Abstract

Bandit algorithms have been predominantly analyzed in the convex setting with function-value based stationary regret as the performance measure. In this paper, we propose and analyze bandit algorithms for both general and structured nonconvex problems with nonstationary (or dynamic) regret as the performance measure, in both stochastic and non-stochastic settings. First, for general nonconvex functions, we consider nonstationary versions of first-order and second-order stationary solutions as a regret measure, motivated by similar performance measures for offline nonconvex optimization. In the case of second-order stationary solution based regret, we propose and analyze online and bandit versions of the cubic regularized Newton’s method. The bandit version is based on estimating the Hessian matrices in the bandit setting, based on second-order Gaussian Stein’s identity. Our nonstationary regret bounds in terms of second-order stationary solutions have interesting consequences for avoiding saddle points in the bandit setting. Next, for weakly quasi convex functions and monotone weakly submodular functions we consider nonstationary regret measures in terms of function-values; such structured classes of nonconvex functions enable one to consider regret measure defined in terms of function values, similar to convex functions. For this case of function-value, and first-order stationary solution based regret measures, we provide regret bounds in both the low- and high-dimensional settings, for some scenarios.

1 Introduction

Consider a sequence of functions \( \{ f_t(x) = E_\xi[F_t(x, \xi)] \}_{t=1}^T \), such that \( f_t : \mathbb{R}^d \to \mathbb{R} \), for all \( t = 1, \ldots, T \), with the corresponding sequence of minimal vectors \( \{ x_t^* \in \text{argmin}_{x \in X} f_t(x) \}_{t=1}^T \), where \( X \subset \mathbb{R}^d \). Here, the random variable \( \xi \) corresponds to the noise in the observations. Online bandit optimization is a sequential decision making problem in which the decision maker picks a decision \( x_t \) (or several decisions) in each round and observes the stochastic loss suffered \( F_t(x_t, \xi_t) \) as a consequence of the decision, \( a \text{ posteriori} \). The goal of the decision maker is to select the decisions \( x_t \) to minimize the so-called regret, which compares the accumulated loss over all \( T \) rounds, against the loss suffered by a certain oracle decision rule that could be computed only knowing all the functions, \( a \text{ priori} \). In the most well-studied setting of this decision making problem, the loss functions \( f_t \) are typically assumed to be convex and the oracle decision rule compared against, is chosen to be a fixed rule \( \bar{x}^* \defeq \text{argmin}_{x \in X} \sum_{t=1}^T f_t(x) \). In this case, a natural notion of stationary regret is given by \( R = \sum_{t=1}^T f_t(x_t) - \sum_{t=1}^T f_t(\bar{x}^*) \). It is easy to see that the regret of any non-trivial decision rule should grow sub-linearly in \( T \) and several algorithms exists for attaining such regret – we refer the reader to [FKM03, CBL06, HA07, AD10, AFH11, ST11, BCB12, Sha13, Sha17] for a non-exhaustive overview of such algorithms and their optimality properties under different assumptions on \( f_t \).

Recently, the focus of online optimization literature has been increasingly on the case when the oracle decision rule compared against is not a fixed vector, but is rather assumed to change. Assuming convex loss functions, a natural choice to compare against, is the sequence of minimal vectors \( \{ x_t^* \}_{t=1}^T \). In this case, the non-stationary regret is defined as \( R = \sum_{t=1}^T f_t(x_t) - \sum_{t=1}^T f_t(\bar{x}^*) \); see also [BW02, HS09, BGZ14, BGZ15, HW15, YZJY16]. Indeed, to obtain sub-linear regret in this setting, the degree of allowed non-stationarity in terms of either the functions or the minimal vectors is assumed to be bounded [BGZ15, YZJY16]. Additional issues arise when the loss functions are assumed to be nonconvex. As the optimal value of a function can be computationally hard to obtain in general, the notion of the above function value based regret, might become meaningless from a computational point of view. In this case, more structural assumptions need to be assumed about the functions \( f_t \) to still provide tractable regret bounds in terms of function values. Two such assumptions are quasi convexity and submodularity. In the absence of such assumptions, we focus on regret measures based on first- or second-order stationary solutions, motivated by standard nonlinear nonconvex optimization literature [Nes18]. A step towards the above two directions have been made in [HSZ17] and [GLZ18] respectively. Specifically, [HSZ17] considered general nonconvex functions with appropriately defined notions of first- and second-order stationary point based regrets and [GLZ18] extended the results of [BGZ15, YZJY16], where regret is defined in terms of function values, to the case of weak pseudo-convex (WPC) functions assuming bounds on the degree of allowed nonstationarity. While [HSZ17] focused only on the online nonconvex optimization setting (where gradient and/or Hessian information about \( f_t \) are available as feedback \( a \text{ posteriori} \)), [GLZ18] also considered the bandit setting.

In this paper, we consider several notions of regret for nonstationarity online nonconvex optimization, and make progress on several fronts. First, we propose a notion of nonstationary regret based on gradient size where the allowed degree of nonstationarity is bounded, similar to [BGZ15, GLZ18]. We provide constant-regret bounds in both the low- and high-dimensional setting, for the above mentioned notion of regret. Next, we propose a second-order stationary...
point based nonstationary regret measure for nonconvex online optimization, where the allowed degree of nonstationarity in the functions \( f_t \) is bounded. This notion is different from the smoothed second-order stationary point based regret measure proposed in [HSZ17]. We then propose online and bandit versions of cubic-regularized Newton method and obtain bounds for the above mentioned notion of nonstationary regret. The proposed bandit Newton method is motivated by the recently proposed estimator of Hessian with a three-point feedback mechanism from [BG18] and is based on second-order Gaussian Stein’s identity. To the best of our knowledge, we provide the first regret analysis of cubic-regularized Newton method in the online and bandit settings.

Finally, we establish sub-linear regret bounds in terms of function-value based regret measures for the class of K-Weak Quasi Convex (K-WQC) functions and weakly DR submodular functions. For this purpose, we use a Gaussian Stein’s identity based two-point feedback algorithm (based on [NS17]) and use a notion of nonstationary regret based on function values, proposed in [GLZ18]. We quantify the dependence of this regret on the dimensionality \( d \) (which is polynomial in \( d \) and is referred to as the low-dimensional setting). To allow for the dimensionality to grow faster, we also propose structural sparsity assumptions on the functions \( f_t \) and obtain regret bounds that depend only poly-logarithmically on \( d \); such a scenario is referred to as the high-dimensional setting. It is worth mentioning that recently, [WDBS18] and [BG18] proved related results for high-dimensional stochastic zeroth-order offline optimization. Furthermore, [CZHK19] proved related results for zeroth-order offline submodular maximization.

Our Contributions: To summarize the discussion above, in this paper, we make the following three contributions. The precise rates obtained are summarized in Table 1 in Appendix Section 7.

- **Gradient-size regret**: We first propose and establish sub-linear regret bounds for gradient-size based nonstationary regret measures in both the low- and high-dimensional setting for general nonconvex functions \( f_t \) whose variation is bounded in the sense of Definition 2.2.

- **Second-order regret**: Next, we propose a notion of second-order stationary point based regret, when the nonconvex functions \( f_t \) are assumed to be nonstationary in the sense of Definition 2.2. We then propose and analyze online and bandit versions of cubic-regularized Newton method and establish sub-linear bounds for the above mentioned regret measures.

- **Function-value based regret**: Finally, we analyze Gaussian smoothing based Bandit algorithms and establish regret bounds in both the low- and high-dimensional setting for a class of K-Weak Quasi Convex functions (Assumption 2.0) and DR weakly submodular functions (Definition 2.3).

2 Preliminaries

We now outline the basic notations, assumptions and definitions used throughout the paper. Additional details are introduced in the respective sections. We first state our assumptions about the zeroth-order oracle model.

**Assumption 2.1 (Zeroth-order oracle)** Let \( \| \cdot \| \) and \( \| \cdot \|_\ast \) be a norm and the corresponding dual norm on \( \mathbb{R}^d \). For any \( x \in \mathbb{R}^d \), the zeroth order oracle outputs an estimator \( F (x, \xi) \) of \( f (x) \) such that \( \mathbb{E} [ F (x, \xi) ] = f (x) \), \( \mathbb{E} [ \nabla F (x, \xi) ] = \nabla f (x) \), \( \mathbb{E} [ \| \nabla F (x, \xi) - \nabla f (x) \|_\ast^2 ] \leq \sigma^2 \), \( \mathbb{E} [ \nabla^2 F (x, \xi) ] = \nabla^2 f (x) \), and \( \mathbb{E} [ \| \nabla^2 F (x, \xi) - \nabla^2 f (x) \|_2^4 ] \leq \zeta^4 \).
Note that in the deterministic case, we have access to \( f(x), \nabla f(x), \) and \( \nabla^2 f(x) \) instead of their noisy approximations. Consequently, in the deterministic case, \( \sigma = 0 \) and \( \zeta = 0 \). We also require the following different assumptions, that are standard in the optimization literature \cite{BCB12, Nes18}, characterizing smoothness properties of the function.

**Assumption 2.2 (Lipschitz Function)** The functions \( F_t \) are \( L \)-Lipschitz, almost surely for any \( \xi \), i.e., \( |F_t(x, \xi) - F_t(y, \xi)| \leq L \|x - y\| \). Here, we assume \( \| \cdot \| = \| \cdot \|_2 \), unless specified explicitly.

**Assumption 2.3 (Lipschitz Gradient)** The functions \( F_t \) have Lipschitz continuous gradient, almost surely for any \( \xi \), i.e., \( \| \nabla F_t(x, \xi) - \nabla F_t(y, \xi) \| \leq L_G \|x - y\|_s \), where \( \| \cdot \|_s \) denotes the dual norm of \( \| \cdot \| \). This also implies \( |F_t(y, \xi) - F_t(x, \xi) - \langle \nabla F_t(x, \xi), y - x \rangle| \leq \frac{L_G}{2} \|y - x\|^2 \).

**Assumption 2.4 (Lipschitz Hessian)** The functions \( f_t \) have Lipschitz continuous Hessian, i.e., \( \| \nabla^2 f_t(x) - \nabla^2 f_t(y) \| \leq L_H \|x - y\| \).

In the above assumptions, the choice of the norm is fixed later in the individual sections. We also make the following assumption on the gradients to facilitate high-dimensional regret bounds; we refer the reader to \cite{WDBS18, BG18} for a motivation of such an assumption in the context of zeroth-order optimization.

**Assumption 2.5 (Sparse Gradient)** \( f_t(x) \) has \( s \)-sparse gradient, i.e., \( \| \nabla f_t(x) \|_0 \leq s \), where \( s \ll d \).

Next, following \cite{BGZ15, GLZ18}, we also define the so-called uncertainty sets corresponding to the functions \( \{f_t\}_{t=1}^T \) that capture the degree of nonstationarity allowed either in term of minimal vectors (Definition 2.1) or function values (Definition 2.2).

**Definition 2.1 (\cite{GLZ18})** For a given \( V_T \geq 0 \), the uncertainty set of functions \( \mathcal{S}_T \) is defined as

\[
\mathcal{S}_T(\{f_t\}_{t=1}^T) := \left\{ \{f_t\}_{t=1}^T : \{x_t^*\}_{t=1}^T \text{ satisfy } \sum_{t=1}^{T-1} \|x_t^* - x_{t+1}^*\| \leq V_T \right\}.
\]

**Definition 2.2 (\cite{BGZ15})** For a given \( W_T \geq 0 \), with \( \|f_t - f_{t+1}\| := \sup_{x \in \mathcal{X}} |f_t(x) - f_{t+1}(x)| \), the uncertainty set \( \mathcal{D}_T \) of functions is defined as

\[
\mathcal{D}_T(\{f_t\}_{t=1}^T) \overset{\text{def}}{=} \left\{ \{f_t\}_{t=1}^T : \sum_{t=1}^{T-1} \|f_t - f_{t+1}\| \leq W_T \right\}.
\]

Recall that for the case of function-value based regret, we need certain classes of structured nonconvex functions. We first state and provide two examples of functions that satisfy the following \( K\)-\text{WQC} condition.

**Assumption 2.6 (\( K\)-weak-quasi-convexity (\( K\)-WQC))** The function \( f_t \) satisfies \( K\)-WQC with respect to \( x_t^* \), i.e., \( f_t(x) - f_t(x_t^*) \leq K\nabla f_t(x)^\top (x - x_t^*) \) for some \( K > 1 \).

**Example 1** The first example based on the relation between 1-WQC functions and star-convex function. A function \( f(x) \) is defined to be star convex over a set \( \mathcal{X} \), if its set of global minima \( \mathcal{X}^* \) is non-empty, and for any \( x^* \in \mathcal{X}^* \) and \( x \in \mathcal{X} \) the following holds: \( f(\alpha x^* + (1 - \alpha) x) \leq \alpha f(x^*) + (1 - \alpha) f(x) \forall \alpha \in [0, 1] \). See \cite{NP04} for more details. It is shown in \cite{GG17} if the function \( f(x) \) in addition differentiable, then \( f(x) \) is star-convex iff \( f(x) \) is 1-WQC.
Example 2 The next example is based on a certain class of homogenous function, defined in [GLZ18]. A function is said to be $\alpha$-homogenous with respect to its minimum if there exists $\alpha > 0$ for which the following holds

$$f (\beta (x - x^*) + x^*) - f (x^*) = \beta^\alpha (f (x) - f (x^*)) \quad \forall x \in \mathcal{X}, \ \beta \geq 0$$

(3)

where $x^* = \arg\min_{x \in \mathcal{X}} f (x)$, and $\mathcal{X}$ is a convex set. The following proposition relates $\alpha$-homogenous to K-WQC functions.

