Abstract—We consider the framework of learning over decentralized networks, where nodes observe unique, possibly correlated, observation streams. We focus on the case where agents learn a regression function that belongs to a reproducing kernel Hilbert space (RKHS). In this setting, a decentralized network aims to learn nonlinear statistical models that are optimal in terms of a global stochastic convex functional that aggregates data across the network, with only access to a local data stream. We incentivize coordination while respecting network heterogeneity through the introduction of nonlinear proximity constraints. To solve it, we propose applying a functional variant of stochastic primal-dual (Arrow-Hurwicz) method which yields a decentralized algorithm. To handle the fact that the RKHS parameterization has complexity proportionate with the iteration index, we project the primal iterates onto Hilbert subspaces that are greedily constructed from the observation sequence of each node. The resulting proximal stochastic variant of Arrow-Hurwicz, dubbed Heterogeneous Adaptive Learning with Kernels (HALK), is shown to converge in expectation, both in terms of primal sub-optimality and constraint violation to a neighborhood that depends on a given constant step-size selection. Simulations on a correlated spatio-temporal random field estimation problem validate our theoretical results, which are born out in practice for networked oceanic sensing buoys estimating temperature and salinity from depth measurements.

I. INTRODUCTION

In decentralized optimization, each agent \( i \in \mathcal{V} \) in a network \( \mathcal{G} = (\mathcal{V}, \mathcal{E}) \) has a local objective but seek to cooperate with other agents to minimize the global network objective. The agents communicate only with their neighbors for solving the global objective. This global objective is sum of local convex objectives available at different nodes of the network and depends upon the locally observed information. This framework has yielded, for instance, networked controllers [2], [3], distributed signal processing [4], and federated machine learning [5], which have been successfully applied in robotics [6], and communications [7], and social media [8].

As compared to the existing classical distributed settings, where the agents agree to a common decision, i.e., consensus, we consider the setting where the neighboring agents decision are not necessarily equal but close to each other. In specific, when the observations of each agent are independent but not identically distributed then assuming consensus among agents observation may yield a sub-optimal solution. These type of heterogeneous networks are widely seen in robotic applications [9] where there are multiple number of aerial and ground robots gathering some local information where the decisions of neighboring robots will be close but need not be necessarily equal. Similarly, in case of wireless channel estimation problem, the channels estimated by neighboring nodes are supposed to be close but not equal to the channels estimated by every other node. By forcing all nodes decision to be equal to one another, we may degrade the local predictive performance [9], [10] by ignoring the diversity, whereas neglecting the behavior of neighbors would fail to utilize the relevant information overlap. This phenomenon may be mathematically encapsulated as convex non-linear proximity constraints. We focus on the case where each agent’s objective depends on a data stream, i.e., the online case [11], and the observations provided to the network are heterogeneous [9], [10], when agents decisions are defined not by a standard parameter vector but instead a nonlinear regression function that belongs to a reproducing kernel Hilbert space (RKHS).

Setting aside the constraints, the solution of stochastic programs, assuming no closed form exists, necessitates iterative tools. The simplest, gradient descent, requires evaluating an expectation which depends on infinitely many data realizations. This issue may be overcome through stochastic gradient descent (SGD) [12]. SGD is widely used in large-scale learning problems for this reason [11], but its limiting properties are intrinsically tied to the parameterization of the statistical model (decision variable) one chooses. For vector-valued parameterizations, i.e., linear statistical models, the convergence of SGD is well-understood [13] via convexity.

However, the optimization problems induced by nonlinear statistical models, which have much richer descriptive capability (owing to universal approximation [14]), are more challenging. Dictionary learning [15] and deep networks [16] lose convexity in pursuit of descriptive richness, which has led to a flurry of interest in non-convex stochastic optimization [17]. Generally, overcoming non-convexity requires adding noise that degrades parameter estimates [18], [19].

Alternatively, one may preserve convexity while obtaining nonlinearity (universality) through the “kernel trick,” a quirk of RKHS [20]. This fact motivates our focus on RKHS. Owing to the Representer Theorem [21], we may transform the function variable to an inner product of weights and kernel evaluations at samples. Unfortunately, the representational complexity is proportional with the sample size \( N \) [21], which for online settings \( N \rightarrow \infty \). To address this issue, we apply hard-thresholding projections that project functions onto subspaces extracted from the history of data observations, as in [22], which nearly preserves global convergence.
Now, we shift focus to multi-agent optimization. Typically, the global cost is additive across agents’ individual costs. Thus decentralized schemes may be derived by constraining agents’ decisions to be equal. One may solve such problems via primal-only schemes via penalty method [3], reformulating the consensus constraint in the dual domain [24, 25], and primal-dual approaches [26, 27] which alternate primal/dual descent/ascent on the augmented Lagrangian method with saddle point algorithm in Sec III. To address the problem a new collaborative learning systems methodology (Sec III), and obtain constrained problem [10]. This problem has been solved for we adopt a primal-dual approach to solving the proximity-constrained problem [10]. This problem has been solved for parametric settings in [10], [29], [50], and in the RKHS setting for consensus [31]. Here we generalize RKHS primal-dual method [32] to multi-agent optimization (Sec II), and obtain a new collaborative learning systems methodology (Sec III).

Next, we highlight the major contributions of this work. We formulate collaborative learning among heterogeneous agents as a constrained function-valued optimization problem in Sec II and derive a functional variant of stochastic saddle point algorithm in Sec III. To address the problem of memory growth in online function learning framework, we combine the alternating primal/dual stochastic gradient descent/ascent on the augmented Lagrangian method with compressive projections. The image of these projections are lower dimensional subspaces constructed greedily from past samples via matching pursuit [33].

Our main technical contribution of Sec. IV is to show that the proposed algorithm with constant step size converges to samples via matching pursuit [33].

Approximate primal-dual approaches [26], [27] which alternate primal/dual descent/ascent steps on the Lagrangian. Approximate dual primal-dual approaches [26], [27] which alternate primal/dual descent/ascent on the augmented Lagrangian method with saddle point algorithm in Sec III. To address the problem a new collaborative learning systems methodology (Sec III), and obtain a new collaborative learning systems methodology (Sec III).

In this work, we focus on extensions of the formulation in [1] to the case where data is scattered across an interconnected network that represents, for instance, robotic teams, communication systems, or sensor networks. To do so, we define a symmetric, connected, and directed network $G = (V, E)$ with $|V| = V$ nodes and $|E| = M$ edges and denote as $n_i := \{j: (i,j) \in E\}$ the neighborhood of agent $i$. Each agent $i \in V$ observes a local data sequence as realizations $(x_{i,t}, y_{i,t})$ from random pair $(x_i, y_i) \in \mathcal{X} \times \mathcal{Y}$ and seeks to learn a regression function $f_i$. This setting may be encoded by associating to each node $i$ a convex local proximity function $\ell_i: \mathcal{H} \times \mathcal{X} \times \mathcal{Y} \rightarrow \mathbb{R}$ that quantifies the merit of the estimator $f_i(x_i)$ evaluated at feature vector $x_i$, and defining the goal for each node as the minimization of the common global loss

$$\hat{f}^* = \arg\min_{f_i \in \mathcal{H}} \sum_{i \in V} \left( E_{x_i, y_i} \left[ \ell_i(f_i(x_i), y_i) \right] + \frac{\lambda}{2} \|f_i\|^2_\mathcal{H} \right).$$

Observe that for a connected network, the solution node-stacking of $V$ equivalent problems (2) is equivalent to (1) if $t_i$ nodes’ distinct functions are constrained to be equal $f_i = f_j$ for $j \in n_i$, as is standard in consensus – see, for instance, [3].

As a consequence of this formalism, the proximity constraint is to be symmetric, i.e., $h_{ij}(f_i, f_j) = h_{ji}(f_j, f_i)$. Thus, our goal is the stochastic program:

$$\mathbf{f}^* = \arg\min_{\{f_i\} \in \mathcal{H}} \sum_{i \in V} \left( E_{x_i, y_i} \left[ \ell_i(f_i(x_i), y_i) \right] + \frac{\lambda}{2} \|f_i\|^2_\mathcal{H} \right)$$

subject to $E_{x_i} \left[ h_{ij}(f_i(x_i), f_j(x_i)) \right] \leq \gamma_{ij}$, for all $j \in n_i$. (3)

Subsequently, define the space $\mathcal{H}^V$ of functions aggregated over the network whose elements are stacked functions $\mathbf{f}(\cdot) = [f_1(\cdot); \cdots; f_V(\cdot)]$ that yield vectors of length $V$ when evaluated at local random vectors $f(x) = [f_1(x_1); \cdots; f_V(x_V)] \in \mathbb{R}^V$. Moreover, define the stacked random vectors $x = [x_1; \cdots; x_V] \in \mathcal{X}^V \subseteq \mathbb{R}^{pV}$ and $y = [y_1; \cdots; y_V] \in \mathbb{R}^V$ that represents $V$ labels or physical measurements, for instance.
Observe that if \( h_{ij}(f_i(x_i)), f_j(x_j) = f_i(x_i) - f_j(x_i) \) and \( \gamma_{ij} = 0 \), the problem \( (3) \) specializes to online consensus optimization in RKHS, which has recently been solved in an approximate manner using penalty methods in \([31]\). Here, we seek to obtain exact optimal solutions to \( (3) \), where exactness refers to constraint satisfaction. In the subsequent section, we shift focus to doing so based upon Lagrange duality \([35]\). We specifically focus on distributed online settings where nodes do not know the distribution of the random pair \((x_i, y_i)\) but observe local independent samples \((x_{i,n}, y_{i,n})\) sequentially. In the following subsection, we detail the technical specifications of our choice of function space \( \mathcal{H} \).

### A. Function Estimation in Reproducing Kernel Hilbert Spaces

The optimization problem in \((1)\), and hence \((3)\), is intractable in general, since it defines a variational inference problem integrated over the unknown joint distribution \( P(x, y) \). However, when \( \mathcal{H} \) is equipped with a reproducing kernel \( \kappa : \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R} \) (see \([36, 37]\), a function estimation problem of the form \((1)\) may be reduced to a parametric form via the Representer Theorem \([38, 39]\). Thus, we restrict the Hilbert space to be reproducing Kernel Hilbert Space (RKHS), i.e., for \( f : \mathcal{X} \rightarrow \mathbb{R} \) in \( \mathcal{H} \), it holds that

\[
(i) \langle \hat{f}, \kappa(x_i, \cdot) \rangle_{\mathcal{H}} = \hat{f}(x_i), \quad (ii) \mathcal{H} = \text{span}\{\kappa(x_i, \cdot)\}
\]

for all \( x_i \in \mathcal{X} \). Here \( \langle \cdot, \cdot \rangle_{\mathcal{H}} \) denotes the Hilbert inner product for \( \mathcal{H} \). Further assume that the kernel is positive semidefinite, i.e. \( \kappa(x_i, x_i') \geq 0 \) for all \( x_i, x_i' \in \mathcal{X} \).

