t)}}.\]

Proposition 4.3.2. — Let \(D\) be a divisor in \(\mathcal{X}\). There exists an integer \(N\) such that for all \(s \geq N\) the following holds.

Let \(z_s \in X_0 H_0\) be a CM point of pseudo-conductor \(s\), and let \(\tau_d\) be its closure in \(\mathcal{X}\). Then there exist a unique irreducible component \(V \subset \mathcal{X}_s\) and a positive constant \(\rho \in \mathbb{Q}^{\geq 1}\), such that:

- the denominator of \(\rho\) is bounded independently of \(z_s\);
- if we write

\[D = c \mathcal{X}_s + D',\]

with \(c \in \mathbb{Q}\) and \(D' \in \text{Div}(\mathcal{X}_s)\) a divisor supported away from \(V\), then

\[(\tau_d \cdot D) = c[\kappa(y) : \kappa]q_{E^{(t)}} + \rho(V \cdot D).\]

Proof. — By linearity and Lemma 4.3.1 it suffices to prove the first formula for an irreducible divisor \(D \neq V\) (once found which \(V\) is to be chosen). We will omit all subscripts \(v, \mathfrak{m}\) and use some of the notation introduced in the proof of Lemma 4.3.1.

Let \(y \in \mathcal{X}_s\), let \(\Delta\) be any irreducible horizontal divisor in \(\mathcal{X}_y\). We claim that the intersection multiplicities

\[(\Delta : z_s),\]

are bounded by an absolute constant as \(z_s\) ranges among CM points of sufficiently large pseudo-conductor reducing to \(y\). Indeed \((\Delta : z_s)\) is bounded by the degree of \(q: \mathcal{X} \rightarrow \mathcal{X}_s\) near \(y\), times the intersection multiplicities of the pushforward divisors to \(\mathcal{X}_s\). Similarly to the proof of Lemma 4.3.1 we may estimate this intersection in the base change of \(\mathcal{X}_s\) to \(E^{\text{un}}_E\). The base-change of the divisor \(q_s z_s\) equals a sum of CM points of \(\mathcal{X}_s \times \text{Spec} \mathcal{O}^{\text{un}}_E\) Spec \(\mathcal{O}^{\text{un}}_E\); because \(H_s / H_0\) is totally ramified, the number of points in this divisor is bounded by an absolute constant and the conductors of all those CM points go to infinity with \(s\). Thus it suffices to show that if \(\Delta_0\) is a fixed horizontal divisor on \(\mathcal{X}_s \times \text{Spec} \mathcal{O}_E\), its intersection multiplicity with CM points of conductor \(t\) is bounded as \(t \rightarrow \infty\).

Now write \(\Delta_0 = \mathcal{O}^{\text{un}}_E[a]/(f), with \(f = \sum_{i=1}^d a_i u^i\) an integral non-constant monomial. Let \(\tilde{f} \in E^{\text{un}}\) be the reduction of \(f\). Let \(z \in \mathcal{X}_s \times \mathcal{O}^{\text{un}}_E\) be a CM point of conductor \(t\). Then

\[(\Delta_0 : z) = \dim E^{\text{un}} E^{\text{un}}[u]/(f, \mu_t) = \dim_k \mathcal{O}_E^{(t)}/(f(\varpi^{(t)})) = \dim_k \mathcal{O}_E^{(t)}/((\varpi^{(t)})^{\deg(\tilde{f})}) = \deg(\tilde{f}) \leq d.\]
4.2.1 Write \( |\mathcal{Y}_{y, \kappa}| = \sum_{V} e_{V} V' \), and consider the ultrametric distance \( d_{\Delta} \) of Proposition 4.2.1 (applied to \( R = \mathcal{O}_{\mathcal{X}_{y, \kappa}} \)). As
\[
\sum_{V} \frac{e_{V}}{(\overline{z}_{s} \cdot \Delta)(V \cdot \Delta)} = \frac{d_{\Delta}(\overline{z}_{s}, V')^{-1}}{(\overline{z}_{s} \cdot \Delta)}
\]
goese to infinity with \( s \) and the coefficients of the \( d_{\Delta}(\overline{z}_{s}, V')^{-1} \) are bounded, the minimum of the \( d_{\Delta}(\overline{z}_{s}, V') \) goes to 0 with \( s \). Let \( V \subset \mathcal{Y}_{y, \kappa} \) be a vertical component realising the minimum. Then if \( s \) is sufficiently large and \( D \neq V \) is irreducible, \( d_{\Delta}(\overline{z}_{s}, V) < d_{\Delta}(V, D) \), so that by Proposition 4.2.1,
\[
d_{\Delta}(\overline{z}_{s}, D) = d_{\Delta}(V, D).
\]
Unwinding the definitions
\[
(\overline{z}_{s} \cdot D) = \rho(V \cdot D), \quad \rho = \frac{(\overline{z}_{s} \cdot \Delta)}{(V \cdot \Delta)},
\]
so that the denominator of \( \rho \) is bounded by \( \max_{V} \{(V \cdot \Delta)\} \). Applied to a vertical \( D = V' \neq V \), the formula shows the uniqueness of \( V \) for large \( s \).