Proposition 2.1 If a function is differentiable and satisfies $\alpha$-homogeneity w.r.t its minimum then the function is K-WQC where $K = \max \left(1, \frac{1}{\alpha} \right)$.

Proof Taking derivative on both sides of (3) w.r.t $\beta$ and setting $\beta = 1$ we get, $\nabla f (x)^\top (x - x^*) = \alpha (f (x) - f (x^*))$. Setting $K = \max \left(1, \frac{1}{\alpha} \right)$ we get, $f (x) - f (x^*) \leq K \nabla f (x)^\top (x - x^*)$.

Example 3 As defined in [GLZ18], the gradient of a function $f (x)$ is said to satisfy acute angle condition, if there is $Z > 0$ such that,

$$\cos (\nabla f (x), x - x^*) = \frac{\nabla f (x)^\top (x - x^*)}{\|\nabla f (x)\| \|x - x^*\|} \geq Z > 0$$

for all $x \in \mathcal{X}$ where $x^* \in \arg\min_{x \in \mathcal{X}} f (x)$ with the convention $\frac{\nabla f (x)}{\|\nabla f (x)\|} = 0$ when $\|\nabla f (x)\| = 0$. If the gradient of a Lipschitz continuous function satisfies acute angle condition then the function is $K\frac{\|\nabla f (x)\|}{Z}$-WQC.

Remark 1 The difference between K-WQC and WPC defined in [GLZ18] is as follows, namely, a subset of submodular functions. If a K-WQC function is L-Lipschitz then the function is KL-WPC. In this sense K-WQC is a weaker assumption than WPC. As an example, consider the function $f (x) = \|x\|^2$, which is K-WQC for $K \geq 2$ but not WPC, as $f (x)$ is not Lipschitz continuous. The difference between our results and that of [GLZ18] is that, [GLZ18] make two more assumptions, namely error bound and Lipschitz continuity of gradient as well to prove their sub-linear non-stationary regret bounds.

Finally, we define the next class of structured nonconvex functions. Let $\mathcal{A} := \prod_{i=1}^d A_i$ where $A_i$ are closed intervals on $\mathbb{R}_+$. Without loss of generality we assume, $\mathcal{A} = [0, a_i]$.  

Definition 2.3 ([CHK18]) A function $f : \mathcal{A} \rightarrow \mathbb{R}_+$ is called $\gamma$-weakly DR-submodular monotone if the following holds:

1. It is monotone, i.e., $f (x) \leq f (y)$, if $x \leq y$.
2. DR submodular, i.e., $f (x) + f (y) \geq f (x \vee y) + f (x \wedge y)$, for all $x, y \in \mathcal{A}$ and $\nabla f (x) \geq \nabla f (y)$, for all $x \leq y$.
3. The co-efficient of weak DR submodularity is given by

$$\gamma = \inf_{x, y \in \mathcal{A}, x \leq y} \inf_{i \in [d]} \frac{\|\nabla f (x)\|_i}{\|\nabla f (y)\|_i}$$

(4)

where $[\nabla f (x)]_i = \frac{\partial f (x)}{\partial x_i}$, and $\gamma \geq 0$. 

3 Nonstationary Regret bounds for Gradient-size

The assumption of $K$-WQC allows for a class of nonconvex function that preserve several useful properties of convex function which enables one to get regret bounds in terms of function values. In the absence of such an assumption, considering such regret bounds in terms of function values would lead to intractable bounds. Furthermore, it has been shown in [HSZ17] that if Assumption 2.2 and Assumption 2.3 hold for a sequence of bounded functions (possibly non-convex), a smoothed version of a particular gradient-size based regret is $\Omega(T)$. Hence, we assume $f_t$s are general nonconvex function, but satisfying the condition in Definition 2.2. Indeed such an assumption is made for convex function in [BGZ15]. To get tractable regret bounds, we consider the following notion of gradient-size based nonstationary regret.

**Definition 3.1 (Expected Gradient-size Regret)** The expected gradient-size regret of a randomized online algorithm is defined as

$$\mathcal{R}_G(p) := \sum_{t=1}^{T} E \left[ \|\nabla f_t(x_t)\|_p^p \right]$$

(5)

Similar to the previous section, we now obtain both low- and high-dimensional regret bounds for Algorithm 3.

**Theorem 3.1** Let $\{x_t\}_1^T$ be generated by Algorithm 3 with $\mathcal{X} = \mathbb{R}^d$, and Assumption 2.3 holds for any sequence of $\{f_t\}_1^T \in \mathcal{D}_T$.

(a) Choosing

$$\nu = \frac{1}{\sqrt{TL_G(d+6)}}, \quad \eta = \frac{1}{4L_G(d+4)\sqrt{T}},$$

(6)

we have

$$\mathcal{R}_G^{(2)}(T) \leq O\left((dW_T + \sigma^2)\sqrt{T}\right).$$

(7)

In the deterministic case, as $\sigma = 0$, choosing $\eta = \frac{1}{4L_G(d+4)}$, we get

$$\mathcal{R}_G^{(2)}(T) \leq O(dW_T).$$

(8)

(b) Additionally, if Assumption 2.2 holds, by choosing

$$\nu = \min \left\{ \frac{L}{L_G(d+6)}, \frac{1}{(TL_G^2d^5)^{\frac{1}{2}}} \right\}, \quad \eta = \frac{\sqrt{W_T}}{L\sqrt{TL_G}(d+4)},$$

(9)

we have

$$\mathcal{R}_G^{(2)}(T) \leq O\left(\sqrt{dTW_T} (1 + \sigma^2)\right).$$

(10)

For the deterministic case $\sigma = 0$. 

6
The proof is in Section 8.1. We now state the corresponding high-dimensional result.

**Theorem 3.2** Let Assumption 2.3 be satisfied with \( \| \cdot \| = \| \cdot \|_\infty \) and Assumption 2.5 hold for any sequence of \( \{ f_t \}_1^T \in D_T \).

(a) By choosing
\[
\nu = \frac{1}{\sqrt{2T}} \min \left\{ \sqrt{\frac{1}{CL_G \log d} \cdot s \sqrt{\frac{C \log d}{L_G}}} \right\} \quad \eta = \frac{\sqrt{W_T}}{32CL_Gs (\log d)^2 \sqrt{T}}
\]
we have
\[
\mathcal{R}_G^{(1)} (T) \leq O \left( (s \log d)^2 + \sigma^2 \right) \sqrt{TW_T}
\]

In the deterministic case, setting \( \sigma = 0 \), we get
\[
\mathcal{R}_G^{(1)} (T) \leq O \left( (s \log d)^2 \sqrt{TW_T} \right)
\]

(b) If, in addition, Assumption 2.2 holds w.r.t \( \infty \)-norm, by choosing
\[
\nu = \left[ \frac{1}{2Ts^2C^3L_GL^2 (\log d)^4} \right]^{\frac{1}{5}} \quad \eta = \frac{\sqrt{W_T}}{2\sqrt{TCL_GL \log d}}
\]
we obtain
\[
\mathcal{R}_G^{(1)} (T) \leq O \left( s \log d \left( 1 + \sigma^2 \right) \sqrt{TW_T} \right).
\]

In the deterministic case, setting \( \sigma = 0 \), we get
\[
\mathcal{R}_G^{(1)} (T) \leq O \left( s \log d \sqrt{TW_T} \right).
\]

The proof is in Section 8.2.

4 Nonstationary Second-Order Regret Bounds

While gradient-size based regret (in Definition 3.1) controls first-order stationary solutions, it does not allow us to avoid saddle-points that are prevalent in nonconvex optimization problems in machine learning and game theory [DPG+14, HSZ17]. Hence, we propose a notion of second-order stationary point based regret, in both online setting (Definition 4.1) and bandit setting (Definition 4.2). We then propose online and bandit versions of cubic regularized Newton method and obtain the respective nonstationary regret bounds.
Algorithm 1 Online Cubic-Regularized Newton Algorithm (OCRN)

Input: Horizon $T$, $M$, $m_t$, $b_t$

for $t = 1$ to $T$ do

Set $\bar{G}_t = \frac{1}{m_t} \sum_{i=1}^{m_t} \nabla F(x_t, \xi_{G_{i,t}})$

Set $\bar{H}_t = \frac{1}{b_t} \sum_{i=1}^{b_t} \nabla^2 F(x_t, \xi_{H_{i,t}})$

Update $x_{t+1} = \arg\min_y \tilde{f}_t(x_t, y, \bar{G}_t, \bar{H}_t, M)$ (18)

where

$$
\tilde{f}_t(x_t, y, \bar{G}_t, \bar{H}_t, M) = \bar{G}_t^\top (y - x_t) + \frac{1}{2} \langle \bar{H}_t (y - x_t), (y - x_t) \rangle + \frac{M}{6} \| y - x_t \|^3
$$

end for

4.1 Online Cubic-regularized Newton Method

The standard cubic-regularized Newton method [NP06] has been recently extended to the stochastic setting in [TSJ+18] and to the zeroth-order setting in [BG18]. In Algorithm 1, we consider it in the online setting. Note that [HAK07] used online Newton method previously in the context of online convex optimization to obtain logarithmic regret bounds under certain assumptions and [HSZ17] used a modified online Newton method in the context of online nonconvex optimization. Here, we consider the following notion of regret, based on second-order stationary solutions, and provide a regret bound for the online cubic-regularized Newton method.

Definition 4.1 (Second-order Regret) The second-order regret of an online algorithm is defined as

$$
\mathcal{R}_{NC} (T) = \sum_{t=1}^{T} r_{NC} (t) := \sum_{t=1}^{T} \max \left( \| \nabla f_t (x_t) \|, \left( -\frac{2}{L_H} \lambda_{\min} (\nabla^2 f_t (x_t)) \right)^{\frac{3}{2}} \right)
$$

(17)

Theorem 4.1 Let us choose the parameters for Algorithm 1 as follows:

$$
M = L_H \quad m_t = m = T^{\frac{4}{9}} \quad b_t = b = T^{\frac{4}{9}}
$$

(20)

Let Assumption 2.3 and Assumption 2.4 hold for any sequence of functions $\{f_t\} \in D_T$. Then, Algorithm 1 with the choice of $M \geq L_H$ produces updates such that

$$
\mathcal{R}_{ENC} (T) \leq O \left( T^{\frac{4}{9}} (1 + W_T) + T^{\frac{4}{9}} (\sigma + \zeta^2) \right),
$$

(21)

where the second-order regret $\mathcal{R}_{ENC}$ is defined in (17).

In the deterministic case, setting $\sigma$, and $\zeta$ to 0 we get,

$$
\mathcal{R}_{ENC} (T) \leq O \left( T^{\frac{4}{9}} (1 + W_T) \right),
$$

(22)
Algorithm 2 Bandit Cubic Regularized Newton Algorithm (BCRN)

Input: Horizon $T$, $M, m_t, b_t$

for $t = 1$ to $T$ do

Generate $u_t^{G(H)} = \begin{bmatrix} u_{t,1}^{G(H)}, u_{t,2}^{G(H)}, \ldots, u_{t,m_t(b_t)}^{G(H)} \end{bmatrix}$ where $u_{t,i}^{G(H)} \sim N(0, I_d)$

Set $\tilde{G}_t = \frac{1}{m_t} \sum_{i=1}^{m_t} F_t(x_i + \nu u_{t,i}^{G(H)}, \xi_{t,i}^{G(H)}) - F(x, \xi_{t,i}^{G(H)}) u_{t,i}^{G}$

Set $\tilde{H}_t = \frac{1}{b_t} \sum_{i=1}^{b_t} F_t(x_i + \nu u_{t,i}^{G(H)}, \xi_{t,i}^{G(H)}) + F_t(x_i - \nu u_{t,i}^{G(H)}, \xi_{t,i}^{G(H)}) - 2F(x_t, \xi_{t,i}^{G(H)}) \left( u_{t,i}^{H}(u_{t,i}^{H})^\top - I_d \right)$

Update

$$x_{t+1} = \arg\min_y \tilde{f}_t(x_t, y, \tilde{G}_t, \tilde{H}_t, M)$$

where

$$\tilde{f}_t(x_t, y, \tilde{G}_t, \tilde{H}_t, M) = G_t^\top(y - x_t) + \frac{1}{2} \langle \tilde{H}_t(y - x_t), (y - x_t) \rangle + \frac{M}{6} \|y - x_t\|^3$$

end for

The proof is in Section 9.1.