For kernelized and regularized empirical risk minimization (ERM), the Representer Theorem \([21, 40]\) establishes that the optimal \( \hat{f} \) in hypothesized function class \( \mathcal{H} \) admits an expansion in terms of kernel evaluations only over training examples

\[
\hat{f}(x_i) = \sum_{k=1}^{N} w_{i,k} \kappa(x_i, x_i),
\]

where \( w_i = [w_{i,1}, \ldots, w_{i,N}]^{T} \in \mathbb{R}^{N} \) denotes a set of weights. Here \( N \) in \((5)\) is referred to as the model order. For ERM the model order and sample size are equal.

Suppose, for the moment, that we have access to \( N \) i.i.d. realizations of the random pairs \((x_i, y_i)\) for each agent \( i \) such that the expectation in \((3)\) is computable, and we further ignore the proximity constraint. Then the objective in \((3)\) becomes:

\[
f^* = \arg\min_{f \in \mathcal{H}^N} \frac{1}{N} \sum_{i=1}^{N} \ell_i(f(x_i), y_i) + \frac{\lambda}{2} \|f\|_{\mathcal{H}}^{2}.
\]

From the Representer Theorem [cf. \([5]\)], it follows that \( (6) \) can be written as

\[
f^* = \arg\min_{w_i \in \mathbb{R}^{N}} \frac{1}{N} \sum_{k=1}^{N} \ell_i(w^{T}_k \kappa(x_i, x_i), y_i) + \frac{\lambda}{2} w^{T}_i \mathbf{K}_{x_i,x_i} w_i,
\]

where we have defined the Gram (or kernel) matrix \( \mathbf{K}_{x_i,x_i} \in \mathbb{R}^{N \times N} \), with entries given by the kernel evaluations between \( x_{i,m} \) and \( x_{i,n} \) as \( [\mathbf{K}_{x_i,x_i}]_{m,n} = \kappa(x_{i,m}, x_{i,n}) \). We further define the vector of kernel evaluations \( \mathbf{k}_{x_i, \cdot} = [\kappa(x_{i,1}, \cdot) \ldots \kappa(x_{i,N}, \cdot)]^{T} \) related to the kernel matrix as

\[
\mathbf{K}_{x_i,x_i} = [\kappa_{x_i,x_i}(x_{i,1}, \ldots, x_{i,N})],
\]

whose dictionary of associated training points is defined as \( \mathbf{X}_i = [x_{i,1}, \ldots, x_{i,N}] \).

The Representer Theorem allows us to transform a nonparametric infinite dimensional optimization problem in \( \mathcal{H}^{N} \) into a finite \( NV \)-dimensional parametric problem \((7)\). Thus, for ERM, the RKHS permits solving nonparametric regression problems as a search over \( \mathbb{R}^{N} \) for a set of coefficients.

However, to solve problems of the form \((6)\) when training examples \((x_{i,k}, y_{i,k})\) become sequentially available or their total number \( N \) is not finite, the objective in \((6)\) becomes an expectation over random pairs \((x_i, y_i)\) as \([20]\):

\[
f^* = \arg\min_{f \in \mathcal{H}^N} \frac{1}{N} \sum_{i=1}^{N} \mathbb{E}_{x_i,y_i} \left[ \ell_i(f(x_i), y_i) \right] + \frac{\lambda}{2} \|f\|_{\mathcal{H}}^{2}
\]

\[
+ \frac{\lambda}{2} \sum_{m,n \in I} w_{i,m} w_{i,n} \kappa(x_{i,m}, x_{i,n}) \|h_i\|_{H}^{2}.
\]

The Representer Theorem is generalized for the case of the infinite sample-size in \([39]\), and involves a countably infinite index set \( I \). That is, as the data sample size \( N \rightarrow \infty \), the representation of \( f_i \) becomes infinite as well. Our goal is to solve \((6)\) in an approximate manner such that each \( f_i \) admits a finite representation near \( f_i^* \), while satisfying the proximity constraints \( \mathbb{E}_{x_i} [h_{ij}(f_i(x_i), f_j(x_i))] \leq \gamma_{ij} \) for \((i, j) \in \mathcal{E}\), omitted for the sake of discussion between \((6)\) - \((8)\).

One wrinkle in the story is that the Representer Theorem in its vanilla form \([21, 40]\), does not apply to constrained problems \((3)\). However, recently, it has been generalized to the Lagrangian of constrained problems in RKHS \([32, 37]\)[Theorem 1]. To this end, some preliminaries are required, let us define the Lagrangian relaxation of \((3)\)

\[
\hat{L}(f, \mu) = \sum_{i \in \mathcal{V}} \mathbb{E}_{x_i,y_i} \left[ \ell_i(f_i(x_i), y_i) \right] + \frac{\lambda}{2} \|f_i\|_{\mathcal{H}}^{2}
\]

\[
+ \sum_{j \in n_i} \mu_j \mathbb{E}_{x_i} \left[ h_{ij}(f_i(x_i), f_j(x_i)) - \gamma_{ij} \right]
\]

where \( \mu = (\mu_1^{T}, \ldots, \mu_V^{T}) \) with each \( \mu_i \) associated with ith nodes constraints. The \( \mu_i \) is defined as \( \mu_i = (\mu_{i1}, \ldots, \mu_{i|n_i|})^{T} \), where \( |n_i| \) is the number of neighbors of node \( i \). Each \( \mu_i \in \mathbb{R}^{+} \) is the nonnegative Lagrange multiplier associated with constraint \( \mathbb{E}[h_{ij}(f_i(x_i), f_j(x_i))] \leq \gamma_{ij} \).

Throughout, we assume Slater’s condition, implying strong duality \([41]\). Hence the optimal of \((5)\) is identical to that of the primal-dual optimal pair \((f^*, \mu^*)\) of the saddle-point problem

\[
(f^*, \mu^*) = \arg\max_{f} \min_{\mu} \hat{L}(f, \mu).
\]

### Function Representation

Now, we shift to establishing the Representer Theorem applied to a version of the Lagrangian defined in \((10)\). Consider the empirical approximation of \((9)\) where the training set of node \( i \) is defined as \( S_i = \{x_{i,1}, y_{i,1}, \ldots, x_{i,N}, y_{i,N} \} \) with \( N \) samples. The empirical version of \((10)\) over samples \( S := \{S_1, \ldots, S_V\} \) is given by

\[
(f^*, \mu^*) = \arg\max_{f} \min_{\mu} \hat{L}^e(f, \mu),
\]
where $L^c(f, \mu)$ the empirical form of the Lagrangian:

$$L^c(f, \mu) := \sum_{i \in V} \left[ \frac{1}{N} \sum_{k=1}^{N} \left[ \ell_i(f_i(x_{i,k}), y_{i,k}) + \frac{\lambda}{2} \|f_i^k\|^2_{H^i} \right] \right]$$

(12)

$$+ \sum_{j \in n_i} \left( h_{ij}(f_i(x_{i,k}), f_j(x_{i,k})) - \gamma_{ij} \right),$$

Now, with this empirical formulation, we generalize the Representer Theorem for constrained settings to the multi-agent problem (12) as a corollary of [2] Theorem 1 with the proof provided in Appendix B of the supplementary material.

**Corollary 1** Let $\mathcal{H}$ be a RKHS equipped with kernel $\kappa$ and $S$ be the training data of the network. Each function $i$ that is a primal minimizer of (12) takes the form

$$f_i^* = \sum_{k=1}^{N} w_{i,k} \kappa(x_{i,k}, \cdot)$$

(13)

where $w_{i,k} \in \mathbb{R}$ are coefficients, and hence (13) applies to (11).

Next, we shift to solving (3) in distributed online settings where nodes do not know the distribution of the random pair $(x_i, y_i)$ but observe local samples $(x_{i,k}, y_{i,k})$ sequentially, through use of the Representer Theorem as stated in Corollary 1 that makes the function parameterization computable.

### III. ALGORITHM DEVELOPMENT

This section develops an online and decentralized algorithm for solving (3) when the functions $f_i, j \in V$ are elements of a RKHS. To do so, define the augmented Lagrangian relaxation of (3) as

$$\mathcal{L}(f, \mu) = \sum_{i \in V} \left[ \mathbb{E}_{x_i, y_i} \left[ \ell_i(f_i(x_i), y_i) \right] + \frac{\lambda}{2} \|f_i\|^2_{H^i} \right]$$

(14)

$$+ \sum_{j \in n_i} \left\{ \mu_{ij} \mathbb{E}_{x_i} \left[ \kappa_{ij}(f_i(x_i), f_j(x_i)) \right] \left[ \mathbb{E}_{x_i} \left[ \kappa_{ij}(f_i(x_i), f_j(x_i)) \right] \right] \right\}$$

where $\delta, \eta > 0$ for the dual variable $\mu_{ij}$ and we use the compact notation $\kappa_{ij}(f_i(x_i), f_j(x_i)) := h_{ij}(f_i(x_i), f_j(x_i))$ since $\gamma_{ij}$ is a constant. The regularization term in (14) is included in the design to control the violation of non-negative constraints on the dual variable over time $t$. We consider the stochastic estimate of the augmented Lagrangian evaluated at sample $(x_{i,t}, y_{i,t})$.

$$\hat{\mathcal{L}}(f, \mu) := \sum_{i \in V} \left[ \ell_i(f_i(x_{i,t}), y_{i,t}) + \frac{\lambda}{2} \|f_i\|^2_{H^i} \right]$$

(15)

$$+ \sum_{j \in n_i} \left\{ \mu_{ij} \mathbb{E}_{x_i} \left[ \kappa_{ij}(f_i(x_{i,t}), f_j(x_{i,t})) \right] \right\}$$

With this definition, we propose applying Arrow-Hurwicz to (15) — see [42]. To do so, we first require the functional stochastic gradient of (15) evaluated at a sample point $(x_{i,t}, y_{i,t})$. Begin by considering the local loss term in (15):

$$\nabla_{f_i} \ell_i(f_i(x_{i,t}), y_{i,t})(\cdot) = \frac{\partial \ell_i(f_i(x_{i,t}), y_{i,t})}{\partial f_i} \frac{\partial f_i(x_{i,t})}{\partial f_i}(\cdot)$$

(16)

where we have applied the chain rule. Now, define the shorthand notation $\ell_i'(f_i(x_{i,t}), y_{i,t}) := \partial \ell_i(f_i(x_{i,t}), y_{i,t})/\partial f_i(x_{i,t})$, for the derivative of $\ell_i(f(x_{i,t}), y_{i,t})$ with respect to its first scalar argument $f_i(x_{i,t})$ evaluated at $x_{i,t}$.