**Corollary 4.3.3.** — If \( D \in \text{Div}^0(X_{H_{0}})_{L} \) is any degree-zero divisor, then for all sufficiently large \( s \) and all \( a \),
\[
m_{\overline{w}}(Z_{a, \overline{w}}(\phi^{\infty})[1]_{U}, D) = O(q_{F, s}^{\delta})
\]
in \( L \), where the implied constant can be fixed independently of \( a \) and \( s \).

**Proof.** — Let \( \tilde{D} \) be a flat extension of \( D \) to a divisor on \( \mathcal{X} \) (with coefficients in \( L \)), and let \( \overline{Z}_{a, s} \) be the Zariski closure of \( Z_{a, \overline{w}}(\phi^{\infty})[1]_{U} \). Then by Propositions 4.1.4 and 4.3.2,
\[
m_{\overline{w}}(Z_{a, \overline{w}}(\phi^{\infty})[1]_{U}, D) = (\overline{Z}_{a, s} \cdot \tilde{D}) = Aq_{F}^{\delta} + \sum_{i} \lambda_{i}(V_{i} \cdot \tilde{D})
\]
for some vertical components \( V_{i} \) and \( A, \lambda_{i} \in L \) whose denominators are bounded independently of \( a \). (For \( \lambda_{i} \), the boundedness is part of Proposition 4.1.4; for \( A \), it holds because each \( c \) in (4.3.1) is.) By definition of flat divisor, \((V_{i} \cdot \tilde{D}) = 0 \) for all \( i \).

4.4. Decay of local heights. — Recall that we need to prove (Proposition 3.6.3) that
\[
T_{v}(\sigma^{\vee}) \tilde{Z}(\phi^{\infty}, \chi)(v)
\]
is a \( v \)-critical element of \( \overline{S} \). As in [1, §9.2, proof of Proposition 9.2.1], this follows if we show that for all \( v \) and all \( a \in A_{\text{c1, c2}, \infty} \) with \( w(a) = r_{v} \),
\[
(4.4.1) \quad \langle \tilde{Z}_{a, \overline{w}}(\phi^{\infty})_{U}[1], T_{v}(\sigma^{\vee})_{U}t_{\chi} \rangle_{\overline{w}} = O(q_{F, v}^{\delta})
\]
in \( \Gamma_{F} \tilde{\otimes} L(\chi) \). (Here \( T_{v}(\sigma^{\vee})_{U} \) is a certain correspondence.) By using, as in loc. cit.,(6) the integrality result of Proposition 4.2.3 *ibid.*, the left hand side of (4.4.1) can be expressed as
\[
(4.4.2) \quad c_{\overline{w}}^{-1}(d_{0} + d_{1, s} + d_{2}) N_{H_{0, \overline{w}}/F_{0}} \circ N_{s}(h_{s}), \quad h_{s} \in H_{s, \overline{w}} \tilde{\otimes} \mathcal{O}_{L(\chi)},
\]
where \( c \in \mathcal{O}_{L(\chi)} \). \( \overline{w}(L(\chi)) \) is a uniformiser in \( L(\chi) \), \( N_{i} \) is the norm from \( H_{s, \overline{w}} \) to \( H_{0, \overline{w}} \), and the integers \( d_{0}, d_{1, s}, d_{2} \) are as recalled before Lemma 4.4.2 below, where we show they are bounded independently of \( s \). Thus it suffices to show that, for some constant \( c' \),
\[
(4.4.3) \quad N_{s}(h_{s}) \equiv 0 \quad \text{in } H_{s, \overline{w}} \tilde{\otimes} \mathcal{O}_{L(\chi)}/q^{a-c'} \mathcal{O}_{L(\chi)},
\]
(6)Our field \( H_{s} \) should be compared to the \( H'_{s} \) of loc. *cit.*
Lemma 4.4.1. — For all $s' \leq s$, the restriction of the $\varpi$-adic valuation yields an isomorphism of $\mathcal{O}_{L(\chi)}$-modules

$$N_s(H_\varpi^X \hat{\otimes} \mathcal{O}_{L(\chi)})/q^s \cdot (H_\varpi^X \hat{\otimes} \mathcal{O}_{L(\chi)}) \to \mathcal{O}_{L(\chi)}/q^{s'} \mathcal{O}_{L(\chi)}.$$  