Remark 2 We now compare our second-order regret bound to that in [HSZ17], which is given by

$$\mathcal{R}_{NC}(T) = \sum_{t=1}^{T} \hat{r}_{NC}(t) = \sum_{t=1}^{T} \max_i \left( \|\nabla f_t(x_t)\|^2, -\frac{4L_G}{3L_H^2} \lambda_{\min}(\nabla^2 f_t(x_t)) \right)^{3} \leq O(T).$$

This bound is obtained by assuming each loss function $f_t$ is bounded instead of assuming their total gradual variation is bounded as we have it in Definition 4.2. Noting that $\hat{r}_{NC}(t) \leq O\left( \sqrt{\hat{r}_{NC}(t)} + \hat{r}_{NC}(t) \right)$, we can bound our regret by using the second-order method in [HSZ17] such that

$$\mathcal{R}_{NC}(T) \leq O\left( \sqrt{T \mathcal{R}_{NC}(T) + \mathcal{R}_{NC}(T)} \right) \leq O(T),$$

where the first inequality follows from Hölder’s inequality. We immediately see that an improved second-order regret bound in achieved in [21], in comparison to [HSZ17].

4.2 Bandit Cubic-regularized Newton Method

We now extend the online cubic-regularized Newton method to the bandit setting. In order to do so, we leverage the three-point feedback based Hessian estimation technique, proposed in [BG18], which is based on Gaussian Stein’s identity. The bandit cubic-regularized Newton method is provided in Algorithm 2. We now define the notion of second-order regret for the bandit setting and provide nonstationary regret bounds in Theorem 4.2.

Definition 4.2 (Expected Second Order Regret) The expected second-order regret of a randomized online algorithm is defined as

$$\mathcal{R}_{ENC}(T) = \sum_{t=1}^{T} \mathbb{E}[r_{NC}(t)] = \sum_{t=1}^{T} \mathbb{E}\left[ \max_i \left( \|\nabla f_t(x_t)\|, \left( -\frac{2}{L_H} \lambda_{\min}(\nabla^2 f_t(x_t)) \right)^{3} \right) \right]$$

9
Theorem 4.2 Let us choose the parameters for Algorithm 2 as follows:

\[ M = L_H, \quad \nu = \min \left\{ \frac{1}{(d+3)\frac{2}{3}T^\frac{2}{3}}, \frac{1}{(d+16)\frac{2}{3}T^\frac{2}{3}} \right\} \]

\[ m_t = m = (d+5)T^\frac{4}{3}, \quad b_t = b = 4(1 + 2\log 2d)(d+16)^4T^\frac{4}{3} \]  

(27)

Let Assumption 2.3, and Assumption 2.4 be true. For any sequence of such functions \( \{ f_t \}_T^T \in D_T \), Algorithm 2 produces updates for which \( \mathcal{R}_{ENC}(T) \) is bounded by,

\[ \mathcal{R}_{ENC}(T) \leq O \left( T^\frac{2}{3} (1 + W_T) + \sigma T^\frac{1}{3} \right) \]  

(28)

In the deterministic case, setting \( \sigma = 0 \), we get,

\[ \mathcal{R}_{ENC}(T) \leq O \left( T^\frac{2}{3} (1 + W_T) \right) \]  

(29)

Remark 3 Although, the bound obtained in Theorem 4.2 is independent of dimension, we emphasize that we are sampling the function at multiple points during each time step. The total number of function calls is hence,

\[ \sum_{t=1}^T (m_t + b_t) = T(m + b) \text{ over a horizon } T \] is upper bounded as \( O \left( dT^\frac{4}{3} + (\log d) d^dT^\frac{4}{3} \right) \). Reducing this query-complexity is a challenging open-problem.

Remark 4 Recall that our results are based on estimating gradients and Hessian matrix based on Gaussian Stein’s identities. It is common in the literature to also consider gradient estimators based on random vectors in the unit sphere; see for example [NY83, FKM05]. Hence, it is natural to ask if Hessian estimators could be constructed based on random vectors on the unit sphere. Here we provide an approach for estimating Hessian matrix of a deterministic function; we leave the analysis and algorithmic applications of such estimators as future work. Let \( S^{d-1} \), and \( B^d \) denote the unit \( d \) dimensional ball, and the unit \( d \)-sphere respectively. We will use \( S \), and \( B \) instead of \( S^{d-1} \), and \( B^d \) respectively where the dimension is understood clearly. Let \( u_1 \), and \( u_2 \) are chosen randomly on \( S^{d-1} \) and \( v_1 \), and \( v_2 \) are chosen randomly from \( B^d \).

\[ \mathbb{E} \left[ f(x + \nu u_1 + \nu u_2) u_1 u_2^\top \right] = C_1 \int \int_S f(x + \nu u_1 + \nu u_2) u_1 u_2^\top \, du_1 \, du_2 \]

\[ = C_2 \int \int_S f(x + \nu u_2 + z_1) z_1 \, du_2 \]

\[ = C_3 \int \nabla \int_B f(x + \nu v_2 + v_1) \, dv_1 \, du_2 \]

The last equality follows from Stoke’s theorem. Let

\[ \nabla \int_B f(x + \nu v_2 + \nu v_1) \, dv_1 = [g_1(x + \nu v_2), g_2(x + \nu v_2), \cdots, g_d(x + \nu v_2)]^\top, \]

and \( x = [x_1, x_2, \cdots, x_d]^\top \). Then, using Stoke’s theorem again, we have

\[ \int_S g_1(x + \nu v_2) u_2^\top \, dv_2 = C_4 \int_{\nu B} g_1(x + v_2) \, dv_2 \]
Algorithm 3 Gaussian Bandit Gradient Descent (GBGD)

Input: Horizon $T$, $\eta$ and $\nu$.

for $t = 1$ to $T$ do
Sample $u_t \sim N(0, I_d)$
Pull $x_t$ and $x_t + \nu u_t$
Receive feedbacks $F_t(x_t, \xi_t)$ and $F_t(x_t + \nu u_t, \xi_t)$
Set $G'_t(x_t, u_t, \xi_t) = \frac{F_t(x_t + \nu u_t, \xi_t) - F_t(x_t, \xi_t)}{\nu} u_t$
update $x_{t+1} = \mathcal{P}_X(x_t - \eta G'_t(x_t, u_t, \xi_t))$
end for

So we can write,

$$\nabla^2 \mathbb{E}[f(x + \nu v_1 + \nu v_2)] = \mathbb{E}[C_7 f(x + \nu u_1 + \nu u_2) u_1 u_2^\top]$$

$C_i$ for $i = 1, 2, \cdots, 7$ are constants. Hence, we have a bandit Hessian estimator, as this relates the Hessian of the function to point queries of the function.

5 Nonstationary Regret bounds for Function Values

As opposed to stationary solution based regret measures, in this section, we consider classes of structured nonconvex functions for which one could provide function-value based regret bounds. We provide such regret bounds when the functions $\{f_t\}_{t=1}^T$ satisfy (i) K-Weak Quasi Convexity, as in Assumption 2.6 and (ii) $\gamma$-weak DR submodularity, as in Definition 2.3.

5.1 $K$-WQC in Low-dimensions

We first consider the low-dimensional setting. We also assume the constraint set $\mathcal{X}$ is convex and bounded and the diameter of the set $\mathcal{X} \subset \mathbb{R}^d$ is bounded by $R < \infty$, i.e., $\forall x, x' \in \mathcal{X}, \|x - x'\|_2 \leq R$, where $R > 0$. Following [Spa98, NS17, BG18], we define the Gaussian Stein’s identity based gradient estimator of $\nabla f_t(x_t)$ as,

$$G'_t(x_t, u_t, \xi_t) = \frac{F_t(x_t + \nu u_t, \xi_t) - F_t(x_t, \xi_t)}{\nu} u_t.$$  \hspace{1cm} (30)

where $u_t \sim N(0, I_d)$. Based on this, the Gaussian bandit gradient descent algorithm is given in Algorithm 3. We denote the filtration generated up to the $t$-th iteration of Algorithm 3 by $\mathcal{F}_t$. The use of two point feedback to estimate the gradient in this algorithm, leads us to the following definition of nonstationary regret; see also [GLZ18].
Definition 5.1 (Expected Non-stationary Regret) For \( \nu > 0 \) and \( u_t \sim N(0, I_d) \), the expected non-stationary regret of a randomized online algorithm is defined as

\[
\mathcal{R}_{NS} \left( \{x_t\}_1^T, \{x_t + \nu u_t\}_1^T \right) := E \left[ \sum_{t=1}^T \left( f_t(x_t) + f_t(x_t + \nu u_t) - 2f_t(x^*_t) \right) \right]
\]  

(31)

where the expectation is taken w.r.t filtration generated by \( \{x_t\}_1^T \), and \( \{u_t\}_1^T \).

Theorem 5.1 Let \( \{x_t\}_1^T, \{x_t + \nu u_t\}_1^T \) be generated by Algorithm 3 for any sequence of K-WQC loss functions \( \{f_t\}_1^T \in S_T \) defined in (1).

a) Under Assumption 2.2 and by choosing

\[
\nu = \sqrt{\frac{d}{T}}, \quad \eta = \frac{\sqrt{R^2 + 3RV_T}}{L(d+4)\sqrt{T}},
\]

(32)

the following bound holds for expected nonstationary regret:

\[
\mathcal{R}_{NS} \left( \{x_t\}_1^T, \{x_t + \nu u_t\}_1^T \right) \leq O \left( d\sqrt{T + V_TT} \right).
\]

(33)

We get the same result for the deterministic case as well.

b) If, in addition, Assumption 2.3 holds and if

\[
\nu = \min \left\{ \frac{1}{\sqrt{T}}, \frac{L}{L_G(d+6)} \right\}, \quad \eta = \frac{\sqrt{R^2 + 3RV_T}}{L(2d+4)T},
\]

(34)

then the above regret bound is improved to

\[
\mathcal{R}_{NS} \left( \{x_t\}_1^T, \{x_t + \nu u_t\}_1^T \right) \leq O \left( \sqrt{d(T + V_TT)} \left( 1 + \sigma^2 \right) \right).
\]

(35)

In the deterministic case the upper bound becomes \( O \left( \sqrt{d(T + V_TT)} \right) \) as \( \sigma = 0 \).

The proof of this theorem is in Section 10.1.

5.2 K-WQC in high-dimensions

The dependence of the expected nonstationary regret on the dimensionality \( d \) is of polynomial order, which restricts the applicability of the algorithm for high-dimensional problems. In order to address this issue, in this section, we make structural sparsity assumptions to get improved regret bounds that depend only poly-logarithmically on the dimensionality. Specifically, we first get improved regret bounds (in terms of dimensionality), under the assumption that the function \( f_t \) depend only on \( s \) of the \( d \) coordinates – see Section 10.2 in Appendix for more details. In this section, we make sparsity assumptions on the gradient and optimal vectors to get similar regret bounds. In order to do so, we also require the truncated bandit gradient descent algorithm, as described in Algorithm 4. Furthermore, we require the constraint set \( \mathcal{X} \) to preserve the sparsity structure, when projected onto. We also show that any norm-ball based constrained set \( \mathcal{X} := \{x \in \mathbb{R}^d : \|x\| \leq R\} \) satisfies such an assumption.
Algorithm 4 Gaussian Bandit Truncated Gradient Descent (GBTGD)

Input: Horizon $T$, $\eta$

for $t = 1$ to $T$
do

Sample $u_t \sim N(0, I_d)$
Pull $x_t$ and $x_t + \nu u_t$

Receive feedbacks $F_t(x_t, \xi_t)$ and $F_t(x_t + \nu u_t, \xi_t)$

Set $G_t^\nu(x_t, u_t, \xi_t) = \frac{F_t(x_t + \nu u_t, \xi_t) - F_t(x_t, \xi_t)}{\nu} u_t$

update $x_{t+1} = P_X (P^*_s (x_t - \eta G_t^\nu(x_t, u_t, \xi_t)))$, where $P_s(x)$ keeps the $s$ largest components (in absolute value) of $x$ and sets the other components to 0.

end for

Assumption 5.1 (Sparsity Preserving Projection) Let $X$ be a convex decision set such that projection of a point onto this set preserves the sparsity of the point before projection, i.e., the projection $P_X(y)$ of a $s$-sparse vector $y$ on $X$, has zeros at the same indices where $y$ had zeros.

Lemma 5.1 Projection onto set $X := \{x \in \mathbb{R}^d : \|x\| \leq R\}$ is sparsity preserving, i.e., the projection $P_X(y)$ of a $s$-sparse vector $y$ on $X$, has 0 at the indices where $y$ has 0.

Proof W.L.G assume that the first $s$ indices of a vector $y \in \mathbb{R}^d$ are non-zero. Let $a = P_X(y)$ be given such that there exists at least one $i \in \{s + 1, \ldots, d\}$ with $a_i \neq 0$. Define vector $b \in \mathbb{R}^d$ such that $b_j = a_j$ for $i \neq j$ and $b_i = 0$. Clearly, $\|b\| \leq \|a\|$ and hence $b \in X$. Furthermore, $\|b - y\| \leq \|a - y\|$ contradicting the assumption of $a = P_X(y)$.

Such decision sets are common in machine learning, e.g., $l_1$-norm arises in compressed sensing to achieve sparse solutions. Such constraints also help us achieve better bias-variance tradeoffs. Finally, we also assume that the optimal vectors have a sparse structure and state our regret bound.