To evaluate the second term on the right-hand side of (16), differentiate both sides of the expression and use the reproducing property of the kernel with respect to $f_i$ to obtain

$$\frac{\partial f_i(x_{i,t})}{\partial f_i} = \frac{\partial (f_i, \kappa(x_{i,t}, \cdot))}{\partial f_i} = \kappa(x_{i,t}, \cdot).$$

(17)

Now, we substitute the kernel at $x_{i,t}$ on the right-hand side of (17) into the first term in (16) to obtain

$$\nabla_{f_i} \hat{\mathcal{L}}(f_i, \mu_i) = \ell_i'(f_i(x_{i,t}), y_{i,t}) \kappa(x_{i,t}, \cdot) + \lambda f_i$$

(18)

$$+ \sum_{j \in n_i} \mu_{ij} \kappa_{ij}(f_i(x_{i,t}), f_j(x_{i,t})) \kappa(x_{i,t}, \cdot).$$

where we apply analogous logic as that which yields (16) to (18). To simplify, define the $V$-fold stacking of (18) as

$$\nabla \hat{\mathcal{L}}(f_i, \mu_i) = \text{vec} \left[ \nabla f_i \hat{\mathcal{L}}(f_i, \mu_i) \right].$$

(19)

With these definitions, saddle point method on the augmented Lagrangian (14), which operates by alternating primal/dual stochastic gradient descent/ascent steps, is given as [42]:

$$f_{i+1} = f_i(1 - \eta \lambda) - \eta \text{vec} \left[ \ell_i'(f_i(x_{i,t}), y_{i,t}) \right.$$

$$+ \sum_{j \in n_i} \mu_{ij} \kappa_{ij}(f_i(x_{i,t}), f_j(x_{i,t})) \left] \right)^{\top}.$$

(20)

$$\mu_{i+1} = \mu_i + \eta \nabla \hat{\mathcal{L}}(f_i, \mu_i) \right].$$

(21)

Moreover, we require the step-size $\eta < 1/\lambda$ for regularization parameter $\lambda > 0$ in (1). Observe that (20) decouples along each agent $i \in V$:

$$f_{i,t+1} = f_{i,t}(1 - \lambda \eta) - \eta \left[ \ell_i'(f_{i,t}(x_{i,t}), y_{i,t}) \right.$$

$$+ \sum_{j \in n_i} \mu_{ij} \kappa_{ij}(f_{i,t}(x_{i,t}), f_j(x_{i,t})) \right] \kappa(x_{i,t}, \cdot)$$

(22)

Moreover, the dual update in (21) is vector-valued, and defined for each edge $(i, j) \in \mathcal{E}$. Since the constraints involve only pairwise interactions between nodes $i$ and neighbors $j \in n_i$, the dual update separates along each edge $(i, j)$:

$$\nabla \mu_{ij} \hat{\mathcal{L}}(f_i, \mu_i) = \mu_{ij} \kappa(x_{i,t}, \cdot) - \eta \mu_{ij} \kappa(x_{i,t}, \cdot)$$

(23)

The update of $\mu_{ij}$ is carried out by substituting (23) in (21) and using the fact that vector-wise projection is applied entry-wise thereby separating the vector of dual variables into local updates $\mu_{ij}$ as

$$\mu_{ij,t+1} = \left[ \mu_{ij,t}(1 - \delta \eta^2) + \eta \left( g_{ij}(f_{i,t}(x_{i,t}), f_j(x_{i,t})) \right) \right] \right].$$

(24)

The sequence of $(f_i, \mu_i)$ is initialized by $f_0 = 0 \in \mathcal{H}^V$ and $\mu = 0 \in \mathbb{R}^n_{+}$. Then the Representer theorem implies function
Combining the update in (22) along with the kernel expansion
\[ P \xi_{i,t} \kappa_{\xi_{i,t}}(\mathbf{x}) = \mathbf{w}_i^T \kappa_{\xi_{i,t}}(\mathbf{x}). \]  
We note that for the update in (22), the model order is
added to the columns in \( \xi_{i,t} \).

From (26) we note that each time one more column gets
added to the columns in \( \xi_{i,t} \), an instance of the curse of
kernelization [43]. We define the number of data points, i.e.,
the number of columns of \( \xi_{i,t} \) at time \( t \) as the model order.
We note that for the update in (22), the model order is
\( t - 1 \) and it grows unbounded with iteration index \( t \). This
challenge often appears in connecting nonparametric statistics
and optimization methods [20]. Next, motivated by (22),
we subsequently define compressive subspace projections of the
function sequence defined by (26) to trade off memory and
optimality.

1) Complexity Control via Subspace Projections: To al-
leviate the aforementioned memory bottleneck, we project the
function sequence (22) onto a lower dimensional subspace
such that \( \mathcal{D}_{i,t} \subseteq \mathcal{H} \), where \( \mathcal{D}_{i,t} \) is represented by a dictionary
\( \mathbf{D} = [\mathbf{d}_1, \ldots, \mathbf{d}_M] \). Being specific, \( \mathcal{H} \) has the
form \( \mathcal{H} = \{ f : \| f \| = \sum_{i=1}^M w_i \kappa(\mathbf{d}_i, \cdot) = \mathbf{w}^T \kappa(\cdot) \} = \mathcal{S}(\kappa(\mathbf{d}_1, \cdot), \ldots, \kappa(\mathbf{d}_M, \cdot)), \) and \( \mathbf{D} \) as
the resulting kernel matrix from this dictionary. In a similar
manner, we define dictionaries \( \mathbf{D}_{i,t} \) and subspace \( \mathcal{H}_{i,t} \),
for each agent at time \( t \). Similarly, the model order (i.e.,
the number of columns) of the dictionary \( \mathbf{D}_{i,t} \) is denoted by \( M_{i,t} \).
We enforce function parsimony by selecting dictionaries \( \mathbf{D}_i \)
with \( M_i << \mathcal{O}(t) \) for each \( i \).

Now, we propose projecting the update in (22) to a lower
dimensional subspace \( \mathcal{H}_{i,t+1} = \mathcal{S}(\kappa(\mathbf{d}_1, \cdot), \ldots, \kappa(\mathbf{d}_{M_{i,t}}, \cdot)) \) as
\[ f_{i,t+1} = \arg \min_{f \in \mathcal{H}_{i,t+1}} \left\| f - \left( f_{i,t} - \eta \nabla_{\mathbf{f}_i} \hat{L}_{i}(\mathbf{f}_i, \mu_i) \right) \right\|_{\mathcal{H}}^2 \]  
\[ := \mathcal{P}_{\mathcal{H}_{i,t+1}} \left[ f_{i,t} (1 - \eta \lambda) \right] - \eta \left[ \ell_i^* (f_{i,t}(\mathbf{x}_i), y_{i,t}) \right]
+ \sum_{j \in \mathcal{N}_i} \mu_{ij} g_j^* (f_{i,t}(\mathbf{x}_i), f_j(\mathbf{x}_i)) \kappa(\mathbf{x}_i, \cdot) \]
where we define the projection operator \( \mathcal{P}_{\mathcal{H}_{i,t+1}} \) onto subspace
\( \mathcal{H}_{i,t+1} \subset \mathcal{H} \) by the update (27).

Algorithm 1 Heterogeneous Adaptive Learning with Kernels (HALK)

Require: \{\( \mathbf{x}_i, y_{i,t}, \epsilon_t \}_{t=0,1,2,\ldots}, \eta \) and \( \delta \)
initialize \( f_{i,0}(\cdot) = 0, \mathbf{D}_{i,0} = [], \mathbf{w}_0 = [], \) i.e. initial
dictionary, coefficients are empty for each \( i \in \mathcal{V} \)
for \( t = 0, 1, 2, \ldots \) do
loop in parallel for agent \( i \in \mathcal{V} \)
Observe local training example realization \((\mathbf{x}_{i,t}, y_{i,t})\)
Send \( \mathbf{x}_{i,t} \) to neighbors \( j \in \mathcal{N}_i \) and receive \( f_{j,t}(\mathbf{x}_{i,t}) \)
Receive \( f_{j,t} \) from neighbors, \( j \in \mathcal{N}_i \) and send \( f_{i,t}(\mathbf{x}_{j,t}) \)
Compute unconstrained stochastic grad. step using (22)
Update dual variables for \( j \in \mathcal{N}_i \) using (24)
Update params: \( \mathbf{D}_{i,t+1} = [\mathbf{d}_{i,t}, \mathbf{x}_{i,t}], \mathbf{w}_{i,t+1} \) [cf. (26)]
Greedily compress function using matching pursuit
\((f_{i,t+1}, \mathbf{D}_{i,t+1}, \mathbf{w}_{i,t+1}) = \text{COMP}(\hat{f}_{i,t+1}, \mathbf{D}_{i,t+1}, \mathbf{w}_{i,t+1}, \epsilon_t)\)
end loop
end for

2) Coefficient update: The update (27), is equivalent to finding
coefficients of kernels evaluated at points of fixed dictionary
\( \mathbf{D}_{i,t+1} \in \mathbb{R}^{p \times M_i} \).

To notice this fact, we first form the original dictionary
\( \mathbf{D}_{i,t+1} \) and coefficient vector \( \mathbf{w}_{i,t+1} \)
\[ \mathbf{D}_{i,t+1} = [\mathbf{d}_{i,t}, \mathbf{x}_{i,t}], \]  
\[ \mathbf{w}_{i,t+1} = \left\{ \begin{array}{ll}
(1 - \eta \lambda) \left[ \mathbf{w}_{i,t} \right]_u, & \text{for } 0 \leq u \leq t - 1 \\
-\eta \left[ \ell_i^*(f_{i,t}(\mathbf{x}_i), y_{i,t}) \right]
+ \sum_{j \in \mathcal{N}_i} \mu_{ij} g_j^*(f_{i,t}(\mathbf{x}_i), f_j(\mathbf{x}_i)) \right), & \text{for } u = t
\end{array} \right. \]  
from the un-projected functional update step in (22). We
denote the un-projected functional functional update as
\[ \hat{f}_{i,t+1} = f_{i,t} - \eta \nabla_{\mathbf{f}_i} \hat{L}_i(\mathbf{f}_i, \mu_i) . \]
The stacked functional update of (29) using the stacked
functional stochastic gradient given in (19) can be written as
\[ \hat{f}_{i,t+1} = f_{i,t} - \eta \nabla_{\mathbf{f}_i} \hat{L}_i(\mathbf{f}_i, \mu_i) . \]