Proof. — We drop all subscripts $\varpi$. Recall that the extension $H_s/H_0$ is totally ramified of degree $q^s$. Let $\varpi_s \in \mathcal{O}_{H_s}$ be a uniformiser; then $\omega_0 := N_s(\varpi_s)$ is a uniformiser of $H_0$. For $* = 0, s$ we have the decompositions

$$H_\varpi^X \hat{\otimes} \mathcal{O}_{L(\chi)} = \mathcal{O}_{H_s}^X \hat{\otimes} \mathcal{O}_{L(\chi)} \oplus \varpi_s \otimes \mathcal{O}_{L(\chi)}.$$  

The map $N_s$ respects the decompositions and, by local class field theory, has image

$$q^s \cdot (\mathcal{O}_{H_s}^X \hat{\otimes} \mathcal{O}_{L(\chi)}) \oplus \varpi_0 \otimes \mathcal{O}_{L(\chi)}.$$  

The valuation map annihilates the first summand and sends the second one isomorphically to $\mathcal{O}_{L(\chi)}$. The result follows.  

Proof of Proposition 3.6.3. — By the discussion in the present subsection, we are reduced to showing (4.4.3); equivalently, thanks to the previous lemma, that

$$\varpi(N_s(h_s)) \equiv 0 \pmod{q^s \mathcal{O}_{L(\chi)}}.$$  

By the construction of $h_s$ and [I, Proposition 4.3.1] applied to the curve $X_{U/H_0}$, we have

$$\varpi(N_s(h_s)) = c\varpi^{-(d_0+d_1+\cdots+d_k)}\prod\mathbb{Z}_{\mathcal{O}_{H_s},(\phi^\infty)U[1],T_\infty}((\sigma^*)_U[t_\chi]).$$  

By Corollary 4.3.3 applied to $D = t_\chi$, together with the next lemma proving the boundedness of $d_{1,s}$, the right-hand side of (4.4.4) is $O(q_s^p)$.  

Finally, we take care of the sequence

$$d_{1,s} := \text{length}_{\mathcal{O}_{L}} \mathcal{H}^1(H_0,\mathcal{O}_{L}^X(1) \otimes L'/\mathcal{O}_{L})_{\text{cors}},$$  

where $T_s' \subset T_pJ_U$ is the same sub-$\mathcal{O}_{L}[\varpi_F]$-module as in [I, Proof of Proposition 9.2.3], and $L' = L(\chi)$. As

$$\mathcal{H}^1(H_0,\mathcal{O}_{L}^X(1) \otimes L'/\mathcal{O}_{L})_{\text{tors}} \cong H^0(H_0,\mathcal{O}_{L}^X(1)) \subset H^0(E_w, T_pJ_U(1)_{\text{tors}} \otimes \mathcal{O}_{L}^\times \text{Gal}(H_s/\varpi/E_w)), $$

the boundedness follows from the next lemma.

Lemma 4.4.2. — Let $\Gamma_\infty := \text{Gal}(H_\infty,\varpi/E_w) \cong E^\times \backslash E_A^\times /U^\circ U_{F,w}^\circ$. We have

$$H^0(E_w, T_pJ_U(1) \otimes \mathcal{O}_{L}[\Gamma_\infty]) = 0.$$  

Proof. — The proof is largely similar to that of [I, Lemma 2.9.4], to which we refer for more details. It suffices to show that for all Hodge-Tate characters $\psi: \mathcal{O}_{E_w} \to L^\times$ factoring through $\Gamma_\infty$, the space

$$H^0(E_w, V_pJ_U(\psi)) = \mathcal{D}_{\text{cris}}(V_pJ_U(\psi))^\bullet = 1$$

is zero. Here $\varphi$ is the crystalline Frobenius, and we may prove the same result after replacing it with $\varphi^d$, $d = [E_w : E_{w,0}]$ where $E_{w,0}$ the maximal unramified extension of $\mathbb{Q}_p$ contained in $E_w$. Since $\varphi^d$ acts with negative weights on $\mathcal{D}_{\text{cris}}(V_pJ_U)$, it suffices to show that it acts with weight 0 on $\mathcal{D}_{\text{cris}}(\psi^m)$ for $m$ such that $\psi^m$ is crystalline.

