Impulsive control of nonlocal transport equations

Nikolay Pogodaev∗† Maxim Staritsyn∗

August 2, 2019

Abstract
The paper extends an impulsive control-theoretical framework towards dynamical systems in the space of measures. We consider a transport equation describing the time-evolution of a conservative “mass” (probability measure), which represents an infinite ensemble of interacting particles. The driving vector field contains nonlocal terms and is affine in control variable. The control is assumed to be common for all the agents, i.e., it is a function of time variable only. The main feature of the addressed model is the admittance of “shock” impacts, i.e. controls, which can be arbitrary close in their influence on each an agent to Dirac-type distributions. We construct an impulsive relaxation of this system and of the corresponding optimal control problem. For the latter we establish a necessary optimality condition in the form of Pontryagin’s Maximum Principle.

Keywords: optimal control, impulsive control, ensemble control, multi-agent systems, nonlocal transport equations, necessary optimality conditions, Pontryagin’s Maximum Principle

1 Introduction
Transport equations with nonlocal terms are extensively studied in the recent years. This is mainly inspired by the two reasons: On one hand, such equations give a natural concept of dynamical system in the space of probability measures. On the other hand, they can often be viewed as certain limits of ordinary systems describing ensembles of indistinguishable interacting “particles” (multi-agent systems), as the number of such particles tends to infinity. The latter feature entails the appearance of this sort of distributed systems when modeling collective behaviour in mathematical biology and social science [16, 17, 20, 22, 30].

Along with modeling issues, various control problems for transport equations (including optimal control and dynamic games) naturally arise. A significant progress in analysing such problems has been made in the last few years, mainly thanks to modern achievements in geometry and analysis on metric spaces of probability measures [3, 39]. The existing works are mainly concentrated in two directions: one collection of studies is devoted to necessary optimality conditions [8–10, 20, 33], another part is focused on the dynamic programming approach [5, 6, 18, 28]. In all cited papers, the driving vector field is assumed to be $L^\infty$ bounded in time variable, which makes the problem relatively regular. On the other hand, in

∗Matrosov Institute for System Dynamics and Control Theory, 134 Lermontov str., Irkutsk, 664033, Russia. Email: nickpogo@gmail.com, starmaxmath@gmail.com
†Krasovskii Institute of Mathematics and Mechanics, 16 Kovalevskay str., Yekaterinburg, 620990, Russia.
some applications it is reasonable to deal with “unbounded” vector fields (e.g., constrained in \( L^1 \)). For example, in opinion formation models [1,38], different types of “chock” events (financial defaults, acts of terrorism etc.) are sometimes unavoidable and should be taken into account. These shocks can produce “almost discontinuous” trajectories of the modeled dynamic processes; here, the reader can easily imagine (or remember) a situation when the public opinion, social environment or economic indicators change dramatically in a very short time period. Our goal is to investigate such “impulsive” phenomena in the control-theoretical context.

More precisely, we study the transport equation

\[
\partial_t \mu_t + \nabla \cdot (v_t \mu_t) = 0, \quad t \in [0,T], \quad \mu_0 = \vartheta,
\]

actuated by a nonlocal vector field

\[
v_t(x) = f_0(x) + \sum_{i=1}^m u_i(t) f_i(x) + (g \ast \mu_t)(x).
\]

Here, \( t \mapsto \mu_t \) is a one-parametric family of probability measures, \([0,T]\) is a given time interval, and \( \vartheta \) is a given initial probability measure; \( g \ast \mu \) denotes the convolution of a function \( g \) and a measure \( \mu \), defined by

\[
(g \ast \mu)(x) = \int_{\mathbb{R}^n} g(x-y) \, d\mu(y), \quad x \in \mathbb{R}^n.
\]

In the setup of multi-agent systems, \( \mu_t \) represents the portion of “individuals” occupying a subset of the state space \( \mathbb{R}^n \) at a time moment \( t \). Function \( f_0 : \mathbb{R}^n \mapsto \mathbb{R}^n \) represents the influence of the media (natural drift), \( f_i : \mathbb{R}^n \mapsto \mathbb{R}^n, \ i = 1, \ldots, m \), are control vector fields, and \( g : \mathbb{R}^n \mapsto \mathbb{R}^n \) models the communication of the agents.

Controls \( u = (u_1, \ldots, u_m) \) are chosen from the class \( \mathcal{U} \) of Borel measurable essentially bounded functions \([0,T] \mapsto \mathbb{R}^m\), which are integrally constrained by a given constant \( M > 0 \):

\[
F_{|u|}(T) = \int_0^T \sum_{i=1}^m |u_i(t)| \, dt \leq M
\]

(hereinafter, \( F_f(t) = \int_0^t f(s) \, ds \) denotes the cumulative distribution of \( f \) on \([0,T]\); we agree that \( F_{f}(0^-) = 0 \)).

This choice of the set of admissible controls leads to the ill-posedness of the model (1.1)–(1.3) in the sense that the tube of its trajectories is not closed in the space of continuous measure-valued curves, which causes, in particular, the absence of solutions to associated optimal control problems. Thus, one requires an appropriate mathematical technique for describing “limit” control processes with possibly discontinuous trajectories.

Such techniques were developed for control ODEs, whose trajectories may jump (change very fast) [12,23,30,31,35,40–42] or “vibrate” rapidly [13]. The most common approach here is based on the so-called discontinuous time reparameterization [29], which “extends” instants of jumps of a limit trajectory into intervals and associates the limit trajectory to a trajectory

\[\text{[1]} \text{Since we shall deal with different measures on } [0,T], \text{ not necessarily absolutely continuous with respect to the Lebesgue measure, we always assume all the functions Borel measurable not to care about their measurability with respect to a concrete measure.} \]
of certain auxiliary ODE (the reduced equation) “living” on the extended time scale. In turn, the reduced equation can be transformed into an object called the \emph{generalized differential equation}, which is controlled by first-order distributions (vector-valued Borel measures) and admits discontinuous trajectories of bounded variation.

In this paper, we adapt the time reparameterization approach to control system (1.1)–(1.3). As a byproduct, we construct a relaxation of the Mayer type optimal control problem

\[
\inf \left\{ \int_{\mathbb{R}^d} \ell(x) \, d\mu_T(x) \mid \mu \text{ is a trajectory of (1.1)--(1.3)} \right\}. \tag{P}
\]

This relaxation takes the form of an optimal control problem for the reduced transport equation. Its solutions, which do always exist, characterize the minimizing sequences of (P). Finally, we provide a necessary optimality condition in the form of Pontryagin’s Maximum Principle for the relaxed problem.

The study extends our recent works \cite{36, 37} to the nonlocal case.

Outline. The manuscript is organized as follows: The introductory Section 1 performs a very brief state of the art, and organization of the paper. Section 2 collects notations and a few preliminaries related to measure theory (§2.2) and nonlocal transport equations (§2.3). Section 3 is devoted to the relaxation of control system (1.1)–(1.3) and minimization problem (P). In §3.1 we establish the well-posedness (i.e. the continuous dependence of a distributional solution on both control input and initial data) of the Cauchy problem for nonlocal transport equations with bounded vector fields. Next, in §3.2 we reduce our pre-impulsive model to an auxiliary PDE with measurable uniformly bounded inputs. §3.3 exposes the actual extension of the original control system and its specification in the tradition of impulsive control theory. §3.4 discusses a representation of the impulsive control system in the case of commutative control vector fields, and §3.5 establishes the connection between the extremal problems, stated over the reduced and impulsive equations. The main result of the paper — the necessary optimality condition for the relaxed control problem in the form of Pontryagin’s Maximum Principle (PMP) — is presented in Section 4 (§4.4), preceded by some reasonings, such as the approximate PMP for the case of purely atomic initial distribution (§§4.1, 4.2) and analysis of the Hamiltonian system (§4.3). In concluding Section 5 we discuss possible applications of the obtained results to numeric analysis of ensemble and mean-field control problems and mention their natural generalizations. In order to clarify the presentation, the (most bulky) proofs of two auxiliary theorems — the well-posedness and approximate Maximum Principle — are given in Appendices A and B.

2 Preliminaries

2.1 Notations

\begin{align*}
\mathbb{N} & \quad \text{the set of positive integers} \\
\mathbb{R}^n & \quad \text{the } n\text{-dimensional arithmetic space} \\
|\cdot| & \quad \text{the Manhattan norm on } \mathbb{R}^n \\
\mathbb{R}_+ & \quad \text{the set of nonnegative reals} \\
C_c^\infty(U) & \quad \text{the space of smooth functions with compact support lying in } U \subset \mathbb{R}^m \\
\text{Lip}_\kappa(\mathbb{R}^m) & \quad \text{the space of } \kappa\text{-Lipschitz functions } \mathbb{R}^m \to \mathbb{R}, \kappa \geq 0 \\
C^0(\mathbb{R}^m; \mathbb{R}^n) & \quad \text{the space of continuous functions } \mathbb{R}^m \to \mathbb{R}^n \\
C^1(\mathbb{R}^m; \mathbb{R}^n) & \quad \text{the space of continuously differentiable functions } \mathbb{R}^m \to \mathbb{R}^n
\end{align*}
2.2 Facts from measure theory

Recall that $\mathcal{P}_1$ is the set composed of all measures with finite first moment, i.e., such that

$$\int_{\mathbb{R}^n} |x| \, d\mu(x) < \infty.$$  

This set admits a natural structure of complete separable metric space \cite{39} when it is endowed with the so-called Wasserstein distance $W_1$ defined through the Kantorovich norm (see \cite{7}) as follows

$$W_1(\mu, \nu) = \|\mu - \nu\|_K = \sup \left\{ \int_{\mathbb{R}^n} \varphi \, d(\mu - \nu) : \varphi \in \text{Lip}_1(\mathbb{R}^n) \right\}.$$  

We always assume that $\mathcal{P}_1$ is equipped with the metric $W_1$. Remark that $\mu^j \to \mu$ in $\mathcal{P}_1$ iff

$$\int \varphi \, d\mu^j \to \int \varphi \, d\mu,$$

for all sublinear continuous functions $\varphi : \mathbb{R}^n \to \mathbb{R}$, i.e., continuous functions such that $|\varphi(x)| \leq C(1 + |x|)$ for some $C > 0$ (see \cite{39} Chapter 6).

Given a probability measure $\mu$ on $\mathbb{R}^m$ and a Borel measurable $F : \mathbb{R}^m \to \mathbb{R}^n$, the push-forward of $\mu$ through $F$, denoted by $F_\# \mu$, is a probability measure on $\mathbb{R}^n$ such that

$$F_\# \mu(E) = \mu(F^{-1}(E))$$

for any Borel $E \subset \mathbb{R}^n$.

For any $F_\# \mu$-integrable function $\varphi : \mathbb{R}^n \to \mathbb{R}$, the following change of variables formula holds:

$$\int_{\mathbb{R}^n} \varphi(y) \, dF_\# \mu(y) = \int_{\mathbb{R}^m} (\varphi \circ F)(x) \, d\mu(x).$$

Given an abstract metric space $\mathcal{X} = (\mathcal{X}, d)$ and a closed interval $[0, T] \subset \mathbb{R}_+$, a function $F : \mathbb{R} \to \mathcal{X}$ is said to have bounded variation (BV) on $[0, T]$ iff

$$\text{Var}_{[0,T]} F = \sup \sum_{i=1}^{N-1} d(F_{t_i}, F_{t_{i+1}}) < \infty,$$
where sup is taken over all finite partitions \( \{t_i\}_{i=0}^{N} \subset [0,T] \), \( t_i < t_{i+1}, t_0 = 0, t_N = T \) of \([0,T]\). Note that, for any \( BV \) function \( F_{(\cdot)} \), the set \( \Delta_F \subset [0,T] \) of its discontinuity points ("jump points") is at most countable.

On the set \( BV_+([0,T];\mathcal{X}) \) of right continuous \( BV \) functions we introduce the following notion of convergence: \( F_k \to F \) iff \( F_k(t) \to F(t) \) at all continuity points of \( F \) and at the boundary points of the interval \([0,T]\). In the special case where \( \mathcal{X} = \mathbb{R} \) and all \( F_k \) are monotone, the convergence \( F_k \to F \) is equivalent to the weak convergence of the respective (nonnegative or nonpositive) Lebesgue-Stieltjes measures \( dF_k \to dF \).

Finally, recall that any \( F \in BV_+([0,T];\mathbb{R}^n) \) admits a unique Lebesgue decomposition \( F = F_c + F_d \equiv F_{ac} + F_{sc} + F_d \), where \( F_{ac} \) and \( F_{sc} \) are the absolutely continuous and singular continuous (with respect to \( L^1 \)) functions, and \( F_d \) is the sum of jumps \( F(\tau) - F(\tau^-), \tau \in \Delta_F \).