The number of columns of dictionary \( \mathbf{D}_{i,t+1} \) is \( M_{i,t+1} \), which is
also the length of \( \mathbf{w}_{i,t+1} \). For now, to simplify notation, we
denote \( \tilde{M}_{i,t+1} := M_{i,t+1} + 1 \). For a given dictionary
\( \mathbf{D}_{i,t+1} \), projecting \( \hat{f}_{i,t+1} \) onto the subspace \( \mathcal{H}_{i,t+1} \) is equivalent
to finding the coefficients \( \mathbf{w}_{i,t+1} \) associated with dictionary
\( \mathbf{D}_{i,t+1} \) which are given as
\[ \mathbf{w}_{i,t+1} = \mathbf{K}^{-1}_{\mathbf{D}_{i,t+1}, \mathbf{D}_{i,t+1}} \mathbf{K}_{\mathbf{D}_{i,t+1}, \mathbf{D}_{i,t+1}} \mathbf{w}_{i,t+1} , \]
where we define the cross-kernel matrix \( \mathbf{K}_{\mathbf{D}_{i,t+1}, \mathbf{D}_{i,t+1}} \) whose
\((n, m)\)th entry is given by \( \kappa(\mathbf{d}_{i,n}, \mathbf{d}_{i,m}) \). The other kernel
matrices \( \mathbf{K}_{\mathbf{D}_{i,t+1}, \mathbf{D}_{i,t+1}} \) and \( \mathbf{K}_{\mathbf{D}_{i,t+1}, \mathbf{D}_{i,t+1}} \) are defined similarly.
The number of columns in \( \mathbf{D}_{i,t+1} \) is \( M_{i,t+1} \), while the number
of columns in \( \mathbf{D}_{i+1} \) [cf. (28)] is \( M_{i+1} = M_{i,t+1} + 1 \). Next we
see, how the kernel dictionary \( \mathbf{D}_{i,t+1} \) is obtained from the
kernel dictionary \( \mathbf{D}_{i,t+1} \).
3) Dictionary Update: The kernel dictionary \( \mathbf{D}_{i,t+1} \) is selected based on a greedy compression technique \cite{43}. The kernel dictionary \( \mathbf{D}_{i,t+1} \) is formed from \( \mathbf{D}_{i,t+1} \) by selecting a subset of \( M_{i,t+1} \) columns from \( M_{i,t+1} \) number of columns of \( \mathbf{D}_{i,t+1} \) that best approximate \( \hat{f}_{i,t+1} \) in terms of Hilbert norm error, i.e., \( \| f_{i,t+1} - \hat{f}_{i,t+1} \|_H \leq \epsilon_t \), where \( \epsilon_t \) is the error tolerance. This can be done by kernel orthogonal matching pursuit (KOMP) \cite{45, 46}.

\[
(f_{i,t+1}, \mathbf{D}_{i,t+1}, \mathbf{w}_{i,t+1}) = \text{KOMP}(\hat{f}_{i,t+1}, \mathbf{D}_{i,t+1}, \mathbf{w}_{i,t+1}, \epsilon_t).
\]  

We use a destructive variant of KOMP with pre-fitting as done in \cite{22}. This algorithm starts with the full dictionary \( \mathbf{D}_{i,t+1} \) and sequentially removes the dictionary elements till the condition \( \| f_{i,t+1} - \hat{f}_{i,t+1} \|_H \leq \epsilon_t \) is violated. In order to ensure the boundedness of the primal iterates in the subsequent section, we consider a variant of KOMP that explicitly enforces the projection to be contained within a finite Hilbert norm ball, which has the practical effect of thresholding the coefficient vector if it climbs above a certain large but finite constant. Next, we analyze the theoretical performance of updates \cite{27} and \cite{24}, summarized as Algorithm 1.

IV. CONVERGENCE ANALYSIS

In this section, we establish the convergence of Algorithm 1 by characterizing both objective sub-optimality and constraint violation in expectation. Before doing so, we define terms to clarify the analysis. Specifically, the projected functional stochastic gradient associated with \cite{27} is defined as

\[
\nabla_f \hat{L}_t(f_t, \mu_t) = \left( f_{i,t} - P_{\mathcal{H}_{D_{i,t+1}}} [f_{i,t} - \eta \nabla_f \hat{L}_t(f_t, \mu_t)] \right) / \eta.
\]

Using \cite{33}, the update \cite{27} can be rewritten as \( f_{i,t+1} = f_{i,t} - \eta \nabla_f \hat{L}_t(f_t, \mu_t) \). We stack the projected stochastic functional gradient \( \nabla_f \hat{L}_t(f_t, \mu_t) \) and define the stacked version \( \nabla_f \hat{L}_t(f_t, \mu_t) = [\nabla_f \hat{L}_t(f_t, \mu_t), \ldots, \nabla_f \hat{L}_t(f_t, \mu_t)] \). Using this stacked gradient, the overall functional update \cite{27} takes the form

\[
f_{i+1} = f_t - \eta \nabla_f \hat{L}_t(f_t, \mu_t).
\]

Next, we state the assumptions required for the convergence.

Assumption 1 The feature space \( \mathcal{X} \subset \mathbb{R}^p \) and target domain \( \mathcal{Y} \subset \mathbb{R} \) are compact, and the kernel map may be bounded as

\[
\sup_{x \in \mathcal{X}} \sqrt{k(x, x)} = X < \infty
\]

Assumption 2 The local losses \( \ell_i(f_t(x), y) \) are convex and differentiable with respect to the first (scalar) argument \( f_t(x) \) on \( \mathbb{R} \) for all \( x \in \mathcal{X} \) and \( y \in \mathcal{Y} \). Moreover, the instantaneous losses \( \ell_i: \mathcal{X} \times \mathcal{X} \times \mathcal{Y} \to \mathbb{R} \) are \( C_t \)-Lipschitz continuous

\[
|\ell_i(z, y) - \ell_i(z', y)| \leq C_t |z - z'| \quad \text{for all } z \text{ with } y \text{ fixed. (36)}
\]

Further define \( C := \max_t C_t \) as the largest modulus of continuity.

Assumption 3 The constraint functions \( h_{ij} \) for all \((i, j) \in \mathcal{E} \) are all uniformly \( L_h \)-Lipschitz continuous in its first (scalar) argument; i.e., for any \( z, z' \in \mathbb{R} \), there exist constant \( L_h \), such that

\[
|h_{ij}(z, y) - h_{ij}(z', y)| \leq L_h |z - z'|
\]

and is also convex w.r.t the first argument \( z \).

Assumption 4 There exists strictly feasible local functions \( f_i, f_j \in \mathcal{H} \) s.t. \( E_z \left[h_{ij}(f_i(x_i), f_j(x_i)) \right] < \gamma_{ij} \), for all \( j \in n_i \).

Assumption 5 The functions \( f_{i,t+1} \) output from KOMP have Hilbert norm bounded by \( R_B \leq \infty \). Also, the optimal \( f^*_i \) lies in the ball \( B \) with radius \( R_B \).

Often, Assumption 1 holds by data domain itself. Assumptions 2 and 3 ensure that the constrained stochastic optimization problem is convex and smooth, which are typical of first-order methods. Assumption 4 i.e., Slater’s condition, ensures the feasible set of \cite{5} is non-empty, and is standard in primal-dual methods \cite{41}. Assumption 5 ensures that the algorithm iterates and the optimizer are finite, and their domains overlap. Under these conditions, the following bounds on the primal and dual stochastic gradients used for \cite{27} and \cite{24}, respectively, hold.

**Lemma 1** Using Assumptions 1-4, the mean-square magnitude of the primal and dual gradients of the stochastic augmented Lagrangian \( L_t(f, \mu) \) defined in \cite{15} are upper-bounded as

\[
E[\| \nabla_f \hat{L}_t(f_t, \mu_t) \|_2^2] \leq 4V^2 X^2 C_t^2 + 4V X^2 L_h^2 M \| \mu \|_2^2
\]

\[
+ 2V^2 \ell_1^2 R_B^2
\]

\[
E \left[ \| \nabla_{\mu} \hat{L}_t(f_t, \mu_t) \|_2^2 \right] \leq M \left( 2K_1 + 2L_h^2 X^2 R_B^2 + 2\delta^2 \ell_1^2 \right) \| \mu \|_2^2
\]

for some \( 0 < K_1 < \infty \).

The proof of Lemma 1 is provided in Appendix A. Now with these primal and dual variable gradient bound, we move to analyze the convergence of objective function error and accumulation of constraint violation in expectation. First, the following lemma bounds the difference of projected stochastic functional gradient and un-projected stochastic functional gradient (proof in Appendix C in the supplementary material).

**Lemma 2** The difference between the stochastic functional gradient defined by \( \nabla_f \hat{L}_t(f_t, \mu_t) \) and projected stochastic functional gradient \( \nabla_f \hat{L}_t(f_t, \mu_t) - \hat{L}_t(f_t, \mu_t) \), is bounded as

\[
\| \nabla_f \hat{L}_t(f_t, \mu_t) - \nabla_f \hat{L}_t(f_t, \mu_t) \|_H \leq \frac{\sqrt{v} \epsilon_t}{\eta}
\]

for all \( t > 0 \). Here, \( \eta > 0 \) is the algorithm step-size and \( \epsilon_t > 0 \) is the error tolerance parameter of the KOMP.

Next, Lemma 3 (proof in Appendix C in the supplementary material) characterizes the instantaneous Lagrangian difference \( \hat{L}_t(f_t, \mu_t) - \hat{L}_t(f_t, \mu_t) \).
Lemma 3 If the Assumptions \(\mathcal{C}\) hold and we have primal
and dual update generated from Algorithm \(\mathcal{D}\) then the instantaneous
Lagrangian difference satisfies the following decrement property
\[
\tilde{L}_t(f_t, \mu_t) - \tilde{L}_{t+1}(f_{t+1}, \mu_{t+1}) \leq \frac{1}{2\eta} \left( \|f_t - f_t\|^2_H + \|f_{t+1} - f_t\|^2_H + \|\mu_t - \mu_{t+1}\|^2 - \|\mu_{t+1} - \mu_t\|^2 \right) + \eta \frac{2}{7} \left( \|\nabla f_t(\tilde{L}_t(f_t, \mu_t))\|^2_H + \|\nabla f_{t+1}(\tilde{L}_t(f_t, \mu_t))\|^2_H \right) + \frac{\sqrt{V} \epsilon_t}{\eta} \|f_t - f_t\|^2_H + \frac{V \epsilon_t^2}{\eta}.
\]

Based upon these lemmas, we may establish our central result,
which is the mean convergence of Algorithm \(\mathcal{I}\) in terms of sub-optimality and feasibility.

Theorem 1 Suppose Assumptions \(\mathcal{P}\) hold, and denote as
\((f_t, \mu_t)\) the primal-dual sequence of Algorithm \(\mathcal{I}\) under constant
step-size \(\eta = T^{-1/2}\) and compression budget \(\epsilon = 7\eta^2\).
Here the scalar \(P > 0\) is defined as the parsimony constant.

i) The time-aggregation of the expected sub-optimality grows sub-linearly with horizon \(T\) as
\[
\sum_{t=1}^{T} \mathbb{E}[S(f_t) - S(f^*)] \leq \mathcal{O}(\sqrt{T}).
\]
where \(S(f_t) := \sum_{i \in V} \left[ \hat{L}_t(f_i, x_i) + \frac{1}{2} \|f_i\|^2_H \right]\) and \(f^*\) is defined by \(\mathcal{I}\).

ii) Moreover, the average time-aggregation of constraint violation grows sub-linearly with horizon \(T\) as
\[
\sum_{(i,j) \in E} \mathbb{E} \left[ \sum_{t=1}^{T} (\hat{h}_{ij}(f_i, x_i), f_j(x_i)) - \gamma_{ij} \right] \leq \mathcal{O}(T^{3/4}).
\]