Assumption 5.2 (Sparse Optimal Solution) For all $t$, $f_t(x)$ has sparse optimal solution $x^*_t$ such that $\|x^*_t\|_0 \leq s^*$, where $s^* \approx s$.

Theorem 5.2 Let the decision set $X$ satisfy Assumption 5.1. Also suppose that Assumption 2.2 w.r.t $l_\infty$-norm, Assumptions 2.3, 5.2 hold for any sequence of $K$-WQC loss functions $\{f_t\}_1^T \in \mathcal{S}_T$.

a) Applying Algorithm 4 with

$$\nu = \frac{\sqrt{(2s + s^*) \log d}}{T \sqrt{C}} \quad \eta = \frac{\sqrt{R^2 + 3R\nu T}}{2L \sqrt{CT} (2s + s^*) \log d}$$

the following bound holds for expected non-stationary regret:

$$R_{NS} \left(\{x_t\}_1^T, \{x_t + \nu u_t\}_1^T\right) \leq O \left(\log d \sqrt{(2s + s^*) (T + V_T T)}\right).$$

We get the the same result for the deterministic case as well.
b) If, in addition, Assumption 2.3 holds and
\[ \nu = \min \left\{ \frac{1}{T\sqrt{C}}, \frac{L}{L_G \log d} \right\}, \quad \eta = \frac{\sqrt{R^2 + 3RV_T}}{2\log d \sqrt{CT(2\hat{s} + s^*) (L^2 + \sigma^2)}}. \]
(38)

the above regret bound is improved to
\[ R_{NS} \left( \{x_t\}_1^T, \{x_t + \nu u_t\}_1^T \right) \leq O \left( \log d \sqrt{(2\hat{s} + s^*)(T + V_T T)} \right). \]
(39)

In the deterministic case we have to set \( \sigma = 0 \) while choosing \( \eta \).

The proof is in Section 10.3.

5.3 Submodular function: Gradient Ascent

The next class of structured nonconvex functions are the class of submodular functions, for which we consider the maximization problem (as opposed to minimization problem in the previous sections). Submodular function maximization in the offline setting has a long history since the seminal work of [NWF78]. Motivated by several applications in machine learning [Bil15], several works have provided improved algorithms in both the offline and online setting; see for example, [B+13, CVZ14, BLKB17, HSK17, CHK18, Bac19, CZHK19] for a non-exhaustive overview.

Here, we consider bandit algorithms for submodular maximization in the nonstationary setting. In order to proceed, we first require the following definition of regret.

**Definition 5.2 (Expected \( \alpha \)-Nonstationary Regret)** For \( \nu > 0 \), and \( 0 < \alpha < 1 \), the expected \( \alpha \)-nonstationary regret of a randomized online algorithm is defined as
\[ R_{\alpha,NS} \left( \{x_t\}_1^T, \{x_t + \nu u_t\}_1^T \right) := \mathbb{E} \left[ \sum_{t=1}^T \left( 2\alpha f_t(x_t^*) - f_t(x_t) - f_t \left( x_t + \nu \frac{u_t}{\|u_t\|}, \xi_t \right) \right) \right] \]
(40)

where \( u_t \sim N(0, I_d) \), and the expectation is taken w.r.t filtration generated by \( \{x_t\}_1^T \), and \( \{u_t\}_1^T \).

We also modify our Gaussian gradient estimator to account for the fact that the submodular functions are defined on the domain \( \mathcal{A} \) as opposed to \( \mathbb{R}^d \). We define the gradient estimator of \( \nabla f_t(x_t) \) as,
\[ G_{t,SM}^\nu (x_t, u_t, \xi_t) = \frac{F_t \left( x_t + \nu \frac{u_t}{\|u_t\|}, \xi_t \right) - F_t (x_t, \xi_t)}{\nu} u_t \| u_t \|. \]
(41)

where \( u_t \sim N(0, I_d) \). We need to sample the function at \( x_t + \nu \frac{u_t}{\|u_t\|} \) to calculate \( G_{t,SM}^\nu (x_t, u_t, \xi_t) \). But this point may lie outside the box \( \mathcal{A} \) where the function is not defined. To bypass this problem, following [CZHK19], we look for a solution in the box \( \mathcal{A}_\nu' = \prod_{i=1}^d [\nu, a_i - \nu] \). If \( \nu \) is small enough, under Assumption 2.2, we can find a sequence of points which achieves the same bound as we would expect if we could sample points from \( \mathcal{A} \). Unlike [CZHK19], which use random vectors on the \( d \)-dimensional unit sphere, our gradient estimators are based on Gaussian smoothing technique. Finally, we assume that the constraint set \( K \subseteq \mathcal{A} \) is convex and diameter of \( K \) is \( R \). Our Bandit Gradient Ascent (BGA) algorithm for nonstationary submodular maximization is stated in Algorithm 5.3. We now provide the following regret bounds for our algorithm.
Algorithm 5 Bandit Gradient Ascent (BGA)

**Input:** Horizon $T$, $\eta$, $\nu$

for $t = 1$ to $T$
do
Sample $u_t \sim N(0, I_d)$
pull $x_t$ and $x_t + \nu \frac{u_t}{\|u_t\|}$
receive feedbacks $F_t(x_t, \xi_t)$ and $F_t\left(x_t + \nu \frac{u_t}{\|u_t\|}, \xi_t\right)$
set $G_{t,SM}^\nu(x_t, u_t, \xi_t) = \frac{F_t(x_t + \nu \frac{u_t}{\|u_t\|}, \xi_t) - F_t(x_t, \xi_t)}{\|u_t\|}$
update $x_{t+1} = \mathcal{P}_{K_1}\left(x_t + \eta G_{t,SM}^\nu(x_t, u_t, \xi_t)\right)$
end for

**Theorem 5.3** Let $\{x_t, x_t + \nu u_t\}_T^T$ be generated by Algorithm 5 for a sequence of monotone, $\gamma$-weakly DR-submodular function $f_t : A \to \mathbb{R}^+$, where $\{f_t\}_T^T \in \mathcal{F}$. Then, under Assumption 2.2 and Assumption 2.3, and choosing $\nu = \frac{1}{dT}$, $\eta = \frac{\sqrt{2R^2 + 6R + 3RV_T}}{dT}$ \quad (42)

the following bound holds for $\alpha$-nonstationary regret:

$$R_{\alpha,NS}\left(\{x_t\}_T^T, \{x_t + \nu \frac{u_t}{\|u_t\|}\}_T^T\right) \leq O\left(d \sqrt{T + V_T} T\right) \quad (43)$$

where $\alpha = \frac{\gamma^2}{1 + \gamma}$.

Interestingly, under our assumptions the rates remain the same for the stochastic and deterministic cases. The proof is in Section 10.4. Providing regret bounds for nonstationary submodular maximization in the high-dimensional setting for has eluded us thus far. It would be interesting to reduce the dimension dependence under different structural assumptions on the submodular functions – we leave this as future work.

**6 Discussion**

In this paper, we provide regret bounds for nonstationary nonconvex optimization problems in the bandit setting. We make three specific contributions: (i) low and high-dimensional regret bounds in terms of gradient-size for general nonconvex function with bounded stationarity, (ii) online and bandit versions of cubic regularized Newton method for bounding second-order stationary solution based nonstationary regret, and (iii) low and high-dimensional regret bounds in terms of function values for $K$-WQC functions and low-dimensional regret bounds in terms of function values for submodular function maximization.

There are several avenues for future work: (i) obtaining lower bounds for the regrets considered is challenging, (ii) defining other notions of uncertainty set that provide improved regret bounds is also interesting, (iii) obtaining parameter-free algorithms, similar to the convex setting (see for example, [JRSS15, LS15, CSLZ18, ACG+19]) is interesting and (iv) establishing connections between online nonparametric regression and nonstationary regret bounds (see for example [BW19]) is interesting.

Table 1: A list of regret bounds obtained in this work for nonstationary nonconvex optimization.
8 Proofs for Section 3

8.1 Proof of Theorem 3.1

Proof Under Assumption 2.3 we get

\[ f_t(x_{t+1}) \leq f_t(x_t) + \nabla f_t(x_t)^\top (x_{t+1} - x_t) + \frac{L_G}{2} \|x_{t+1} - x_t\|^2 \]

\[ = f_t(x_t) - \eta \nabla f_t(x_t)^\top G_t^\nu (x_t, u_t, \xi_t) + \frac{\eta^2 L_G}{2} \|G_t^\nu (x_t, u_t, \xi_t)\|^2 \]

\[ = f_t(x_t) - \eta \|\nabla f_t(x_t)\|^2 + \eta \nabla f_t(x_t)^\top (\nabla f_t(x_t) - G_t^\nu (x_t, u_t, \xi_t)) + \frac{\eta^2 L_G}{2} \|G_t^\nu (x_t, u_t, \xi_t)\|^2 \]

Taking conditional expectation on both sides, we get

\[ \mathbb{E} [f_t(x_{t+1}) | \mathcal{F}_t] \leq f_t(x_t) - \eta \|\nabla f_t(x_t)\|^2 + \eta \|\nabla f_t(x_t)\|^2 \mathbb{E} [G_t^\nu (x_t, u_t, \xi_t) | \mathcal{F}_t] + \frac{\eta^2 L_G}{2} \mathbb{E} [\|G_t^\nu (x_t, u_t, \xi_t)\|^2 | \mathcal{F}_t] \]

Using Young’s inequality,

\[ \mathbb{E} [f_t(x_{t+1}) | \mathcal{F}_t] \leq f_t(x_t) - \eta \|\nabla f_t(x_t)\|^2 + \frac{\eta^2 L_G}{2} \|G_t^\nu (x_t, u_t, \xi_t)\|^2 + \frac{\eta^2 L_G}{2} \mathbb{E} [\|G_t^\nu (x_t, u_t, \xi_t)\|^2 | \mathcal{F}_t] \]

\[ \text{Re-arranging the terms and noting Lemma 10.2 we obtain} \]

\[ \frac{\eta}{2} \|\nabla f_t(x_t)\|^2 \leq f_t(x_t) - \mathbb{E} [f_t(x_{t+1}) | \mathcal{F}_t] + \frac{\eta}{8} \nu^2 L_G^2 (d + 3)^3 \]

\[ + \frac{\eta^2 L_G}{2} \left( \frac{\nu^2}{2} L_G^2 (d + 6)^3 + 2 (d + 4) \left( \|\nabla f_t(x_t)\|^2 + \sigma^2 \right) \right) \]

Summing from \( t = 1 \) to \( T \), and using Definition 2.2 we get

\[ \sum_{t=1}^{T} \mathbb{E} [\|\nabla f_t(x_t)\|^2] \leq \frac{2}{\eta} (f_1(x_1) - \mathbb{E} [f_T(x_{T+1})] + W_T) + \frac{T}{4} \nu^2 L_G^2 (d + 3)^3 \]

\[ + \eta T \frac{\nu^2}{2} L_G^3 (d + 6)^3 + 2 \eta L_G (d + 4) \sum_{t=1}^{T} \mathbb{E} [\|\nabla f_t(x_t)\|^2 + \sigma^2] \].

(45)

Now we split the proof in two parts corresponding to the parts in Theorem 3.1

\( \text{(a) From (15) we get,} \)

\[ \sum_{t=1}^{T} (1 - 2 \eta L_G (d + 4)) \mathbb{E} [\|\nabla f_t(x_t)\|^2] \leq \frac{2}{\eta} (f_1(x_1) - \mathbb{E} [f_T(x_{T+1})] + W_T) + \frac{T}{4} \nu^2 L_G^2 (d + 3)^3 \]

\[ + \eta T \frac{\nu^2}{2} L_G^3 (d + 6)^3 + 2 \eta T L_G (d + 4) \sigma^2. \]

Choosing \( \nu \) and \( \eta \) according to (6), we get (7).
(b) It is possible to improve the dependence of the regret bound on the problem dimension assuming that the loss functions are Lipschitz continuous. In this case, we have $\|\nabla f_t(x_t)\| \leq L$ which together with (45), imply that

$$
\sum_{t=1}^{T} E \left[ \|\nabla f_t(x_t)\|^2 \right] \leq \frac{2}{\eta} \left( f_1(x_1) - E[f_T(x_{T+1})] + W_T + \frac{T}{4} \nu^2 L_G^2 (d + 3)^3 \right)
$$

$$
+ \eta T L_G \left( \frac{\nu^2}{2} L_G^2 (d + 6)^3 + 2 (d + 4) (L^2 + \sigma^2) \right)
$$

(46)

Choosing $\nu$ and $\eta$ according to (9), we obtain (10).