2.3 Basic assumptions

In what follows, we accept the standard structural hypotheses

(A1) There exist \( C, L > 0 \) such that

\[
\sum_{i=0}^{m} \left| f_i(x) \right| + g(x) \leq C \quad \text{for all } x \in \mathbb{R}^n, \text{ and }
\]

\[
\sum_{i=0}^{m} \left| f_i(x^1) - f_i(x^2) \right| + \left| g(x^1) - g(x^2) \right| \leq L |x^1 - x^2| \quad \text{for any } x^1, x^2 \in \mathbb{R}^n.
\]

These assumptions guarantee that (1.1), (1.2) admits a unique solution, for any \( u \in L^\infty([0,T];\mathbb{R}^m) \) and \( \vartheta \in \mathcal{P}_1 \) (see [22] or Theorem 3.1 below). Recall that solutions of (1.1), (1.2) shall be understood in the weak sense, i.e., as absolutely continuous curves \( \mu: [0,T] \to \mathcal{P}_1 \) satisfying the relations: \( \mu_0 = \vartheta \),

\[
\int_0^T \int_{\mathbb{R}^n} \left( \partial_t \varphi(t,x) + \left( v_i(t,x), \nabla_x \varphi(t,x) \right) \right) \, d\mu_t(x) \, dt = 0
\]

for all \( \varphi \in C_c^\infty((0,T) \times \mathbb{R}^n) \), and (1.2) for all \( x \in \mathbb{R}^n \) and a.e. \( t \in [0,T] \).

We abbreviate system (1.1)–(1.3) as (S), and denoted the set of its distributional solutions by \( \mathcal{M} \). Here, we shall stress again that the set \( \mathcal{M} \) of all such curves is not closed inside \( C^0([0,T];\mathcal{P}_1) \). Indeed, put \( f_0 = g = 0, f_j = 1, j = \overline{1,m}, \vartheta = \delta \), and take a sequence \( \{u_k\} \subset \mathcal{U} \) such that \( u_k \mathcal{L}^n \to \delta \) narrowly. Then the respective trajectories of (1.1) converge to a discontinuous function, which is not admitted by (S).

3 Impulsive relaxation

The forthcoming construction of a desired relaxation relies on the discontinuous time reparameterization technique [29], which is a standard workhorse of the finite-dimensional impulsive

\footnote{This convergence is well-defined. Indeed, let \( F', F'' \in BV_+ \) be such that \( F_k \to F' \) and \( F_k \to F'' \). By the definition of \( \to \), \( F'(t) = F''(t) \) as soon as \( t \in [0,T] \) or \( t \in (0,T) \) is a continuity point of both \( F' \) and \( F'' \). Fixed an arbitrary \( \tau \in (0,T) \), consider a sequence of points \( t_j \in (0,T) \) such that \( t_j > \tau \), \( \lim_{j \to \infty} t_j = \tau \), and \( t_j \) are continuity points of both \( F' \) and \( F'' \) (such a sequence does exist because the set of continuity points of a \( BV \)-function is dense in \( (0,T) \)). Since both \( F' \) and \( F'' \) are right continuous, and \( F'(t_j) = F''(t_j) \) for all \( t_j \), we have that \( F'(\tau) = \lim_{j \to \infty} F'(t_j) = \lim_{j \to \infty} F''(t_j) = F''(\tau) \). Thus, \( F' = F'' \) on the whole \([0,T] \).}
control theory, first adapted to the framework of transport equations in [36]. Such a reparametrization reduces system \((S)\), driven by an “unbounded” vector field \(v\), to an auxiliary PDE, actuated by another control-affine vector field \(w\) with geometrically constrained inputs. In view of this, prior to the announced time reparameterization, we establish the well-posedness of solutions to a certain general nonlocal transport equation, controlled by uniformly bounded input signals.

### 3.1 Bounded controls: well-posedness

Consider a general nonlocal transport equation

\[
\partial_t \mu_t + \nabla \cdot \left( V[\mu_t, u(t)] \mu_t \right) = 0, \quad t \in [0, T], \quad \mu_0 = \vartheta,
\]

where \(V: P_1 \times \mathbb{R}^m \to C^0(\mathbb{R}^n; \mathbb{R}^n)\) is a function which maps states and control parameters to vector fields. Note that the choice \(V[\mu, v] = f_0 + \sum_{i=1}^m v_i f_i + g \ast \mu\) boils equation (3.1) down to (1.1), (1.2).

Here we assume that the controls \(u\) are taken from the class \(\tilde{U} \cong \mathcal{L}^\infty([0, T]; U)\) produced by a compact convex set \(U \subset \mathbb{R}^m\), which means that \(\tilde{U}\) is bounded in \(\mathcal{L}^\infty\), in contrast to \(U\).

**Theorem 3.1.** Suppose that \(V\) meets the following assumptions:

1. There exist \(C, L > 0\) such that, for all \(x, x' \in \mathbb{R}^n\), \(\mu, \mu' \in P_1\), and \(v \in U\), one has
   \[
   |V[\mu, v](x)| \leq C(1 + |x|), \quad |V[\mu, v](x) - V[\mu, v](x')| \leq L |x - x'|, \quad |V[\mu, v](x) - V[\mu', v](x)| \leq L \|\mu - \mu'\|_K.
   \]

2. For any curve \(\mu \in C^0([0, T]; P_1)\) and any \(u \in \tilde{U}\), the time dependent vector field \(v\) constructed by the rule \(v_t \equiv V[\mu_t, u(t)]\) is measurable in \(t\). Moreover, \(u^k \overset{K}{\to} u\) implies \(v^k_t(x) \overset{K}{\to} v_t(x)\) for any \(x\), whenever \(u^k \in \tilde{U}\), \(v^k_t \equiv V[\mu^k_t, u(t)]\), and \(k \in \mathbb{N}\).

Then, for any \(u \in \tilde{U}\) and \(\vartheta \in P_1\), equation (3.1) has a unique solution \(\mu[u, \vartheta]\). Furthermore, the map \((u, \vartheta) \mapsto \mu[u, \vartheta]\) is continuous as a function \(\tilde{U} \times P_1 \to C^0([0, T]; P_1)\), where \(\tilde{U}\) is equipped with the weak-* topology of \(\mathcal{L}^\infty\).

The proof of Theorem 3.1 is rather standard, so we defer it to Appendix A.

For each \(N \in \mathbb{N}\), define the map \(f_N: \mathbb{R}^{(N+1)n} \times U \to \mathbb{R}^n\) as follows:

\[
f_N(x, y_1, \ldots, y_N, v) = V \left( \frac{1}{N} \sum_{j=1}^N \delta_{y_j}, v \right)(x), \quad v \in U, \quad x, y_j \in \mathbb{R}^n, \quad j = 1, N.
\]

By the first assumption of Theorem 3.1 \(f_N\) is sublinear and Lipschitz in \(x\) and all \(y_j\) with some constant independent of \(N\), while, thanks to the second assumption, the map \(t \mapsto f_N(x, y_1, \ldots, y_N, u(t))\) is measurable for any \(u \in \tilde{U}\). Furthermore, one can note that \(f_N\) is symmetric in \(y_j\), that is

\[
f_N(x, y_{\sigma(1)}, \ldots, y_{\sigma(N)}, v) = f_N(x, y_1, \ldots, y_N, v),
\]
for any permutation \( \sigma \) of \( \{1, \ldots, N\} \). Hence, the following system of ODEs

\[
\dot{x}_k(t) = f_N \left( x_k(t), x_1(t), \ldots, x_N(t), u(t) \right), \quad k = 1, N, \tag{3.2}
\]
is well-defined in the sense that it has a unique solution for any initial point \((x_0^0, \ldots, x_N^0)\).

**Proposition 3.2** (Discrete initial data). Under the assumptions of Theorem 3.1, the solution of (3.1) corresponding to the initial measure \( \mu^N \) takes the form

\[
\mu_t^N \left[ u, \vartheta^N \right] = \frac{1}{N} \sum_{k=1}^N \delta_{x_k(t)}, \quad t \in [0, T],
\]

where \((x_1(\cdot), \ldots, x_N(\cdot))\) satisfies (3.2) with initial conditions \(x_k(0) = x_k^0, k = 1, N\).

The proof of Proposition 3.2 is given in Appendix A as well.

**Remark 3.3.** In view of Theorem 3.1 and Proposition 3.2 one can consider (3.1) as a limit form of (3.2) as \( N \to \infty \). Indeed, for any fixed \( u \in \mathcal{U} \), the ODE (3.2) allows to construct \( \vartheta^N \) and \( \mu^N \) in the way of Proposition 3.2. Now, suppose that \( \vartheta^N \) converges in the weak*-topology to some \( \vartheta \in \mathcal{P}_1 \). Then, by Theorem 3.1, \( \mu^N \) converges uniformly to \( \mu[u, \vartheta] \), i.e., to the unique solution of (3.1) corresponding to the initial measure \( \vartheta \).

### 3.2 Unbounded controls: time rescaling and system relaxation

Consider the following reduced control continuity equation \((\hat{S})\), “living” in the extended time scale \([0, S], S = T + M:\)

\[
\begin{align*}
\partial_s \nu_s + \nabla \cdot (w_s \nu_s) &= 0, & s \in [0, S], & \nu_0 = \vartheta, \\
w_s(x) &= \alpha(s) \left( f_0(x) + (g * \nu_s)(x) \right) + \sum_{i=1}^m f_i(x) \beta_i(s),
\end{align*}
\]

\[(\alpha, \beta) \in \hat{\mathcal{U}}, & \quad \beta = (\beta_1, \ldots, \beta_m), \tag{3.3}
\]

\[
\hat{\mathcal{U}} \doteq \left\{ (\alpha, \beta) \in \mathbf{L}^\infty([0, S]; \mathcal{A}) : \int_0^S \alpha(s) \mathrm{d}s = T \right\},
\]

\[A \doteq \left\{ (a, b) \in \mathbb{R}^{1+m} : a \geq 0, a + \sum_{j=1}^m |b_j| \leq 1 \right\}.\]

**Remark 3.4.** As is easily checked, the map \( V[\nu, \vartheta] = \alpha(f_0 + g * \nu) + \sum_{i=1}^m f_i \beta_i \) with \( \nu = (\alpha, \beta), \) satisfies all the assumptions of Theorem 3.1. According to this theorem, for each \((\alpha, \beta) \in \hat{\mathcal{U}} \) and \( \vartheta \in \mathcal{P}_1 \), equation (3.3), (3.4) has a unique solution \( \nu[\alpha, \beta, \vartheta] \). Moreover, the map \((\alpha, \beta, \vartheta) \mapsto \nu[\alpha, \beta, \vartheta] \) is continuous as a function \( \hat{\mathcal{U}} \times \mathcal{P}_1 \hookrightarrow \mathbf{C}^0([0, S]; \mathbb{R}^m) \) when \( \hat{\mathcal{U}} \) is equipped with the weak*-topology. In other words, control system \((\hat{S})\) is well-posed.

The original system \( (S) \) is naturally embedded in \((\hat{S})\) by the change of variable \( t = \xi(s) \), where \( \xi \) is the inverse of

\[
\Xi(t) \doteq t + \int_0^t \sum_{i=1}^m |u_i(s)| \mathrm{d}s, \quad t \in [0, T].
\]
Indeed, setting

\[ \alpha(s) = \frac{1}{1 + \sum_{i=1}^m |u_i(t)|} \left. \frac{d}{ds} \xi(s) \right|_{t = \xi(s)} \quad \text{and} \quad \beta_i(s) = \frac{u_i(t)}{1 + \sum_{i=1}^m |u_i(t)|} \left. \frac{d}{ds} \xi(s) \right|_{t = \xi(s)}, \]

one observes that \((\alpha, \beta) \in \hat{U}\), more precisely, \(\alpha > 0\) and \(\alpha + \sum_{j=1}^m |\beta_j| = 1\) \(L^1\)-a.e. on \([0, S]\). Furthermore, suppose that \((\mu, u)\) and \((\nu, \alpha, \beta)\) are related by (3.6) and \(\nu_s = \mu_{\xi(s)}\). Then \((\mu, u)\) satisfies (S) iff \((\nu, \alpha, \beta)\) satisfies (3.3), (3.4) (see, e.g., [2]). Note that \(\xi\) meets

\[ \xi(s) = \int_0^s \alpha(s) \, d\zeta, \quad s \in [0, S], \]

and \(\xi(S) = T\).

Taken an arbitrary control \((\alpha, \beta) \in \hat{U}\), define \(\xi = \xi[\alpha]\) by (3.7). Now, the function \(t \mapsto \xi(t)\) is not strictly monotone anymore, and its inverse \(\Xi = \xi^{-1}\) is undefined. Still, one can introduce the pseudo-inverse \(\xi^{-}\) of \(\xi\) as

\[ \xi^{-}(t) = \begin{cases} \inf \left\{ s \in [0, S] : \xi(s) > t \right\}, & t \in [0, T), \\ S, & t = T. \end{cases} \]

The following assertion claims that, along with control processes of (S), reduced system \((\hat{S})\) also describes all their limits if the convergence is understood in an appropriate sense.

**Theorem 3.5.** Suppose that a sequence \((\mu^k, u^k)\) of control processes of (S) converges to some \((\mu, \Omega) \in BV_+([0, T]; \mathcal{P}_1) \times BV_+([0, T]; \mathbb{R}^m)\) in the sense that \(\mu^k \to \mu\) and \(F_{\nu^k} \to \Omega\). Let \((\nu^k, \alpha^k, \beta^k)\) be the control processes of \((\hat{S})\) associated with \((\mu^k, u^k)\), i.e., \((\alpha^k, \beta^k)\) are defined by (3.6) with \(u = u^k\), and \(\nu^k\) is the corresponding solution of (3.3), (3.4). Then

1. the sequence \((\nu^k, \alpha^k, \beta^k)\) has at least one cluster point \((\nu, \alpha, \beta)\) in \(C^0([0, T]; \mathcal{P}_1) \times L_w^\infty([0, T]; \mathbb{R}^{m+1})\);
2. each cluster point \((\nu, \alpha, \beta)\) is a control process of \((\hat{S})\);
3. each cluster point \((\nu, \alpha, \beta)\) satisfies the following identities:

\[ \mu_t = \nu_{\xi^{-}(t)}, \quad \Omega(t) = \int_0^{\xi^{-}(t)} \beta(s) \, ds, \quad t \in [0, T], \]

where \(\xi\) is defined by (3.7).