Proof: The proof depends on the result of Lemma 3 defined in \(\mathcal{I}\). We expand the left-hand side of \(\mathcal{I}\) using \(\mathcal{I}\) and use the definition of \(S(f_t)\) stated in the Theorem \(\mathcal{I}\) and obtain the following expression,
\[
\sum_{i \in V} \left[ \hat{L}_t(f_i, x_i), y_{i,t} + \frac{\lambda}{2} \|f_i\|^2_H \right] + \sum_{(i,j) \in E} \left[ \mu_{ij}, (g_{ij}(f_i, x_i), f_j(x_i)) \right] - \frac{\delta \eta}{2} \mu_{ij}^2 \right]
\]
\[
\sum_{i \in V} \left[ \hat{L}_t(f_i, x_i), y_{i,t} + \frac{\lambda}{2} \|f_i\|^2_H \right] + \sum_{(i,j) \in E} \left[ \mu_{ij}, (g_{ij}(f_i, x_i), f_2(x_i)) \right] - \frac{\delta \eta}{2} \mu_{ij}^2 \right]
\]
\[
\leq \frac{1}{2\eta} \left( \|f_t - f_t\|^2_H + \|f_{t+1} - f_t\|^2_H + \|\mu_t - \mu_{t+1}\|^2 - \|\mu_{t+1} - \mu_t\|^2 \right) + \frac{\sqrt{V} \epsilon_t}{\eta} \|f_t - f_t\|^2_H + \frac{V \epsilon_t^2}{\eta}.
\]

Before discussing the analysis, we introduce the following compact notations to make the analysis clear and compact. We will denote the expressions involving \(g_{ij}(\cdot, \cdot)\) as
\[
g_{ij}(f_i(x_i)) := \hat{g}_{ij}(f_i, x_i, f_j(x_i))
\]
\[
g_{ij}(f_i(x_i)) := \hat{g}_{ij}(f_i, x_i, f_j(x_i)).
\]

Next, we compute the expectation not only on the random pair \((x, y)\) but also on the entire algorithm history, i.e., on sigma algebra \(F_t\) which measures the algorithm history for times \(u \leq t\), i.e., \(F_t \supseteq \{x_u, y_u, f_u, \mu_u\}_{u=0}^{t-1}\) on both sides of \(\mathcal{I}\). The left hand side of \(\mathcal{I}\) becomes
\[
\mathbb{E}[S(f_t) - S(f) + \sum_{(i,j) \in E} \left[ \mu_{ij}, (g_{ij}(f_i(x_i))) - \delta \eta \right] \cdot \mu_{ij}^2 - \|\mu_{t+1} - \mu_t\|^2 \right]
\]
\[
+ \frac{\sqrt{V} \epsilon_t}{\eta} \|f_t - f_t\|^2_H + \frac{V \epsilon_t^2}{\eta}
\]
\[
= \left[ \frac{\delta \eta}{2} \|\mu_t\|^2 \right] + \left[ \frac{\eta}{2} \right] \left( \frac{2(4V^2C^2 + 4V^2L^2M^2 + 2V^2 \lambda \cdot R_B)}{\eta} \right) + \left[ \frac{\eta}{2} \right] \left( 2K + 2L^2 M^2 \cdot R_B^2 + 2\delta^2 \eta^2 \|\mu_t\|^2 \right)
\]

Since each individual \(f_i, t, f_i\) for \(i = \ldots, V\) in the ball \(B\) have finite Hilbert norm and is bounded by \(R_B\), the term \(\|f_t - f_t\|^2_H\) can be upper bounded by \(2\sqrt{V} R_B\). Next, we define \(K := 8V^2L^2M + 2M\delta^2 \eta^2 - \delta\). Next, we select the constant parameter \(\delta\) such that \(C(\delta) \leq 0\), which then allows us to drop the term involving \(\|\mu_t\|^2\) from the second expected term of right-hand side of \(\mathcal{I}\). Further, we set the approximation budget \(\epsilon_t = \epsilon\), take the sum of the expression
in (48) over times \( t = 1, \ldots, T \), assume the initialization \( f_1 = 0 \in \mathcal{H}^V \) and \( \mu_1 = 0 \in \mathbb{R}^M_+ \), we get

\[
\sum_{t=1}^{T} \mathbb{E} \left[ S(f_t) - S(f^*) \right] + \sum_{(i,j) \in E} \left[ \mu_{ij}(g_{ij}(f_t(x_i))) - \mu_{ij}(g_{ij}(f(x_i))) \right] - \frac{\delta \eta T}{2} \| \mu \|^2 \leq \frac{1}{2\eta} \left( \| f \|_2^2 + \| \mu \|_2^2 \right) + \frac{2V_{T} R_B + V \epsilon T}{\eta} + \eta KT. \tag{49} \]

where we drop the negative terms remaining after the telescopic sum since \( \| f_T - f \|_2^2 \) and \( \| \mu_T - \mu \|_2^2 \) are always positive. It can be observed from (49) that the right-hand side of this inequality is deterministic. We now take \( f \) to be the solution \( f^* \) of (3), which in turn implies \( f^* \) must satisfy the inequality constraint of (3). This means that \( f^* \) is a feasible point, such that \( \sum_{t=1}^{T} \sum_{(i,j) \in E} \mu_{ij}(g_{ij}(f_t^*(x_i(t)), f_T^*(x_i(t)))) \leq 0 \) holds. Thus we can simply drop this term and collecting the terms containing \( \| \mu \|^2 \) together, we further obtain

\[
\sum_{t=1}^{T} \mathbb{E} \left[ S(f_t) - S(f^*) \right] + \sum_{(i,j) \in E} \left[ \mu_{ij}(g_{ij}(f_t(x_i))) \right] - z(\eta, T) \| \mu \|^2 \leq \frac{1}{2\eta} \| f \|_2^2 + \frac{V_T}{\eta} \left( 2R_B + \epsilon \right) + \eta KT. \tag{50} \]

where \( z(\eta, T) := \left( \frac{\delta \eta T}{2} + \frac{T}{2\eta} \right) \). Next, we maximize the left-hand side of (50) over \( \mu \) to obtain the optimal Lagrange multiplier which controls the growth of the long-term constraint violation. Specifically, the function of \( \mu \) has a minimizer \( \bar{\mu} \in \mathbb{R}^M_+ \). Thus for any \( i = 1, \ldots, V \) and \( j = 1, \ldots, M \), the optimal value of \( \mu_{ij} \) is given by

\[
\bar{\mu}_{ij} = \mathbb{E} \left[ \frac{1}{2(\delta \eta T + 1/\eta)} \sum_{t=1}^{T} \left( g_{ij}(f_t(x_i)) \right) \right].
\]

Now, substituting \( \bar{\mu} \) in place of \( \mu \) in the left hand side of (50), it becomes

\[
\mathbb{E} \left[ \sum_{t=1}^{T} \left[ S(f_t) - S(f^*) \right] + \sum_{(i,j) \in E} \left[ \sum_{t=1}^{T} g_{ij}(f_t(x_i)) \right]^2 \right] \leq \frac{\sqrt{T}}{2} K_2. \tag{51} \]

The first term in (51) denotes the primal optimality gap and the second term denotes the commutative constraint violation. We consider step-size \( \eta = 1/\sqrt{T} \) and approximation budget \( \epsilon = P\eta^2 = P/T \), where \( P > 0 \) is a fixed constant. Substituting these in (51) and then considering the upper bound in (50), we get

\[
\mathbb{E} \left[ \sum_{t=1}^{T} \left[ S(f_t) - S(f^*) \right] + \sum_{(i,j) \in E} \left[ \sum_{t=1}^{T} g_{ij}(f_t(x_i)) \right]^2 \right] \leq \frac{\sqrt{T}}{2} K_2. \tag{52} \]

where \( K_2 := \left( \| f \|_2^2 + 4VPR_B + \frac{2V\epsilon^2}{\eta^2} + K \right) \). The expression in (52) serves as the basis which allows us to derive convergence result of both the objective function and the feasibility of the proposed iterates. Considering first the objective error sequence \( \mathbb{E}[S(f_t) - S(f^*)] \), we observe from (52) that the second term present on the left-side of the inequality can be dropped without affecting the inequality owing to the fact that it is positive. So we obtain

\[
\sum_{t=1}^{T} \mathbb{E}[S(f_t) - S(f^*)] \leq O(\sqrt{T}) \tag{53} \]

which is as stated in (42) of Theorem 1. Next, we establish the sublinear growth of the constraint violation in \( T \). For this consider the objective error sequence,

\[
S(f_t) - S(f^*) = \mathbb{E} \left[ \sum_{i \in V} \delta_{t,i} \left( f_{t,i}(x_t) - f_{t,i}'(x_t) \right) \right] + \frac{\lambda}{2} \sum_{i \in V} \left( \| f_{t,i} \|_{\mathcal{H}}^2 - \| f_{t,i}^* \|_{\mathcal{H}}^2 \right). \tag{54} \]

Next, we bound the objective error sequence as

\[
S(f_t) - S(f^*) \leq \mathbb{E} \left[ \sum_{i \in V} \left( \| f_{t,i} \|_{\mathcal{H}}^2 - \| f_{t,i}^* \|_{\mathcal{H}}^2 \right) \right] + \frac{\lambda}{2} \sum_{i \in V} \left( \| f_{t,i} \|_{\mathcal{H}}^2 - \| f_{t,i}^* \|_{\mathcal{H}}^2 \right). \tag{55} \]

where using triangle inequality we write the first inequality and then using Assumption 2 of Lipschitz-continuity condition we write the second inequality. Further, reproducing property of \( \kappa \) and Cauchy-Schwartz inequality, we simplify \( f_{t,i}(x_{t,i}) - f_{t,i}^*(x_{t,i}) \) in (55) as

\[
f_{t,i}(x_{t,i}) - f_{t,i}^*(x_{t,i}) = \| f_{t,i} - f_{t,i}^* \|_{\mathcal{H}} \cdot \| \kappa(x_{t,i}, \cdot) \|_{\mathcal{H}} \leq 2R_B X \tag{56} \]

where the last inequality comes from Assumption 1 and 4. Now, we consider the \( \| f_{t,i} \|_{\mathcal{H}}^2 - \| f_{t,i}^* \|_{\mathcal{H}}^2 \) present in the right-hand side of (55),

\[
\| f_{t,i} \|_{\mathcal{H}}^2 - \| f_{t,i}^* \|_{\mathcal{H}}^2 \leq \| f_{t,i} - f_{t,i}^* \|_{\mathcal{H}} \cdot \| f_{t,i} + f_{t,i}^* \|_{\mathcal{H}} \leq 4R_B \| X \|_{\mathcal{H}} \tag{57} \]

Substituting (56) and (57) in (55), we obtain

\[
S(f_t) - S(f^*) \leq 2V\epsilon R_B X + 2V\epsilon R_B = 2V\epsilon R_B (C_X + \lambda R_B). \tag{58} \]

Thus \( S(f_t) - S(f^*) \) can be lower bounded as

\[
S(f_t) - S(f^*) \geq -2V\epsilon R_B (C_X + \lambda R_B). \tag{59} \]

Substituting this lower bound in (52), we get

\[
\mathbb{E} \left[ -TK_3 + \sum_{(i,j) \in E} \left( \sum_{t=1}^{T} g_{ij}(f_t(x_i)) \right)^2 \right] \leq \frac{\sqrt{T}}{2} K_2. \tag{59} \]

where \( K_3 := 2V\epsilon R_B (C_X + \lambda R_B) \). After re-arranging (59), we get

\[
\mathbb{E} \left[ \sum_{(i,j) \in E} \left( \sum_{t=1}^{T} g_{ij}(f_t(x_i)) \right)^2 \right] \leq 2\sqrt{T}(\delta+1) \left( \frac{\sqrt{T}}{2} K_2 + TK_3 \right) \tag{60} \]

\[
= 2T^{1.5}(\delta+1) \left( \frac{K_2}{2\sqrt{T}} + K_3 \right). \tag{60} \]
Since the square of individual proximity constraint violation is a positive term thus it is upper bounded by the square of the network in-aggregate constraint violation and we can write
\[ \mathbb{E}\left[ \sum_{t=1}^{T} g_{ij}(f_{t}\{x_{t}\}) \right]^{2} \leq \mathbb{E}\left[ \sum_{(i,j) \in E} \sum_{t=1}^{T} g_{ij}(f_{t}\{x_{t}\}) \right]^{2}. \] (61)

Thus by using (61) in (60) we can write,
\[ \mathbb{E}\left[ \sum_{t=1}^{T} g_{ij}(f_{t}\{x_{t}\}) \right]^{2} \leq 2T^{1.5}(\delta + 1) \left[ K_{2}/2\sqrt{T} + K_{3} \right]. \] (62)

Taking square root of both the sides of (62) and summing over all the edges, we get the desired result in (63).