Since $\psi$ is trivial on $U_{F,w}^\circ$, the Hodge-Tate weights $(n_\tau)_{\tau \in \text{Hom}(E_w,\varpi)}$ satisfy $n_\tau + n_{-\tau} = 0$ where $c$ is the complex conjugation of $E_w/F_w$. The action of $\varphi^d$ on $\mathcal{D}_{\text{cris}}(\psi^m)$ is by

$$\psi \circ \text{rec}_{E_w}(\varpi_w)^{-m}, \prod_{\tau \in \text{Hom}(E_w,\varpi)} \varpi_w^{n_{\tau}}.$$  

(4.4.5)
where \( \varpi_w \in E_w \) is any uniformiser. Choose \( \varpi_w \) so that \( \varpi_w^{(E_w/F_v)} = \varpi_v \) is a uniformiser in \( F_v \).

Then \( \varpi_w^p = \pm \varpi_w \), so that the second factor in (4.4.5) is \( \pm 1 \). On the other hand, the subgroup \( F_e^+ F_w^+ / U_{F_v}(U_v \cap F_w^+) \subseteq \Gamma_\infty \) is finite, hence \( \varpi_v \) and \( \varpi_w \) have finite order in \( \Gamma_\infty \). It follows that the first factor in (4.4.5) is a root of unity too, hence \( \varphi^d \) acts with weight 0 on \( D_{cris}(\psi^m) \).

Summary. — We have just completed the proof of Proposition 3.6.3. It implies Proposition 3.6.2, which together with Theorem 3.6.1 implies the kernel identity of Theorem 3.4.3. By Corollary 3.4.4, that implies Theorem 2.2.1, which in turn is equivalent to Theorem B by Lemma 2.2.2.

Appendix A. Local integrals

Throughout this appendix, unless otherwise noted \( v \) denotes a place of \( F \) above \( p \). If \( w | v \) is a place of \( E \), we denote by \( q_v: E_v \to F_v \) and \( q_w: E_w \to F_v \) the norm maps.

A.1. Gamma factors. — We study local gamma factors, in order to relate the interpolation factors of the \( p \)-adic \( L \)-function used here and those of the one from [I].

**Lemma A.1.1.** — Let \( \xi: E_w^\times \to \mathbb{C}^\times \) and \( \psi: E_w^\times \to \mathbb{C}^\times \) be characters, with \( \psi \neq 1 \). Let \( dt \) be a Haar measure on \( E_w^\times \). Then

\[
\int_{E_w^\times} \xi(t) \psi(t) dt = \frac{dt}{d\psi t} \cdot \xi(-1) \cdot \gamma(\xi, \psi)^{-1}.
\]

The left-hand side is to be understood in the sense of analytic continuation from characters \( \xi|\cdot|^s \) for \( \Re(s) > 0 \).

**Proof.** — We may fix \( dt = d\psi t \). Then the result follows from the functional equation for \( GL_1 \) ([BH06, (23.4.4)]):

\[
(A.1.1) \quad Z(\phi, \xi) = \gamma(\xi, \psi)^{-1} Z(\hat{\phi}, \xi^{-1} | ),
\]

where for a Schwartz function \( \phi \) on \( E_w^\times \),

\[
Z(\phi, \xi) := \int_{E_w^\times} \phi(t) \xi(t) d\psi t, \quad \hat{\phi}(t) := \int_{E_w^\times} \phi(x) \psi(xt) d\psi x.
\]

Namely, we insert in (A.1.1) the function \( \hat{\phi} := \delta_{-1 + \varpi_v \sigma_F} := \text{vol}(1 + \varpi_v^n \sigma_F v, d\psi t)^{-1} 1_{-1 + \varpi_v^n \sigma_F v} \), \( n \geq 1 \), approximating a delta function at \( t = -1 \). Then by Fourier inversion \( \phi(t) = \hat{\phi}(-t) = \delta_{1 + \varpi_v \sigma_F} * \psi(t) \), which if \( n \) is sufficiently large (depending on the conductor of \( \xi \)) has the same integral against \( \xi \) as \( \psi(t) \).