**Proof.** Since \(\hat{U} \subset L^\infty\) is closed and convex, it is also closed in the weak (and thus in the weak-* topology of \(L^\infty\)). Now, it follows from the Banach-Alaoglu theorem that \(\hat{U}\) is compact in \(L^\infty\). This fact and the continuity of the input-output map \((\alpha, \beta) \mapsto \nu[\alpha, \beta, \vartheta]\) imply assertions (1) and (2).

Let us prove assertion (3). Without loss of generality, we can assume that \((\nu^k, \alpha^k, \beta^k)\) converges to \((\nu, \alpha, \beta)\). Consider the distribution functions \(\xi^k, \zeta^k, \xi, \zeta\) of controls \(\alpha^k, \beta^k, \alpha, \beta\), and denote by \(\Xi^k\) the inverse of \(\xi^k\). In view of (3.3), one has

\[ \zeta^k(\Xi^k(t)) = \int_0^{\Xi^k(t)} \beta^k(s) \, ds = \int_0^{\Xi^k(t)} \frac{\beta^k(s)}{\alpha^k(s)} \frac{d\xi^k(s)}{ds}. \]
By assumptions of the theorem, \( F_{\nu_k} \to \mu \). Now, the convergence \( \zeta^k \circ \Xi^k \to \zeta \circ \xi^\to \) would imply the identity \( \Omega(t) = \int_0^{\xi^\to(t)} \beta(s) \, ds \). Analyzing the inequality
\[
\left| \zeta^k \circ \Xi^k(t) - \zeta \circ \xi^\to(t) \right| \leq \left| \zeta^k \circ \Xi^k(t) - \zeta \circ \Xi^k(t) \right| + \left| \zeta \circ \Xi^k(t) - \zeta \circ \xi^\to(t) \right|,
\]
we conclude that, after passing to the limit, the first term from the right-hand side vanishes because \( \zeta^k \to \zeta \) uniformly, while the second term vanishes at all continuity points of \( \xi^\to \) and at \( T \) since \( \Xi^k \to \xi^\to \) due to [29] Lemma 2.5. This gives \( \zeta^k \circ \Xi^k \to \zeta \circ \xi^\to \).

Since \( \xi^\to \) is right continuous and \( \text{BV} \), we deduce that \( \nu_{\xi^\to} \in \text{BV}_+([0,T];P_1) \) and it has the same set of continuity points as \( \xi^\to \). It remains to show that \( \mu^k \to \nu_{\xi^\to} \). To this end, recall that \( \mu_t^k = \nu_{\Xi_k(t)}^k \) and consider the inequality
\[
\left\| \nu_{\Xi_k(t)}^k - \nu_{\xi^\to(t)} \right\|_K \leq \left\| \nu_{\Xi_k(t)}^k - \nu_{\Xi(t)} \right\|_K + \left\| \nu_{\Xi(t)} - \nu_{\xi^\to(t)} \right\|_K.
\]
Again, passing to the limit as \( k \to \infty \), the first term in the right-hand side tends to zero because \( \nu^k \to \nu \) uniformly (this follows from Theorem 3.1 applied to \( \hat{S} \)), and the second term tends to zero at all points of continuity of \( \nu_{\xi^\to} \) since \( \Xi^k \to \xi^\to \).

**Remark 3.6.** (i) Any sequence \( (\mu^k, u^k) \) of control processes of \( S \) contains a subsequence converging to some \( (\mu, \Omega) \) in the sense of Theorem 3.5.

(ii) The sequence \( (\nu^k, \alpha^k, \beta^k) \) may contain many cluster points. But all of them are “projected” by the discontinuous time change \( \xi^\to \) to the same point \( (\mu, \Omega) \).

The next result can be considered as an inverse of Theorem 3.5.

**Theorem 3.7.** Let \( (\nu, \alpha, \beta) \) be a control process of the reduced system \( \hat{S} \). Then the pair \( (\mu, \Omega) \) defined by (3.8) is a limit point for some sequence \( (\mu^k, u^k) \) of control processes of \( S \).

**Proof.** One just needs to approximate \( (\alpha, \beta) \) in \( L_\infty^w \) by a sequence \( (\alpha^k, \beta^k) \in \hat{U} \) satisfying \( \alpha^k > 0 \) \( L^1 \)-a.e. on \([0,S]\), and recruit the same arguments as in proof of Theorem 3.7. An appropriate approximation can be designed as in [29] Proof of Lemma 5.2. \( \square \)

### 3.3 Impulsive control theory formalism

The following definition, extending [30], is an infinite-dimensional version of the notion [29] of generalized solution to a control system:

**Definition 3.8.** A function \( \mu \in \text{BV}_+([0,T];P_1) \) is called a generalized solution of \( S \) if there is a sequence \( \{\mu^k\} \subset M \) such that \( \mu^k \to \mu \).

\footnote{Indeed, by the classical Helly’s selection principle, \( \{F_{\nu_k}\} \) contains a subsequence \( \{F_{\nu_{k_j}}\} \) converging pointwise to a \( \text{BV} \) function \( F \). By changing \( F \) at its discontinuity points, we obtain a right continuous function \( \Omega \) such that \( F_{\nu_{k_j}} \to \Omega \). Consider the sequence \( (\alpha^k, \beta^k, \mu^k) \) of control processes of \( \hat{S} \) associated to \( (\mu^k, u^k) \). Theorem 3.5 says that there is a cluster point \( (\nu, \alpha, \beta) \) being a control process of \( \hat{S} \). Recalling the arguments from the proof of assertion (3) of Theorem 3.5 one ensures that \( \mu^k \to \nu_{\xi^\to} \). It remains to define \( \mu \) by (3.8).}
The set of generalized solutions is denoted by $\overline{\mathcal{M}}$. By construction, this is the sequential closure of $\mathcal{M}$ in $\left(\mathbf{BV}_+(\,[0,T]\,; \mathcal{P}_1), \to \right)$. Moreover, Theorems 3.5 and 3.7 say that the trajectories of the reduced system $(\dot{S})$, after an appropriate discontinuous time reparameterization, produce exactly the set $\overline{\mathcal{M}}$.

Below, we obtain an alternative representation of $\overline{\mathcal{M}}$ through a specific impulsive system on $\mathcal{P}_1$, i.e., a “measure-driven equation in the space of measures” (see equation (3.11)).

Consider a generalized solution $\mu$ produced by a sequence $\{\mu^k\} \subset \mathcal{M}$ of admissible arcs of $(S)$. Let $\{u^k\} \subset \mathcal{U}$ be the corresponding control sequence. We can always assume that cumulative distributions $\{F_{u^k}, F_{u^k}\}$ converge in $\left(\mathbf{BV}_+(\,[0,T]\,; \mathbb{R}^{m+1}), \to \right)$ to a function $(\Omega, \mathfrak{U}, \mathfrak{F})$ and agree that $(\Omega, \mathfrak{U}, \mathfrak{F})$ and that $(\Omega, \mathfrak{U}, \mathfrak{F}) - \mathfrak{U}(\mathfrak{F}) \neq 0$. Note that $|\Omega| \leq \mathfrak{U}$ (not necessarily “=”), and $\mathfrak{U}(T) \leq M$.

**Proposition 3.9.** Let $\mu$ be a generalized solution produced by a control sequence $\{u^k\} \subset \mathcal{U}$, and $(F_{u^k}, F_{u^k}) \to (\Omega, \mathfrak{U})$. Assume that $\mathfrak{U}^\infty = 0$, and (at most countable) set $\Delta_\mathfrak{U} = \{\tau \in [0,T] : \mathfrak{U}(\tau) - \mathfrak{U}(\tau^-) \neq 0\}$ is naturally ordered, i.e., $\Delta_\mathfrak{U} = \{0 \leq \tau_1 < \tau_2 < \ldots < \tau_j < \tau_j+1 < \ldots \leq T\}$. Then there exist

- measurable functions $u^\tau_i : [0,T] \to \mathbb{R}, \tau \in \Delta_\mathfrak{U}, i = 1, m, T \supseteq \mathfrak{U}(\tau) - \mathfrak{U}(\tau^-),$ satisfying
  \[
  \sum_{i=1}^{m} |u^\tau_i| = 1; \quad \int_0^{T_\tau} u_i(\xi) \, d\xi = \mathfrak{U}(\tau) - \mathfrak{U}(\tau^-), \quad i = 1, m, \]  \[ (3.9) \]

- absolutely continuous curves $m^\tau : [0,T] \to \mathcal{P}_1$ with the property
  \[
  m^\tau_0 = \mu_{\tau^-}, \quad m^\tau = \mu_{\tau}, \quad \tau \in \Delta_\mathfrak{U}, \]  \[ (3.10) \]

such that $\mu$ satisfies the following equation

\[
0 = \int_0^{T_\tau} \int_{\mathbb{R}^n} \left( \partial_t \varphi(t, x) + \left[ f_0(x) + \sum_{i=1}^{m} u^\tau_i(t) f_i(x) \right] \nabla \varphi(t, x) \right) \, d\mu_i(x) \, dt \]
\[
+ \sum_{\tau \in \Delta_\mathfrak{U}} \int_0^{T_\tau} \int_{\mathbb{R}^n} \left( \partial_\tau \varphi^\tau(\xi, x) + \left[ \sum_{i=1}^{m} u^\tau_i(\xi) f_i(x) \right] \nabla \varphi^\tau(\xi, x) \right) \, dm^\tau_i(x) \, d\xi \]  \[ (3.11) \]

for all collections $\Phi = (\varphi, \{\varphi^\tau\}_{\tau \in \Delta_\mathfrak{U}})$ of test functions $\varphi : (0,T) \times \mathbb{R}^n \to \mathbb{R}, \varphi^\tau : [0,T_\tau] \times \mathbb{R}^n \to \mathbb{R}, \tau \in \Delta_\mathfrak{U}$, with the properties:

- $\varphi$ is right continuous in $t$ for all $x \in \mathbb{R}^n$, and is $C^\infty_c$ on each $(\tau_j, \tau_{j+1}) \times \mathbb{R}^n$;
- all $\varphi^\tau, \tau \in \Delta_\mathfrak{U}$, are $C^\infty_c$ on the respective sets $(0, T_\tau) \times \mathbb{R}^n$, and
- $\varphi(\tau^-, x) = \varphi^\tau(0, x)$ and $\varphi(\tau, x) = \varphi^\tau(T_\tau, x)$, for all $\tau \in \Delta_\mathfrak{U}$ and $x \in \mathbb{R}^n$.

\[ ^4 \text{Again, if it is not the case, we can pass to a pointwise converging subsequence of} \{F_{(u^k, u^k)}\}, \text{ whose existence is guaranteed by the Helly’s selection principle, and make it right continuous.} \]

\[ ^5 \text{The natural ordering of jump points of} \mathfrak{U}, \text{ as well as the triviality of the singular continuous part} \mathfrak{U}^\infty, \text{ are rather artificial assumptions, which are hard to be guaranteed a priori. Meanwhile, this situation takes place in all known to us applications of impulsive control theory (see e.g. [12, 23, 24, 12]).} \]
**Proof.** In accordance with Theorem 3.3, there exist a control process \((\nu, \alpha, \beta)\) of \((\hat{S})\) such that \((\mu, \Omega, \mathcal{V})\) are related to \((\nu, \alpha, \beta)\) by the formulas

\[
\mu(t) = \nu_{\xi^{-}(t)} = \Upsilon(t) = \int_0^{\xi^{-}(t)} \beta(s) \, ds, \quad \Omega(t) = \int_0^{\xi^{-}(t)} |\beta(s)| \, ds, \quad \xi(s) = \int_0^s \alpha(\zeta) \, d\zeta.
\]

We observe that \(\Upsilon\) and \(\Omega\) are combinations of a continuous function (the Lebesgue integral of a measurable function with variable upper limit) and a \(BV\) function \(\xi^{-}\), which implies that \(\Delta_{\Upsilon} = \Delta_{\Omega} \subseteq \Delta_{\xi^{-}}\), and the (possibly, trivial) jumps of \(\Upsilon\) and \(\Omega\) at points \(\tau \in \Delta_{\xi^{-}}\) are calculated as follows:

\[
\Upsilon(\tau) = \Upsilon(\tau^{-}) = \int_{\xi^{-}(\tau^{-})}^{\xi^{-}(\tau)} \beta(s) \, ds, \quad \Omega(\tau) = \Omega(\tau^{-}) = \int_{\xi^{-}(\tau^{-})}^{\xi^{-}(\tau)} |\beta(s)| \, ds.
\]

At the same time, by the definition of \(\xi^{-}\), its jumps correspond to disjoint closed intervals \([\xi^{-}(\tau^{-}), \xi^{-}(\tau)]\) of constancy of \(\xi\).

In view of the assumption \(\Omega^{ac} = 0\) (which immediately implies \(\Upsilon^{ac} = 0\)), we find out that there could be no set \(\Omega \subset [0, S]\) satisfying the following three conditions: i) \(\Omega\) is nowhere dense, ii) \(\alpha = 0 = L^1\)-a.e. on \(\Omega\), and iii) \(L^1(\Omega \cap spt(\beta)) > 0\).