Theorem 1 establishes that the time-aggregation of the sub-optimality sequence associated of Algorithm 1 when run with fixed algorithm step-size \( \eta = 1/\sqrt{T} \) is bounded by constant less than \( T \), i.e., \( O(\sqrt{T}) \). Moreover, the constraint violation decays at a \( O(T^{3/4}) \) rate. Thus both the sub-optimality and constraint violation vanish on average when time \( T \) is large.

These results match standard constrained stochastic approximation rates for unconstrained settings \[47\] and constrained settings \[10\]. The radius of these error neighborhood may be reduced by appropriately adjusting the step-size \( \eta = 1/\sqrt{T} \). We present these results in this form so the link between mean convergence behavior of stochastic methods and regret analysis of online learning \[34\] is clear. Thus in this paper we generalize the result of sublinear convergence of objective error sequence and constraint violation in \[32\] to multi-agent settings with proximity constraints. We next move to numerically evaluate our proposed Algorithm 1 in the next section for solving proximity constrained function learning problems in RKHS on synthetic data set and real data set.

V. NUMERICAL RESULTS

In this section, we apply the proposed algorithm to solve a spatial temporal random field estimation problem and an another problem of inferring from oceanographic data.

A. Spatio-temporal Random Field Estimation

The estimation of a spatio-temporal field using a set of sensors spread across a region with required level of accuracy is an important challenge in wireless sensor networks (WSNs) \[48, 49\]. Various phenomena exhibit spatial temporal variation, as in environmental, biological and geophysical processes. The variation of spatio-temporal field over space and time can be modelled by its correlation [50].

Consider the problem of estimating a temporally varying spatial planar correlated Gaussian random field in a given region \( \mathcal{G} \subset \mathbb{R}^{2} \) space. A spatial temporal random field is a random function of the spatial components \( u \) (for x-axis) and \( v \) (for y-axis) across a region \( \mathcal{G} \) and time. Moreover, random field is parameterized by the correlation matrix \( \mathbf{R}_{\mathcal{G}} \), which depends on the location of the sensors. Each element of \( \mathbf{R}_{\mathcal{G}} \) is assumed to have a structure of the form \( \Omega(l_{i}, l_{j}) = e^{-\|l_{i} - l_{j}\|} \), where \( l_{i} \) and \( l_{j} \) are the respective locations of sensor \( i \) and \( j \) in region \( \mathcal{G} \) [51]. From this correlation, note that the nodes close to each other have high correlation whereas nodes located far away are less correlated. This captures the fact that the observations collected from the nearby nodes are more relevant than observations from distant nodes.

We considered a sensor network with \( V \) nodes where each node \( i \) collects the observation \( y_{i,t} \) at time instant \( t \). In the collected data, \( y_{i,t} \) denotes the noisy version of the original field \( s_{i,t} \) at node \( i \) for time instant \( t \). The observation model is given by \( y_{i,t} = s_{i,t} + n_{i,t} \), where \( n_{i,t} \sim \mathcal{N}(0,0.5) \) is i.i.d. The objective of each node is to sequentially minimize its own local loss i.e., \( (y_{i,t} - \hat{s}_{i,t})^{2} \), where \( \hat{s}_{i,t} \) is the estimated value of actual field \( s_{i,t} \).

For simulation, we considered a network of randomly connected 40 nodes which are spatially distributed in a 100 \( \times \) 100 meter square area. The instantaneous observation \( s_{i} \) across the network is given by \( s_{i} = \pi + \mathbf{C} \{1 \sin(\omega t) + \nu_{t}\} \), where \( \mathbf{C} \) is a vector of ones of length \( V \), \( \sin(\omega t) \) is a sinusoidal with angular frequency \( \omega = 2 \). \( \pi = \{1/V, 2/V, \ldots, 1\} \) is a fixed mean vector of length \( V \). \( \nu_{t} \sim \mathcal{N}(0,0.1I) \), where \( I \) denotes an identity matrix of dimension 40 by 40. We select tolerance parameter to be \( \gamma = 0.05 \). The observations \( s_{i} \) denote the physical quantity such as temperature or height of tides. For instance, the temperature would rise during day time and fall during night time. Hence, the the angular frequency denotes the rate of temperature variation over time.

We solve the problem (3) of minimizing the regularized loss function over \( f_{t} \) where we learn the function \( f_{t}(t) \), which is the function approximation to the actual field, \( s_{i,t} \), i.e., we solve a curve fitting problem. We use our proposed Algorithm 1 to minimize the loss between \( f_{t}(t) \) and \( y_{i,t} \) using (22) and (24) and do compression using KOMP with parsimony constant, \( P \) set at 8 [Theorem 1]. The Gaussian kernel is used to do the function approximation with a bandwidth parameter \( \sigma = 0.05 \). The bandwidth parameter of the Gaussian kernel is taken 0.05 such that we capture the variation of sinusoidal function with angular frequency of 2. The primal and dual regularizer parameter, \( \lambda \) and \( \delta \) are set at \( 10^{-5} \). We run the algorithm for 1500 iterations with a constant step size of \( \eta = 0.01 \).

For comparison purposes, we consider two other techniques to solve the same problem namely; consensus with kernels via penalty method [31] and proximity-constrained linear decentralized statistical models, which we call linear method [10]. For comparison with the penalty method, the penalty coefficient is 0.08 which is tuned for the best performance while all the other simulation parameters are same as that of the proposed algorithm. For linear method, we consider three parametric models: (a) Quadratic polynomial; (b) Cubic polynomial and (c) Sine polynomial (i.e., of the form \( at^{2} + b \sin(\zeta t) \) where \( a \) and \( b \) are the model parameters and \( \zeta \) is the angular frequency taken to be 1 in the simulations). All the three linear methods are linear with respect to the parameters of the polynomial.

Fig. 1 [32] displays the results of this comparison. In particular, Fig. 1a compares the global network wide averaged loss for three different methods, which shows that the linear method is unable to effectively track the target variable the model behavior. The linear sine polynomial model (denoted as “Sine”) is closer to the target than the quadratic (denoted as “Degree 2”) or cubic polynomial (denoted as “Degree 3”). The RKHS
proximity-constrained method (Algorithm 1) improves upon penalty method. Fig. 1b demonstrates that Algorithm 1 also performs better in terms of constraint violation relative to penalty method, and is comparable to the linear method. Doing so allows nodes estimates to be close to neighbors, and the level of closeness is encoded through proximity tolerances.

Fig. 1c plots the model order for primal-dual method and penalty method, which omits linear method plots because its a parametric method with fixed complexity equal to the parameter dimension $p$. Early on, primal-dual method (being an exact method) has higher complexity than penalty method. In steady state, Algorithm 1 and penalty method have comparable complexity. With a similar model complexity, we attain near-exact constraint satisfaction via primal-dual method as compared to penalty method. Overall, the model complexity of 30 is orders of magnitude smaller than sample size 1500.

B. Inferring Oceanographic Data

Wireless sensor networks may also be used to monitor various environmental parameters, especially in oceanic settings. To this end, we associate each node in the network to an oceanic buoy tasked with estimating salinity and temperature when deployed at standard depths. Decentralization is advantageous here due to the fact that server stations are impractical at sea, and centralization may exceed the cost of computation per node [52]. Thus, we run Algorithm 1 on the World Oceanic Database [53], obtained from multiple underwater sensors in the Gulf of Mexico. In this Gulf of Mexico Regional Climatolog data set, temperature, salinity, oxygen, phosphate, silicate, and nitrate are recorded at various depth levels.

We restrict focus to temperature and salinity parameters at different locations with varying depths, during the winter time-period. The readings of the climatological fields are obtained for a particular latitude and longitude at standard depths starting from 0 meters to 5000 meters. The latitude and longitude specifies the node (sensor) location. Similar readings are obtained for various locations spanning the water body. The experiment is carried out considering 50 nodes, where edges are determined by measuring the distance between two nodes, and drawing an edge to a particular node if its distance is less than 1000 kilometers away. The proximity parameter $\gamma_{ij}$ between two nodes is obtained by evaluating $\exp(-\text{dist}(i,j)/1000)$, where $\text{dist}(i,j)$ measures the distance between two nodes in kilometers.

We use Algorithm 1 to learn $y_i = f_i(d)$ which gives the value of climatological field $y_i$ at a depth $d_i$ such as salinity or temperature at each node $i$. We solve problem 3 by minimizing the regularized quadratic loss between estimated climatological field $f_i(d_i)$ and observed climatological field $y_i$ over function $f_i$ using Algorithm 1. A key benefit of doing so is the ability to interpolate missing measurements which are a rampant issue due to, e.g., limited battery life or bandwidth availability. Next, we discuss the specific implementation details and compare the performance to a centralized approach.
where all data is shipped to a single location.

1) Temperature: Here we use the Algorithm 1 for predicting the statistical mean of the temperature field of different nodes at varying depths. The real data obtained from the World Oceanic database has statistical mean of the temperature field.

We run the the algorithm for 2430 iterations with constant step-size $\eta = 0.01$ and regularizers $\lambda, \delta$ set to $10^{-5}$. The Gaussian kernel is used for the function learning with a bandwidth parameter $\sigma = 50$, and parsimony constant is fixed at two values, $P = 0.4$ and $P = 40$. The parsimony constant for learning a single function $f$ for all the data obtained across different locations is set at $P = 0.001$ to ensure a fair comparison of comparably sized models between the decentralized and centralized methods.

Fig. 2 shows the numerical experiment results for the ocean data. Fig. 2a demonstrates that the prediction error for test cases reduces with increasing samples, a consequence of stochastic descent behavior. In Fig. 2a the centralized function (denoted as “Single”) for all the data obtained across different locations gives a poor fit resulting in high loss relative to the distributed case (denoted as “Distributed”). Fig. 2a shows the model order for the distributed case with parsimony constant 0.4 for all the 50 nodes is 34 times 50, i.e., 1700, less compared to the complexity of the centralized case, i.e., 2223. Thus, the centralized function fails to fit the data with higher number of points in the dictionary compared to the distributed case. Moreover, increasing the parsimony constant from 0.4 to 40, i.e., increasing the error tolerance reduces model complexity at the cost of degrading model fitness.