8.2 Proof of Theorem 3.2

Proof Under Assumption 2.3 w.r.t $l_\infty$-norm and similar to (44), we get

$$
E \left[ f_t(x_{t+1}) \mid \mathcal{F}_t \right] \leq f_t(x_t) - \eta \|\nabla f_t(x_t)\|^2 + \frac{\eta}{2\delta} \|\nabla f_t(x_t)\|^2 + \frac{\eta s}{2} \|\nabla f_t(x_t)\| \|G_{\nu t}^\top (x_t, u_t, \xi_t) \mid \mathcal{F}_t\|_{\infty}
$$

$$
+ \frac{\eta^2 L_G^2}{2} E \left[ \|G_{\nu t}^\top (x_t, u_t, \xi_t)\|_{\infty} \mid \mathcal{F}_t \right].
$$

Noting Lemma 10.5 the fact that $\|\nabla f_t(x_t)\| \leq \sqrt{s} \|\nabla f_t(x_t)\|_2$ under Assumption 2.5 and after re-arranging the terms, we obtain

$$
\frac{\eta}{2\delta} \left[ 1 - 16 C \eta L_G s (\log d)^2 \right] \|\nabla f_t(x_t)\|^2 \leq f_t(x_t) - E [f_t(x_{t+1}) \mid \mathcal{F}_t]
$$

$$
+ C \eta L_G (\log d)^2 \left[ s \nu^2 C L_G \log d + 2 \eta \left( \nu^2 L_G^2 \log d + 4 \sigma^2 \right) \right].
$$

Summing up both sides of the above inequality, noting (11) and Definition 2.2 we get (12). Noting Lemma 10.4 under Assumption 2.2 part b) follows similarly.

9 Proofs for Section 4

9.1 Proof of Theorem 4.1

Proof In order to prove the above theorem, we require the following result from [NP06].

Lemma 9.1 ([NP06]) Let $\{x_t\}$ be generated by Algorithm 1 with $M \geq L_H$. Then, we have

$$
\tilde{G}_t + \tilde{H}_t h_t + \frac{M}{2} \|h_t\| h_t = 0
$$

(47a)

$$
\tilde{H}_t + \frac{M}{2} \|h_t\| I_d \succ 0
$$

(47b)

$$
\tilde{G}_t^\top h_t \leq 0
$$

(47c)

Lemma 9.2 Under Assumption 2.2 and Assumption 2.3 we have

$$
E \left[ \|\tilde{G}_t - \nabla_t\|^2 \right] \leq \frac{\sigma^2}{m_t}
$$

(48)
Lemma 9.3 Under Assumption 2.3 and Assumption 2.4 we have

\( E \left[ \| \tilde{H}_t - \nabla_t^2 \|^2 \right] \leq \frac{\zeta^2}{b_t} \quad (49a) \)

\( E \left[ \| \tilde{H}_t - \nabla_t^2 \|^3 \right] \leq \frac{2\zeta^3}{b_t^3} \quad (49b) \)

In the rest of the proof we use \( \nabla_t, \nabla_t^2, h_t, and \lambda_{\text{t.min}} \) to denote \( \nabla f_t(x_t), \nabla^2 f_t(x_t), (x_{t+1} - x_t), \) and the minimum eigenvalue of \( \nabla^2 f_t(x_t) \) respectively. Using Assumption 2.3

\[ \| \nabla f_t(x_t) \| - \| \nabla f_t(x_{t+1}) \| \leq \| \nabla f_t(x_t) - \nabla f_t(x_{t}) \| \leq L_G \| h_t \| \quad (50) \]

Using, Assumption 2.4, (47), (50), and Young’s inequality,

\[ \| \nabla f_t(x_{t+1}) - \nabla_t - \nabla_t^2 h_t \| \leq \frac{L_H}{2} \| h_t \|^2 \]

\[ \| \nabla f_t(x_{t+1}) \| \leq \| \nabla_t - \tilde{G}_t \| + \| \nabla_t^2 - \tilde{H}_t \| \| h_t \| + \frac{L_H + M}{2} \| h_t \|^2 \]

\[ \| \nabla_t \| \leq L_G \| h_t \| + \| \nabla_t - \tilde{G}_t \| + \| \nabla_t^2 - \tilde{H}_t \| \frac{2}{2(L_H + M)} + (L_H + M) \| h_t \|^2 \]

From (47b),

\[ -\frac{2}{M} \lambda_{\text{t.min}} \leq \| h_t \| + \frac{2}{M} \| \nabla_t^2 - \tilde{H}_t \| \]

\[ \implies \left( -\frac{2}{M} \lambda_{\text{t.min}} \right)^3 \leq \frac{32}{M^3} \| \tilde{H}_t - \nabla_t^2 \|^3 + 4 \| h_t \|^3 \]

Combining (53), and (54), and choosing \( M = L_H \) we get

\[ r_{NC} (t) = \max \left( \| \nabla_t \|, -\frac{8}{L_H^3} \lambda_{\text{t.min}}^3 \right) \leq L_G \| h_t \| + \frac{1}{2} \left( L_H + M \right) \| h_t \|^2 + 4 \| h_t \|^3 + \frac{32}{M^3} \| \tilde{H}_t - \nabla_t^2 \|^3 \]

\[ + \| \nabla_t - \tilde{G}_t \| + \frac{\| \nabla_t^2 - \tilde{H}_t \|^2}{2(L_H + M)} \]

Lemma 9.4 Under Assumption 2.3, and Assumption 2.4, for \( M \geq L_H \), the points generated by Algorithm 2 satisfy the following

\[ \frac{M}{36} \| h_t \|^3 \leq f_t(x_t) - f_t(x_{t+1}) + \frac{4}{\sqrt{3M}} \| \nabla_t - \tilde{G}_t \|^2 + \frac{24}{M^2} \| \nabla_t^2 - \tilde{H}_t \|^3 \quad (52) \]

Proof If \( M \geq L_H \), using Assumption 2.3

\[ f_t(x_{t+1}) \leq f_t(x_t) + \nabla_t^\top h_t + \frac{1}{2} \langle \nabla_t^2 h_t, h_t \rangle + \frac{M}{6} \| h_t \|^3 \]

\[ \leq f_t(x_t) + \tilde{G}_t^\top h_t + \frac{1}{2} \langle \tilde{H}_t h_t, h_t \rangle + \| \nabla_t - \tilde{G}_t \| \| h_t \| + \frac{1}{2} \| \nabla_t^2 - \tilde{H}_t \| \| h_t \|^2 + \frac{M}{6} \| h_t \|^3 \]
Using (59a) we get

\[ f_t(x_{t+1}) \leq f_t(x_t) - \frac{1}{2} \langle \tilde{H}_t h_t, h_t \rangle + \|\nabla_t - \bar{G}_t\| \|h_t\| + \frac{1}{2} \|\nabla^2_t - \bar{H}_t\| \|h_t\|^2 - \frac{M}{3} \|h_t\|^3 \]  \quad (53)

Combining (59a), and (59c) we get

\[-\frac{1}{2} \langle \tilde{H}_t h_t, h_t \rangle - \frac{M}{3} \|h_t\|^3 \leq -\frac{M}{12} \|h_t\|^3\]

which combined with (66) gives

\[ f_t(x_{t+1}) \leq f_t(x_t) + \|\nabla_t - \bar{G}_t\| \|h_t\| + \frac{1}{2} \|\nabla^2_t - \bar{H}_t\| \|h_t\|^2 - \frac{M}{12} \|h_t\|^3 \]

Rearranging terms we get

\[ \frac{M}{12} \|h_t\|^3 \leq f_t(x_t) - f_t(x_{t+1}) + \|\nabla_t - \bar{G}_t\| \|h_t\| + \frac{1}{2} \|\nabla^2_t - \bar{H}_t\| \|h_t\|^2 \]

Using Young’s inequality

\[ \frac{M}{12} \|h_t\|^3 \leq f_t(x_t) - f_t(x_{t+1}) + \frac{4}{\sqrt{3M}} \|\nabla_t - \bar{G}_t\|^\frac{3}{2} + \frac{24}{M^2} \|\nabla^2_t - \bar{H}_t\|^3 + \frac{M}{18} \|h_t\|^3 \]

\[ \implies \frac{M}{36} \|h_t\|^3 \leq f_t(x_t) - f_t(x_{t+1}) + \frac{4}{\sqrt{3M}} \|\nabla_t - \bar{G}_t\|^\frac{3}{2} + \frac{24}{M^2} \|\nabla^2_t - \bar{H}_t\|^3 \]

\[ \implies \frac{M}{36} \|h_t\|^3 \leq f_t(x_t) - f_t(x_{t+1}) + \frac{4}{\sqrt{3M}} \|\nabla_t - \bar{G}_t\|^\frac{3}{2} + \frac{24}{M^2} \|\nabla^2_t - \bar{H}_t\|^3 \]

**Proof** [Proof of Theorem 4.1] Let us consider two cases \(\|h_t\| \leq T^{-\frac{1}{3}}\), and \(\|h_t\| > T^{-\frac{1}{3}}\).

1. \(\|h_t\| \leq T^{-\frac{1}{3}}\)

\[ r_{NC}(t) \leq L_G T^{-\frac{3}{4}} + \frac{1}{2} \left( L_H + M \right) T^{-\frac{7}{4}} + 4T^{-1} + \|\nabla_t - \bar{G}_t\| + \frac{\|\nabla^2_t - \bar{H}_t\|^2}{2(L_H + M)} + \frac{32}{M^3} \|\nabla_t - \bar{G}_t\|^3 \]

2. \(\|h_t\| > T^{-\frac{1}{3}}\)

Using (66) we get,

\[ r_{NC}(t) \leq \left( \frac{L_G T^2}{M} + \frac{1}{2} \left( \frac{L_H + M}{M} + 1 \right) \right) \|h_t\|^3 + \|\nabla_t - \bar{G}_t\| + \frac{\|\nabla^2_t - \bar{H}_t\|^2}{2(L_H + M)} + \frac{32}{M^3} \|\nabla_t - \bar{G}_t\|^3 \]

\[ \leq \left( \frac{36L_G}{M} + 18 \left( \frac{L_H + M}{M} + 1 \right) \right) T^\frac{3}{4} \left( f_t(x_t) - f_t(x_{t+1}) + \frac{4}{\sqrt{3M}} \|\nabla_t - \bar{G}_t\| \right) + \frac{24}{M^2} \|\nabla^2_t - \bar{H}_t\|^3 + \|\nabla_t - \bar{G}_t\| + \frac{\|\nabla^2_t - \bar{H}_t\|^2}{2(L_H + M)} + \frac{32}{M^3} \|\nabla_t - \bar{G}_t\|^3 \]

Combining (54), and (55),

\[ r_{NC}(t) \leq \left( L_G T^{-\frac{1}{4}} + \frac{1}{2} \left( L_H + M \right) T^{-\frac{7}{4}} + 4T^{-1} \right) \]

23
\[ + \frac{32}{M^3} \| \tilde{H}_t - \nabla_t^2 \|^3 + \| \nabla_t - \nabla_t \| + \frac{\| \nabla_t^2 - H_t \|^2}{2(L_H + M)} \]
\[ + \left( 36 \frac{L_G}{M} + 18 \left( \frac{L_H}{M} + 1 \right) + \frac{144}{M} \right) T^\frac{3}{2} \left( f_t(x_t) - f_t(x_{t+1}) + \frac{4}{\sqrt{3M}} \| \nabla_t - \nabla_t \|^3 + \frac{24}{M^2} \| \nabla_t^2 - H_t \|^3 \right) \]

Summing both sides from \( t = 1 \) to \( T \), taking expectation on both sides and using Definition 4.2, we get

\[ \mathcal{R}_{ENC}(T) = \sum_{t=1}^{T} \mathcal{E} \left[ r_{NC}(t) \right] \leq \left( L_G T^\frac{3}{2} + \frac{1}{2} (L_H + M) T^\frac{3}{2} + 4 \right) + \sum_{t=1}^{T} \left( \frac{32}{M^3} \mathcal{E} \left[ \| \tilde{H}_t - \nabla_t^2 \|^3 \right] \right. \\
+ \left. \mathcal{E} \left[ \| \nabla_t - \tilde{G}_t \| \right] + \frac{\mathcal{E} \left[ \| \nabla_t^2 - H_t \|^2 \right]}{2(L_H + M)} \right) \\
+ \left( 36 \frac{L_G}{M} + 18 \left( \frac{L_H}{M} + 1 \right) + \frac{144}{M} \right) T^\frac{3}{2} \left( f_t(x_1) - f_T(x_{T+1}) + W_T \right) \\
+ \frac{4}{\sqrt{3M}} \sum_{t=1}^{T} \mathcal{E} \left[ \| \nabla_t - \tilde{G}_t \| \right] + \frac{24}{M^2} \sum_{t=1}^{T} \mathcal{E} \left[ \| \nabla_t^2 - H_t \|^3 \right] \]  

(57)

Now choosing \( \nu, m_t, \) and \( b_t \) as in (20) and Lemma 9.2 and Lemma 9.3, we get

\[ \mathcal{E} \left[ \| \nabla_t - \tilde{G}_t \|^2 \right] \leq C_1 T^{-\frac{3}{2}} \]  

(58a)

\[ \mathcal{E} \left[ \| \nabla_t - G_t \|^2 \right] \leq \sqrt{\mathcal{E} \left[ \| \nabla_t - \tilde{G}_t \|^2 \right]} \leq C_2 T^{-\frac{3}{2}} \]  

(58b)

\[ \mathcal{E} \left[ \| \nabla_t - \tilde{G}_t \|^3 \right] \leq C_3 T^{-1} \]  

(58c)

\[ \mathcal{E} \left[ \| \nabla_t^2 - H_t \|^2 \right] \leq C_4 T^{-\frac{3}{2}} \]  

(58d)

\[ \mathcal{E} \left[ \| \nabla_t^2 - \tilde{H}_t \|^2 \right] \leq C_5 T^{-\frac{3}{2}} \]  

(58e)

\[ \mathcal{E} \left[ \| \nabla_t^2 - \tilde{H}_t \|^3 \right] \leq C_6 T^{-1} \]  

(58f)

where \( C_i \) are constants independent of \( T \) and \( d \) for all \( i = 1, 2, \ldots, 6 \). Now combining the set of conditions in (71) with (54) we get,

\[ \mathcal{R}_{ENC}(T) \leq O \left( T^\frac{3}{2} (1 + W_T) + T^\frac{1}{2} \left( \sigma + \zeta^2 \right) \right) \]

\[ \square \]

9.2 Proof of Theorem 4.2

Before we prove the theorem, we state some preliminary results that are required for the proof.