Let \(\mathcal{S}\) denote the maximal in inclusion (existing due Zorn’s lemma) subset of \([0, S]\) with properties i), ii), on which \(\alpha = |\beta| = 0 = L^1\)-a.e. Since the vector field \(w_{\delta}\) of the reduced system \((\hat{S})\) is linear in \((\alpha, \beta)\), we have \(w_{\delta} = 0\) for \(L^1\)-a.e. \(s \in \mathcal{S}\). Hence, the corresponding solution \(s \mapsto \nu_{\nu}[\alpha, \beta, \vartheta]\) stays in rest along \(\mathcal{S}\). This means that we can exclude \(\mathcal{S}\) by an appropriate time rescaling such that the respective measure-valued arc remains continuous, or just assume \(\mathcal{S} = \emptyset\).

Now, the set \(\{s \in [0, S] : \alpha = 0\}\) is nothing more than the unification of intervals \([\xi^{-}(\tau^{-}), \xi^{-}(\tau)]\) over \(\tau \in \Delta_{\xi^{-}}\), up to an \(L^1\)-null set. Therefore, the remaining continuous part \(\Upsilon^c = \Upsilon^{ac}\) of \(\Upsilon\) is represented as

\[
\Upsilon^{ac}(t) = \int_0^{\xi^{-}(t)} \chi_{\{\alpha > 0\}}(s) \beta(s) \, ds
\]

(\(\chi_{\{\alpha > 0\}}\) stands for the characteristic function of the set \(\{s \in [0, S] : \alpha(s) > 0\}\), with a certain fixed representative of \(\alpha\), and the classical Lebesgue theorem on the change of variables under the sign of the Lebesgue-Stieltjes integral gives:

\[
\Upsilon^{ac}(t) = \int_0^{\xi^{-}(t)} \beta(s) \alpha(s)^\oplus (\chi_{\{\alpha > 0\}}(s) \alpha(s)) \, ds = \int_0^{\xi^{-}(t)} \beta(s) \alpha(s)^\oplus \, d\xi(s)
\]

\[
= \int_0^t (\beta \alpha)^\oplus |_{s=\xi^{-}(\zeta)} \, d\zeta \Leftrightarrow \Upsilon^{ac} = (\beta \alpha)^\oplus \circ \xi^{-}. \tag{3.12}
\]

Here, the operation \(\oplus\) is defined as follows: \(a^\oplus = \begin{cases} a^{-1}, & \text{if } a \neq 0, \\ 0, & \text{if } a = 0. \end{cases}\)

Now, the definition of the distributional solution writes

\[
0 = \int_0^S \int_{\mathbb{R}^n} \left( \partial_s \psi(s, x) + \left( \alpha(s) f_0(x) + \sum \beta_i(s) f_i(x), \nabla \psi(s, x) \right) \right) \, d\nu_s(x) \, ds = I_1 + \sum_{\tau \in \Delta_{\Omega}} I_2^\tau.
\]

11
where
\[ I_1 = \int_0^T \mathcal{I}(s) \chi_{\{s > 0\}}(s) \alpha(s) \, ds, \quad \mathcal{I}(s) = \int_{\mathbb{R}^n} q(s, x) \, d\nu_s(x), \]

\[ q(s, x) = \partial_s \psi(s, x) + \left( f_0(x) + \sum \beta_i(s) \alpha(s) f_i(x), \nabla \psi(s, x) \right) \]

(again, \((\alpha, \beta)\) is an arbitrary fixed representative), and
\[ I_2^\tau = \int_{\xi^-(-\tau)}^{\xi^+(-\tau)} \int_\mathbb{R}^n \left( \partial_s \psi(s, x) + \left( \sum \beta_i(s) f_i(x), \nabla \psi(s, x) \right) \right) \, d\nu_s(x) \, ds. \]

By the change of variable \( s = \xi^+(t) \) we derive:
\[ I_1 = \int_0^{\xi^+(T)} \mathcal{I}(s) \, d\xi(s) = \int_0^T \mathcal{I}\left(\xi^+(t)\right) \, dt. \]

Let \( \varphi(t, x) = \psi\left(\xi^+(t), x\right) \), for all \( t \in (0, T) \) and \( x \in \mathbb{R}^n \), and note that, on \( \{ s \in [0, S] : \alpha(s) > 0 \} \), it holds
\[ q(s, x) = \frac{\partial}{\partial s} \psi(s, x) + \left( f_0(x) + \sum \hat{\beta}^c(s) f_i(x), \nabla \psi(s, x) \right), \]

while \( \partial_t \varphi(t, x) = \frac{d}{dt} \psi\left(\xi^+(t), x\right) = \frac{\partial}{\partial s} \psi(s, x) \bigg|_{s=\xi^+(t)} \) and \( \nabla \varphi(t, x) = \nabla \psi(s, x) \bigg|_{s=\xi^+(t)} \).

In view of [8,12], we come to the representation
\[ I_1 = \int_0^T \int_{\mathbb{R}^n} \left( \partial_t \varphi(t, x) + \left( f_0(x) + \sum \hat{\beta}^c(t) f_i(x), \nabla \varphi(t, x) \right) \right) \, d\mu(t) \, dt. \]

Set \( v(s) = \int_0^s |\beta(\varsigma)| \, d\varsigma, \) \( \Upsilon^\tau(\varsigma) = \inf\{ s : v(s) - \mathcal{W}(\tau^-) > \varsigma \} = \psi\left(\Upsilon^\tau(\varsigma), x\right), \) for all \( \varsigma \in [0, T_\tau] \) and \( x \in \mathbb{R}^n \). As is simply checked, the collection \( \Phi = (\varphi, \left\{ \varphi^\tau \right\}_{\tau \in \Delta_0}) \) meets all the hypotheses of the theorem.

Introduce functions \( u_i^\tau, i = 1, m, \tau \in \Delta_0, \) as \( u_i^\tau = (\beta_i |\beta|^{\circ}) \circ \Upsilon^\tau, \) and curves \( \varsigma \mapsto m_i^\tau, \tau \in \Delta_0, \) by compositions \( m_i^\tau = \nu^\tau(\varsigma), \varsigma \in [0, T_\tau]. \) Clearly, \( m_i^\tau \equiv \nu^\tau(\tau^-) \equiv \mu_\tau \) and \( m_i^{\tau_-} \equiv \nu^{\tau^-}(\tau^-) \equiv \mu_\tau \) by construction.

Substitution \( \varsigma = v(s) - \mathcal{W}(\tau^-) \) maps \( [\xi^-(\tau^-), \xi^+(\tau^-)] \) to \([0, T_\tau],\) and its pseudo-inverse \( s = \Upsilon^\tau(\varsigma) \) gives:
\[ I_2^\tau = \int_{\Upsilon^\tau(0)}^{\Upsilon^\tau(T_\tau)} \mathcal{I}(s) \, ds = \int_0^{T_\tau} \mathcal{I}\left(\Upsilon^\tau(\varsigma)\right) \, d\left(\Upsilon^\tau\right)^{-1}(\varsigma) = \int_0^{T_\tau} \mathcal{I}\left(\Upsilon^\tau(\varsigma)\right) \left|\beta(\varsigma)\right|^{\circ} \bigg|_{s=\Upsilon^\tau(\varsigma)} \, d\varsigma, \]

where
\[ \mathcal{I}(s) = \int_{\mathbb{R}^n} \left( \partial_s \psi(s, x) + \left( \sum \beta_i(s) f_i(x), \nabla \psi(s, x) \right) \right) \, d\nu_s(x). \]

Again, noted that \( \partial_\varsigma \varphi^\tau(\varsigma, x) = \frac{d}{d\varsigma} \psi\left(\Upsilon^\tau(\varsigma), x\right) = \frac{d\Upsilon^\tau(\varsigma)}{d\varsigma} \partial_s \psi(s, x) \bigg|_{s=\Upsilon^\tau(\varsigma)} \) and \( \nabla \varphi^\tau(\varsigma, x) = \nabla \psi(s, x) \bigg|_{s=\Upsilon^\tau(\varsigma)}, \) we come to
\[ I_2^\tau = \int_0^{T_\tau} \int_{\mathbb{R}^n} \left( \partial_\varsigma \varphi^\tau(\varsigma, x) + \left( \sum_{i=1}^m u_i^\tau(\varsigma) f_i(x), \nabla \varphi^\tau(\varsigma, x) \right) \right) \, d\mu^\tau(\varsigma) \, d\varsigma, \]

12
as desired. It remains to observe that \( u_1^i, i = 1, m \), enjoy conditions (3.9) by their definition, which finishes the proof. \( \square \)

**Remark 3.10.** In the tradition of impulsive control theory \[27, 29\], collection \( \{m^\tau_\sigma\}_{\tau, \sigma \in \Delta V} \) is naturally named the graph completion of a discontinuous curve \( t \mapsto \mu_t \). The main idea behind the notion of graph completion is to regard each a jump of \( \mu \) as a sort of “fast motion”, connecting the one-sided limits \( \mu_{\tau-} \) and \( \mu_{\tau+} \) at a point \( \tau \in \Delta V \). From (3.11), we see that the time-lapse representation of such a fast motion is given by the curve \( \varsigma \mapsto m^\tau_\varsigma \) being a distributional solution on the interval \([0, T_\tau]\) of a linear PDE, to be named the limit transport equation:

\[
\int_0^{T_\tau} \int_{\mathbb{R}^n} \varphi^\tau(t, x) d\mu_{\tau-} (x) = \int_0^{T_\tau} \int_{\mathbb{R}^n} \left( \partial_t \varphi^\tau(\varsigma, x) + \sum_{i=1}^{m} u_i^\tau(\varsigma) f_i(x) \right) \cdot \nabla \varphi^\tau(\varsigma, x) \right) d m^\tau_\varsigma(x) d\varsigma. \tag{3.13}
\]

We also note that the actual input of the relaxed system (3.10), (3.11) is not only function \( \Omega \) but the collection \((\Omega, \mathfrak{Z}, \{u^\tau\})\), i.e., an \( \mathbb{R}^m \)-valued function of bounded variation (or rather, vector measure on \([0, T]\)), accompanied by a certain majorant of its total variation and some additional “attached” measurable controls \( u^\tau \), which drive the above mentioned fast motions \( \varsigma \mapsto m^\tau_\varsigma \). It is natural to call collections \((\Omega, \mathfrak{Z}, \{u^\tau\})\) satisfying (3.9) impulsive controls.

### 3.4 The case of commutative vector fields

Looking at (3.13), we observe that the nonlocal part \( g * \mu \) of the driving vector field does not, actually, participate in the phase of jump (during fast motions). As is well-known, a solution of (3.13) can be represented in terms of the pushforward of the initial measure \( \mu_{\tau-} \) through the flow \( \Phi^\tau \) of the respective characteristic system

\[
\dot{\varsigma} = \sum_{i=1}^{m} u_i^\tau f_i(\varsigma), \quad \varsigma(0) = x, \tag{3.14}
\]

that is,

\[
m^\tau_\varsigma = \Phi^\tau_{0, \varsigma} \mu_{\tau-}.
\]

Now, assumed that vector fields \( f_i \) commute, i.e.,

\[
[f_i, f_j] \equiv (f_i)_x f_j - (f_j)_x f_i = 0, \quad i, j = 1, m, \quad i \neq j,
\]

by the well-known Frobenius theorem, a solution of (3.14) takes the form \[14\] (see also \[29\] Lemma 2.7 and Section 4.2.2):

\[
\varsigma^\tau(\varsigma) = X_n \left( F_{u_n^\tau}(\varsigma), X_{n-1}(F_{u_{n-1}^\tau}(\varsigma), \ldots, X_1(F_{u_1^\tau}(\varsigma), x) \right),
\]

where \( \varsigma \mapsto X_i(\varsigma, x) \) is a solution of

\[
\dot{\varsigma} = f_i(\varsigma), \quad \varsigma(0) = x. \tag{3.15}
\]

\textsuperscript{4}By the Frobenius theorem, this representation takes place only for sufficiently small \( t > 0 \), but assumptions (A1) enable to extend it to the whole \([0, T_\tau]\).
Thus, we come to the following representation of jump exit points $\mu_\tau \doteq m_{\tau T}$ of $\mu$:

$$m_{\tau T} = \left( \Psi_{0,\omega_0}^{n} \circ \Psi_{0,\omega_{n-1}}^{n-1} \circ \ldots \circ \Psi_{0,\omega_1}^{1} \right) \mu_{\tau -},$$

(3.16)

where $\Psi_{0,\varsigma}$ denotes the flow $x \mapsto X_i(\varsigma, x)$ of (3.15) along $[0, \varsigma]$, and $\omega_i^\tau = \int_0^{\tau_i} u_i^\tau (\varsigma) \, d\varsigma = \mathcal{U}(\tau) - \mathcal{U}(\tau^-)$ (recall (3.9)). We observe that (3.16) does not involve the actual information about fast-time controls $u^\tau$, and depends only on $\mathcal{U}$. This means that, in the case of commutative control vector fields, the limiting curve $\mu$ does not depend on the approximating sequence $\{\mu^k\}$. The picture is, thus, pretty same as in the finite-dimensional case [29].