In what follows, by a ‘Weil–Deligne representation of (the Weil group) of \( E_v \) we mean the data, for each place \( w | v \) of \( E_v \), of a Weil–Deligne representation of the Weil group of \( E_w \). To such an object we attach additively \( L \), \( \gamma \), and \( \varepsilon \)-factors. The induction functor \( \text{Ind}_{E_v}^F \): from Weil–Deligne representations of \( E_v \) to Weil–Deligne representations of \( F_v \) is defined when \( E_v = F_v \oplus F_v \) too.

**Lemma A.1.2.** — Let \( W \) be a Weil–Deligne representation of the Weil group of \( F_v \) and let \( \psi: F_v \to \mathbb{C}^\times \) be a nontrivial character. Then for any \( a \in F_v^\times \),

\[
\gamma(W, a, \psi)^{-1} = \det W(a) \cdot \gamma(W, \psi)^{-1}.
\]

**Proof.** — This follows from the corresponding result for \( \varepsilon \)-factors, proved in [Tat79].

For the rest of this appendix, we denote \( \psi_{E,v} = \psi_v \circ \text{Tr}_{E_v/F_v} \).
Lemma A.1.3. — Let $W$ be a Weil–Deligne representation of the Weil group of $E_v$. Then
\[ C'_v(W_v, \psi_v) := \gamma(W_v, \psi_{E,v})/\gamma(\text{Ind}^{E_v}_{E_v}(W_v, \psi_v)) \]
depends only on $\psi_v$ and dim $W$. It satisfies $C'_v(a, \psi_v) = \eta_v^{\dim W}(a)C'_v(\psi_v)$.

Proof. — As $L$-factors are inductive and independent of $\psi_v$, we may replace $\gamma$ by $\varepsilon$-factors in the statement. The ratio $C_v(W_v, \psi_v)$ descends to a function on the Grothendieck group $R$ of virtual Weil–Deligne representations. By [Tat79], this group is generated by the trivial representation and representations of degree 0, and the ratio is 1 for representations of degree 0 ($\varepsilon$-factors). We deduce that $C(W_v, \psi_v)$ equals $\varepsilon(\eta_v, \psi_v)^{\dim W}$ up to a function depending only on dim $W$ and not on $\psi_v$.

Proposition A.1.4. — The ratio $C(\chi'_p, \psi_p)$ defined in (2.1.3) is independent of $\chi'_p$. It defines an element of $\Theta(\Psi_p, \omega_p, \alpha_p^{-2}|\cdot|_p^{-2})$.

Proof. — By the definition of $e_p(V(A, \chi'_p))$ and a comparison of [I, Lemma A.1.1] with Lemma A.1.1 applied to $\prod_{v|v} \chi'_w \alpha_v |\cdot|_v \circ q_w$, we have
\[ C(\chi'_p, \psi_p) = \prod_{v|p} \frac{C'_v(W_v^+, \psi_v)}{\gamma(\text{ad}(W_v(1)^{++}))}, \]
where $\psi_p = \prod_{v|p} \psi_v$ and $\text{ad}(W_v(1)^{++})$ is defined above Theorem A. Then the independence of $\chi'$ follows from the first part of Lemma A.1.3. The equivariance property follows from the second part of the latter, together with Lemma A.1.2 and the computation
\[ \det(W_v^+ \otimes \text{Ind}^{E_v}_{E_v} \chi'_p) = \eta_v^{\alpha_v^2} |\cdot|_{E_v}^{\alpha_v^2} \chi'_p \]

A.2. Toric period at $p$. — We compare the toric period at a $p$-adic place with the interpolation factor.

Lemma A.2.1. — The quotient space $K^{1}_{1}(\varpi^{r'})/\text{GL}_{2}(\mathcal{O}_{F,v})$ admits the set of representatives
\[ n^-(c) := \left\{ \begin{array}{ll} \left( \begin{array}{ll} 1 & 1 \\ c & 1 \end{array} \right) & \text{if } c \neq \infty \\ \left( \begin{array}{ll} -1 & 1 \\ c & 1 \end{array} \right) & \text{if } c = \infty \end{array} \right. \]
for $c \in \mathcal{O}_{F,v}/\varpi^{r'} \mathcal{O}_{F,v} \cup \{ \infty \}$.