**Lemma 9.5** Let \( x_{t+1} = \arg \min_y \tilde{f}_t(x_t, y, \tilde{G}_t, \tilde{H}_t, h_t, M) \) and \( M \geq L_H \). Then, we have

\[ G_t + \tilde{H}_t h_t + \frac{M}{2} \| h_t \| h_t = 0 \]  

(59a)

\[ \tilde{H}_t + \frac{M}{2} \| h_t \| I_d \succeq 0 \]  

(59b)

\[ \tilde{G}_t h_t \leq 0 \]  

(59c)
Lemma 9.6 (BG18) Under Assumption 2.2 and Assumption 2.3 we have
\[
E \left[ \left\| \tilde{G}_t - \nabla t \right\|_2^2 \right] \leq \frac{3M^2}{2} L^2_G (d+3)^3 + \frac{4 (L^2 + \sigma^2) (d+5)}{m_t} \tag{60}
\]

Lemma 9.7 (BG18) For \( b_t \geq 4 (1 + 2 \log 2d) \), under Assumption 2.3 and Assumption 2.4 we have
\[
E \left[ \left\| \tilde{H}_t - \nabla \tilde{H}_t \right\|_2^2 \right] \leq 3L^2_H (d+16)^5 \nu^2 + \frac{128 (1 + 2 \log 2d) (d+16)^4 L^2_H}{3b_t} \tag{61a}
\]
\[
E \left[ \left\| \tilde{H}_t - \nabla \tilde{H}_t \right\|_2^3 \right] \leq 21L^3_H (d+16)^{18} \nu^3 + \frac{160 \sqrt{1+2 \log 2d} (d+16)^6 L^3_H}{b_t^4} \tag{61b}
\]

Lemma 9.8 Under Assumption 2.2, Assumption 2.3 and Assumption 2.4, the points generated by Algorithm 2 satisfy the following
\[
r_{NC} (t) = \max \left( \left\| \nabla t \right\|, -\frac{8}{L^3_H} \lambda^3_{t, \text{min}} \right) \leq L_G \left\| h_t \right\| + \frac{1}{2} \left( L_H + M \right) \left\| h_t \right\|^2 + 4 \left\| h_t \right\|^3 + \frac{32}{M^3} \left\| \tilde{H}_t - \nabla \tilde{H}_t \right\|^3 + \left\| \nabla t - \tilde{G}_t \right\| + \frac{\left\| \nabla \tilde{H}_t - \tilde{H}_t \right\|^2}{2 \left( L_H + M \right)} \tag{62}
\]

Proof Under Assumption 2.3, using (59a) and Young’s inequality, we have
\[
\left\| \nabla f_t (x_{t+1}) - \nabla t - \nabla \tilde{H}_t h_t \right\| \leq \frac{L_H}{2} \left\| h_t \right\|^2
\]
\[
\implies \left\| \nabla f_t (x_{t+1}) \right\| \leq \left\| \nabla t - \tilde{G}_t \right\| + \left\| \nabla \tilde{H}_t - \tilde{H}_t \right\| (x_{t+1} - x_t) + \frac{L_H + M}{2} \left\| h_t \right\|^2
\]
\[
\leq \left\| \nabla t - \tilde{G}_t \right\| + \frac{\left\| \nabla \tilde{H}_t - \tilde{H}_t \right\|^2}{2 \left( L_H + M \right)} + \left( L_H + M \right) \left\| h_t \right\|^2
\]

Under Assumption 2.3 we get
\[
\left\| \nabla t \right\| \leq L_G \left\| h_t \right\| + \left\| \nabla t - \tilde{G}_t \right\| + \frac{\left\| \nabla \tilde{H}_t - \tilde{H}_t \right\|^2}{2 \left( L_H + M \right)} + \left( L_H + M \right) \left\| h_t \right\|^2 \tag{63}
\]

From (59b) we get,
\[
-\frac{2}{M} \lambda_{t, \text{min}} \leq \frac{2}{M} \left\| \tilde{H}_t - \nabla \tilde{H}_t \right\| + \left\| h_t \right\|
\]
\[
\implies \left(-\frac{2}{M} \lambda_{t, \text{min}} \right)^3 \leq \frac{32}{M^3} \left\| \tilde{H}_t - \nabla \tilde{H}_t \right\|^3 + 4 \left\| h_t \right\|^3 \tag{64}
\]

Combining (63) and (64), and choosing \( M = L_H \) we get
\[
r_{NC} (t) = \max \left( \left\| \nabla t \right\|, -\frac{8}{L^3_H} \lambda^3_{t, \text{min}} \right) \leq L_G \left\| h_t \right\| + \frac{1}{2} \left( L_H + M \right) \left\| h_t \right\|^2 + 4 \left\| h_t \right\|^3 + \frac{32}{M^3} \left\| \tilde{H}_t - \nabla \tilde{H}_t \right\|^3 + \left\| \nabla t - \tilde{G}_t \right\| + \frac{\left\| \nabla \tilde{H}_t - \tilde{H}_t \right\|^2}{2 \left( L_H + M \right)}
\]}
Lemma 9.9 Under Assumption 2.3, and Assumption 2.4, for $M \geq L_H$, the points generated by Algorithm 2 satisfy the following

$$\frac{M}{36} \|h_t\|^3 \leq f_t(x_t) - f_t(x_{t+1}) + \frac{4}{\sqrt{3M}} \|\nabla_t - \tilde{G}_t\|^2 + \frac{24}{M^2} \|\nabla_t^2 - \tilde{H}_t\|^3 \tag{65}$$

**Proof** If $M \geq L_H$, using Assumption 2.3

$$f_t(x_{t+1}) \leq f_t(x_t) + \nabla_t^T h_t + \frac{1}{2} \langle \nabla_t^2 h_t, h_t \rangle + \frac{M}{6} \|h_t\|^3$$

$$\leq f_t(x_t) + G_t^T h_t + \frac{1}{2} \langle H_t h_t, h_t \rangle + \|\nabla_t - G_t\| \|h_t\| + \frac{1}{2} \|\nabla_t^2 - \bar{H}_t\| \|h_t\|^2 + \frac{M}{6} \|h_t\|^3$$

Using (59a) we get

$$f_t(x_{t+1}) \leq f_t(x_t) - \frac{1}{2} \langle H_t h_t, h_t \rangle + \|\nabla_t - \bar{G}_t\| \|h_t\| + \frac{1}{2} \|\nabla_t^2 - \bar{H}_t\| \|h_t\|^2 - \frac{M}{3} \|h_t\|^3 \tag{66}$$

Combining (59a), and (59c) we get

$$-\frac{1}{2} \langle H_t h_t, h_t \rangle - \frac{M}{3} \|h_t\|^3 \leq -\frac{M}{12} \|h_t\|^3$$

which combined with (66) gives

$$f_t(x_{t+1}) \leq f_t(x_t) + \|\nabla_t - \bar{G}_t\| \|h_t\| + \frac{1}{2} \|\nabla_t^2 - \bar{H}_t\| \|h_t\|^2 - \frac{M}{12} \|h_t\|^3$$

Rearranging terms we get

$$\frac{M}{12} \|h_t\|^3 \leq f_t(x_t) - f_t(x_{t+1}) + \|\nabla_t - \bar{G}_t\| \|h_t\| + \frac{1}{2} \|\nabla_t^2 - \bar{H}_t\| \|h_t\|^2$$

Using Young’s inequality

$$\frac{M}{12} \|h_t\|^3 \leq f_t(x_t) - f_t(x_{t+1}) + \frac{4}{\sqrt{3M}} \|\nabla_t - \bar{G}_t\|^2 + \frac{24}{M^2} \|\nabla_t^2 - \bar{H}_t\|^3 + \frac{M}{18} \|h_t\|^3$$

$$\implies \frac{M}{36} \|h_t\|^3 \leq f_t(x_t) - f_t(x_{t+1}) + \frac{4}{\sqrt{3M}} \|\nabla_t - \bar{G}_t\|^2 + \frac{24}{M^2} \|\nabla_t^2 - \bar{H}_t\|^3 \tag{67}$$

**Proof** [Proof of Theorem 4.2] Let us consider two cases $\|h_t\| \leq T^{-\frac{1}{4}}$, and $\|h_t\| > T^{-\frac{1}{4}}$.

1. $\|h_t\| \leq T^{-\frac{1}{4}}$

$$r_{NC}(t) \leq L_G T^{-\frac{1}{4}} + \frac{1}{2} (L_H + M) T^{-\frac{1}{2}} + 4T^{-1} + \|\nabla_t - \bar{G}_t\| + \frac{\|\nabla_t^2 - \bar{H}_t\|^2}{2 (L_H + M)} + \frac{32}{M^3} \|\bar{H}_t - \nabla_t^2\|^3 \tag{67}$$

2. $\|h_t\| > T^{-\frac{1}{4}}$

Using (52) we get,

$$r_{NC}(t) \leq \left( L_G T^{\frac{5}{4}} + \frac{1}{2} (L_H + M) T^{\frac{5}{2}} + 4 \right) \|h_t\|^3 + \|\nabla_t - \bar{G}_t\| + \frac{\|\nabla_t^2 - \bar{H}_t\|^2}{2 (L_H + M)} + \frac{32}{M^3} \|\bar{H}_t - \nabla_t^2\|^3$$
\[
\begin{align*}
\leq & \left( \frac{36 L_G}{M} + 18 \left( \frac{L_H}{M} + 1 \right) + \frac{144}{M} \right) T^\frac{2}{\nu} \left( f_t(x_t) - f_t(x_{t+1}) + \frac{4}{\sqrt{3M}} \| \nabla_t - \tilde{G}_t \|^\frac{2}{\nu} \right) \\
& + \frac{24}{M^2} \| \nabla_t^2 - \tilde{H}_t \|^3 + \| \nabla_t - \tilde{G}_t \| + \frac{\| \nabla_t^2 - \tilde{H}_t \|^2}{2 (L_H + M)} + \frac{32}{M^3} \| \tilde{H}_t - \nabla_t^2 \|^3
\end{align*}
\]

(68)

Combining (67), and (68),

\[
\begin{align*}
\mathcal{R}(t) \leq & \left( L_G T^{-\frac{3}{\nu}} + 1 \right) \left( L_H - M + \frac{2}{2} + 4T^{-1} \right) + \frac{32}{M^3} \| \tilde{H}_t - \nabla_t^2 \|^3 + \| \nabla_t - \tilde{G}_t \| + \frac{\| \nabla_t^2 - \tilde{H}_t \|^2}{2 (L_H + M)} \\
& + \left( 36 \frac{L_G}{M} + 18 \left( \frac{L_H}{M} + 1 \right) + \frac{144}{M} \right) T^\frac{2}{\nu} \left( f_t(x_t) - f_t(x_{t+1}) + \frac{4}{\sqrt{3M}} \| \nabla_t - \tilde{G}_t \|^\frac{2}{\nu} + \frac{24}{M^2} \| \nabla_t^2 - \tilde{H}_t \|^3 \right)
\end{align*}
\]

(69)

Summing both sides from \( t = 1 \), to \( T \), taking expectation on both sides and using Definition 4.2 we get

\[
\mathcal{R}(T) = \sum_{t=1}^{T} \mathbb{E} \left[ \mathcal{R}(t) \right] \leq \left( L_G T^{-\frac{3}{\nu}} + \frac{1}{2} (L_H + M) T^\frac{4}{\nu} + 4 \right) + \sum_{t=1}^{T} \left( \frac{32}{M^3} \mathbb{E} \left[ \| \tilde{H}_t - \nabla_t^2 \|^3 \right] \right)
\]

\[
+ \mathbb{E} \left[ \| \nabla_t - \tilde{G}_t \| \right] + \frac{\mathbb{E} \left[ \| \nabla_t^2 - \tilde{H}_t \|^2 \right]}{2 (L_H + M)}
\]

\[
+ \left( 36 \frac{L_G}{M} + 18 \left( \frac{L_H}{M} + 1 \right) + \frac{144}{M} \right) T^\frac{2}{\nu} \left( f_t(x_t) - f_T(x_{T+1}) + W_T \right)
\]

\[
+ \frac{4}{\sqrt{3M}} \sum_{t=1}^{T} \mathbb{E} \left[ \| \nabla_t - \tilde{G}_t \| \right] + \frac{24}{M^2} \sum_{t=1}^{T} \mathbb{E} \left[ \| \nabla_t^2 - \tilde{H}_t \|^3 \right]
\]