In Fig. 2b we display the constraint violation over time (for decentralized case only). Note that it approaches null across choice of parsimony constant. Moreover, Fig. 2a demonstrates that the complexity of nodes’ functions does not grow, but rather remains stable even in the face of experimental oceanic data, settling to $M_{4,t} = 34$ compared to sample size 2430.

2) Salinity: We now implement Algorithm 1 for predicting the mean salinity from various oceanic locations and depths. Again, we set the primal and dual regularizer $\lambda$ and $\delta$ to $10^{-5}$, and run it for $T = 2500$ iterations with constant step-size of 0.01. We select two values of the parsimony constant $P \in \{0.4, 40\}$. For the centralized case, we fix $P = 0.001$ so that its complexity is comparable to the decentralized approach to ensure a fair comparison. Across the settings, the bandwidth of the Gaussian kernel is fixed as 50 for the simulation.

We display these results in Fig. 3. Fig. 3a demonstrates that learning a single function to fit all data is unable to filter out correlation effects and hence gives poor model fitness, as compared to fitting multiple $f_i$’s to different nodes considering proximity constraints. Moreover, the average model order for a single node for the distributed case is 39 for $P = 0.4$, thus giving an aggregate complexity of 1950 for 50 nodes. This is less than the centralized model order of 2372 for a single function. Thus the decentralized approach yields improved accuracy with reduced complexity. We note that increasing the parsimony constant results in worse model fit but saves complexity, yielding a tunable tradeoff between fitness and complexity. In Fig. 3b we may observe that Algorithm 1 incurs attenuating constraint violation for both values of parsimony constant. Overall, complexity settles to around 39, which is orders of magnitude smaller than the 2500 sample size.

VI. CONCLUSION

We propose learning in heterogeneous networks via constrained functional stochastic programming. We model heterogeneity using proximity constraints, which allows agents to make decisions which are close but not necessarily equal. To solve this problem, we formulated the augmented Lagrangian, and proposed a stochastic saddle point method to solve it. The Lagrangian is node/edge separable along the primal/dual, permitting the algorithm to be decentralized. However, due to the fact we focus on cases where decision variables are functions belonging to RKHS, not parameters, we required generalizing the Representer Theorem to this setting, and further projecting the primal iterates onto subspaces greedily constructed from subsets of past observations. The overall result we call Heterogeneous Adaptive Learning with Kernels (HALK). The end result is an algorithm which is provably convergent in terms of primal sub-optimality and constraint violation, and attains a controllable trade-off between global convergence and model complexity.

We validated the proposed approach for estimating a spatial temporal Gaussian random field in a heterogeneous sensor network. Experimentally, we observed performance gains in a decentralized scheme for predicting oceanic temperature and salinity from depth. In future work, we hope to relax communications requirements, enforce privacy, and control the spread of learning rates of agents across the network.
where for the first equality we have used the fact that the functional gradient is a concatenation of functional gradients associated with each agent. The second inequality is obtained by considering the worst case estimate across the network.

In the right-hand side of (63), we substitute the value of \( \nabla f_i \hat{\ell}_i(f_i, \mu_i) \) from (18) to obtain,

\[
E[\nabla f_i \hat{\ell}_i(f_i, \mu_i)]^2 \leq V \max_{i \in V} E[\left[ \ell_i'(f_i, (x_{i,t}), y_{i,t}) \right]^2 + \sum_{j \in n_i} \mu_{ij} h_{ij}'(f_i, (x_{i,t}), f_j, (x_{j,t})) \right] \kappa(x_{i,t}, \cdot') + \lambda f_i, t]_2^2 \]

\[
\leq V \max_{i \in V} E\left[2\left[ \ell_i'(f_i, (x_{i,t}), y_{i,t}) \right]^2 + \sum_{j \in n_i} \mu_{ij} h_{ij}'(f_i, (x_{i,t}), f_j, (x_{j,t})) \right] \kappa(x_{i,t}, \cdot') \right]_2^2 + 2V^2 \lambda^2 \|f_i\|^2_2, \tag{64}
\]

In (64), we have used the fact that \( \|a + b\|^2_2 \leq 2 (\|a\|^2_2 + \|b\|^2_2) \) for any \( a, b \in \mathcal{H} \), i.e., the sum of squares inequality. Next we again use the sum of squares inequality for the first bracketed term in the right-hand side of (64) and also used Assumption 4 to upper bound \( \|f_i\|^2_2 \) by \( R_2^2 \) and get,

\[
E[\nabla f_i \hat{\ell}_i(f_i, \mu_i)]^2 \leq V \max_{i \in V} E\left[4\left[ \ell_i'(f_i, (x_{i,t}), y_{i,t}) \right]^2 \kappa(x_{i,t}, \cdot') \right] + 4\sum_{j \in n_i} \mu_{ij} h_{ij}'(f_i, (x_{i,t}), f_j, (x_{j,t})) \kappa(x_{i,t}, \cdot') \right]_2^2 + c(\lambda), \tag{65}
\]

where \( c(\lambda) := 2V^2 \lambda^2 \cdot R_2^2 \). Using Cauchy-Schwartz inequality, the first term on the right-hand side of (65) can be written as \( \|\ell_i'(f_i, (x_{i,t}), y_{i,t}) \kappa(x_{i,t}, \cdot')\|^2 \leq \|\ell_i'(f_i, (x_{i,t}), y_{i,t})\|^2 \kappa(x_{i,t}, \cdot') \|^2 \). Then using Assumptions 1 and 2 we bound \( \|\ell_i'(f_i, (x_{i,t}), y_{i,t})\|^2 \) by \( C^2 \) and \( \|\kappa(x_{i,t}, \cdot')\|^2 \) by \( X^2 \). Similarly we use Cauchy-Schwartz inequality for the second term in (65) and bound \( \|\kappa(x_{i,t}, \cdot')\|^2 \) by \( X^2 \). Now using these, (65) can be written as,

\[
E[\nabla f_i \hat{\ell}_i(f_i, \mu_i)]^2 \leq 4V^2 C^2 + 4V^2 \left(\sum_{j \in n_i} \mu_{ij} h_{ij}'(f_i, (x_{i,t}), f_j, (x_{j,t})) \right)^2 \|f_i\|^2_2 + c(\lambda), \tag{66}
\]

where \( V := V X^2 \). Using Assumption 3 we bound \( h_{ij}'(f_i, (x_{i,t}), f_j, (x_{j,t})) \) present in the second term on the right-hand side of (66) by \( L_b \) and then taking the constant \( L_b \) out of the summation, we get

\[
E[\nabla f_i \hat{\ell}_i(f_i, \mu_i)]^2 \leq 4V^2 C^2 + 4V^2 L_b^2 \|\sum_{j \in n_i} \mu_{ij}\|^2 + c(\lambda). \tag{67}
\]

Here, \( |n_i| \) denotes the number of neighborhood nodes of agent \( i \). Then we have used the fact \( \|\sum_{j \in n_i} \mu_{ij}\|^2 \leq |n_i| \|\sum_{j \in n_i} \mu_{ij}\|^2 \) and got

\[
E[\nabla f_i \hat{\ell}_i(f_i, \mu_i)]^2 \leq 4V^2 C^2 + 4V^2 L_b^2 |n_i| \sum_{j=1}^{n_i} |\mu_{ij}|^2 + c(\lambda). \tag{68}
\]

Next we upper bound \( |n_i| \) and \( \|\mu_i\|^2 \) by \( M \) and \( \|\mu\|^2 \) and write (68) as

\[
E[\nabla f_i \hat{\ell}_i(f_i, \mu_i)]^2 \leq 4V^2 C^2 + 4V^2 L_b^2 M |\mu_i|^2 + c(\lambda). \tag{69}
\]

Thus (69) which establishes an the upper bound on \( E[\nabla f_i \hat{\ell}_i(f_i, \mu_i)]^2 \) is valid.

With this in hand, we now shift focus to deriving a similar upper-bound on the magnitude of the dual stochastic gradient of the Lagrangian \( E[\nabla \mu \hat{\beta}_i(f_i, \mu_i)]^2 \) as

\[
E[\nabla \mu \hat{\beta}_i(f_i, \mu_i)]^2 \leq M \left(2E[\| h_{ij}(f_i, (x_{i,t}), f_j, (x_{j,t}))\|^2_\mathcal{H} + 2\delta^2 \|h_{ij}\|^2_\mathcal{H} \right) + 2\delta^2 \|h_{ij}\|^2_\mathcal{H} \tag{71}
\]

Then we bound the first term in (71) using Assumption 3 and the second term is upper bounded by \( \|\mu\|^2 \)

\[
E[\nabla \mu \hat{\beta}_i(f_i, \mu_i)]^2 \leq M \left(2(K_1+L_b^2 E[\| h_{ij}(f_i, (x_{i,t}))\|^2_\mathcal{H}] + 2\delta^2 \|h_{ij}\|^2_\mathcal{H} \right) \tag{72}
\]

Then we use \( \| h_{ij}(f_i, (x_{i,t}))\|^2_\mathcal{H} = \| h_{ij}(\kappa(x_{i,t'}, \cdot)\|^2_\mathcal{H} \leq \| h_{ij}\|^2_\mathcal{H} \cdot \|\kappa(x_{i,t'}, \cdot)\|^2_\mathcal{H} \) and then we have upper bounded \( \| f_i, t\|^2_\mathcal{H} \) and \( \|\kappa(x_{i,t'}, \cdot)\|^2_\mathcal{H} \) by \( R_2^2 \) and \( X^2 \), and we obtain

\[
E[\nabla \mu \hat{\beta}_i(f_i, \mu_i)]^2 \leq M \left((2K_1+2L_b^2 X^2 \cdot R_2^2) + 2\delta^2 \|h_{ij}\|^2_\mathcal{H} \right) \tag{73}
\]

REFERENCES

APPENDIX B
SUPPLEMENTARY MATERIAL FOR:
ADAPTIVE KERNEL LEARNING IN HETEROGENEOUS NETWORKS

PROOF OF COROLLARY 1

Proof: The proof generalizes that of the classical Representer Theorem. The inner minimization in (11) with respect to f can be written as

\[ E(f; S, \mu) = \sum_{i \in V} \frac{1}{N} \sum_{k=1}^{N} \left[ \ell_i(f_i(x_{i,k}), y_{i,k}) + \sum_{j \in n_i} \mu_{ij} \left( h_{ij}(f_i(x_{i,k}), f_j(x_{i,k})) - \gamma_{ij} \right) \right]. \] (74)

Let the subspace of functions spanned by the kernel function \( \kappa(x_{i,t}, \cdot) \) can be written as

\[ \mathcal{F}_{\kappa,S_i} = \text{span}\{\kappa(x_{i,k}) : 1 \leq k \leq N\}. \] (75)