Proposition A.2.2. — Let $\chi \in \mathcal{B}^{L,c}$ be a finite-order character, let $r$ be sufficiently large (that is, satisfying the $\nu$-component of Assumption 3.4.2), and let $W_v$ be as in (3.1.1), $\phi_v = \phi_{v,r}$ be as in (3.1.4).

Let $(\cdot)_v: \pi_v \times \pi_v^\vee \to L$ be a duality pairing satisfying the compatibility of [I, (5.1.2)] with the local Shimizu lift. Finally, let $Z_v^0(\alpha_v, \chi_v)$ be the interpolation factor of the $p$-adic $L$-function of [I, Theorem A].

Then for all sufficiently large $r' > r$,
\[ Q(\cdot, v, \pi_v, \chi_v, \alpha_v) := \int_{E_v/\mathcal{O}_{F_v}} \chi(t)(\pi(t)f_1, f_2) dt, \]
where $Q(\cdot, v, \pi_v, \chi_v, \alpha_v)$ uses the measure $d^{\alpha_v} t_v = |\varpi|_{v}^{-1/2} |D|_{v}^{-1/2} dt$.

Proof. — We drop all subscripts $v$, and assume as usual that $\psi$ has level $d^{-1}$. Let
\[ \xi(\cdot, f_1, f_2, \chi_v) = \int_{E_v/\mathcal{O}_v} \chi(t)(\pi(t)f_1, f_2) dt, \]

(7) In loc. cit., the pairing $(\cdot)_v$ is denoted by $\mathcal{F}_v$. 

[Comment: In preparing your answer, we aim for clarity and accuracy. The text has been formatted to enhance readability and coherence. Each section is clearly marked, and the content is organized to facilitate understanding.]
where \( dt \) is the usual Haar measure on \( E^*/F^* \), giving volume \(|d|^{1/2}|D|^{1/2}\) to \( \mathcal{O}_E^*/\mathcal{O}_F^* \).

By the definitions and [I, Lemma A.1.1] (which expresses \( Z^v \) as a normalised integral), it suffices to show that
\[
Q^T(\vartheta(W, \alpha) \cdot (w)^{-r} w_{r,n}(\phi), \chi) = |d|^{3/2}|D| \cdot L(1, \eta)^{-1} \cdot \int_{E^x} \alpha \cdot | \circ q(t) \chi(t) w_E(t) dt.
\]

By [I, Lemma 5.1.1] (which spells out a consequence of the normalisation of the local Shimizu lifting) and Lemma A.2.1 we can write
\[
Q^T := Q(\vartheta(W, \alpha) \cdot (w)^{-r} w_{r,n}(\phi_v), \chi_v) = \sum_{c \in \mathcal{P}(\mathcal{O}_E/F^* \cap \mathcal{O}_F)} Q^{T,c}(c)
\]
for each \( c \),
\[
Q^{T,c} := |d|^{-3/2} \cdot \int_{E^x} W((y^c) n^{-1}(c)) \int_{T(F)} \chi(t) \int_{P((w)^{-r})} |y| r(n^{-1}(c) k w_{r,n}(\phi)(gt^{-1}, y^{-1} q(t))) dk dt \frac{d^x y}{|y|^1}.
\]
Here \( P((w)^{-r}) = P \cap \mathcal{K}_1^1((w)^{-r}) \), where \( P \subset \mathcal{G}_2(F) \) is the upper triangular Borel subgroup.

It is easy to see that \( Q^{T,\infty} = 0 \) (observe that \( \phi_{2,r}(0) = 0 \)). For \( c \neq \infty \), we have
\[
n^{-1}(c) w_{r,n}^{-1} = w_{r,n}^{-1} \begin{pmatrix} 1 & -c w^{-r} \\ -1 & 1 \end{pmatrix},
\]
and when \( x = (x_1, x_2) \) with \( x_2 = 0 \):
\[
r(n^{-1}(c) w_{r,n}(\phi)(x, u)) = \int_{E} \psi_E(ux_1) \psi(-ucq(\xi)) \phi_r(\xi, w^{-r} u) d\xi
\]
On the support of the integrand we have \( v(u) = (w)^{-r} \) and \( v(q(\xi)) \geq r, \) the by definition of \( \phi_r \). If \( v(c) < r' - r - v(d) \), the integration in \( d\xi \) gives 0; hence \( Q^{T,c} = 0 \) in that case.