(70)

Now choosing \( \nu, m_t, \) and \( b_t \) as in (7) and Lemma 9.6 and Lemma 9.7 we get

\[
\mathbb{E} \left[ \| \nabla_t - \tilde{G}_t \|^2 \right] \leq C_1 T^{-\frac{4}{\nu}}
\]

(71a)

\[
\mathbb{E} \left[ \| \nabla_t - \tilde{G}_t \| \right] \leq \sqrt{\mathbb{E} \left[ \| \nabla_t - \tilde{G}_t \|^2 \right]} \leq C_2 T^{-\frac{4}{\nu}}
\]

(71b)

\[
\mathbb{E} \left[ \| \nabla_t - \tilde{G}_t \|^3 \right] \leq C_3 T^{-1}
\]

(71c)

\[
\mathbb{E} \left[ \| \nabla_t^2 - \tilde{H}_t \|^2 \right] \leq C_4 T^{-\frac{4}{\nu}}
\]

(71d)

\[
\mathbb{E} \left[ \| \nabla_t^2 - \tilde{H}_t \| \right] \leq \sqrt{\mathbb{E} \left[ \| \nabla_t^2 - \tilde{H}_t \|^2 \right]} \leq C_5 T^{-\frac{4}{\nu}}
\]

(71e)

\[
\mathbb{E} \left[ \| \nabla_t^2 - \tilde{H}_t \|^3 \right] \leq C_6 T^{-1}
\]

(71f)

where \( C_i \) are constants independent of \( T \) and \( d \) for all \( i = 1, 2, \ldots, 6 \). Now combining the set of conditions in (71) with (70) we get,

\[
\mathcal{R}(T) \leq O \left( T^\frac{2}{\nu} (1 + W_T) + \sigma T^\frac{4}{\nu} \right)
\]

\]
10 Proofs for Section 5

We start with some preliminary results on the Gaussian Stein’s identity based gradient estimator. For the sake of convenience, we first recall the gradient estimator as defined in Equation (30) below:

\[ G_t^\nu(x_t, u_t, \xi_t) = \frac{F_t(x_t + \nu u_t, \xi_t) - F_t(x_t, \xi_t)}{\nu} u_t. \]

It is well-known (see e.g., [NS17]) that \( \mathbb{E} \left[ G_t^\nu(x_t, u_t, \xi_t) \right] = \nabla f_t^\nu(x) \), where \( f_t^\nu \) is a Gaussian approximation of \( f_t \) defined as

\[ f^\nu(x) = \frac{1}{(2\pi)^{d/2}} \int f(x + \nu u) \, e^{-\frac{\|u\|^2}{2}} \, du = \mathbb{E} \left[ f(x + \nu u) \right]. \]  

(72)

The results below outline some properties of \( f^\nu \) and its gradient estimator.

Lemma 10.1 [NS17] Let \( f_t^\nu \) and \( G_t^\nu \) be defined in (72) and (30), respectively. If Assumption 2.2 holds for \( f_t(x) \), for any \( x \in \mathbb{R}^d \), we have

\[ |f_t^\nu(x) - f_t(x)| \leq \nu L \sqrt{d}, \]

\[ \mathbb{E} \left[ \| G_t^\nu(x, u, \xi) \|^2 \right] \leq L^2 (d + 4)^2. \]  

(73)

Lemma 10.2 [NS17] Let the gradient estimator be defined as (30) and let Assumption 2.3 hold for \( f_t(x) \). Then we have for any \( x \in \mathbb{R}^d \),

\[ \| \mathbb{E} \left[ G_t^\nu(x, u, \xi) \right] - \nabla f_t(x) \|_2 \leq \frac{\nu}{2} L_G (d + 3)^{\frac{3}{2}}, \]  

(74)

\[ \mathbb{E} \left[ \| G_t^\nu(x, u, \xi) \|^2 \right] \leq \frac{\nu^2}{2} L_G^2 (d + 6)^3 + 2 (d + 4) (\| \nabla f_t(x) \|^2 + \sigma^2). \]  

(75)

Lemma 10.3 If \( f_t \) is K-WQC, so is \( f_t^\nu \).

Proof Assuming that \( f_t \) is K-WQC, for any \( x \in \mathbb{R}^d \), we have \( f(x + \nu u) - f(x^* + \nu u) \leq K \nabla f(x + \nu u)^\top (x - x^*) \), for \( \nu > 0 \) and \( u \sim N(0, I_d) \). Taking expectation from both sides of the above inequality and noting (72), we have \( f_t^\nu(x) - f_t^\nu(x^*) \leq K \nabla f_t^\nu(x)^\top (x - x^*) \).

10.1 Proof of Theorem 5.1

Proof Let \( z_t := \| x_t - x_t^* \|_2 \). Based on the non-expansiveness of the Euclidean projections and our boundedness assumption on \( \mathcal{X} \), we have

\[ z_{t+1}^2 = \| x_{t+1} - x_{t+1}^* \|_2^2 \]

\[ = \| x_{t+1} - x_t^* \|_2^2 + \| x_t^* - x_{t+1}^* \|_2^2 + 2 (x_{t+1} - x_t^*)^\top (x_t^* - x_{t+1}^*) \]

\[ = \| x_{t+1} - x_t^* \|_2^2 + R \| x_t^* - x_{t+1}^* \|_2^2 + 2 R \| x_t^* - x_{t+1}^* \|_2 \]

\[ = \| P_{\mathcal{X}} (x_t - \eta G_t^\nu(x_t, u_t, \xi_t)) - x_t^* \|_2^2 + 3 R \| x_t^* - x_{t+1}^* \|_2 \]

\[ \leq \| x_t - \eta G_t^\nu(x_t, u_t, \xi_t) - x_t^* \|_2^2 + 3 R \| x_t^* - x_{t+1}^* \|_2 \]

\[ = z_t^2 + \eta^2 \| G_t^\nu(x_t, u_t, \xi_t) \|_2^2 - 2 \eta G_t^\nu(x_t, u_t, \xi_t)^\top (x_t - x_t^*) + 3 R \| x_t^* - x_{t+1}^* \|_2. \]  

28
Rearranging terms we then have
\[ KG_t^\nu (x_t, u_t, \xi_t)^T (x_t - x_t^*) \leq \frac{K}{2\eta} (z_t^2 - z_{t+1}^2 + \eta^2 \| G_t^\nu (x_t, u_t, \xi_t) \|^2_2 + 3R \| x_t^* - x_{t+1}^* \|_2). \] (76)

Taking conditional expectation on both sides of the above inequality and noting Lemma 10.3, we obtain
\[ f_t^\nu (x_t) - f_t^\nu (x_t^*) \leq K \nabla f_t^\nu (x_t)^T (x_t - x_t^*) = K \mathbb{E} [G_t^\nu (x_t, u_t, \xi_t) | \mathcal{F}_t]^T (x_t - x_t^*) \leq \frac{K}{2\eta} (z_t^2 - \mathbb{E} [z_{t+1}^2 | \mathcal{F}_t] + \eta^2 \mathbb{E} \| G_t^\nu (x_t, u_t, \xi_t) \|^2_2 | \mathcal{F}_t] + 3R \| x_t^* - x_{t+1}^* \|), \] (77)

which together with Lemma 10.1 imply that
\[ f_t(x_t) - f_t(x_t^*) \leq 2\nu L \sqrt{d} + \frac{K}{2\eta} (z_t^2 - \mathbb{E} [z_{t+1}^2 | \mathcal{F}_t] + \eta^2 (d + 4)^2 L^2 + 3R \| x_t^* - x_{t+1}^* \|). \] (78)

Now we can bound the nonstationary regret as follows. Combining the above inequality with (76), (31), and under Assumption 2.2 we have
\[ \mathcal{R}_{NS} \left( \{x_t\}_{1}^{T}, \{x_t + \nu u_t\}_{1}^{T} \right) = \mathbb{E} \left[ \sum_{t=1}^{T} (f_t(x_t) + f_t(x_t + \nu u_t) - 2f_t(x_t^*)) \right] \leq \mathbb{E} \left[ \sum_{t=1}^{T} (2f_t(x_t) - 2f_t(x_t^*) + L\nu \| u_t \|_2) \right] \leq \frac{K}{\eta} (z_t^2 - \mathbb{E} [z_{t+1}^2] + T\eta^2 (d + 4)^2 L^2 + 3RV_T) + 2\nu LT \sqrt{d}. \]

Choosing \( \nu \) and \( \eta \) according to (32), we get
\[ \mathcal{R}_{NS} \left( \{x_t\}_{1}^{T}, \{x_t + \nu u_t\}_{1}^{T} \right) \leq 2KL(d + 4) \sqrt{T (R^2 + 3RV_T)} + 2Ld \sqrt{T}. \]

Additionally, if Assumption 2.3 similar to (78), we obtain
\[ f_t(x_t) - f_t(x_t^*) \leq 2\nu L \sqrt{d} + \frac{K}{2\eta} (z_t^2 - \mathbb{E} [z_{t+1}^2 | \mathcal{F}_t] + \eta^2 [0.5\nu^2 L_G^2 (d + 6)^3 + 2 (d + 4) (L^2 + \sigma^2)] + 3R \| x_t^* - x_{t+1}^* \|), \]

which together with (34), imply (35).

\[ \boxed{\text{10.2 Functional Sparsity Assumption}} \]

As mentioned in Section 5.2, in this section, we assume that the functions \( f_t \) depend only on \( s \) of the \( d \) coordinates, where \( s \ll d \). This assumption is motivated by similar sparsity assumption in nonparametric regression and zeroth-order optimization [LW+08, WDBS18, BG18]. We emphasize that support of the functions \( f_t \) need not necessarily be the same, but the variation in the functions \( f_t \) is controlled by constraining them to lie in the set \( \mathcal{S}_T \) in Definition 2.1. In this case, Algorithm 3 enjoys the following nonstationary regret bound.
Theorem 10.1 Let \( \{x_t^T \}, \{x_t + \nu u_t^T \} \) be generated by Algorithm 3 for any sequence of K-WQC loss functions \( \{f_t^T \} \in \mathcal{S}_T \), that depends on only \( s \) of the \( d \) coordinates. Also, suppose that Assumptions 2.2 hold, with \( \| \cdot \| = \| \cdot \|_2 \).

a) By choosing

\[
\nu = \sqrt{\frac{s}{T}}, \quad \eta = \frac{\sqrt{R^2 + 3RV_T}}{L(s + 4)\sqrt{T}},
\]

the expected non-stationary regret is bounded by

\[
\mathcal{R}_{NS} (\{x_t^T \}, \{x_t + \nu u_t^T \}) \leq O \left( s \sqrt{(T + V_T T)} \right).
\]

b) If, in addition, Assumption 2.3 holds and

\[
\nu = \min \left\{ \frac{1}{\sqrt{T}}, \frac{L}{L_G(s + 6)} \right\}, \quad \eta = \frac{\sqrt{R^2 + 3RV_T}}{L\sqrt{2(s + 4)T}},
\]

the above regret bound is improved to

\[
\mathcal{R}_{NS} (\{x_t^T \}, \{x_t + \nu u_t^T \}) \leq O \left( (1 + \sigma^2) \sqrt{s(T + V_T T)} \right).
\]

In the deterministic case the upper bound becomes \( O \left( \sqrt{s(T + V_T T)} \right) \) as \( \sigma = 0 \).

Proof Without loss of generality, let us assume that \( f_t(x) \) depends on the first \( s \) coordinates of \( x \). Every \( u \) can be written as \( u = u^s + u^{ns} \) where the first \( s \) coordinates of \( u^s \) are same as \( u \), and rest are 0. Hence, we have \( f_t(x + \nu u) = f_t(x + \nu u^s) \), and

\[
\mathbb{E}_{u_t, \xi_t} \left[ G^\nu_t (x_t, u_t, \xi_t) \right] = \mathbb{E}_{u_t, \xi_t} \left[ \frac{F_t(x_t + \nu u_t, \xi_t) - F_t(x_t, \xi_t)}{\nu} u_t \right]
\]

\[
= \mathbb{E} \left[ \frac{f_t(x_t + \nu u_t) - f_t(x_t)}{\nu} u_t \right]
\]

\[
= \mathbb{E} \left[ \frac{f_t(x_t + \nu u^s_t) - f_t(x_t)}{\nu} (u^s_t + u^{ns}_t) \right]
\]

\[
= \mathbb{E} \left[ \frac{f_t(x_t + \nu u^s_t) - f_t(x_t)}{\nu} u^s_t \right] + \mathbb{E} \left[ \frac{f_t(x_t + \nu u^s_t) - f_t(x_t)}{\nu} u^{ns}_t \right]
\]

Hence, noting Lemma 10.2 we have,

\[
\mathbb{E} \left[ \| G_t (x_t, u_t, \xi_t) \|_2^2 | \mathcal{F}_t \right] = \mathbb{E} \left[ \| G_t (x_t, u^s_t, \xi_t) \|_2^2 | \mathcal{F}_t \right] \leq (s + 4)^2 L^2.
\]

Using this bound in (76), and choosing \( \nu \) and \( \eta \) according to (79), we obtain (80). Part b) follows similarly to the proof of Theorem 5.1.
10.3 Proof of Theorem 5.2

To prove the theorem, we first require some preliminary results that we state below.