### 3.5 Relaxation of the optimal control problem

Now we shall state the following optimal impulsive control problem:

$$\min \left\{ \int \ell \, d\mu_T : \mu \in \mathcal{M} \right\},$$

which, by the definition of $\mathcal{M}$, is an extension of problem $(P)$. Based on the results of Subsections 3.2 and 3.3, one transforms $(\bar{P})$ into the following optimal control problem stated on trajectories of the reduced system $(\hat{S})$:

$$\min \left\{ \int \ell \, d\nu_S : \nu \text{ is a trajectory of } (\hat{S}) \right\}. \quad (\hat{P})$$

**Theorem 3.11.** Assume that $(A_1)$ holds, and $\ell$ is sublinear and continuous. Then, problems $(\bar{P})$ and $(\hat{P})$ have solutions. Moreover, $\min(\bar{P}) = \min(\hat{P}) = \inf(P)$.

**Proof.** The cost function in $(\hat{P})$, i.e., $(\alpha, \beta) \mapsto \int \ell \, d\nu_S[\alpha, \beta, \vartheta]$, can be expressed as the composition of maps

$$(\alpha, \beta) \mapsto \nu_S[\alpha, \beta, \vartheta] \quad \text{and} \quad \nu \mapsto \int \ell \, d\nu$$

The first one is continuous as $L_ow([0, T]; \mathbb{R}^{m+1}) \mapsto \mathcal{P}_1$ due to Theorem 3.1 applied to $(\hat{S})$; the second one is continuous as $\mathcal{P}_1 \mapsto \mathbb{R}$ by an equivalent definition of $W_1$ convergence (see §2.2). We have mentioned, in the proof of Theorem 3.5, that $\mathcal{U}$ is compact in $L_ow([0, T]; \mathbb{R}^{m+1})$. Thus, $(\hat{P})$ admits a solution by the Weierstrass theorem. Now, according to Theorems 3.5 and 3.7, $(\hat{P})$ has a solution as well, moreover $\min(\hat{P}) = \min(\bar{P})$. Finally, $\min(\bar{P}) = \inf(P)$ follows from the very definition of $\mathcal{M}$. □

Theorems 3.5 and 3.11 imply that any solution of $(\hat{P})$ can be transformed to a solution of $(\bar{P})$ (or rather to a minimizing sequence of $(P)$); such a transformation can be made by explicit formulas similar to [29]. Proof of Theorem 4.7. In turn, minimizers for $(\hat{P})$ can be characterized by a necessary optimality condition which we shall derive in the next section.

### 4 Necessary optimality condition

The necessary optimality condition that we are going to establish (Theorem 4.7) can be formally deduced from a general result by B. Bonnet and F. Rossi [10], who reproduced the
standard proof of Pontryagin’s Maximum Principle \cite{12} (based on the needle variation) in the context of control systems in the space of probability measures. We propose an alternative (less demanding, in our opinion) approach employing discretization of the initial measure and the application of Ekeland’s variational principle.

Hence, we start our analysis by assuming that the initial distribution is a discrete measure. In this case, (P) boils down to a finite-dimensional optimal control problem. For this problem, we can write down an approximate version of Pontryagin’s Maximum Principle ($\varepsilon$-Maximum Principle).

### 4.1 Approximate Pontryagin’s Maximum Principle

Consider the following optimal control problem

\[
\begin{align*}
\text{Minimize} & \quad I = q(x(S)) \\
\text{subject to} & \quad \dot{x}(t) = f(x(t), \alpha(t), \beta(t)), \quad t \in [0, S], \quad x(0) = x_0, \\
& \quad (\alpha, \beta) \in \mathcal{U},
\end{align*}
\]

where

\[f(x, a, b) = a g_0(x) + \sum_{i=1}^{m} b_i g_i(x).\]

Suppose that $f: \mathbb{R}^n \times A \mapsto \mathbb{R}^n$ and $q: \mathbb{R}^n \mapsto \mathbb{R}$ are $C^1$ in $x$, and there exists $K > 0$ such that

\[\left|q(x)\right| + \left|\nabla_x q(x)\right| + \left|f(x, a, b)\right| + \left|\nabla_x f(x, a, b)\right| \leq K \quad \forall (x, a, b) \in \mathbb{R}^n \times A. \tag{4.1}\]

The Hamiltonian of (OCP) takes the form

\[H(x, p, \lambda, a, b) = a \lambda + ap \cdot g_0(x) + \sum_{i=1}^{m} b_i p \cdot g_i(x),\]

where $p \in \mathbb{R}^n$ and $\lambda \in \mathbb{R}$. Simple computations give:

\[
\max_{(a, b) \in A} H(x, p, \lambda, a, b) = \max \left\{p \cdot g_0(x) + \lambda, \max_{1 \leq i \leq m} |p \cdot g_i(x)|\right\}.
\]

**Theorem 4.1** (Pontryagin’s $\varepsilon$-maximum principle). Given $\varepsilon > 0$, let $(\bar{\alpha}, \bar{\beta}) \in \mathcal{U}$ satisfy

\[I[\bar{\alpha}, \bar{\beta}] \leq \inf(OCP) + \varepsilon. \tag{4.2}\]

Then there exists another pair $(\alpha^\varepsilon, \beta^\varepsilon) \in \mathcal{U}$ such that

1. $I[\alpha^\varepsilon, \beta^\varepsilon] \leq I[\bar{\alpha}, \bar{\beta}]$;

2. $\|\bar{\alpha} - \alpha^\varepsilon\|_{\infty} + \sum_{i=1}^{m} \|\bar{\beta}_i - \beta^\varepsilon_i\|_{\infty} \leq \sqrt{\varepsilon}$;

3. there exist $\lambda^\varepsilon \in [\lambda_-, \lambda_+]$ and absolutely continuous arcs $x^\varepsilon, p^\varepsilon: [0, T] \mapsto \mathbb{R}^n$ satisfying the Hamiltonian system

\[
\begin{align*}
\dot{x}(t) &= f(x(t), \alpha^\varepsilon(t), \beta^\varepsilon(t)), \quad x(0) = x_0, \\
\dot{p}(t) &= -p(t) \nabla_x g(x(t), p(t), \alpha^\varepsilon(t), \beta^\varepsilon(t)), \quad p(S) = -\kappa \nabla g(x(T)),
\end{align*}
\]

15
together with the approximate maximum condition

\[
\int_0^S \left[ \max_{(a,b) \in A} H \left( x^\varepsilon(t), \kappa^{-1} p^\varepsilon(t), \lambda^\varepsilon, a, b \right) - H \left( x^\varepsilon(t), \kappa^{-1} p^\varepsilon(t), \lambda^\varepsilon, \alpha^\varepsilon(t), \beta^\varepsilon(t) \right) \right] dt \leq 2\sqrt{\varepsilon}.
\]

Here \( \lambda_- \), \( \lambda_+ \) are finite constants depending only on \( K \), \( S \), and \( T \), while \( \kappa \) is an arbitrary positive real.

The proof of Theorem 4.1 can be found in Appendix B.

A pair \((\alpha, \beta)\) is said to be \(\varepsilon\)-optimal if it meets inequality (4.2), and \(\varepsilon\)-extremal, if it satisfies assumption (3) of Theorem 4.1. In this terminology, the classical Pontryagin Maximum Principle says that any 0-optimal pair \((\alpha, \beta)\) is 0-extremal.

### 4.2 Discrete initial distribution

From now on, in addition to (A1), we assume the following:

(A2) \( g \in C^1(\mathbb{R}^n; \mathbb{R}^n) \) and \( \nabla g(-x) = -\nabla g(x) \) for all \( x \in \mathbb{R}^n \);

(A3) \( \ell \in C^1(\mathbb{R}^n; \mathbb{R}) \) and \( |\ell(x)| + |\nabla x \ell(x)| \leq C \) for all \( x \in \mathbb{R}^n \).

Suppose that \( \nu_0 = \vartheta = \frac{1}{N} \sum_{k=1}^N \delta_{x_k} \), where all \( x_k \in \mathbb{R}^n \) are distinct points. Then (see Proposition 3.2) the reduced equation (3.3), (3.4) is equivalent to the following system of ODEs

\[
y_k' = a\left(f_0(y_k) + \frac{1}{N} \sum_{j=1}^N g(y_k - y_j)\right) + m \sum_{i=1}^m b_i f_i(y_k), \quad y_k(0) = x_k, \quad k = 1, \ldots, N,
\]

(prime denotes the derivative in \( s \)), while \((\hat{P})\) turns into the finite-dimensional optimal control problem \((\hat{P}_N)\):

\[
\min \left\{ \frac{1}{N} \sum_{k=1}^N \ell \left( y_k(S) \right) : y \in C^0([0, S]; \mathbb{R}^{nN}) \text{ satisfies (4.3), (3.5)} \right\}.
\]

Now, we shall apply the \(\varepsilon\)-Maximum Principle (Theorem 4.1) to problem \((\hat{P}_N)\). The Hamiltonian \(\hat{H}_N\) of \((\hat{P}_N)\) takes the form

\[
\hat{H}_N(y, p, \lambda, a, b) = a\lambda + a \left( \sum_k p_k f_0(y_k) + \frac{1}{N} \sum_{k,j} p_k g(y_k - y_j) \right) + \sum_i b_i \sum_k p_k f_i(y_k),
\]

where \( \lambda \in \mathbb{R} \) and \( p = (p_1, \ldots, p_N) \in \mathbb{R}^{nN} \). By (A2), we have

\[

\nabla y_s \left( \sum_{k,j} p_k g(y_k - y_j) \right) = \sum_i (p_s - p_i) \nabla g(y_s - y_i).
\]
Moreover, the flow $\Phi^t_0$ of the vector field $v_s = \vec{H} \left[ \gamma^N_s, \alpha(s), \beta(s) \right] (y_k, p_k)$ pushes the measure $\frac{1}{N} \sum_k \delta(y_k(0), p_k(0))$, whose projection on $x$ is $\frac{1}{N} \sum_k \delta_{x_k}$, to the measure $\frac{1}{N} \sum_k \delta(y_k(S), p_k(S))$, whose projections are connected by the identity

$$\frac{1}{N} \sum_k \delta_{p_k(S)} = \frac{1}{N} \sum_k \delta_{\nabla \ell(y_k(S))} = (-\nabla \ell)^t \left( \frac{1}{N} \sum_k \delta_{y_k(S)} \right).$$

Thus, the Hamiltonian system takes the form

$$
\begin{cases}
y'_k = \frac{1}{N} \sum_j g(y_k - y_j) + \alpha f_0(y_k) + \sum_i \beta_i f_i(y_k), \\
p'_k = -\frac{N}{N} \sum_j (p_k - p_j) \nabla g(y_k - y_j) - p_k \left( \alpha \nabla f(y_k) + \sum_i \beta_i \nabla f_i(y_k) \right),
\end{cases} \quad k = 1, N. \tag{4.4}
$$

Recall the initial condition:

$$y_k(0) = x_k, \quad k = 1, N. \tag{4.5}$$

As for the terminal condition, we have certain freedom in selecting it (see Appendix B). By our option, we choose the following one:

$$p_k(S) = -\nabla \ell (y_k(S)), \quad k = 1, N. \tag{4.6}$$

This corresponds to the choice $\kappa = N$ in Theorem 4.1, in which case the approximate maximum condition turns to contain the corrected Hamiltonian $\hat{H}_N(y, p/N, \lambda, a, b)$.

Taken $(\alpha, \beta) \in \mathcal{U}$, let $(y, p)$ be the associated solution of the Hamiltonian system (4.4) satisfying boundary conditions (4.5), (4.6). Clearly, by setting

$$\gamma^N_s = \frac{1}{N} \sum_{j=1}^N \delta(y_j(s), p_j(s)),$$

we can rewrite the Hamiltonian system in the form

$$
\begin{cases}
y'_k = \alpha \int g(y_k - z) \, d\pi^1_k \gamma^N_s(z) + \alpha f_0(y_k) + \sum_i \beta_i f_i(y_k), \\
p'_k = -\alpha \int (p_k - q) \nabla g(y_k - z) \, d\gamma^N_s(z, q) - p_k \left( \alpha \nabla f_0(y_k) + \sum_i \beta_i \nabla f_i(y_k) \right).
\end{cases}
$$

Next, we introduce the map $\vec{H} : \mathcal{P}_1(\mathbb{R}^{2n}) \times \mathcal{A} \mapsto C^0(\mathbb{R}^{2n}; \mathbb{R}^{2n})$ as

$$\vec{H}[\gamma, a, b](y, p) = \left( \begin{array}{c}
\alpha \int g(y - z) \, d\pi^1_k \gamma (z, q) + \alpha f_0(y) + \sum_k b_k f_k(y) \\
-\alpha \int (p - q) \nabla g(y - z) \, d\gamma(z, q) - p \left( \alpha \nabla f_0(y) + \sum_k b_k \nabla f_k(y) \right)
\end{array} \right) \tag{4.7}
$$

and note that the right-hand side of (4.4) can be expressed as $\vec{H} \left[ \gamma^N_s, \alpha(s), \beta(s) \right] (y_k, p_k)$. One may easily check that $\vec{H}$ meets the assumptions of Theorem 3.1. Therefore, by Proposition 3.2, the curve $\gamma^N : [0, S] \to \mathcal{P}_1(\mathbb{R}^{2n})$ satisfies the nonlocal continuity equation

$$\partial_x \gamma_s + \nabla \ell(y, p) \cdot \left( \vec{H} \left[ \gamma_s, \alpha(s), \beta(s) \right] \right) = 0. \tag{4.8}$$