Suppose from now on that \( v(c) \geq r' - r - v(d) \). Then \( \psi(-ucq(\xi)) = 1 \) and
\[
r(n^{-1}(c) w_{r,n}(\phi)(x, u)) = |d|^{3/2} |D| \cdot L(1, \eta)^{-1} \cdot |w|^{-r} \cdot \psi_E, r(\psi_E, r w^{-r} x_1) \delta_1 u_p, r(\psi_E, r u).
\]
where \( \psi_E, r := \text{vol}(\mathcal{O}_E^{-1}) \cdot \delta_1 r, \cdot \phi_E \), and we have noted that \( \phi_{2,r}(0) = e^{-1} |d| \cdot \text{vol}(q^{-1}(-1 + w^{-r} \mathcal{O}_F) \cap \mathcal{O}_F) = |w|^{-1} |d|^{3/2} L(1, \eta)^{-1} \).

If \( r' \) is sufficiently large, the Whittaker function \( W \) is invariant under \( n^{-1}(c) \). Then
\[
Q^{T,c} = |d|^{3/2} |D| \cdot L(1, \eta)^{-1} \cdot |w|^{-r} \cdot \alpha(\psi^{-r}) \cdot |d|^{1/2} \cdot \xi_{F,v}(1)^{-1} \cdot \int_{E^x} W((y^c_1) \int_{T(F)} \chi(t) \psi_E, r(\psi_E, r w^{-r} x_1) \delta_1 u_p, r(\psi_E, r y^{-1} q(t))) dt d^x y,
\]
where \( |w|^{-r} |d|^{1/2} \xi_{F,v}(1)^{-1} \) appears as \( \text{vol}(P((w)^{-r}) \mathcal{K}_1^1((w)^{-r})) \).

Integrating in \( d^x y \) and summing the above over the \( q_{E,F}^p \), contributes values of \( c \), we find
\[
Q^T = |d|^{3/2} |D| \cdot L(1, \eta)^{-1} \cdot \int_{E^x} \chi(t) \alpha | \circ q(t) \psi_E(t) dt,
\]

as desired. \( \square \)

**Corollary A.2.3.** — If \( \chi_p \) is not exceptional, then the quaternion algebra \( B \) over \( A \) satisfying \( H(\pi_B, \chi) \neq 0 \) is indefinite at all primes \( v \mid p \).

**Proof.** — By Propositions A.2.2 and A.1.4, if \( \chi_p \) is not exceptional, then for all \( v \mid p \) the functional \( Q_v \in H(\pi_{M_2(F_v)}, \chi_v) \otimes H(\pi_{M_2(F_v)}, \chi_v^{-1}) \) is not identically zero. \( \square \)
Appendix B. Errata to [I]

The salient mistakes are the following two: the statement of the main theorem is off by a factor of 2; and the Schwartz function \( \phi_{2,p} \) given by the local Siegel–Weil formula at \( p \) needs to be different from the Schwartz function used to construct the Eisenstein family.

References in italics are directed to [I].

- **Theorem A.** It should be
  \[ L_{p,\alpha} (\sigma_E) \in \mathcal{O}_{\mathfrak{g}'}(\mathfrak{g}', \omega_p^{-1} \alpha_p^2 \cdot |_{p} \chi_{F,\text{univ}}, \mathfrak{b}) \]
  instead of \( \mathcal{O}_{\mathfrak{g}'}(\mathfrak{g}', \omega_p^{-1} \chi_{F,\text{univ}}, \mathfrak{b}) \).

- **Theorem B.** The constant factor should be \( c_E \) and not \( c_E/2 \) (the latter is, according to [I, (1.1.3)], the constant factor of the Gross–Zagier formula in archimedean coefficients). The mistake is introduced in the proof of [I, Proposition 5.4.3], see below.

  The heuristic reason for the difference is that the direct analogue of \( s \mapsto L(1/2 + s, \sigma_E, \chi) \) is \( \chi_F \mapsto L_p(\sigma_E)(\chi \cdot \chi_F \circ q) \) (where \( q \) is the adelisation of the norm from \( E \) to \( F \)), whose derivative at \( \chi_F = 1 \) is twice our \( d_p L_p(\sigma_E)(\chi) \) (because the tangent map to \( \chi_F \mapsto \chi' = \chi \cdot \chi_F \circ q \mapsto \omega^{-1} \cdot \chi'_{A,s} \) is multiplication by 2).

- **Theorem C.** Similarly, the constant factor should be \( c_E/2 \) in part 3, and \( c_E \) in part 4.

- **§2.1.** The space of \( p \)-adic modular forms is the closure of \( M_2(K^p \mathcal{K}_1(p^\infty)_p) \), not \( M_2(K^p \mathcal{K}_1(p^\infty)_{p'}) \).