We denote the projection of \( f_i \) on the subspace \( \mathcal{F}_{\kappa,S_i} \) as \( f_{ip} \) and the component perpendicular to the subspace as \( f_{i\perp} \), which can be written as \( f_{i\perp} = f_i - f_{ip} \). Now we can write

\[ f_i(x_{ik}) = \langle f_i, \kappa(x_{i,k}, \cdot) \rangle = \langle f_{ip}, \kappa(x_{i,k}, \cdot) \rangle + \langle f_{i\perp}, \kappa(x_{i,k}, \cdot) \rangle = \langle f_{ip}, \kappa(x_{i,k}, \cdot) \rangle = f_{ip}(x_{i,k}). \] (76)

Thus the evaluation of \( f_i \) at any arbitrary training point \( x_{ik} \) is independent of \( f_{i\perp} \). Using this fact, we can now write (74) as,

\[ E(f; S, \mu) = \sum_{i \in V} \frac{1}{N} \sum_{k=1}^{N} \left[ \ell_i(f_{ip}(x_{i,k}), y_{i,k}) + \sum_{j \in n_i} \mu_{ij} \left( h_{ij}(f_{ip}(x_{i,k}), f_j(x_{i,k})) - \gamma_{ij} \right) \right]. \] (77)

Thus from (77), we can say that \( E(f; S, \mu) \) is independent of \( f_{i\perp} \). As we are minimizing (12) with respect to \( f_i \), the evaluation of \( f_j \) at the training point of node \( i \) can be treated as a constant in \( E(f; S, \mu) \) which is the first part in (12). Additionally, note that \( \lambda \cdot \|f_i\|_H^2 \cdot 2^{-1} \geq \lambda \cdot \|f_{ip}\|_H^2 \cdot 2^{-1} \). Therefore, given any \( \mu \), the quantity \( E(f; S, \mu) + \sum_{i=1}^{V} \lambda \cdot \|f_i\|_H^2 \cdot 2^{-1} \) is minimized at some \( f^*_i(\mu_i) \) such that \( f^*_i(\mu_i) \) lies in \( \mathcal{F}_{\kappa,S_i} \). This holds specifically for \( \mu_i^* \) where \( f^*_i = f^*_i(\mu_i^*) \), there by completing the proof.

\[ \square \]

APPENDIX C
PROOF OF LEMMA 2

Proof: Considering the squared-Hilbert- norm difference of the left hand side of (40)

\[ \|\nabla f \tilde{L}_i(f_i, \mu_i) - \nabla f \tilde{L}_i(f_i, \mu_i)\|_H^2 = \frac{1}{\eta^2} \|\eta \nabla f \tilde{L}_i(f_i, \mu_i) - \eta \nabla f \tilde{L}_i(f_i, \mu_i)\|_H^2 \] \] (78a)

\[ = \frac{1}{\eta^2} \|\eta \nabla f \tilde{L}_i(f_i, \mu_i) + f_i + f_i - f_i\|^2. \] \] (78b)

In (78b), we used (34) for the second term on the right hand side of (78a), we re-arrange the terms in (78b) and then, we use \( f_i - \eta \nabla f \tilde{L}_i(f_i, \mu_i) \), which can easily by identified as \( f_{i+1} \) given in (30) and obtain

\[ \|\nabla f \tilde{L}_i(f_i, \mu_i) - \nabla f \tilde{L}_i(f_i, \mu_i)\|_H^2 = \frac{1}{\eta^2} \|f_{i+1} + (f_i - \eta \nabla f \tilde{L}_i(f_i, \mu_i))\|^2 \] \] (78c)

\[ = \frac{1}{\eta^2} \|f_{i+1} + \tilde{f}_{i+1}\|^2 \] \] (78d)

In (78c) we used the stacked version of \( \tilde{f}_{i,t+1} \) to substitute \( \tilde{f}_{i+1} \) in place of \( f_t - \eta \nabla f \tilde{L}_i(f_i, \mu_i) \). In (78d) we used the error tolerance parameter of the KOMP update. Then taking the square root of (78d) gives the inequality stated in (40) and concludes the proof.

\[ \square \]
APPENDIX D
PROOF OF LEMMA 3

Proof: Considering the squared hilbert norm of the difference between the iterate $\mathbf{f}_{t+1}$ and any feasible point $\mathbf{f}$ with each individual $f_i$ in the ball $B$ and expanding it using the (34), we get

$$
\|\mathbf{f}_{t+1} - \mathbf{f}\|^2 \leq \|\mathbf{f}_t - \eta \nabla f \mathbf{L}_t(f_t, \mu_t) - \mathbf{f}\|^2 = \|\mathbf{f}_t - \mathbf{f}\|^2 - 2\eta \langle \mathbf{f}_t - \mathbf{f}, \nabla f \mathbf{L}_t(f_t, \mu_t) \rangle + \eta^2 \|\nabla f \mathbf{L}_t(f_t, \mu_t)\|^2
$$

where we have added and subtracted $2\eta \langle \mathbf{f}_t - \mathbf{f}, \nabla f \mathbf{L}_t(f_t, \mu_t) \rangle$ and gathered like terms on the right-hand side. Now to handle the second term on the right hand side of (79), we use Cauchy Schwartz inequality along with the Lemma 2 to replace the directional error associated with sparse projections with the functional difference defined by the KOMP stopping criterion:

$$
\langle \mathbf{f}_t - \mathbf{f}, \nabla f \mathbf{L}_t(f_t, \mu_t) \rangle \leq \|\mathbf{f}_t - \mathbf{f}\|_H \|\nabla f \mathbf{L}_t(f_t, \mu_t)\|_H \leq \frac{\sqrt{\epsilon_t}}{\eta} \|\mathbf{f}_t - \mathbf{f}\|_H.
$$

(80)

Now to bound the norm of $\nabla f \mathbf{L}_t(f_t, \mu_t)$, the last term in the right hand side of (79), we add and subtract $\nabla f \mathbf{L}_t(f_t, \mu_t)$ and then use the identity $\|a + b\|^2 \leq 2(\|a\|^2 + \|b\|^2)$ and further use Lemma 2 and finally get,

$$
\|\nabla f \mathbf{L}_t(f_t, \mu_t)\|^2 \leq \frac{2V \epsilon_t^2}{\eta^2} + 2\|\nabla f \mathbf{L}_t(f_t, \mu_t)\|_H^2.
$$

(81)

Now we substitute the expressions in (80) and (81) in for the second and fourth terms in (79) which allows us to write

$$
\|\mathbf{f}_{t+1} - \mathbf{f}\|^2 \leq \|\mathbf{f}_t - \mathbf{f}\|^2 + \frac{2V \epsilon_t^2}{\eta^2} + \|\nabla f \mathbf{L}_t(f_t, \mu_t)\|^2.
$$

(82)

By re-ordering the terms of the above equation, we get

$$
\langle \mathbf{f}_t - \mathbf{f}, \nabla f \mathbf{L}_t(f_t, \mu_t) \rangle \leq \frac{1}{2\eta} \left[ \|\mathbf{f}_t - \mathbf{f}\|_H^2 - \|\mathbf{f}_{t+1} - \mathbf{f}\|_H^2 \right] + \frac{\sqrt{\epsilon_t}}{\eta} \|\mathbf{f}_t - \mathbf{f}\|_H + \frac{V \epsilon_t^2}{\eta} + \|\nabla f \mathbf{L}_t(f_t, \mu_t)\|_H^2.
$$

(83)

Using the first order convexity condition for instantaneous Lagrangian $\mathbf{L}_t(f_t, \mu_t)$, since it is convex with respect to $f_t$ and write

$$
\mathbf{L}_t(f_t, \mu_t) - \mathbf{L}_t(f, \mu_t) \leq \langle f_t - f, \nabla f \mathbf{L}_t(f_t, \mu_t) \rangle.
$$

(84)

Next we use (84) in (83) and get

$$
\mathbf{L}_t(f_t, \mu_t) \leq \mathbf{L}_t(f_t, \mu_t) \leq \frac{1}{2\eta} \left[ \|\mathbf{f}_t - \mathbf{f}\|_H^2 - \|\mathbf{f}_{t+1} - \mathbf{f}\|_H^2 \right] + \frac{\sqrt{\epsilon_t}}{\eta} \|\mathbf{f}_t - \mathbf{f}\|_H + \frac{V \epsilon_t^2}{\eta} + \|\nabla f \mathbf{L}_t(f_t, \mu_t)\|_H^2.
$$

(85)

Similarly, we consider the squared difference of dual variable update $\mu_{t+1}$ in (21) and an arbitrary dual variable $\mu$,

$$
\|\mu_{t+1} - \mu\|^2 = \left[ \mu_t + \eta \nabla \mu \mathbf{L}_t(f_t, \mu_t) \right]_+ - \mu\|^2 \leq \|\mu_t + \eta \nabla \mu \mathbf{L}_t(f_t, \mu_t) - \mu\|^2.
$$

(86)

The above inequality in (86) comes from the non-expansivity of the projection operator $[.]_+$. Next we expand the square of the right-hand side of (86) and get,

$$
\|\mu_{t+1} - \mu\|^2 \leq \|\mu_t - \mu\|^2 + 2\eta \nabla \mu \mathbf{L}_t(f_t, \mu_t)^T (\mu_t - \mu) + \eta^2 \|\nabla \mu \mathbf{L}_t(f_t, \mu_t)\|^2.
$$

(87)

We re-arrange the terms in the above expression and get,

$$
\nabla \mu \mathbf{L}_t(f_t, \mu_t)^T (\mu_t - \mu) \geq \frac{1}{2\eta} \left( \|\mu_{t+1} - \mu\|^2 - \|\mu_t - \mu\|^2 \right) - \frac{\eta}{2} \|\nabla \mu \mathbf{L}_t(f_t, \mu_t)\|^2.
$$

(88)

Since the instantaneous Lagrangian $\mathbf{L}_t(f_t, \mu_t)$ is concave with respect to the dual variable $\mu_t$, i.e.,

$$
\mathbf{L}_t(f_t, \mu_t) - \mathbf{L}_t(f_t, \mu) \geq \nabla \mu \mathbf{L}_t(f_t, \mu_t)^T (\mu_t - \mu).
$$

(89)

Next we use the left-hand side of the inequality (89) in (88) and get the expression,

$$
\mathbf{L}_t(f_t, \mu_t) - \mathbf{L}_t(f_t, \mu) \geq \frac{1}{2\eta} \left( \|\mu_{t+1} - \mu\|^2 - \|\mu_t - \mu\|^2 \right) - \frac{\eta}{2} \|\nabla \mu \mathbf{L}_t(f_t, \mu_t)\|^2.
$$

(90)

We subtract (90) from (85) to obtain the final expression,

$$
\mathbf{L}_t(f_t, \mu) - \mathbf{L}_t(f_t, \mu_t) \leq \frac{1}{2\eta} \left[ \|f_t - f\|_H^2 - \|f_{t+1} - f\|_H^2 + \|\mu_t - \mu\|^2 - \|\mu_{t+1} - \mu\|^2 \right] + \frac{\eta}{2} \left( 2\|\nabla f \mathbf{L}_t(f_t, \mu_t)\|_H^2 + \|\nabla \mu \mathbf{L}_t(f_t, \mu_t)\|^2 \right)
$$

(91)

[End of proof]