**Lemma 10.4** Let Assumption 2.2 hold with \( \| \cdot \| = \| \cdot \|_{\infty} \). Then for some universal constant \( C > 0 \), we have

\[
|f'(x) - f(x)| \leq \nu LC \sqrt{2 \log d},
\]

\[
E \left[ \left\| G'_t (x_t, u_t, \xi_t) \right\|^{2}_{\infty} | \mathcal{F}_t \right] \leq 4CL^2 (\log d)^2.
\]

**Proof** Using Assumption 2.2 w.r.t \( l_{\infty} \)-norm, we have

\[
|f'(x) - f(x)| \leq E [ |f_t(x + \nu u) - f_t(x)|] \leq \nu L E \left[ \| u \|_{\infty} \right],
\]

\[
\left\| G'_t (x_t, u_t, \xi_t) \right\|^{2}_{\infty} = \left\| \frac{F_t (x_t + \nu u_t, \xi_t) - F_t (x_t, \xi_t)}{\nu} u_t \right\|^{2}_{\infty} \leq L^2 \| u \|^{4}_{\infty},
\]

which together with the fact that \( E \left[ \| u \|^{k}_{\infty} \right] \leq C (2 \log d)^{\frac{k}{2}} \) due to [BG18], imply the result. \( \blacksquare \)

**Lemma 10.5 ([BG18])** Let Assumption 2.3 hold w.r.t \( \| \cdot \| = \| \cdot \|_{\infty} \). Then we have

\[
E \left[ |G_t (x_t, u_t, \xi_t) | \mathcal{F}_t \right] - \nabla f_t (x_t) \|_{\infty} \leq C \nu L G \sqrt{2 (\log d)^{3/2}},
\]

\[
E \left[ \left| G_t (x_t, u_t, \xi_t) \right| \mathcal{F}_t \right] \leq 4C (\log d)^{2} \left[ \nu^2 L G \log d + 4 \| \nabla f_t (x_t) \|^{2} + 4\sigma^2 \right].
\]

**Proof** [Proof of Theorem 5.2] Denoting the index set of non-zero elements of \( x_t \), and \( x^*_t \) by \( J_t \subseteq R^d \) and \( J^*_t \subseteq R^{*} \) respectively, and \( N_t = J_t \cup J_{t+1} \cup J^*_t \), and using Lemma 5.1 we have

\[
z^{2}_{t+1} = \| x_{t+1} - x^*_t \|^{2}_{2}
\]

\[
= \| x_{t+1} \|^{2}_{2} + \| x^*_t - x^*_t \|^{2}_{2} + 3 \| x^*_t - x^*_t \|^{2}_{2} + 3 \| x^*_t - x^*_t \|^{2}_{2}
\]

\[
= \| x_{t+1} \|^{2}_{2} + \| x^*_t - x^*_t \|^{2}_{2} + 3 \| x^*_t - x^*_t \|^{2}_{2}
\]

\[
= \| x_{t+1} \|^{2}_{2} + \| x^*_t - x^*_t \|^{2}_{2} + 3 \| x^*_t - x^*_t \|^{2}_{2}
\]

\[
= z^{2}_{t+1} + \eta^2 \| G'_t (x_t, u_t, \xi_t) \|^{2}_{2} + 3 \| x^*_t - x^*_t \|^{2}_{2}
\]

Rearranging terms and taking conditional expectation we get,

\[
KE \left[ G'_t (x_t, u_t, \xi_t) \mathcal{F}_t \right] (x_t - x^*_t)
\]

\[
\leq \frac{K}{2\eta} \left( z^{2}_{t+1} + \| x^*_t \|^{2}_{2} \right) + \eta^2 E \left[ \left\| G_t (x_t, u_t, \xi_t) \right\|^{2}_{\infty} | \mathcal{F}_t \right] + 3 \| x^*_t - x^*_t \|^{2}_{2}
\]

(85)

where all indexes not in \( N_t \) are 0 in \( G'_t (x_t, u_t)_{N_t} \). Note that \( |N_t| \leq 2\delta + s^* \), and hence

\[
\left\| G'_t (x_t, u_t, \xi_t) \right\|^{2}_{\infty} \leq (2\delta + s^*) \left\| G'_t (x_t, u_t, \xi_t) \right\|^{2}_{\infty} \leq (2\delta + s^*) \left\| G'_t (x_t, u_t, \xi_t) \right\|^{2}_{\infty}.
\]

Following similar steps in proof of Theorem 5.1 by noting (36), (38), Lemmas 10.4 and 10.5 we obtain (37) and (39). \( \blacksquare \)
10.4 Proof of Theorem 5.3

To prove Theorem 5.3 we need the following two Lemma.

**Lemma 10.6** Under Assumption 2.3 the following holds:

\[ E \left[ ||G^\nu_{t,SM} (x_t, u_t, \xi_t) ||_2^2 \right] \leq L^2 (d + 4)^2 . \] (86)

In addition, if Assumption 2.3 holds, then

\[ \| E \left[ G^\nu_{t,SM} (x_t, u_t, \xi_t) \right] - \nabla f_t (x_t) \| \leq \frac{\nu d L G}{2} \] (87)

**Proof**

a) Using Assumption 2.2

\[ E \left[ ||G^\nu_{t,SM} (x_t, u_t, \xi_t) ||_2^2 \right] \leq L^2 E \left[ ||u_t||^4 \right] \leq L^2 (d + 4)^2 \]

a) Using Assumption 2.3

\[
\begin{align*}
&\left\| E \left[ G^\nu_{t,SM} (x_t, u_t, \xi_t) \right] - \nabla f_t (x_t) \right\|
= \left\| E \left[ G^\nu_{t,SM} (x_t, u_t, \xi_t) \right] - E \left[ \langle \nabla f_t (x_t), \frac{u_t}{\|u_t\|} \rangle u_t \|u_t\| \right] \right\|
\leq \frac{1}{\nu} E \left[ \left\| f_t (x_t + \nu \frac{u_t}{\|u_t\|}) - f_t (x_t) - \nu \langle \nabla f_t (x_t), \frac{u_t}{\|u_t\|} \rangle u_t \|u_t\| \right\| \right]
\leq \frac{\nu L G}{2} E \left[ ||u_t||^2 \right] \leq \frac{\nu d L G}{2}
\end{align*}
\]

**Proof** [Proof of 5.3] Let \( \mathcal{K}_1 \triangleq \mathcal{A}_\nu \cap \mathcal{K} \), and \( x^*_{\nu,t} := \text{argmax}_{x \in \mathcal{K}_1} f_t (x) \). Let \( z_t := \| x_t - x^*_{\nu,t} \|_2 \).

\[ z^2_{t+1} = \| x_{t+1} - x^*_{\nu,t+1} \|_2^2 \]
\[ = \| x_{t+1} - x^*_{\nu,t} \|_2^2 + \| x^*_{\nu,t} - x^*_{\nu,t+1} \|_2^2 + 2 \left( x_{t+1} - x^*_{\nu,t} \right)^T \left( x^*_{\nu,t} - x^*_{\nu,t+1} \right) \]
\[ = \| x_{t+1} - x^*_{\nu,t} \|_2^2 + R \| x^*_{\nu,t} - x^*_{\nu,t+1} \|_2^2 + 2R \| x^*_{\nu,t} - x^*_{\nu,t+1} \|_2^2 \]
\[ \leq \| x_t + \eta G^\nu_{t,SM} (x_t, u_t, \xi_t) \| \| x^*_{\nu,t} \|_2^2 + 2R \| x^*_{\nu,t} - x^*_{\nu,t+1} \|_2^2 \leq \| x^*_{\nu,t} \|_2^2 + 2 \eta \| G^\nu_{t,SM} (x_t, u_t, \xi_t) \|_2^2 + 3R \| x^*_{\nu,t} - x^*_{\nu,t+1} \|_2^2 \]
\[ = z^2_t + \eta^2 \| G^\nu_{t,SM} (x_t, u_t, \xi_t) \|_2^2 + 2 \eta \| G^\nu_{t,SM} (x_t, u_t, \xi_t) \|_2^2 + 3R \| x^*_{\nu,t} - x^*_{\nu,t+1} \|_2^2 + 6\nu R \sqrt{d} \]

Rearranging terms we then have

\[ G^\nu_{t,SM} (x_t, u_t, \xi_t)^T (x^*_{\nu,t} - x_t) \leq \frac{1}{2\eta} \left( z^2_t - z^2_{t+1} + \eta^2 \| G^\nu_{t,SM} (x_t, u_t, \xi_t) \|_2^2 + 3R \| x^*_{\nu,t} - x^*_{\nu,t+1} \|_2^2 + 6\nu R \sqrt{d} \right). \] (88)
Taking conditional expectation on both sides of the above inequality and noting Lemma 10.3, we obtain

\[
\mathbb{E} \left[ G_{t,SM}^\nu (x_t, u_t, \xi_t) \mid F_t \right] ^T (x^{*,t}_{\nu,t} - x_t) \leq \frac{1}{2\eta} \left( z_t^2 - \mathbb{E} \left[ z_{t+1}^2 \mid F_t \right] + \eta^2 \mathbb{E} \left[ \| G_{t,SM}^\nu (x_t, u_t, \xi_t) \|_2^2 \mid F_t \right] \right) \\
+ 3R \| x_t^* - x_{t+1}^* \|_2 + 6\nu R\sqrt{d}. \tag{89}
\]

Using (89), and (87), for \( \gamma \)-weakly DR-submodular monotone function,

\[
f_t (x^{*,t}_{\nu,t}) - \left( 1 + \frac{1}{\gamma^2} \right) f_t (x_t) \leq \frac{1}{\gamma} \nabla f_t (x_t) ^T (x^{*,t}_{\nu,t} - x_t) \\
\leq \frac{1}{\gamma} \left( \nabla f_t (x_t) - \mathbb{E} \left[ G_{t,SM}^\nu (x_t, u_t, \xi_t) \mid F_t \right] + \mathbb{E} \left[ G_{t,SM}^\nu (x_t, u_t, \xi_t) \mid F_t \right] ^T (x^{*,t}_{\nu,t} - x_t) \right) \\
\leq \frac{1}{2\eta\gamma} \left( z_t^2 - \mathbb{E} \left[ z_{t+1}^2 \mid F_t \right] + \eta^2 \mathbb{E} \left[ \| G_{t,SM}^\nu (x_t, u_t, \xi_t) \|_2^2 \mid F_t \right] \right) \\
+ 3R \| x_t^* - x_{t+1}^* \|_2 + 6\nu R\sqrt{d} \\
+ \frac{1}{\gamma} \left\| \nabla f_t (x_t) - \mathbb{E} \left[ G_{t,SM}^\nu (x_t, u_t, \xi_t) \mid F_t \right] \| \| x^{*,t}_{\nu,t} - x_t \|,
\]

and

\[
f_t (x^*_t) - \left( 1 + \frac{1}{\gamma^2} \right) f_t (x_t) \leq \frac{1}{2\eta\gamma} \left( z_t^2 - \mathbb{E} \left[ z_{t+1}^2 \mid F_t \right] + \eta^2 \mathbb{E} \left[ \| G_{t,SM}^\nu (x_t, u_t, \xi_t) \|_2^2 \mid F_t \right] \right) \\
+ 3R \| x_t^* - x_{t+1}^* \|_2 + 6\nu R\sqrt{d} + \frac{\nu^2 L^2}{2\gamma} + \nu L\sqrt{d}. \tag{89}
\]

Now we can bound the nonstationary regret as follows. Combining the above inequality with (11), (11), and under Assumption 2.2 and Assumption 2.3 and setting \( \alpha = \frac{\gamma^2}{1+\gamma^2} \) we have

\[
\mathcal{R}_{\alpha,NS} \left( \{x_t\}_1^T, \{x_t + \nu \frac{u_t}{\|u_t\|}\}_1^T \right) = \mathbb{E} \left[ \sum_{t=1}^T \left( 2\alpha f_t (x^*_t) - f_t (x_t) - f_t \left( x_t + \nu \frac{u_t}{\|u_t\|} \right) \right) \right]
\leq \mathbb{E} \left[ \sum_{t=1}^T \left( 2\alpha f_t (x^*_t) - 2f_t (x_t) + \nu L \right) \right]
\leq \frac{\gamma}{\eta (1+\gamma^2)} \left( z_t^2 - z_{t+1}^2 + T\eta^2 L^2 \left( d + 4 \right)^2 + 3R^2 + 6\nu R\sqrt{d} \right)
\leq \frac{2\nu \gamma^2 T}{1 + \gamma^2} \left( \frac{d L^2}{2\gamma} + L\sqrt{d} \right) + \nu LT.
\]

Choosing \( \nu \) and \( \eta \) according to (42), we get

\[
\mathcal{R}_{\alpha,NS} \left( \{x_t\}_1^T, \{x_t + \nu \xi_t\}_1^T \right) \leq \mathcal{O} \left( d \sqrt{T} + T V_T \right).
\]

\[\blacksquare\]