- **Proposition 2.4.4.1.** The multiplier in equation (2.4.3) should be \( |\alpha| \cdot |(\varpi^{-r}) = \prod_{v | p} |\alpha_v| \cdot |\varpi_v \varpi_v^{-r} \), and the statement holds for forms in \( M_2(K^p \mathcal{K}_1(p^\infty)_{p'}) \). Similarly, the definition of \( R_{\varphi,v}^0 \) in Proposition 3.5.1 should have an extra \( |\varpi_v^{-r} \). The result of Proposition A.2.2, as modified below, holds true for this definition of \( R_{\varphi,v}^0(p \) and \( \mathcal{K}_1(p^\infty)_{p} \).

- **Proposition 3.2.3.2** should be corrected as follows: Let \( v | p \) and let \( \phi_{2,v} = \phi_{2,v} \) be as in (3.14) (the present paper). Then
  \[ W_{\alpha, r, v}(1, u, \chi_F) = \begin{cases} |d_v|^{3/2} |D_v|^{1/2} \chi_{F,v}(-1) & \text{if } v(a) \geq 0 \text{ and } v(u) = 0 \\ 0 & \text{otherwise.} \end{cases} \]

- **Equation (3.7.1)** The right-hand side should have an extra factor of \( \prod_{v | p} |d_v^2| |D|_v \) owing to the correction to Proposition A.2.2.

- **Lemma 5.3.1:** the left-hand side of the last equation in the statement should be \( \langle f_1(P_1), f_2(P_2) \rangle_{J,s} \).

- **Proof of Proposition 5.4.3.** The second-last displayed equation should have the factor of 2 on the right-hand side, not the left-hand side:
  \[ 2 \ell_{\varphi, \alpha}(\tilde{Z}(\varphi, \chi)) = |D_F|^{1/2} |D_E|^{1/2} L(1, \eta) \langle T_{\text{alg}, \chi} (\theta_{\varphi, \alpha}(\varphi, \alpha^{(r)} w v^{-1} \phi) \cdot P_\chi, P_\chi^{-1} \rangle. \]

Then the argument shows that, first,
  \[
  \langle T_{\text{alg}, \chi} (f_1 \otimes f_2) P_\chi, P_\chi^{-1} \rangle_{J,s} = \frac{\zeta_p^2(2)}{(\pi^2/2)^{F.A|D_E|^{1/2} L(1, \eta)}} \prod_{v | p} \pi_v(\alpha_v, \chi)_v^{-1} |D_F L_{p, \alpha}(\sigma_{A,E})| (\chi) Q(f_1, f_2, \chi)
  \]

(without an incorrect factor of \( 2 \) introduced in the denominator of the right-hand side of (5.4.1) there); and secondly, that the above equation is equivalent to Theorem B with the correction explained above.

Also, an extra factor \( \prod_{v | p} |d_v^2| |D|_v \) should be inserted in the right-hand sides of the last and fourth-last displayed equation, cf. the corrections to (3.7.1), Proposition A.3.1.
– Proposition 7.1.1(b): should be replaced by Proposition 3.5.1(b-c) of the present paper.

– §7.2, third paragraph: the coefficient in the second displayed equation should have $|D_{E_f}|^{1/2}$, not $|D_{E_f}/f|^{1/2}$, in the denominator.

– Lemma 9.1.1 is corrected by Lemma 4.1.1 of the present paper (this does not significantly affect the rest).

– Lemma 9.1.5: the extension $H_\infty$ is contained in a relative Lubin–Tate extension. This is the only property used.

– Lemma A.2.1: the list of purported representatives is missing the element $n^- (\infty) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$, cf. Lemma A.2.1 above.

– Proposition A.2.2: the statement should be

$$R^2_{E,v}(W_v, \sigma_v, \chi_v^{-1}) = |d_{E_v}^2|D|_v : Z^0_\nu(\chi'_v) := \frac{\zeta_{E,v}(2)L(1, \eta_v)^2}{L(1/2, \sigma^*_{E,v}, \chi'_v) \prod_{w|v} Z_w(\chi'_w)}.$$  

The factor $|d_{E_v}^2|D|_v$ missing from [I] should first appear in the right-hand side of the displayed formula for $\nu(x, u)$ in the middle of the proof.

– Proposition A.3.1: should be replaced by Proposition A.2.2 of the present paper.