Moreover, the flow $\Phi_{0,T}$ of the vector field $v_s = \vec{H} \left[ \gamma^N_s, \alpha(s), \beta(s) \right]$ pushes the measure $\frac{1}{N} \sum_k \delta(y_k(0), p_k(0))$, whose projection on $x$ is $\frac{1}{N} \sum_k \delta_{x_k}$, to the measure $\frac{1}{N} \sum_k \delta(y_k(S), p_k(S))$, whose projections are connected by the identity

$$\frac{1}{N} \sum_k \delta_{p_k(S)} = \frac{1}{N} \sum_k \delta_{\nabla \ell(y_k(S))} = (-\nabla \ell)^t \left( \frac{1}{N} \sum_k \delta_{y_k(S)} \right).$$
In other words, in addition to (4.8), \( \gamma^N \) satisfies the boundary conditions
\[
\pi_1^\gamma \gamma_0 = \vartheta, \quad \pi_2^\gamma \gamma_S = (\nabla \ell)^T (\pi_1^\gamma \gamma_S).
\] (4.9)

Finally, introduce the map \( H : \mathcal{P}_1(\mathbb{R}^{2n}) \times \mathbb{R} \times A \mapsto \mathbb{R} \) as
\[
H(\gamma, \lambda, a, b) = \frac{a}{2} \int \int (p - q) \rho(y, z) d\gamma(y, q) d\gamma(y, p) + a\lambda + a \int pf_0(y) d\gamma(y, p) + \sum b_k \int pf_k(y) d\gamma(y, p),
\] (4.10)
and note that
\[
\hat{H}_N \left( y(s), p(s)/N, \lambda, \alpha(s), \beta(s) \right) = H \left( \gamma^N, \lambda, \alpha(s), \beta(s) \right).
\]

The above computations allow us to formulate the \( \varepsilon \)-Maximum Principle for (\( \hat{P}_N \)) in the following form:

**Theorem 4.2.** Given \( \varepsilon > 0 \), let \((\bar{\alpha}, \bar{\beta}) \in \hat{U}\) be \( \varepsilon \)-optimal for (\( \hat{P}_N \)). Then there exists \((\alpha^\varepsilon, \beta^\varepsilon) \in \hat{U}\) such that

1. \((\alpha^\varepsilon, \beta^\varepsilon)\) is also \( \varepsilon \)-optimal;
2. \(|\bar{\alpha} - \alpha^\varepsilon|_\infty + \sum_{j=1}^m |\bar{\beta}_j - \beta^\varepsilon_j|_\infty \leq \sqrt{\varepsilon};
3. there exists \( \lambda^\varepsilon \in [\lambda_-, \lambda_+] \) and an absolutely continuous arc \( \gamma^\varepsilon : [0, S] \to \mathcal{P}(\mathbb{R}^{2n}) \) satisfying the Hamiltonian system (4.8), where \( \alpha = \alpha^\varepsilon \) and \( \beta = \beta^\varepsilon \), together with the approximate maximum condition
   \[
   \int_0^S \left[ \max_{(a, b) \in A} H(\gamma^\varepsilon_s, \lambda^\varepsilon, a, b) - H(\gamma^\varepsilon_s, \lambda^\varepsilon, \alpha^\varepsilon(s), \beta^\varepsilon(s)) \right] ds \leq 2\sqrt{\varepsilon}.
   \]

Here \( \lambda_-, \lambda_+ \) are finite constants depending only on \( C, L, S, \) and \( T \).

### 4.3 Hamiltonian system

Prior to exhibiting the main result, we shall comment on the Hamiltonian system (4.8), (4.9). First, remark that, in general, this system admits infinite many solutions, unless the initial measure \( \vartheta \) is purely atomic. Below, we construct a particular solution \( \gamma = \gamma(\alpha, \beta, \vartheta) \), which depends continuously on all its parameters \((\alpha, \beta, \vartheta)\).

Let \( F \) and \( G \) denote the components of \( \tilde{H} \), i.e.
\[
\tilde{H}[\gamma, a, b] = \begin{pmatrix} F[\pi_1^\gamma, a, b] \\ G[\gamma, a, b] \end{pmatrix}.
\]

**Lemma 4.3.** If \( \gamma \in C^0([0, S]; \mathcal{P}_1(\mathbb{R}^{2n})) \) satisfies (4.8) then \( \nu \in C^0([0, S]; \mathcal{P}_1(\mathbb{R}^n)) \), defined by \( \nu_s = \pi_1^\gamma \gamma_s \), satisfies
\[
\partial_s \nu_s + \nabla_x \left( F[\nu_s, \alpha(s), \beta(s)] \nu_s \right) = 0.
\] (4.11)
Proof. Fix some $\varphi \in C_c^\infty((0, T) \times \mathbb{R}^n)$ and consider test functions of the form $(s, x, p) \mapsto \varphi(s, x) \psi_R(p)$, where $\psi_R \in C_c^\infty(\mathbb{R}^n)$ is such that $0 \leq \psi \leq 1$, $|\nabla_p \psi_R| \leq 1$ on $\mathbb{R}^n$, and $\psi_R = 1$ inside $B_R(0)$, the ball of radius $R$ centered at 0. It follows from (4.8) that

$$\int_0^S \int_{\mathbb{R}^{2n}} \left( \partial_s \varphi(s, x) \psi_R(p) + F \left[ \pi_1^2 \gamma_s(s, \alpha(s), \beta(s)) \nabla_x \varphi(s, x) + G \left[ \gamma_s, \alpha(s), \beta(s) \right] \nabla_p \psi_R(p) \right] d\gamma_s(x, p) \right) ds = 0. \quad (4.12)$$

We are done if we show that the quantity

$$I \equiv \int_0^S \int_{\mathbb{R}^{2n}} \left( \partial_s \varphi(s, x) + F \left[ \pi_1^2 \gamma_s(s, \alpha(s), \beta(s)) \nabla_x \varphi(s, x) \right] d\gamma_s(x, p) \right) ds$$

vanishes. Note that the difference between $I$ and the left-hand side of (4.12) equals to

$$I = \int_0^S \int_{\mathbb{R}^{2n} \setminus B_R(0)} \left( \partial_s \varphi(s, x) (1 - \psi_R(p)) - G \left[ \gamma_s, \alpha(s), \beta(s) \right] \nabla_p \psi_R(p) \right) d\gamma_s(x, p) ds = 0.$$

Recalling (A₁) and the definition of $G$, we conclude that

$$|I| \leq K \int_0^S \int_{\mathbb{R}^{2n} \setminus B_R(0)} (1 + |p|) d\gamma_s(x, p),$$

for some $K > 0$. Passing to the limit as $R \to \infty$ gives $|I| = 0$, as desired. \qed

Remark 4.4. In the language of geometric control theory, one can say that $s \mapsto \gamma_s$ is a lift of $s \mapsto \nu_s$ from $\mathcal{P}_1(\mathbb{R}^n)$ to $\mathcal{P}_1(\mathbb{R}^{2n})$.

Lemma 4.5. For any $(\alpha, \beta) \in \tilde{\mathcal{U}}$ and $\vartheta \in \mathcal{P}_1(\mathbb{R}^n)$, there exists a curve $s \mapsto \gamma_s[\alpha, \beta, \vartheta]$ satisfying (I unchanged). The mapping $(\alpha, \beta, \vartheta) \mapsto \gamma[\alpha, \beta, \vartheta]$ is continuous as a function $\tilde{\mathcal{U}} \times \mathcal{P}_1(\mathbb{R}^n) \to C^0\left([0, S]; \mathcal{P}_1(\mathbb{R}^{2n})\right)$, where $\tilde{\mathcal{U}}$ is equipped with the weak-* topology.

Proof. Let $\nu = \nu[\alpha, \beta, \vartheta]$ be a solution of (4.11) with initial condition $\nu_0 = \vartheta$, and $\tilde{\gamma} = \tilde{\gamma}[\alpha, \beta, \gamma]$ be a solution of (4.8) with terminal condition $\tilde{\gamma}_S = \gamma$. By Theorem 3.1 both curves depend continuously on all the parameters. Hence their composition

$$\gamma[\alpha, \beta, \vartheta] \equiv \tilde{\gamma}[\alpha, \beta, \nu[\alpha, \beta, \vartheta] \otimes (-\nabla \ell_2) \nu[\alpha, \beta, \vartheta]]$$

is continuous as well. By construction, $\gamma[\alpha, \beta, \vartheta]$ satisfies (4.8) together with the terminal condition

$$\pi_1^2 \gamma_S = (-\nabla \ell_2)(\pi_1^2 \gamma_S).$$

Now, by Lemma 4.3 we conclude that $\tilde{\nu}_s \equiv \pi_1^4 \gamma_s$ meets (4.11). Since $\tilde{\nu}_S = \nu_S$, Theorem 3.1 implies that $\tilde{\nu}_s = \nu_s$ for all $s$. In particular, $\tilde{\nu}_0 = \pi_1^4 \gamma_0 = \vartheta$. \qed
Proposition 3.2 imply that \( \nu \) rem 3.1) implies the continuity of \( \gamma \).

Proof. Now, since discrete measures with rational coefficients are dense in the Hamiltonian system and such that the following maximum condition holds for \( L \) Here, \( \nu \) is a discrete measure:

\[
\pi^2_1 \gamma_S = \frac{1}{N} \sum_k \delta_{-\nabla \ell(y_k(s))}.
\]

Therefore, \( \gamma_S \) is uniquely defined as

\[
\gamma_S = \frac{1}{N} \sum_k \delta_{(y_k(s),-\nabla \ell(y_k(s)))}.
\]

Finally, by Proposition 3.2 there is no other curve satisfying both (4.8) and (4.13).

With Lemmas 4.5 and 4.6 at hand, one easily deduces the following fact: if \( \vartheta \) is atomic then the solution \( \gamma(\alpha, \beta, \vartheta) \) of (4.8), (4.9) from Lemma 4.5 is unique.

4.4 Necessary optimality condition

Now we are ready to exhibit a version of Pontryagin’s Maximum Principle for problem (\( \hat{P} \)).

Theorem 4.7. Assume that (A1.2) hold and let \( (\bar{\alpha}, \bar{\beta}) \in \hat{U} \) be optimal for (\( \hat{P} \)). Then there exist \( \lambda \in \mathbb{R} \) and an arc \( \gamma : [0, S] \to \mathcal{P}_1(\mathbb{R}^{2n}) \) satisfying the Hamiltonian system

\[
\begin{cases}
\partial_s \gamma_s + \nabla_{(y,p)} \left( \overline{H} [\gamma_s, \bar{g}(s), \bar{\beta}(s)] \right) = 0, \\
\pi^2_1 \gamma_0 = \vartheta, \quad \pi^2_2 \gamma_S = (-\nabla \ell)_\vartheta \left( \pi^1_\gamma \gamma_S \right),
\end{cases}
\]

such that the following maximum condition holds for \( \mathcal{L}^1 \)-a.e. \( s \in [0, S] \):

\[
\mathcal{H}(\gamma_s, \lambda, \bar{a}(s), \bar{\beta}(s)) = \max_{(a, b) \in A} \mathcal{H}(\gamma_s, \lambda, a, b) \equiv \max \left\{ \mathcal{H}^1(\gamma_s, \lambda), \mathcal{H}^0(\gamma_s) \right\}.
\]

Here,

\[
\mathcal{H}^1(\gamma, \lambda) = \frac{1}{2} \int \int (p - q) g(y - z) \, d\gamma(z, q) \, d\gamma(y, p) + \int pf_0(y) \, d\gamma(y, p) + \lambda,
\]

and

\[
\mathcal{H}^0(\gamma) = \max_{1 \leq i \leq m} \int pf_i(y) \, d\gamma(y, p).
\]

Proof. 1. The continuity of \( (\alpha, \beta, \vartheta) \mapsto \int \ell(x) \, d\nu_S[\alpha, \beta, \vartheta](x) \) (which follows from Theorem 3.1) implies the continuity of

\[
\vartheta \mapsto \min_{(\alpha, \beta) \in \mathcal{U}} \int \ell(x) \, d\nu_S[\alpha, \beta, \vartheta](x).
\]

Now, since discrete measures with rational coefficients are dense in \( \mathcal{P}_1(\mathbb{R}^{2n}) \) Theorem 6.18], we deduce that, for each \( \varepsilon > 0 \), there exists \( N_\varepsilon \in \mathbb{N} \) and a discrete measure \( \vartheta^\varepsilon = \frac{1}{N_\varepsilon} \sum_{k=1}^{N_\varepsilon} \delta_{x_k} \) such that \( \| \vartheta^\varepsilon - \vartheta \|_K \leq \varepsilon \) and \( (\bar{\alpha}, \bar{\beta}) \) is \( \varepsilon \)-optimal for problem \( (\hat{P}_{N_\varepsilon}) \) associated with \( \vartheta^\varepsilon \).

2. By Theorem 4.2 there exist \( (\alpha^\varepsilon, \beta^\varepsilon) \in \mathcal{U}, \, \lambda^\varepsilon \in [\lambda_-, \lambda_+] \), and \( \gamma^\varepsilon \in C^0([0, T]; \mathcal{P}_1(\mathbb{R}^{2n})) \) with the following properties:
(a) \((\alpha^\varepsilon, \beta^\varepsilon)\) is \(\varepsilon\)-optimal for \((\hat{P}_N)\);

(b) \(\|\bar{\alpha} - \alpha^\varepsilon\|_\infty + \sum_{j=1}^m \|\bar{\beta}_j - \beta_j^\varepsilon\|_\infty \leq \sqrt{\varepsilon};\)

(c) \[
\begin{cases}
\partial_s \gamma_s^\varepsilon + \nabla (y,p) \cdot \left( \tilde{H} \left( \gamma_s^\varepsilon, \alpha^\varepsilon(s), \beta^\varepsilon(s) \right) \right) = 0, \\
\pi_1^1 \gamma_0^\varepsilon = \vartheta, \quad \pi_2^2 \gamma_S^\varepsilon = (\varepsilon \nabla \ell)_2 \left( \pi_1^1 \gamma_S^\varepsilon \right); \\
\end{cases}
\]

(d) \[
\int_0^1 \left[ \max_{(a,b) \in A} H(\gamma_s^\varepsilon, \lambda, a, b) - H(\gamma_s^\varepsilon, \lambda, \bar{\alpha}(s), \bar{\beta}(s)) \right] \, ds \leq 2\sqrt{\varepsilon}.
\]

3. We are going to pass to the limit as \(\varepsilon \to 0\). Without loss of generality, it can be assumed that \(\lambda^\varepsilon\) converges to some \(\lambda \in [\lambda_-, \lambda_+].\) We easily obtain that \(\vartheta^\varepsilon \to \vartheta\) in \(L^\infty\), \(\gamma^\varepsilon \rightharpoonup \gamma [\alpha^\varepsilon, \beta^\varepsilon, \vartheta^\varepsilon] \to \gamma[\bar{\alpha}, \bar{\beta}, \vartheta] \rightharpoonup \gamma\) in \(C^0\) (the latter follows from Lemmas 4.5 and 4.6). It remains to show that passage to the limit in (d) gives

\[
\int_0^1 \left[ \max_{(a,b) \in A} H(\gamma_s, \lambda, a, b) - H(\gamma_s, \lambda, \bar{\alpha}(s), \bar{\beta}(s)) \right] \, ds = 0, \tag{4.15}
\]

because then (4.14) would follow due to the nonnegativity of the integrand.

4. Let us prove (4.15). Since \(H\) depends on \(a\) and \(b\) linearly (see (4.10)), it suffices to show that

\[
\begin{align*}
\int \int (p-q)g(y-z) \, d\gamma_s^\varepsilon(z,q) \, d\gamma_s(y,p) \to & \int \int (p-q)g(y-z) \, d\gamma_s(z,q) \, d\gamma_s(y,p), \\
\int pf_0(y) \, d\gamma_s^\varepsilon(y,p) \to & \int pf_0(y) \, d\gamma_s(y,p), \\
\int pf_k(y) \, d\gamma_s^\varepsilon(y,p) \to & \int pf_k(y) \, d\gamma_s(y,p)
\end{align*}
\]

pointwise. But this fact follows from the convergence \(\gamma_s^\varepsilon \rightharpoonup \gamma_s\) because all the integrands are sublinear. \(\square\)

5 Conclusion

Together with [36], this article presents a “gentleman’s set” of very basic results for optimal impulsive control of distributed multi-agent systems.

There are at least two natural directions of future work. The first one is an interpretation of our necessary condition in terms of the impulsive control system [33], which seems to be just a technical exercise.

Another challenging issue could be developing a numeric algorithm based on the necessary optimality condition. As a motivation, we shall point out that the direct approach (reduction to a mathematical programming problem through discretization in time and space) seems to be totally unworkable for such models, even in the case of local vector fields. At the same time, certain positive experience in applying necessary optimality conditions for numeric analysis of optimal control problems involving the linear transport equation [34] gives us a portion of hope. Here, a crucial difficulty is due to “fast” (numerically efficient) computation of solutions to nonlocal transport equations.

As a final note we stress that, by now, our consideration had been landed on models of homotypic crowds. A very straightforward generalization then is to study the case of non-uniform population. Towards this, one can deal with a system of nonlocal transport equations,
involving the cross-interaction of different “species” [21], or follow a pretty novel approach based on the concept of “graphone” [13].

A Proof of Theorem 3.1

The proof is based on the following version of the Banach contraction mapping theorem

**Theorem A.1** ([12]). Let \((X, d)\) be a complete metric space, \(\Lambda\) a metrizable topological space, and \(F\) a function \(\Lambda \times X \to X\). Assume that

1. the map \(\lambda \mapsto F(\lambda, x)\) is continuous for all \(x \in X\), and
2. the map \(x \mapsto F(\lambda, x)\) is uniformly contractive, i.e., there exists \(0 \leq \kappa < 1\) such that
   \[ d(F(\lambda, x), F(\lambda, y)) \leq \kappa d(x, y) \quad \forall \lambda \in \Lambda, x, y \in X. \]

Then, for each \(\lambda \in \Lambda\), there exists a unique point \(x(\lambda) \in X\) with the property:

\[ x(\lambda) = F(\lambda, x(\lambda)). \]

Furthermore, the map \(\lambda \mapsto x(\lambda)\) is a continuous function \(\Lambda \to X\).

**Proof of Theorem 3.1** 1. We are going to apply Theorem A.1 to the metric space \((X, d) = (C^0([0, T]; P_1), \| \cdot \|_\gamma)\) and the parameter space \(\Lambda = \tilde{U} \times P_1\). Here the norm \(\| \cdot \|_\gamma\) is given by

\[ \| \mu \|_\gamma = \max_{t \in [0, T]} e^{-\gamma t} \| \mu_t \|_K, \]

and it is equivalent to the usual supremum norm. Let us also note that \(\tilde{U}\), equipped with the topology \(\sigma(L^\infty, L^1)\), is metrizable, because \(\tilde{U}\) belongs to a closed ball of \(L^\infty\).

2. Consider two auxiliary operators \(\mathcal{V}\) and \(\mathcal{F}\). The first one maps a control \(u \in \tilde{U}\) and a curve \(\mu \in C^0([0, T]; P_1)\) into a time dependent vector field \(v\) by the rule \(v_t = V[u, \mu]\). The second one maps a probability measure \(\vartheta\) and a time dependent vector field \(v\) to the solution \(\mu\) of the continuity equation

\[ \partial_t \mu_t + \nabla \cdot (v_t \mu_t) = 0, \quad \mu_0 = \vartheta. \]

Recall that \(\mu_t = F(\vartheta, v_t) = \Phi_{0, t} \vartheta\), where \(\Phi\) is the flow of \(v\). We are able now to construct the final ingredient for Theorem A.1 — an appropriate map \(\Lambda \times X \to X\) — by formula

\[ F(\mu, \vartheta) = F(0, \vartheta) = \Phi_{0, t} \vartheta. \]

3. First, let us ensure the contraction property. Take a control \(u \in \tilde{U}\), a measure \(\vartheta \in P_1\), and two continuous curves \(\mu_1, \mu_2 : [0, T] \to P_1\) with \(\mu^1_0 = \mu^2_0 = \vartheta\). Consider the associated
vector fields \( v^1 = \mathcal{V}[u, \mu^1] \), \( v^2 = \mathcal{V}[u, \mu^2] \) and the corresponding flows \( \Phi^1, \Phi^2 \). We shall estimate the norm
\[
\| \mathcal{F}(u, \vartheta, \mu^1) - \mathcal{F}(u, \vartheta, \mu^2) \|_\gamma = \max_{t \in [0, T]} e^{-\gamma t} \| \Phi^1_{0,t} \vartheta - \Phi^2_{0,t} \vartheta \|_\gamma.
\]

Note that
\[
\| \Phi^1_{0,t} \vartheta - \Phi^2_{0,t} \vartheta \|_K = \sup_{\varphi \in \text{Lip}_1(\mathbb{R}^n)} \left\{ \int \varphi \left( \Phi^1_{0,t} \vartheta - \Phi^2_{0,t} \vartheta \right) \right\}
= \sup_{\varphi \in \text{Lip}_1(\mathbb{R}^n)} \left\{ \int \left( \varphi \left( \Phi^1_{0,t}(\xi) \right) - \varphi \left( \Phi^2_{0,t}(\xi) \right) \right) d\vartheta (\xi) \right\}
\leq \int \left| \Phi^1_{0,t}(\xi) - \Phi^2_{0,t}(\xi) \right| d\vartheta (\xi),
\]
and set
\[
x^i(t) = \Phi^i_{0,t}(\xi) = \xi + \int_0^t v^i_1 \left( x^i(s) \right) ds, \quad i = 1, 2.
\]

Thanks to assumption (1), we derive
\[
|x^1(t) - x^2(t)| \leq \int_0^t \left| v^1_1(x^1(s)) - v^2_1(x^2(s)) \right| ds
= \int_0^t \left| V[\mu^1_s, u(s)](x^1(s)) - V[\mu^2_s, u(s)](x^2(s)) \right| ds
\leq L \int_0^t |x^1(s) - x^2(s)| ds + L \int_0^t \| \mu^1_s - \mu^2_s \|_K ds.
\]

The Grönwall inequality then gives
\[
\left| \Phi^1_{0,t}(\xi) - \Phi^2_{0,t}(\xi) \right| = |x^1(t) - x^2(t)| \leq Le^{Lt} \int_0^t \| \mu^1_s - \mu^2_s \|_K ds.
\]

Since the right-hand side of the latter inequality does not depend on \( \xi \), we conclude that
\[
\| \Phi^1_{0,t} \vartheta - \Phi^2_{0,t} \vartheta \|_K \leq \int \left| \Phi^1_{0,t}(\xi) - \Phi^2_{0,t}(\xi) \right| d\vartheta (\xi) \leq Le^{Lt} \int_0^t \| \mu^1_s - \mu^2_s \|_K ds.
\]

Hence,
\[
\| \Phi^1_{0,t} \vartheta - \Phi^2_{0,t} \vartheta \|_K \leq Le^{Lt} \int_0^t e^{\gamma s} \| \mu^1_s - \mu^2_s \|_K ds
\leq Le^{Lt} \int_0^t e^{\gamma s} \| \mu^1_s - \mu^2_s \|_\gamma ds
\leq \frac{L}{\gamma} e^{Lt} (e^{\gamma t} - 1) \| \mu^1_s - \mu^2_s \|_\gamma
\leq \frac{L}{\gamma} e^{(L+\gamma) t} \| \mu^1_s - \mu^2_s \|_\gamma.
\]

Multiplying both sides by \( e^{-\gamma t} \) and taking maximum over \( t \in [0, T] \), we obtain
\[
\| \Phi^1_{0,t} \vartheta - \Phi^2_{0,t} \vartheta \|_\gamma \leq \frac{L}{\gamma} e^{Lt} \| \mu^1_s - \mu^2_s \|_\gamma.
\]
Thus, the choice $\gamma > L e^{L t}$ ensures the desired estimate:

$$
\|F(u, \vartheta, \mu^1) - F(u, \vartheta, \mu^2)\|_\gamma \leq \kappa \|\mu^1 - \mu^2\|_\gamma, \quad \kappa < 1.
$$

**4.** Before passing to the next property, let us look closely at the image of $F$. Given $\mu \in C^0([0, T]; P_1)$ and $u \in \mathcal{U}$, consider the vector field $v = \mathcal{V}(u, \mu)$ and its flow $\Phi$. Assumptions (1) and (2) imply that $v$ is measurable in $t$, Lipschitz continuous in $x$, and sublinear, that is

$$
|v_t(x)| \leq C(1 + |x|), \quad |v_t(x) - v_t(y)| \leq L|x - y| \quad \text{for all } t, x, y.
$$

By the standard arguments from ODE theory, one can easily deduce that, for all $s, t \in [0, T]$ and $x, y \in \mathbb{R}^n$,

$$
|\Phi_{0,s}(x) - \Phi_{0,t}(x)| \leq C \left(1 + (|x| + CT) e^{CT}\right) |s - t|, \quad |\Phi_{0,s}(x) - \Phi_{0,t}(y)| \leq e^{Ls} |x - y|.
$$

(A.2)

The computations similar to (A.1) and the first inequality in (A.2) give

$$
\|\Phi_{0,s} \vartheta - \Phi_{0,t} \vartheta\|_K \leq \int |\Phi_{0,s}(x) - \Phi_{0,t}(x)| \, d\vartheta(x) \leq M \left(1 + \int |x| \, d\vartheta(x)\right),
$$

where

$$
M = C(1 + CT e^{CT} + e^{CT})
$$

In other words, each curve $t \mapsto F(u, \vartheta, \mu)_t$ is Lipschitz with constant $M (1 + \int |x| \, d\vartheta(x))$.

**5.** It remains to establish the continuity of the mapping $(u, \vartheta, \mu) \mapsto F(u, \vartheta, \mu)$. Fix a curve $\mu \in C^0([0, T]; P_1)$ and a sequence $(\mu^j, \vartheta^j) \in \mathcal{U} \times P_1$, $j \in \mathbb{N}$, converging to some $(u, \vartheta) \in \mathcal{U} \times P_1$. As before, we construct the corresponding vector fields $v = \mathcal{V}(u, \mu), \; v^j = \mathcal{V}(u^j, \mu^j), \; j \in \mathbb{N}$, and their flows $\Phi, \Phi^j, \; j \in \mathbb{N}$. Let us show that

$$
\lim_{j \to \infty} \|\Phi^j_{0,t} \vartheta^j - \Phi_{0,t} \vartheta\|_K = 0 \quad \forall t \in [0, T].
$$

(A.3)

To that end, observe that, for any $t \in [0, T]$,

$$
\|\Phi^j_{0,t} \vartheta^j - \Phi_{0,t} \vartheta\|_K \leq \|\Phi^j_{0,t} \vartheta^j - \Phi^j_{0,t} \vartheta\|_K + \|\Phi^j_{0,t} \vartheta - \Phi_{0,t} \vartheta\|_K.
$$

By (A.2), the first term from the right-hand side is majorized by the quantity $e^{Ls} \|\vartheta^j - \vartheta\|_K$, and therefore, converges to 0. It follows from (2) that $v^j_c(x) \to v_c(x)$, for each $x \in \mathbb{R}^n$. Hence, by Lemma 2.8 [33], the second term also vanishes. Thus, (A.3) does hold, and it says that $t \mapsto F(u, \vartheta, \mu)_t$ is a pointwise limit of $t \mapsto F(u^j, \vartheta^j, \mu^j)_t$. Recall that $\vartheta^j \to \vartheta$ implies $\int |x| \, d\vartheta^j(x) \to \int |x| \, d\vartheta(x)$. Now, it follows from step 4 that there exists a common Lipschitz constant for all curves from $\left\{F(u^j, \vartheta^j, \mu^j)\right\}$. As a result, the sequence forms a relatively compact subset of $C^0([0, T]; P_1)$, and thus converges uniformly.

**Proof of Proposition 3.2.** Consider the curve $\mu^N_t = \frac{1}{N} \sum_{k=1}^N \delta_{x_k(t)}$, which generates the vector field

$$
\mathcal{V} \left[u, \rho^N\right] (t, x) = f_N (x, x_1(t), \ldots, x_N(t), u(t)) \equiv v_t(x).
$$

Since $\mathcal{F}[\vartheta^N, v]_{\cdot t}$, defined in the proof of Theorem 3.1, is the pushforward of $\vartheta^N$ through the flow $\Phi_{0,t}$ of $v$, we conclude that

$$
F(u, \vartheta^N, \mu^N)_{\cdot t} = \mathcal{F}[\vartheta^N, v]_{\cdot t} = \frac{1}{N} \sum_{k=1}^N \delta_{x_k(t)} = \mu^N_t,
$$

which completes the proof. 

\[\square\]
B Proof of Theorem 4.1

The $\varepsilon$-Maximum Principle, formulated as Theorem 4.1, is a corollary of the famous Ekeland variational principle [24], proved by I. Ekeland for free-endpoint optimal control problems. Below, the general scheme of Ekeland’s proof remains intact, while the integral constraint $\int_0^S \alpha \, dt = T$ is treated by applying the following corollary of the classical Kuhn-Tucker theorem.

**Lemma B.1.** Let $K$ be a convex subset of a real vector space, $\varphi: K \rightarrow \mathbb{R}$ be convex, and $\psi: K \rightarrow \mathbb{R}$ be affine. Suppose that $\inf_K \varphi$ and $\sup_K \varphi$ are finite and there are $x_1, x_2 \in K$ with $\psi(x_1) > 0$ and $\psi(x_2) < 0$. If $x_*$ solves the minimization problem

$$\min \{ \varphi(x) : \psi(x) = 0, \, x \in K \}$$

then there exists

$$\frac{\inf_K \varphi(x) - \sup_K \varphi(x)}{\psi(x_1)} \leq \lambda \leq \frac{\inf_K \varphi(x) - \sup_K \varphi(x)}{\psi(x_2)}$$

such that

$$\varphi(x) + \lambda \psi(x) \geq \varphi(x_*) \quad \forall x \in K.$$  \hfill (B.1)

**Proof.** By the Kuhn-Tucker theorem [19, Theorem 9.4], there exists a nontrivial pair $(\eta, \lambda) \in \mathbb{R}^2$ such that

$$(\eta \varphi + \lambda \psi)(x) \geq (\eta \varphi + \lambda \psi)(x_*) \geq \eta \varphi(x_*) \quad \forall x \in K.$$  \hfill (B.2)

Note that $\eta$ cannot vanish. Indeed, $\eta = 0$ implies $\lambda \neq 0$ and

$$\lambda \psi(x) \geq 0 \quad \forall x \in K.$$  

Since $\lambda \psi(x_1)$ and $\lambda \psi(x_2)$ have different signs, we come to a contradiction. Taken $\eta = 1$, we immediately come to (B.2). Putting $x = x_1$ and $x = x_2$ in (B.2), one has

$$\lambda \geq \frac{\varphi(x_*) - \varphi(x_1)}{\psi(x_1)}, \quad \lambda \leq \frac{\varphi(x_*) - \varphi(x_2)}{\psi(x_2)}.$$  

Thus, (B.1) does hold, as desired. \hfill \Box

**Proof of Theorem 4.1.** 1. First, let us note that the quantity $H(\alpha^\varepsilon(t), \kappa^{-1} p^\varepsilon(t), \lambda^\varepsilon, a, b)$ does not depend on $\kappa$. This follows from the fact that the second equation in the Hamiltonian system is linear, while $H$ is affine in $p$. Thus, it suffices to prove our theorem for $\kappa = 1$.

2. We are going to apply the Ekeland variational principle to the map $I : \hat{U} \rightarrow \mathbb{R}$. To that end, we equip $\hat{U}$ with the topology of $L^\infty$. This turns $\hat{U}$ into a complete metric space, and guarantees the continuity of $I$. Ekeland’s principle [24] says that, if $(\hat{\alpha}, \hat{\beta})$ is $\varepsilon$-optimal, then there exists $(\alpha^\varepsilon, \beta^\varepsilon)$ such that

$$I(\alpha^\varepsilon, \beta^\varepsilon) \leq I(\hat{\alpha}, \hat{\beta}), \quad \|\alpha^\varepsilon - \hat{\alpha}\|_\infty + \sum_{i=1}^m \|\beta^\varepsilon_i - \hat{\beta}_i\|_\infty \leq \sqrt{\varepsilon},$$

$$I(\alpha^\varepsilon, \beta^\varepsilon) - I(\alpha, \beta) \leq \sqrt{\varepsilon} \left( \|\alpha^\varepsilon - \alpha\|_\infty + \sum_{i=1}^m \|\beta^\varepsilon_i - \beta_i\|_\infty \right) \quad \forall (\alpha, \beta) \in \hat{U}.$$  \hfill (B.3)
Thus, assumptions (1) and (2) of Theorem 4.1 are fulfilled, and it remains to show that \((B.3)\) implies assumption (3).

3. Given \((\alpha, \beta) \in \mathcal{U}\), consider the following variation of \((\alpha^\varepsilon, \beta^\varepsilon)\):

\[
(\alpha^\varepsilon, \beta^\varepsilon) \doteq (\alpha^\varepsilon, \beta^\varepsilon) + \tau (\alpha - \alpha^\varepsilon, \beta - \beta^\varepsilon), \quad \tau \in [0, 1].
\]

Note that \((\alpha^\varepsilon, \beta^\varepsilon) \in \mathcal{U}\) for any \(\tau \in [0, 1]\). By inserting this variation into \((B.3)\), we derive

\[
\mathcal{I}(\alpha^\varepsilon, \beta^\varepsilon) - \mathcal{I}(\alpha^\varepsilon, \beta^\varepsilon) \leq \tau \sqrt{\varepsilon} \left( \|\alpha^\varepsilon - \alpha\|_\infty + \sum_{i=1}^{m} \|\beta_i^\varepsilon - \beta_i\|_\infty \right) \leq 2\tau \sqrt{\varepsilon}.
\]

Thus,

\[
\frac{d}{d\tau} \mathcal{I}(\alpha^\varepsilon, \beta^\varepsilon) \bigg|_{\tau=0} \geq -2\sqrt{\varepsilon}.
\]

It is well-known \([12]\) that the derivative in the left-hand side exists and equals

\[
\int_0^S p^\varepsilon(t) \cdot \left( f \left( x^\varepsilon(t), \alpha^\varepsilon(t), \beta^\varepsilon(t) \right) - f \left( x^\varepsilon(t), \alpha(t), \beta(t) \right) \right) dt,
\]

where \((x^\varepsilon, p^\varepsilon)\) satisfies the Hamiltonian system. Thus, for all \((\alpha, \beta) \in \mathcal{U}\), we have

\[
\int_0^S p^\varepsilon(t) \cdot \left( f \left( x^\varepsilon(t), \alpha(t), \beta(t) \right) - f \left( x^\varepsilon(t), \alpha^\varepsilon(t), \beta^\varepsilon(t) \right) \right) dt \leq 2\sqrt{\varepsilon}. \quad (B.4)
\]

4. Since the latter inequality holds for any \((\alpha, \beta) \in \mathcal{U}\) it should be also satisfied for maximizers of the following extremal problem

\[
\max_{(\alpha, \beta) \in \mathcal{U}} \int_0^S p^\varepsilon(t) \cdot f \left( x^\varepsilon(t), \alpha(t), \beta(t) \right) dt = \max_{\alpha \in \mathcal{A}} \max_{\beta \in \mathcal{B}(\alpha)} \int_0^S p^\varepsilon(t) \cdot f \left( x^\varepsilon(t), \alpha(t), \beta(t) \right) dt, \quad (B.5)
\]

where

\[
\alpha \in \mathcal{A} \doteq \left\{ \alpha \in \mathbf{L}^\infty([0, S]; \mathbb{R}) : \alpha(t) \in [0, 1], \int_0^S \alpha(t) dt = T \right\},
\]

\[
\beta \in \mathcal{B}(\alpha) \doteq \left\{ \beta \in \mathbf{L}^\infty([0, S]; \mathbb{R}^m) : \sum_{i=1}^{m} |\beta_i(t)| \leq 1 - \alpha(t) \right\}.
\]

By Filippov’s lemma \([25]\), problem \((B.5)\) can be rewritten as

\[
\max_{\alpha \in \mathcal{A}} \int_0^S \max_{\|b\|_{1-\alpha(t)} \leq 1} p^\varepsilon(t) \cdot f \left( x^\varepsilon(t), \alpha(t), b \right) dt,
\]

or briefly

\[
\max_{\alpha \in \mathcal{A}} \int_0^S \sigma \left( t, \alpha(t) \right) dt, \quad (B.6)
\]

where

\[
\sigma(t, \alpha) = \alpha h_0(t) + (1 - \alpha) \max_{1 \leq i \leq m} |h_i(t)|, \quad h_i(t) \doteq p^\varepsilon(t) \cdot g_i(x^\varepsilon(t)), \quad j = 0, m.
\]
5. It is easy to see that (B.6) is equivalent to the minimization problem

\[
\begin{align*}
\text{Minimize} & \quad \varphi(\alpha) = -\int_0^S \sigma(t, \alpha(t)) \, dt \\
\text{subject to} & \quad \psi(\alpha) = \int_0^S \alpha(t) \, dt - T = 0, \quad \alpha \in \tilde{A} = L^\infty([0,S];[0,1]) .
\end{align*}
\]

Let us show that this problem satisfies all the assumptions of Lemma \([B.1]\). Indeed, for \(\alpha_1 \equiv 1\) and \(\alpha_2 \equiv 0\), we have \(\psi(\alpha_2) = S - T > 0\) and \(\psi(\alpha_1) = -T < 0\). Finally, \((4.1)\) implies that \(\|h_i\|_{\infty}, i = 0,1, \ldots, n\), can be bounded from above by certain constant depending only on \(M\).

Thus, there exist \(\lambda_-\) and \(\lambda_+,\) depending only on \(M, T\) and \(S\), such that

\[
\lambda_- \leq \inf_{\tilde{A}} \varphi - \sup_{\tilde{A}} \varphi, \quad \inf_{\tilde{A}} \varphi - \sup_{\tilde{A}} \varphi \leq \lambda_+ .
\]

6. By Lemma \([B.1]\) there exists \(\lambda^* \in \mathbb{R}\) such that

\[
\max_{\alpha \in A} \int_0^S \sigma(t, \alpha(t)) \, dt = \max_{\alpha \in A} \left[ \int_0^S \sigma(t, \alpha(t)) \, dt + \lambda^* \left( \int_0^S \alpha(t) \, dt - T \right) \right] .
\]

Since \(T = \int_0^S \alpha^*(t) \, dt\), by Filippov’s lemma again, we conclude that the right-hand side of the latter identity takes the form

\[
\int_0^S \max_{a \in [0,1]} \left( \sigma(s, a) + \lambda^* \left( a - \alpha^*(s) \right) \right) ds .
\]

Here, the integrand is calculated as follows:

\[
\max_{a \in [0,1]} \left( a \left( h_0(t) + \lambda^* \right) + (1-a) \max_{1 \leq j \leq m} \| h_j(t) \| \right) - \lambda^* \alpha^*(t) = \\
\max \left\{ h_0(t) + \lambda^*, \max_{1 \leq j \leq m} \| h_j(t) \| \right\} - \lambda^* \alpha^*(s) .
\]

Finally, plugging the latter expression into \((B.4)\), we obtain

\[
\int_0^S \left[ \max \left\{ h_0(t) + \lambda^*, \max_{1 \leq j \leq m} \| h_j(t) \| \right\} - \alpha^*(t) \left( h_0(t) + \lambda^* \right) + \sum_{j=1}^m \beta_j(t) h_j(t) \right] dt \leq 2\sqrt{\varepsilon} ,
\]

as desired. \(\Box\)
